Various camera configurations

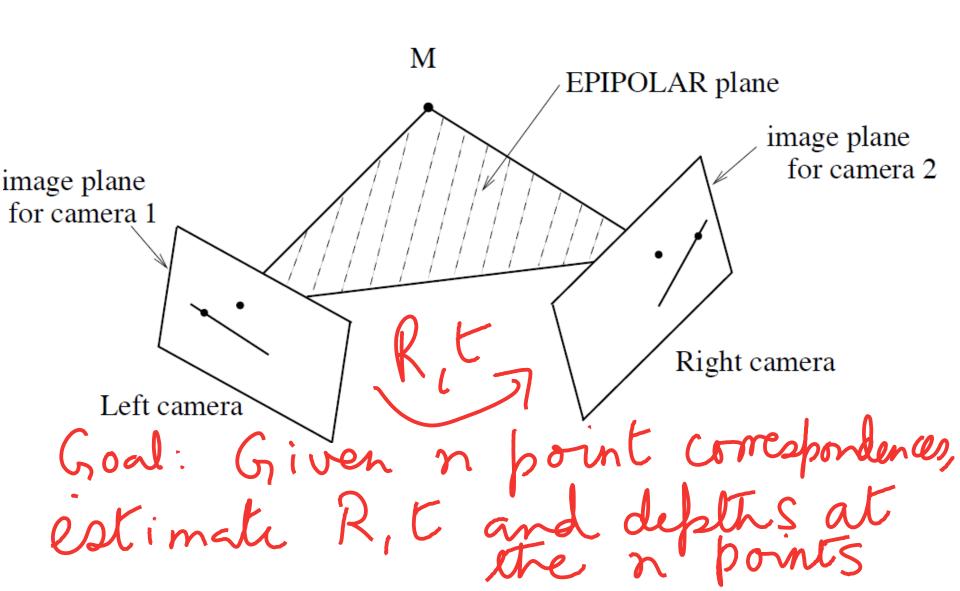

Single point of fixation where optical axes intersect

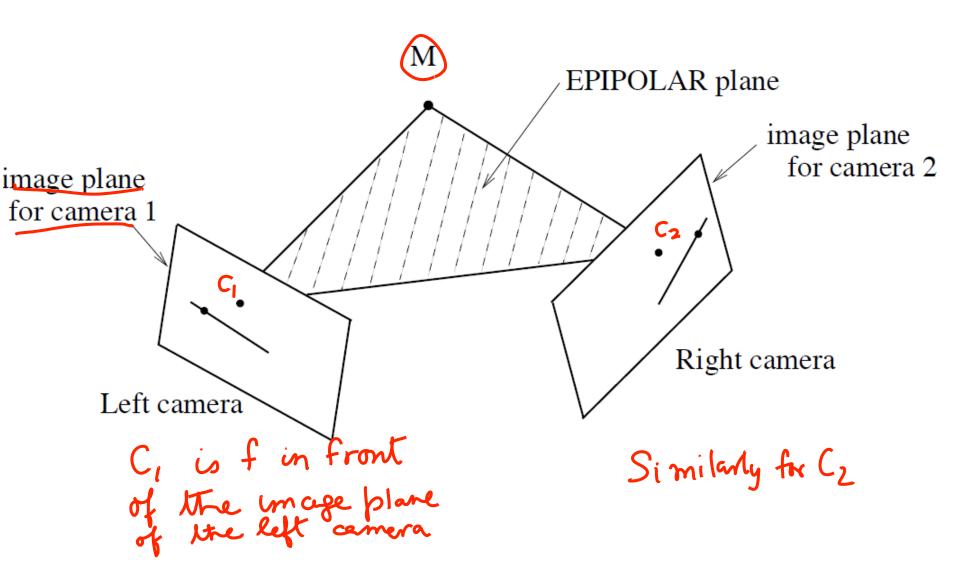

Optical axes parallel (fixation at infinity)

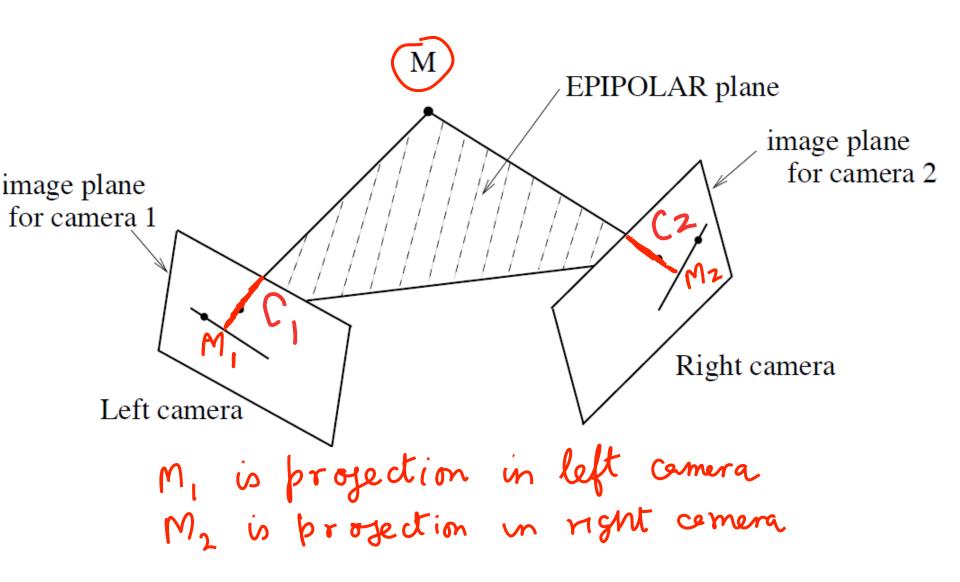

General case

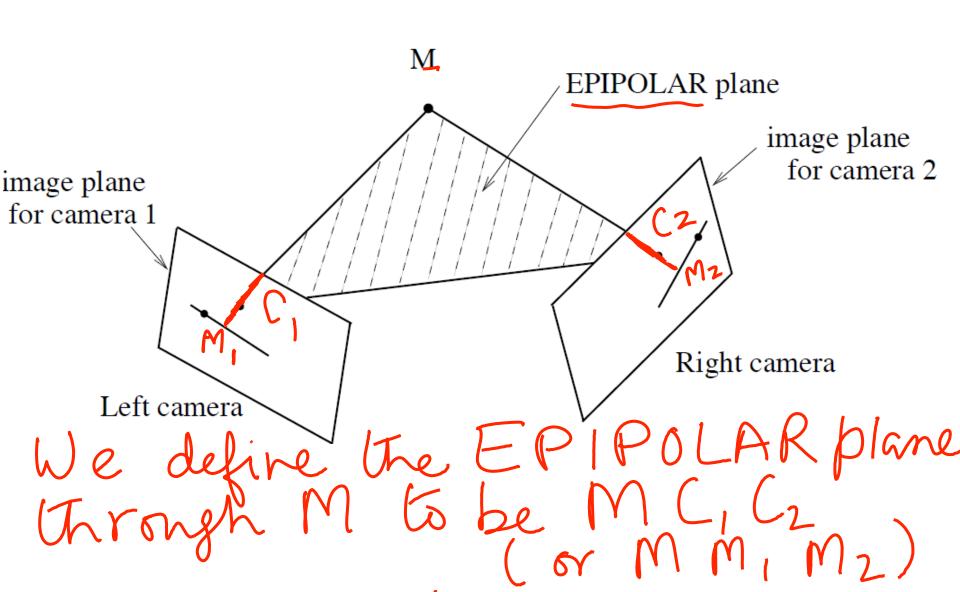

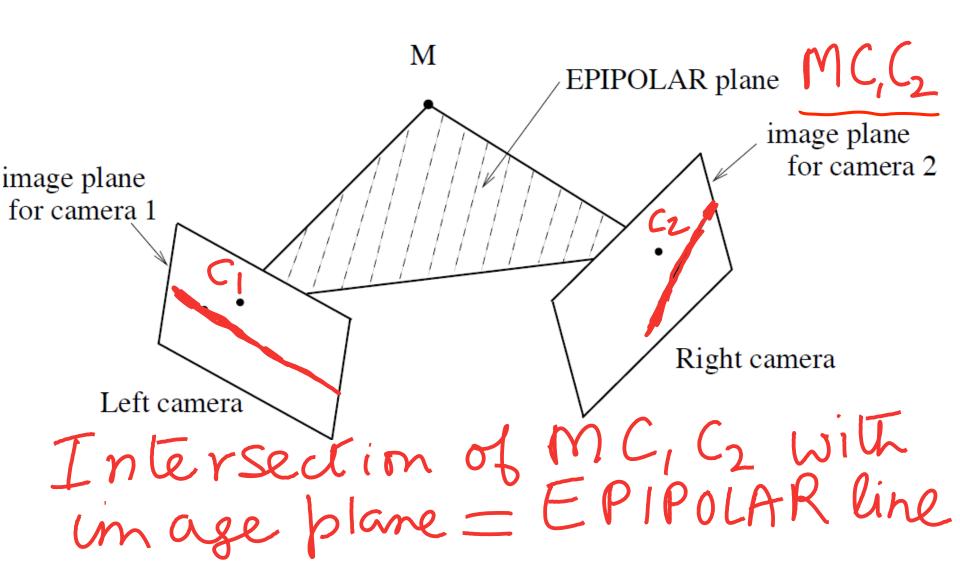

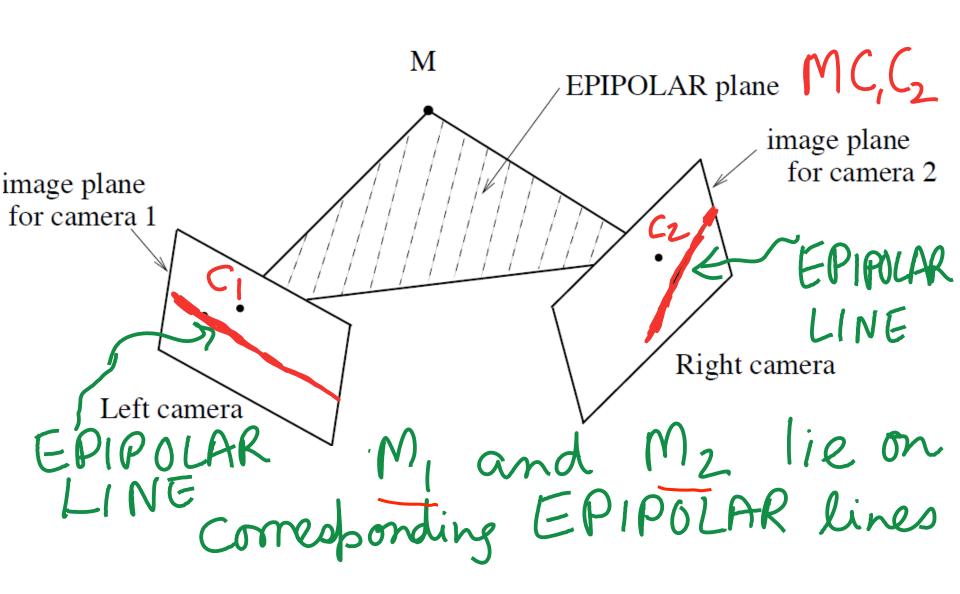

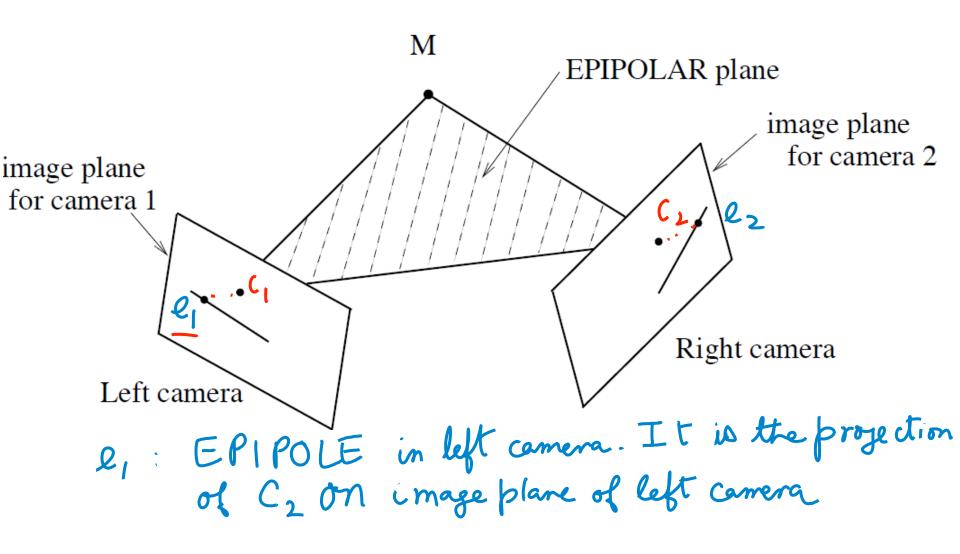

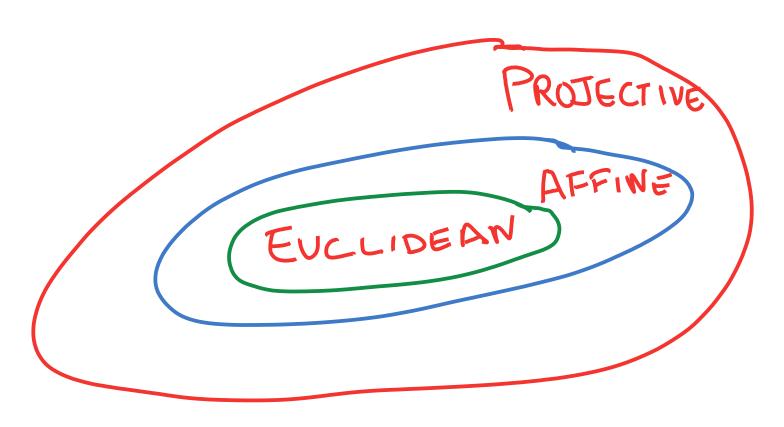

Applications

- Reconstructing a three dimensional object given two or more photos. The relative orientation of the cameras is unknown, such as when using images downloaded from the internet, taken by different people at different times.
- Some examples from Univ. Washington/Microsoft Research:
 - phototour.cs.washington.edu
 - photosynth.net
 - grail.cs.washington.edu/rome/

The approach

- The basic module is recovering 3D structure from 2 views with relative orientation (R, t) of cameras unknown. This has several steps:
 - Finding n corresponding points in the 2 views, i.e. image points which are the projections of the same point in the scene.
 - Estimate the E matrix (= $\hat{T}R$) from these point correspondences.
 - Extract (R, t).
 - Recover depth by triangulation.
- The outer loop combines information from all the cameras in a global coordinate system. Note that not all points will be seen by all cameras. This process is a nonlinear least squares optimization, called bundle adjustment. The error that is minimized is the reprojection error.
- For example, the 3D reconstruction of the Colosseum in Rome was based on 2 K images, and 800 K points.

But first, let us review projective transformations

Projective Transformations

- Under perspective projection, parallel lines can map to lines that intersect. Therefore, this cannot be modeled by an affine transform!
- Projective transformations are a more general family which includes affine transforms and perspective projections.
- Projective transformations are linear transformations using homogeneous coordinates

Homogeneous coordinates

 Instead of using n coordinates for ndimensional space, we use n+1 coordinates.

Key rule

•
$$\begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$
 $\begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$ $\begin{bmatrix} x_1 \\ x_$

Picking a canonical representative

$$\begin{bmatrix} X_{1} \\ X_{2} \\ X_{3} \end{bmatrix} \longmapsto \begin{bmatrix} X_{1}/X_{3} \\ X_{2}/X_{3} \\ X_{3} \neq 0 \end{bmatrix}$$

$$\therefore (X, Y) = \begin{pmatrix} X_{1} \\ X_{3} \end{pmatrix} \times \begin{pmatrix} x_{1} \\ x_{3} \end{pmatrix}$$
Conversely
$$\begin{bmatrix} X \\ Y \end{bmatrix} \longmapsto \begin{bmatrix} X \\ Y \end{bmatrix} \text{ augmented vector}$$

The projective line

Any finite point x can be represented as

$$\begin{bmatrix} x \\ 1 \end{bmatrix}$$
 or $\begin{bmatrix} 2x \\ 2 \end{bmatrix}$ or $\begin{bmatrix} 6.3x \\ 6.3 \end{bmatrix}$ or ...

Any infinite point can be expressed as

The projective plane

Any finite point can be represented as

Any infinite point can be represented as

Thus there is a line at infinity Different ratios X: y give different points.

Lines in homogeneous coordinates

Consider
$$a_1 \times + a_2 y + a_3 = 0$$

Note $\lambda a_1 \times + \lambda a_2 y + \lambda a_3 = 0$ is the Same line $\begin{bmatrix} x_1 \\ y \end{bmatrix} \longleftrightarrow \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}$ with $x = \frac{x_1}{x_3}$, $y = \frac{x_2}{x_3}$
 $a_1 \times \frac{x_1}{x_3} + a_2 \times \frac{x_2}{x_3} + a_3 = 0$
 $a_1 \times \frac{x_1}{x_3} + a_2 \times \frac{x_2}{x_3} + a_3 = 0$

A.
$$\begin{bmatrix} a_1 \\ a_2 \\ a_3 \end{bmatrix} \cdot \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = 0$$

Q. Where do the lines
$$\begin{bmatrix} a_1 \\ a_2 \\ a_3 \end{bmatrix}$$
, $\begin{bmatrix} b_1 \\ b_2 \\ b_3 \end{bmatrix}$ intersect

Incidence of points on lines

A.
$$\begin{bmatrix} a_1 \\ a_2 \end{bmatrix} \land \begin{bmatrix} b_1 \\ b_2 \end{bmatrix}$$

Example:

$$x = 1$$
 and $y = 1$

$$\begin{bmatrix} -1 \\ 0 \end{bmatrix}$$
 $\begin{bmatrix} -1 \\ 1 \end{bmatrix}$

$$\begin{bmatrix} -1 \\ -1 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

(1,1)

Incidence of points on lines

$$\begin{bmatrix} a_1 \\ a_2 \\ a_3 \end{bmatrix} \land \begin{bmatrix} b_1 \\ b_2 \\ b_3 \end{bmatrix}$$

Example:

Line incident on two points

Representing affine transformations

Perspective Projection

Projective transformations

$$\begin{bmatrix} X_{1} \\ X_{2}' \\ X_{3}' \end{bmatrix} = \begin{bmatrix} P_{11} & P_{12} & P_{13} \\ P_{21} & P_{22} & P_{23} \\ P_{31} & P_{32} & P_{33} \end{bmatrix} \begin{bmatrix} X_{1} \\ X_{2} \\ X_{3} \end{bmatrix}$$
in
$$\begin{bmatrix} Y_{1} \\ Y_{2} \\ Y_{3} \end{bmatrix}$$

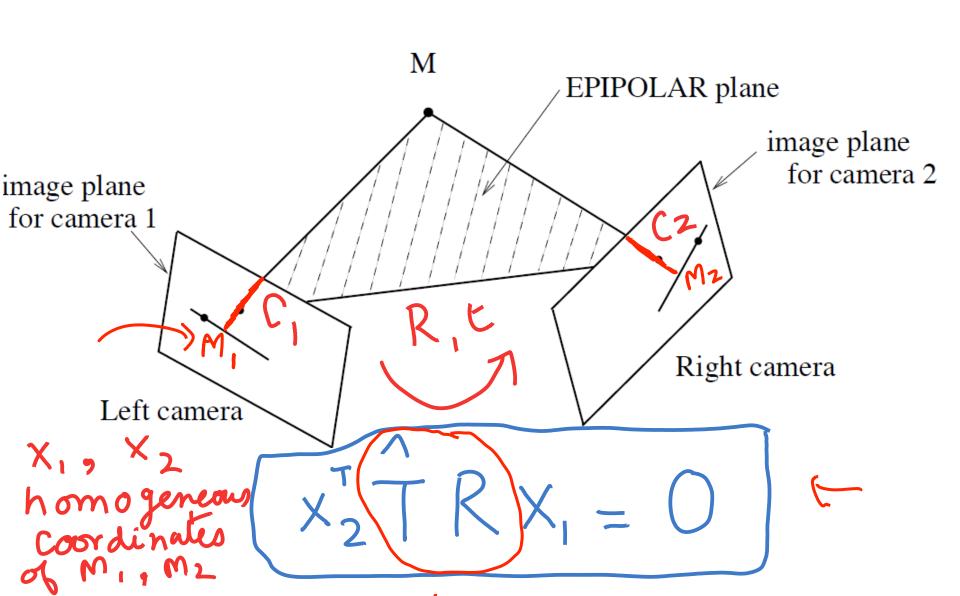

$$\begin{bmatrix} Y_{1} \\ Y_{2} \\ Y_{3} \end{bmatrix}$$

$$\begin{bmatrix} Y_{1} \\ Y_{2} \\ Y_{3} \end{bmatrix}$$

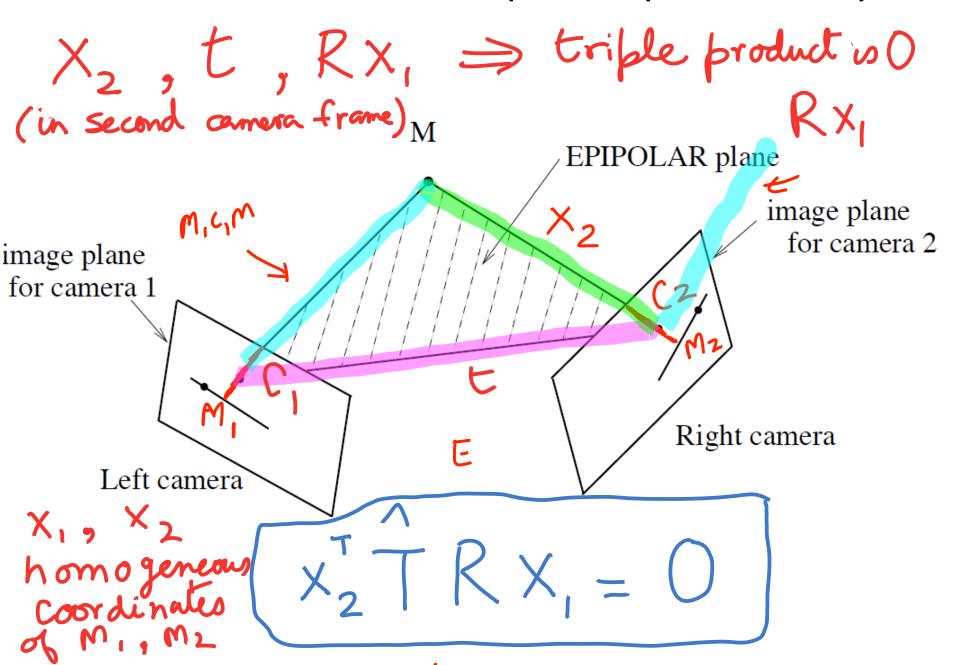

Notes: 8 indépendent parameters matrix required to be non-singular

For projective transforms in P' 3 independent parameters P^3 15 independent parameters

The Essential Matrix Constraint

Proof is based on the co-planarity of three rays

Coplanarity of 3-vectors implies triple product is zero

$$V_1$$
, V_2 , V_3 are coplanar \Rightarrow

$$V_1$$
, $(V_2 \wedge V_3) = 0$

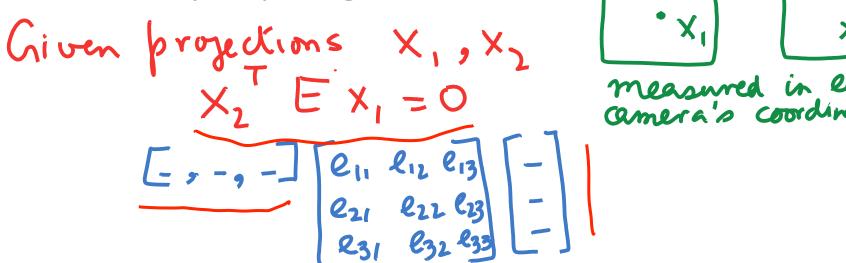

$$V_1^T V_2 V_3 = 0$$

Longuet-Higgins 8 point algorithm

- Find n (≥ 8) corresponding points in the 2 views
- Estimate the E matrix (= $\widehat{T}R$) from these point correspondences.

モーショ

- Extract (*R*, *t*).
- Recover depth by triangulation.

Each point gives a linear equation for E

Summary

- The basic module of recovering 3D structure from 2 views with relative orientation (R, t) of cameras unknown can be implemented using the Longuet-Higgins 8 point algorithm.
- The outer loop combines information from all the cameras in a global coordinate system using bundle adjustment. The error that is minimized is the re-projection error. The big idea is that given the guessed 3d positions of a point, one can predict image plane 2d positions in any camera where it is visible. We wish to minimize the squared error between this predicted position and the actual position, summed over all cameras and over all points.
- Lots of engineering has gone into making these approaches work. Read Szeliski's book, Chapter 7, for more.
