Abstract:

This is a Non-Standards
Track Work Product. The
patent provisions of the
OASIS IPR Policy do not
apply.

This document describes the use of EMIX 1.0 to support Transactive Energy Markets.

Status:

This document was last revised or approved by the OASIS Energy Market Information Exchange (eMIX) TC on the above date. The level of approval is also listed above. Check the "Latest version" location noted above for possible later revisions of this document. Technical Committee members should send comments on this document to the Technical Committee's email list. Others should send comments to the Technical Committee by using the "[Send A Comment](#)" button on the Technical Committee's web page at <http://www.oasis-open.org/committees/emix/>.

1 Introduction

Transactive Energy transactions are for either physically delivered energy or financial hedges, as illustrated the above list. Forward and real time transactions for physical delivery of energy are critical to grid reliability.

2 What is Transactive Energy?

A *Transaction* is defined here as an exchange among entities of a product for a price. *Transactive Energy* is a business process that may result in transactions of energy. Transactive Energy is most useful in decentralized markets, but it has applications in centralized markets. Generator and load response characteristics are not information elements of Transactive Energy; rather, the current responsiveness of supply and usage to price is discovered through frequent priced tenders and transactions.

OASIS EMIX provides an information model for price and product communication for energy transactions. OASIS Energy Interop provides a set of transactive services to communicate EMIX price and product information for energy transactions among entities.

A few examples of Transactive Energy transactions are:

1. purchase of delivered electric energy by a retail customer at posted forward dynamic prices tendered by a regulated or competitive retailer (load serving entity)
2. forward and real time physical delivery of electric energy by a generator to a retailer at negotiated prices and quantities
3. energy futures contracts traded on a bid/ask exchange that are cash-settled against spot prices
4. forward and real time sale of energy by a micro grid to another micro grid at negotiated prices and quantities

Transactive Energy transactions are for either physically delivered energy or financial hedges, as illustrated the above list. Forward and real time transactions for physical delivery of energy are critical to grid reliability.

Transactive Control is a term defined by others that applies to dispatch-like transactions based on explicit customer or generator response characteristics such as bid curves and ramp rates¹. Event-based demand response and system operator dispatch markets are examples of Transactive Control even though a transaction with a price and quantity may result. The REC / VEN flow of control approach² is also an expression of Transactive Control. This note is focused on Transactive Energy; Transactive Control is not otherwise addressed in this note. Transactive Energy and Transactive Control can coexist in markets; EMIX and Energy Interop provide information models and services for both.

TeMIX (Transactive Energy Information Exchange) is a profile of Transactive Energy supporting automated transactions. EMIX Note XX focuses on TeMIX.

3 Transactive Energy Forward Transactions and Positions

Transactive Energy uses forward energy transactions to accumulate forward positions. If the transactions and positions are financial then the final position must be financially balanced to zero. If the forward transactions are for delivery, differences between the forward positions and metered delivery are settled by real-time transactions. Figure 1 illustrates such a sequence of forward transactions and positions for delivery. In some markets, the forward transactions may be with several different counterparties.

FIGURE 1: ILLUSTRATIVE SEQUENCE OF FORWARD AND REAL TIME TRANSACTIONS

4 Transactive Energy Standard Terms and Market Context

The EMIX information model for Transactive Energy products and prices describes (1) quantities of energy in each of one or more designated intervals of time transacted at a defined location on the grid and (2) the price of the energy transaction.

Standard Terms in EMIX are typically used to describe the duration of the interval, currency, and other information. These Standard Terms are referred to as the Market Context for a Transaction. Information elements that vary by transaction such as quantity, price, start time and location are described in the payload for a transactive service.

5 Transactive State

EMIX uses Transactive State to qualify the information model for Transactive Energy products and prices as illustrated in Figure 2 below.

FIGURE 2 : TRANSACTIVE STATES

Five transactive states are used by Transactive Energy³. The information model for a Transaction is an EMIX price and product description. A Tender is a bid or offer for a Transaction with an expiration time. An Indication of Interest is non-binding and may be (1) a request for a Tender, (2) a forecast of usage by a buyer, or (3) a forecast of price by a seller. Delivery is the metered quantity delivered. Publication artifacts include prices, quantities, costs, or revenues, but a Publication is not a Tender. Some Transactive states may not be used in given interactions and markets.

³ EMIX also defines Exercise and Transport Commitment as Transactive States which are actions rather than states and should likely be deleted in future versions of EMIX.

6 Transactive Transport

EMIX Transactions for Transport (transmission and distribution) have the same basic information model and transactive services as EMIX transactions for energy. All EMIX energy transactions have a location specified by an EMIX interface. For Transport, the EMIX Interface specifies a pair of locations. EMIX makes no assumptions on how transport transactions prices are determined.

7 Transactive Options

96
97 EMIX provides an information model for Options on Transactive Energy and Transport products.
98 An Option provides its holder a right to either purchase or sell energy or transport at a strike
99 price. Options can be used to limit the price of energy or transport for risk management, to
100 transact ancillary services, or to facilitate the commitment of distributed generators.

101 **Appendix A. Acknowledgments**
