

Displacement Mapping

A New Method to Achieve Realistic Geo-Specific Feature Densities

Brett Chladny

John Femiani

The Problem/Need

- ▶ 3D features provide visual cues required for low level flight training
 - Assessing speed and height above terrain
 - Motion parallax created by vertical edge
 - Improved realism
- ▶ Limited numbers of features exist in modern day visual simulation
 - Creating feature rich databases is expensive
 - Sending every feature down the graphics pipe can be inefficient

Goal

- ▶ To develop a method for adding unlimited numbers of feature to visual simulations
 - Automate feature extraction from commonly available data sources
 - Deform the terrain's surface to give the appearance of unlimited numbers of features
 - Integrate technique into modern day image generators with minimal impact to the IG performance

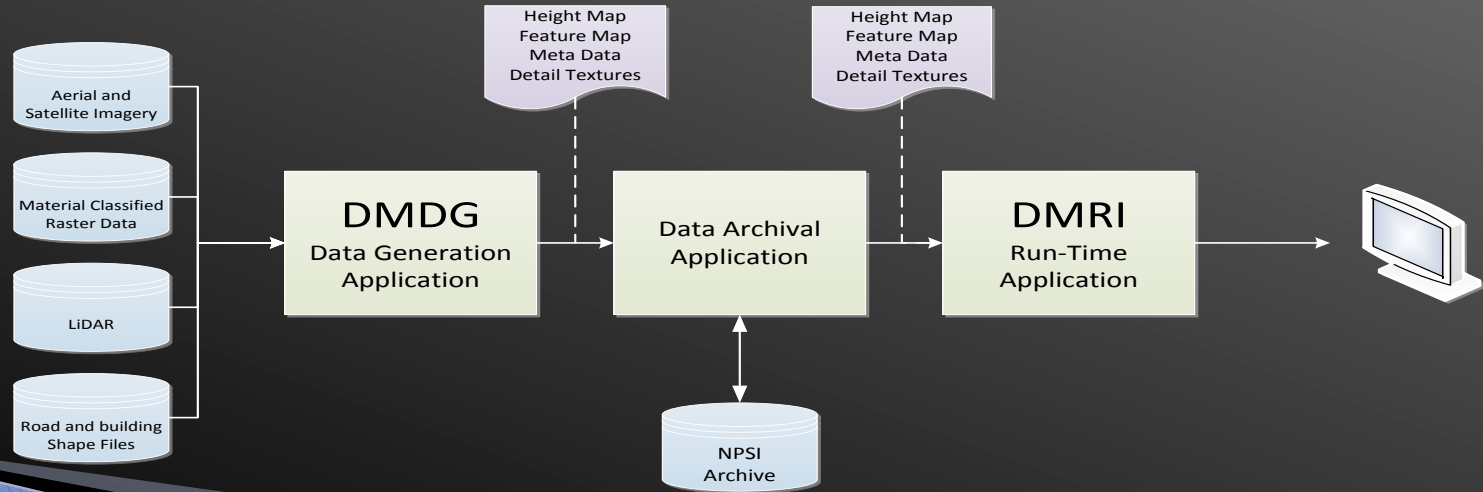

Solution

- ▶ Develop automated way to extract features from commonly available data sources
 - Feature extraction from imagery alone is possible, but difficult
 - Obtain different types of information from different types data
 - Produce plausible results
- ▶ Develop method for visualizing large numbers of features
 - Displacement Mapping
 - Re-tessellate the terrain surface on the GPU
 - Deform the terrain surface to provide the appearance of identified features
 - Polygonal approach
 - Very efficient !!!

Approach

▶ Pipeline solution

- Generate displacement and shape file data
- Archive data as refined source data
- Develop runtime solution that makes use of data

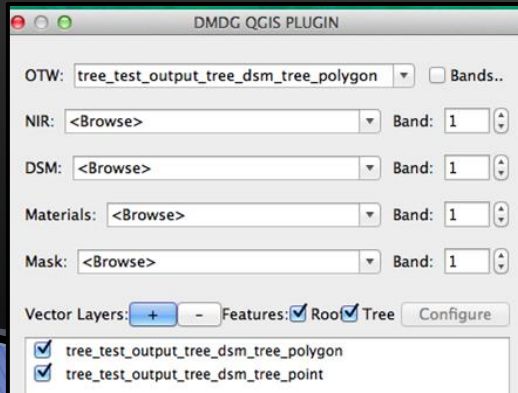

DMDG

Displacement Map Data Generator

What is DMDG?

- ▶ Python (mixed with C / cython) package
- ▶ Command line tool
- ▶ Graphical plug-in to QGIS
- ▶ Can be run locally or remotely on a Linux cluster

```
1 [default.input]
2 otw =
3 rgb = 1 2 3
4 feature = root tree
5 no_extract = False
6 no_heights = False
7 vector_outputs = root tree
8 [general]
9 pp_servers =
10 pp_secret =
11 root_extractor = dmdg.feature.root.RootExtractor
```

DMDG input

- ▶ Data fusion from multiple sources
 - Photopic imagery (out-the-window RGB)
 - NearIR imagery
 - Vector (street maps, building foot prints, etc.)
 - DSMs (from LiDAR, stereo pair imagery, etc.)

Data Fusion

- ▶ Each type of input provides different information:
 - Constraints on where features can be placed
 - Cues to guide model fitting and feature detection
- ▶ Leverage all of the data available
 - Data layers are used to modify a one-per-feature-type “guidance” image.

Vector data adds constraints based on roads and hints from building footprints.

Start with an OTW image

Shadow & vegetation analysis gives additional constraints

DMDG aligns and completes guidance image to match OTW pixels based on RGB data

No Feature

Improbable Feature

No Indicator

Probable Feature

Definite Feature

DMDG output

- ▶ Max height of features at each pixel
- ▶ Point features

Processing Time

- ▶ DMDG is usually run on a cluster of computers
- ▶ Approximately 30s per km² at 1mpp
- ▶ Time varies by image contents & resolution
- ▶ Less than 24 hours for 300 square miles of 25cm imagery
- ▶ Looking into GPU acceleration

FIL

Feature Injection Library

History of Displacement Mapping

- ▶ Polygonal lighting
- ▶ Bump Mapping
- ▶ Parallax Mapping
- ▶ Displacement Mapping

Displacement Mapping Technique

- ▶ Start with normally tessellated terrain skin
- ▶ Re-tessellate terrain skin on GPU
- ▶ Move resulting vertices based on displacement map
- ▶ Render new terrain skin to reveal both the terrain surface and the appearance of features

Comparison with Traditional Methods

- ▶ Traditional rendering approach
 - Each feature is represented by its own set of geometry
 - More features = longer rendering time
- ▶ Displacement mapping
 - Consistent rendering performance
 - **Appearance** of features created by deforming terrain's surface
 - Terrain tessellation based on distance not feature density
 - More features = same rendering time

1000 Feet

500 Feet

A 3D architectural rendering of a residential neighborhood. The houses are arranged in a grid pattern on a street grid. The houses are rendered in a light gray color with a textured roof. The streets are paved and have some greenery, including trees and bushes. A scale bar in the top center indicates a length of 100 feet. The overall scene is a top-down view of a suburban development.

100 Feet

Polygonal Rendering Technique

- ▶ Scene graph independent self contained rendering solution
- ▶ Render features relative to the observer (supports flat and round-earth)
- ▶ Load and render features efficiently!

Polygonal Model Generation

- ▶ Geo-specific footprints – from DMDG
- ▶ Geo-specific elevation – from DTED used to build database
- ▶ Geo-specific roof colors – from OTW imagery
- ▶ Group into tiles that are 1/10,000 of a geo-cells
- ▶ Store data in files on disk

Polygonal Model Rendering

- ▶ Supports both round and flat earth
- ▶ Can be integrated into any OpenGL based IG
- ▶ Reads data files disk and constructs features in parallel thread
- ▶ Constructs OpenGL primitives in VBOs
- ▶ Uses less then 1 ms per frame to upload data to the GPU
- ▶ Sets up pipeline for rendering each frame
- ▶ Directly renders features into active draw context
- ▶ **Plausible** visual result with impressive performance

Frame Rate:59.97

Hybrid Solutions

- ▶ Near-field: Polygon Features
- ▶ Far-field: Displacement mapping
- ▶ Transition zone
 - Polygonal features fade out using alpha
 - Displacement amount starts from zero
- ▶ Displacement mapping only, polygonal features only, and hybrid solution all possible

Use Cases

- ▶ Fixed wing Nap-of-the-Earth flight training
- ▶ Rotor wing flight training
- ▶ UAV and camera operator training
- ▶ Search and rescue training
- ▶ Targeting pod training
- ▶ Mission rehearsal

On to the Demo...
