Cloud Computing Research Center
for Mobile Applications (CCMA)

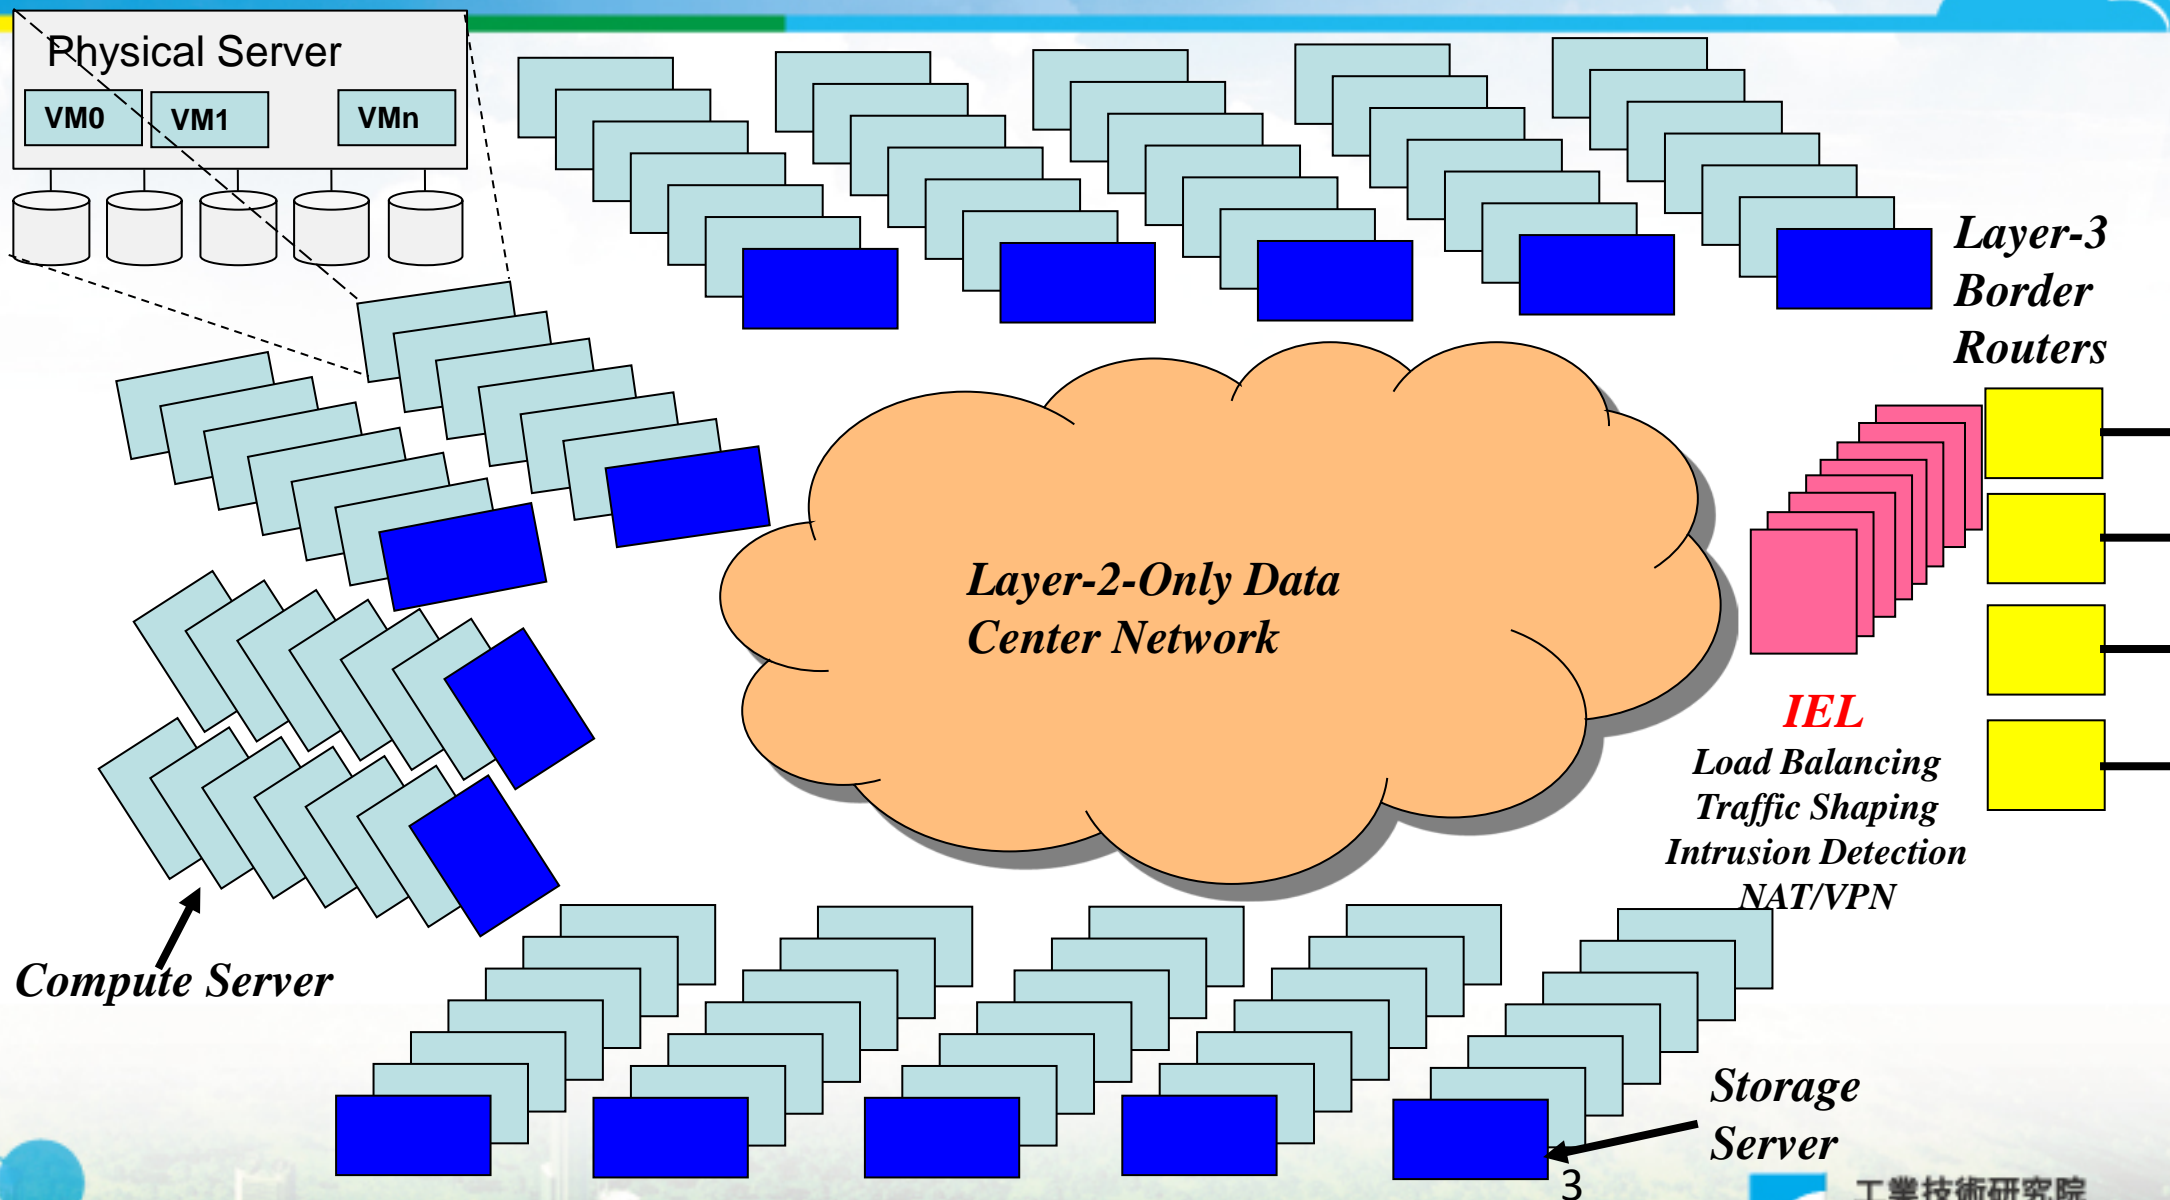

雲端運算行動應用研究中心

Cloud Data Center Solution

- Renting rather than buying IT infrastructure → Build-up of cloud-scale data centers → Need for inexpensive integrated cloud data center solutions
- The user pain point: integration
 - Is it possible to build a cloud data center like “take a HW box, install OS on it, and have an AWS-like IaaS ready to go”?
- A total IaaS solution for both public and private clouds

Container Computer Architecture

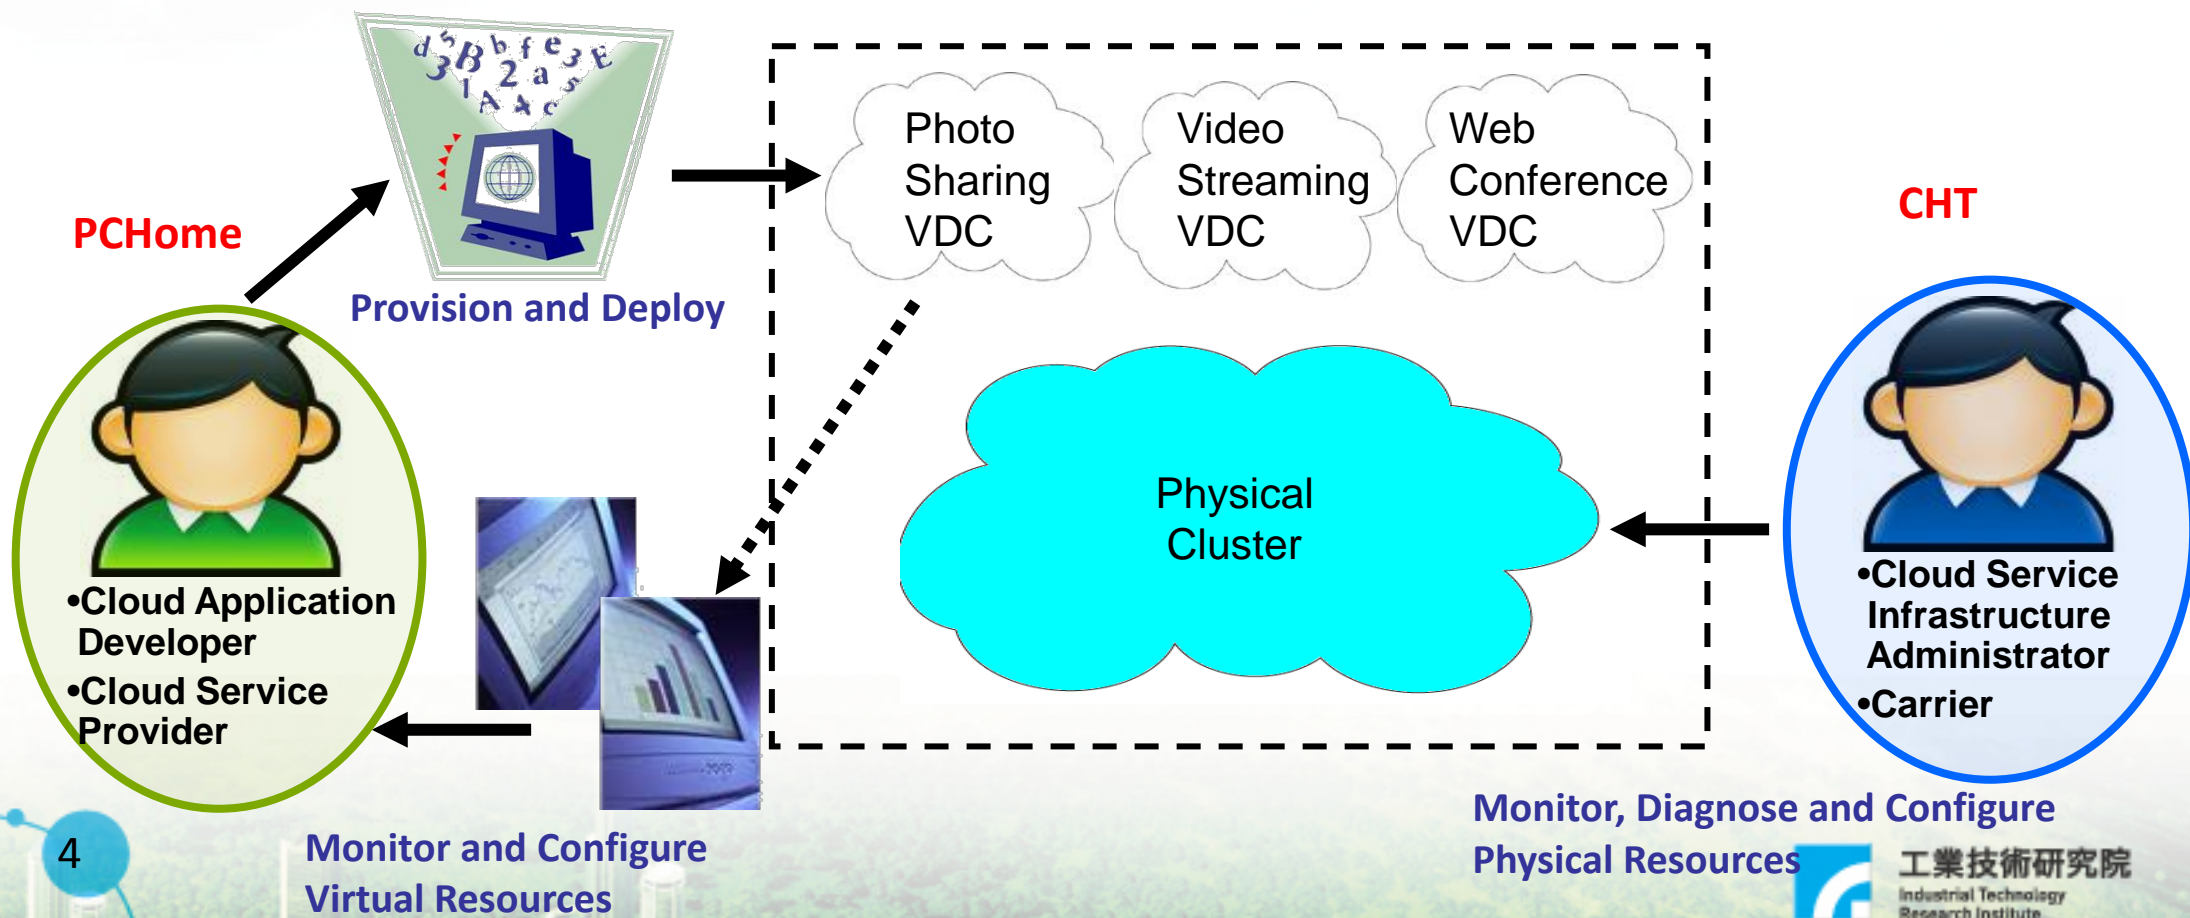

What is Cloud OS?

ITRI Cloud OS

Virtual Data Center Management

Physical Data Center Management

Cloud OS Service Model

- **Virtual data center** consists of one or multiple **virtual clusters**, each of which comprises one or multiple **VMs**
- Users provide a **Virtual Cluster** specification
 - No. of VM instances each with CPU performance and memory size requirement
 - Per-VM storage space requirement
 - External network bandwidth requirement
 - Security policy
 - Backup policy
 - Load balancing policy
 - Network configuration, e.g. public IP address and private IP address range
 - OS image and application image

VDCM – Assets (VDC, VC, VM)

The screenshot displays the CCMA VDCM 1.0 web interface. The left sidebar shows a tree view of assets under 'Assets', with 'test11' expanded and 'test11VC' and 'test22VC' highlighted with red boxes. The main content area shows the configuration for 'test11VC' under the 'Composition' tab. The configuration includes details such as Name, Create Time, Public IP, DNS, SSH/RDP Proxy, Platform, Firewall, Load Balancer, and Auto Scaling. Below the configuration is a table of instances, with one instance 'test11VM1' shown in a 'Running' state.

PDCM Event Monitor

PDCM Network Topology

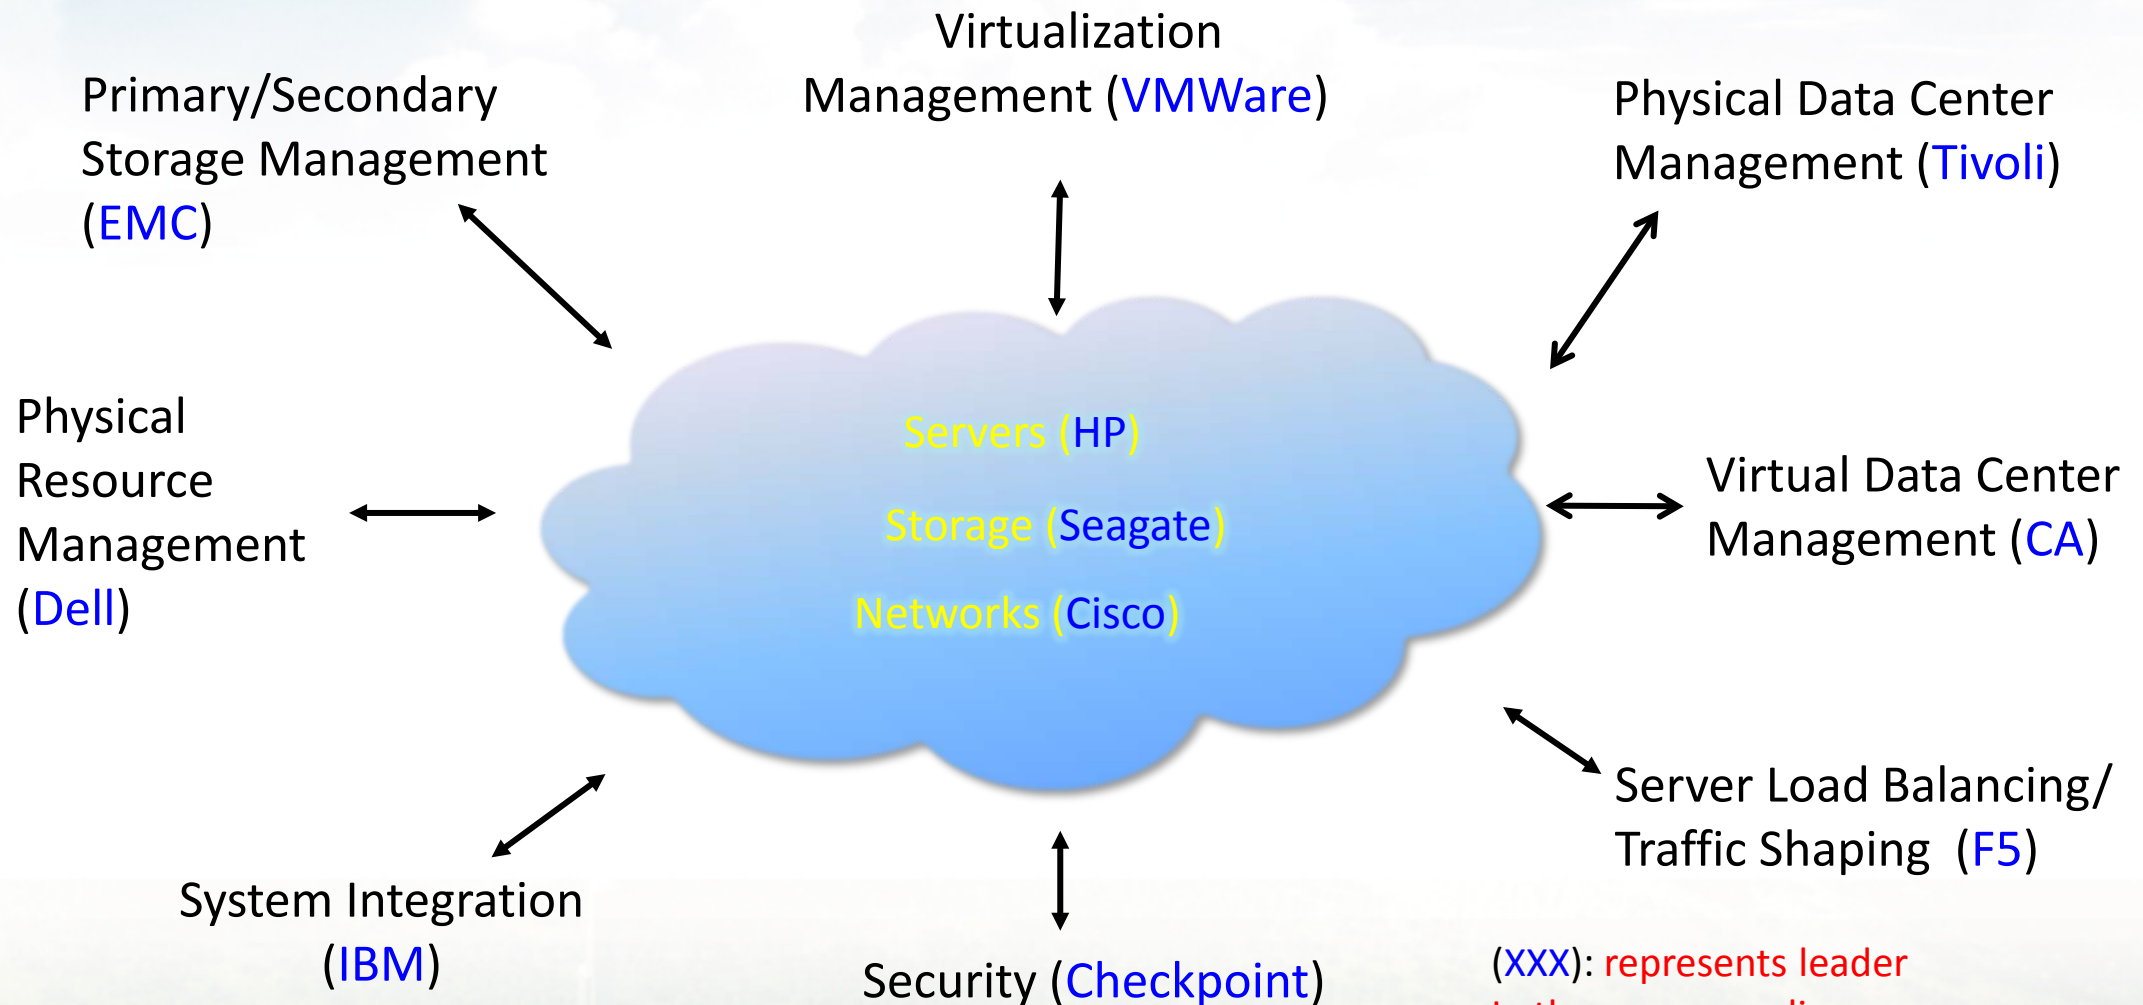

Key Cloud OS 1.0 Features – 1

- **Physical resource management (PRM): BIOS**
 - Centralized installation of all systems software
 - Start up, shut down, and recover a data center computer
- **Data center storage management: file management**
 - Main storage (**DMS**) : Forming a highly available global storage pool from: a set of commodity JBOD storage servers
 - Secondary storage (**DSS**): Offering streamlined disk-based snapshot/backup with configurable policy, and scalable de-duplication
- **Virtualization management: process management**
 - Resource provisioning management (**RPM**): allocate physical data center resources for a given virtual data center and auto-scaling
 - Dynamic virtual resource management (**DVMM**): use VM migration to support consolidation, load balancing and high availability

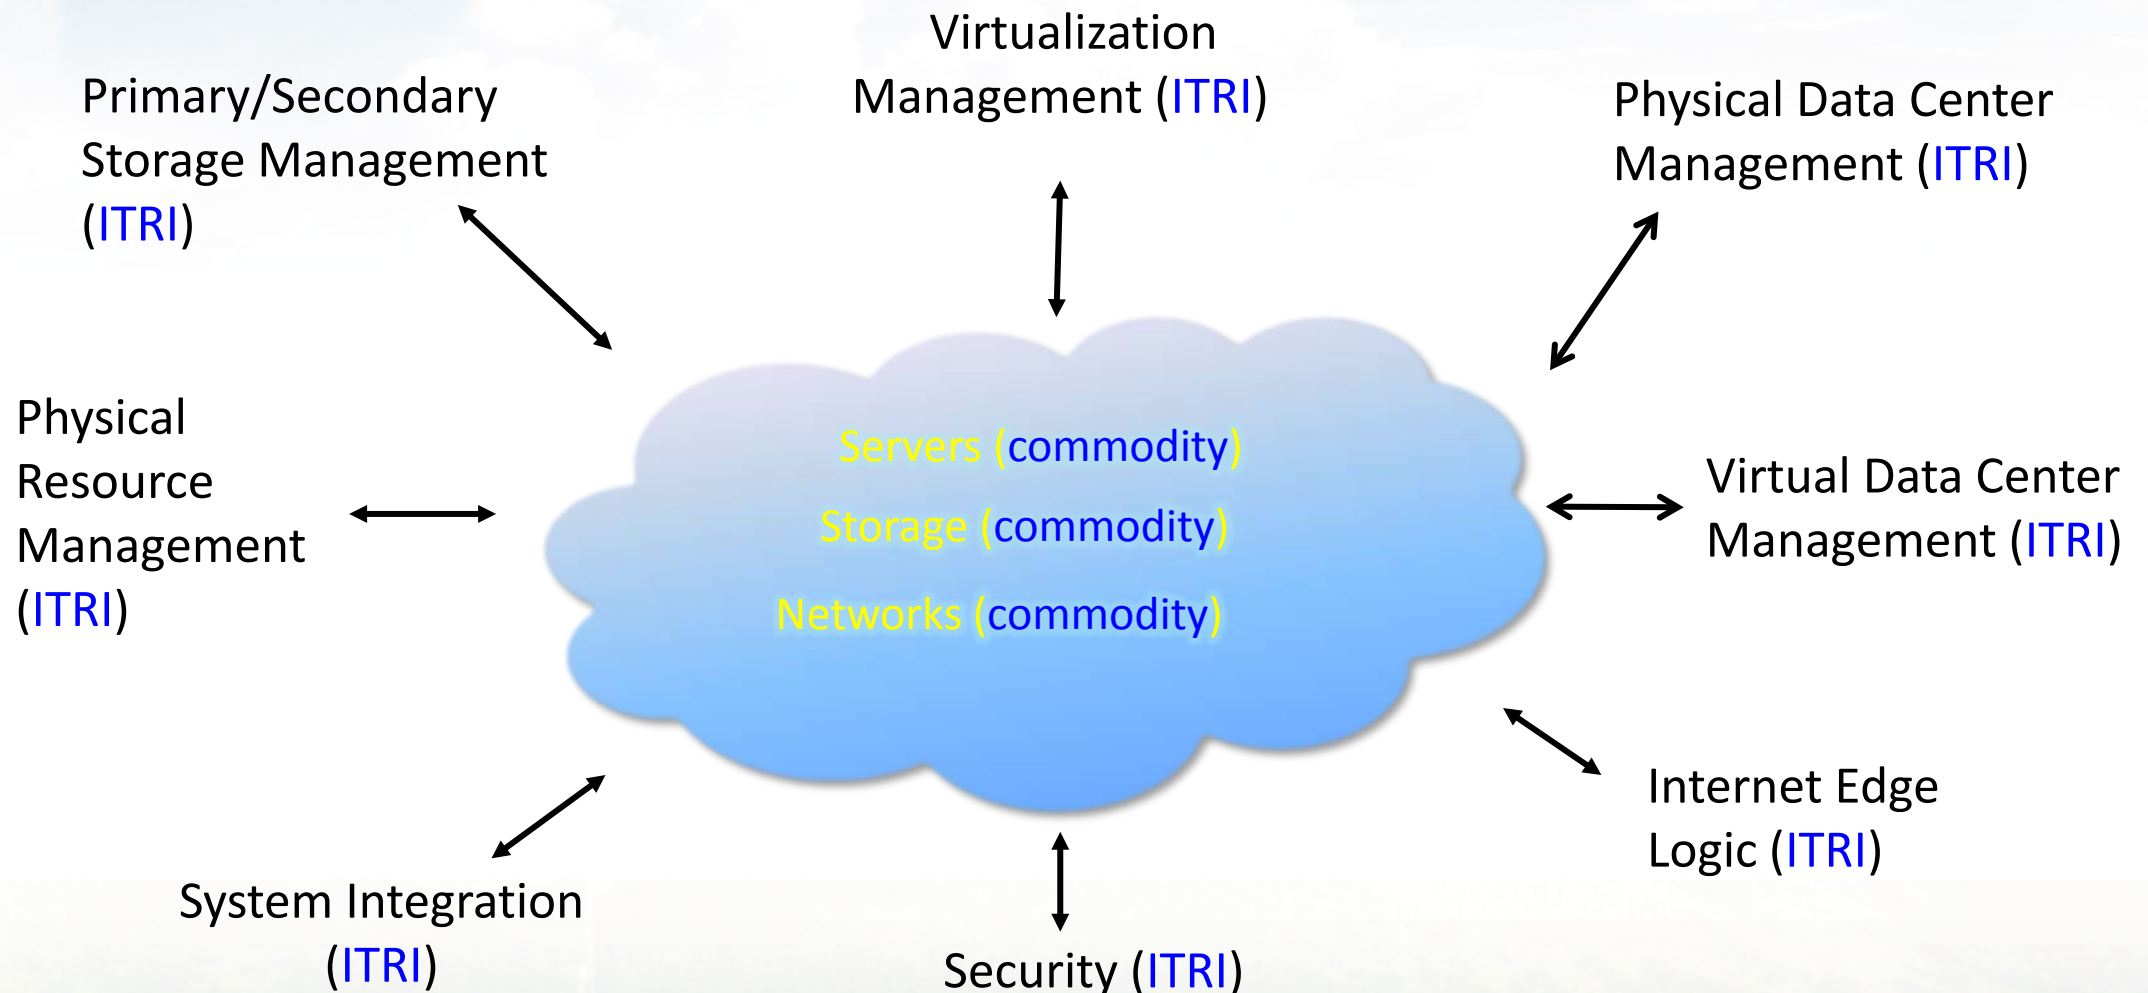

Key Cloud OS 1.0 Features – 2

- **Physical data center management (PDCM): system administration**
 - Comprehensive SNMP-based monitoring
 - Integrated virtual/physical resource mapping view
 - Unified event logging
 - Integrated trouble ticking support
- **Virtual data center management (VDCM): system administration**
 - VDC/VC/VM specification
 - Real-time resource usage and performance monitoring
- **Security: security**
 - Inter-VDC isolation
 - Centralized L3 and distributed L7 and web application firewalling
- **Internet edge logic**
 - Supporting inter-VM load balancing within a VC
 - DDoS attack mediation
 - Distributed traffic shaping

Building Cloud Data Center

ITRI Cloud OS's Way

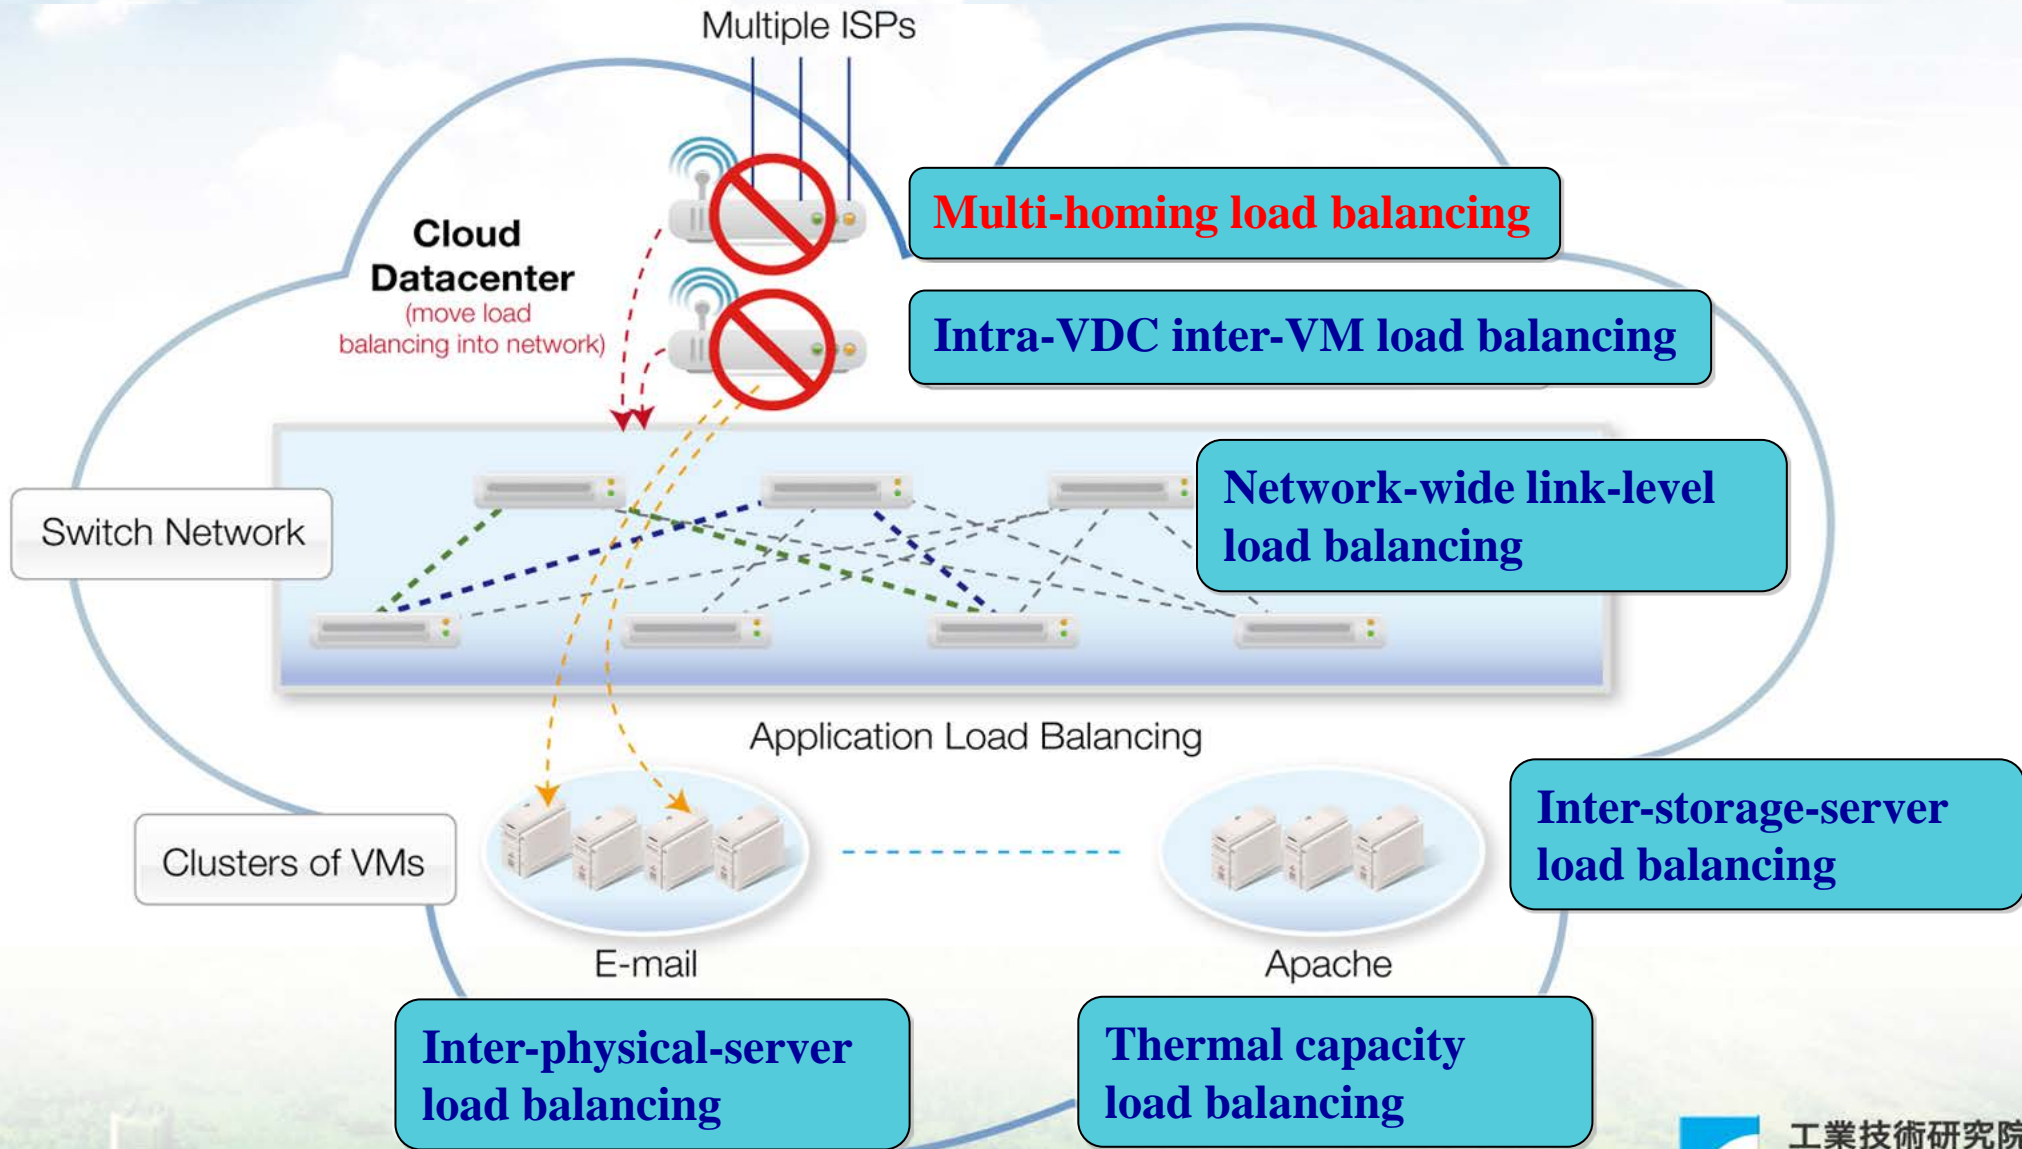

Strong Data Protection

- N-way data **replication** vs. RAID
 - End to end data availability: disk, server, and network failures
- Periodic snapshots for **local data backup** with de-duplication
- **Wide-area data backup**
 - Snapshot frequency: a couple of hours to days
- **Wide-area data replication** (Cloud OS 2.0)
 - Snapshot frequency: a couple of seconds to minutes

High Availability

- **High availability support** for Cloud OS subsystems
 - Active-passive: Linux HA + DRBD + edit logging/recovery
 - Active-active: MySQL and server load balancer
- **Disk state-preserving** fail-over for applications running inside VDCs
 - Shared persistent state + VM restart + take-over
- **Memory state-preserving** fail-over for applications running inside VDCs (Cloud OS 2.0)
 - Shared memory/persistent state + VM resume + take-over

Multi-Dimensional Load Balancing

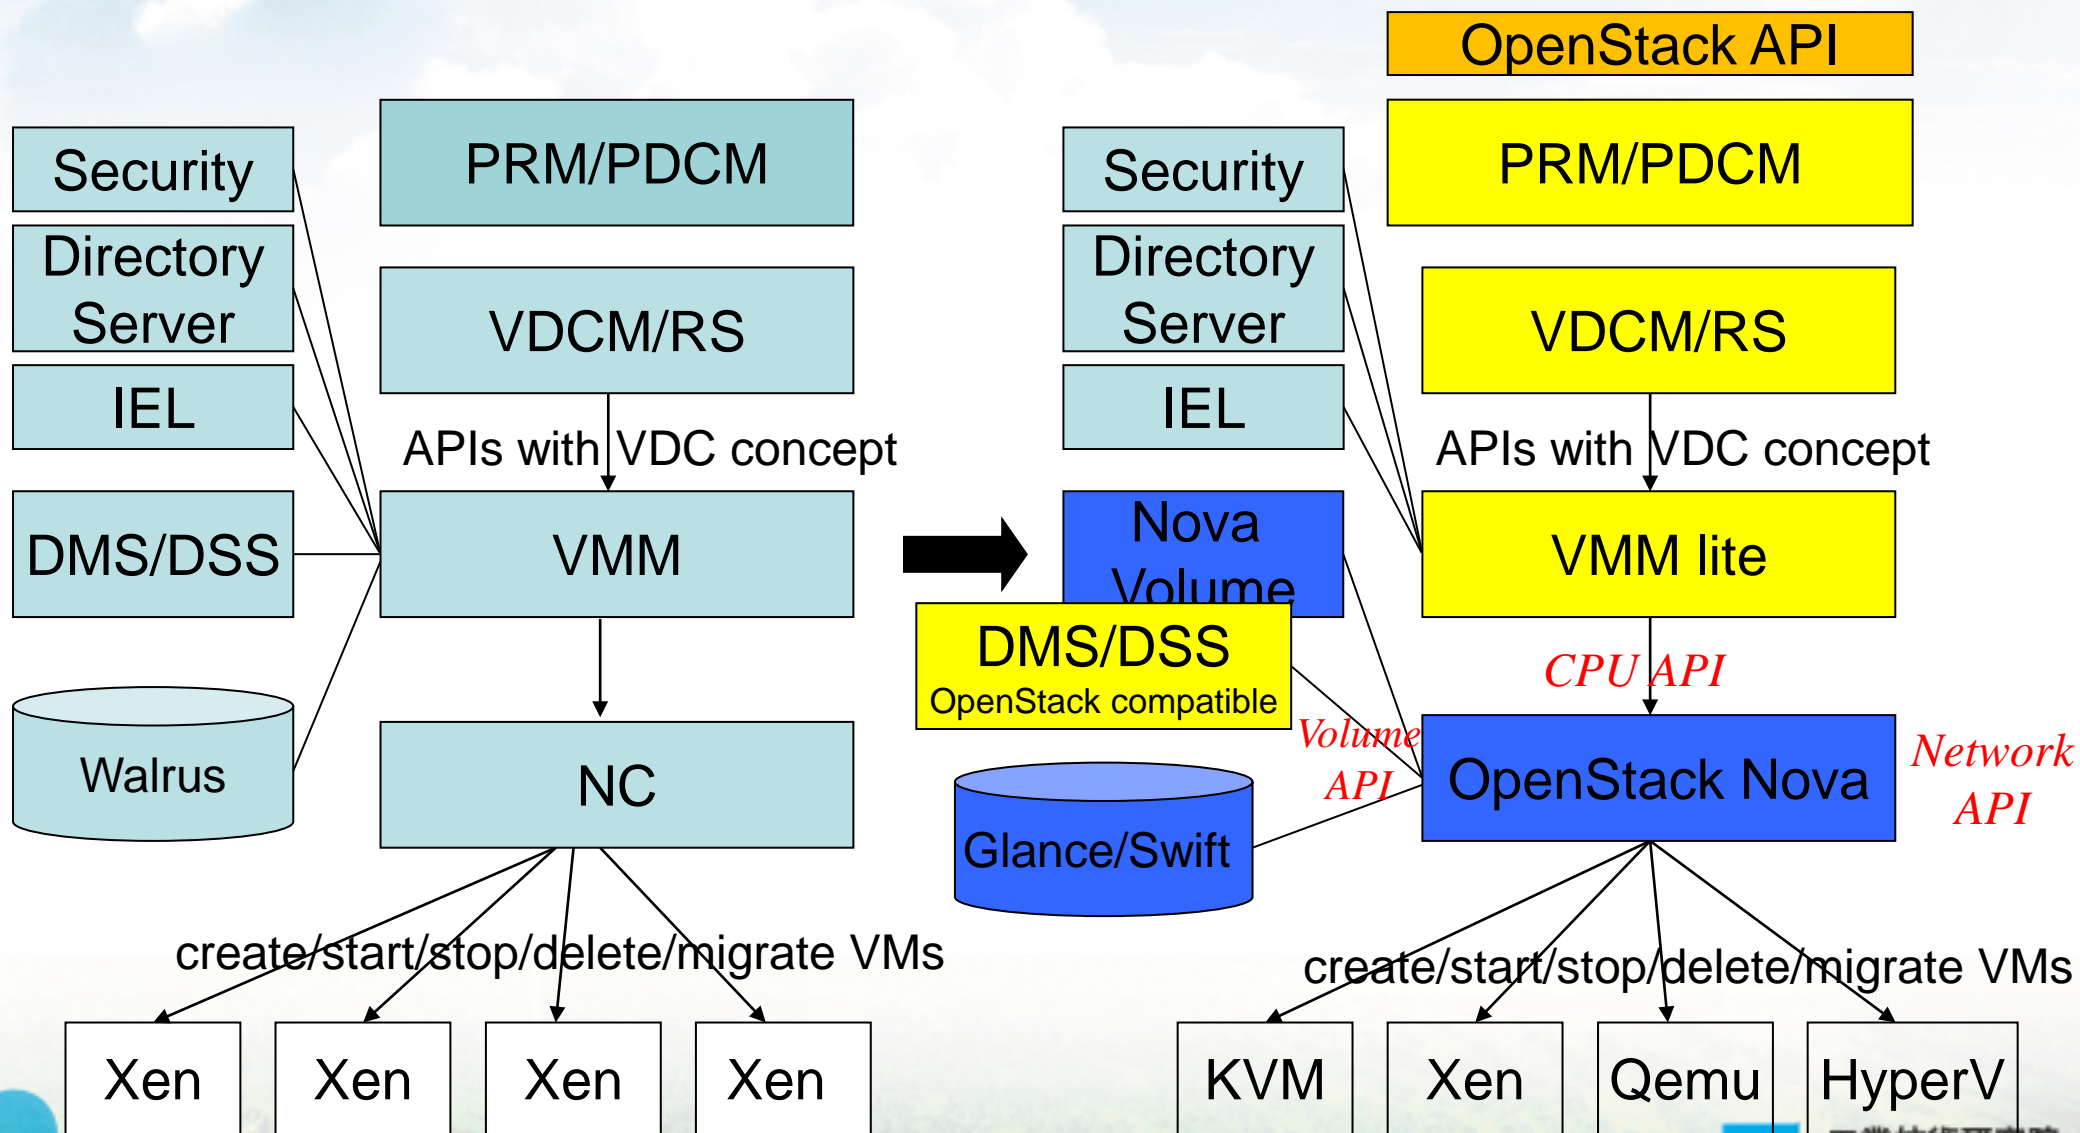

Cloud Security

- Any security breaches that are possible for a physical data center are equally likely for a virtual data center
 - L4/L7 and Web Application Firewall
- New security concerns
 - Interference between tenants on the same physical machines
 - [Inter-VDC isolation](#) vs. VLAN isolation

OpenStack

- Open Stack core:
 - **Nova**: VM provisioning
 - **Glance**: VM image upload and delivery
 - **Swift**: Object data storage
- RPM vs. Nova
 - Boot from remote cloned volume
 - Dynamic load balancing
 - Power consolidation
 - Dedicated physical machine pool
 - Auto-scaling

OpenStack-Compatible Cloud OS

Cloud OS 2.0

- OpenStack Compatible:
 - Nova's compute, volume and network API
 - OpenStack web service API
 - Target date: 10/1/2012
- Data center federation: Support for multi-site data centers
- Network virtualization: Support for hybrid cloud
- Wide-area data replication
- Memory de-duplication

Cloud Data Center Network

- Cloud data centers are **Big** and **Shared**
- **Scalable and available data center fabrics**
 - Not all links are used
 - No load-sensitive routing
 - Fail-over latency is high (> 5 seconds)
- **Network virtualization**: Each virtual data center (VDC) gets to define its own network
 - All VMs in a VDC belong to one flat subnet
 - Each VDC has its own private IP address space
 - Each VDC has a set of public IP addresses
 - Each VDC has a set of external VPN connections
 - Per-VDC Internet traffic shaping policy, intra-VDC and inter-VDC firewalling policy, and server load balancing policy

Peregrine

- A unified Layer-2-only network for LAN and SA
- **Centralized** control plane and **distributed** data plane
- Use only **Commodity** Ethernet switches
 - Army of commodity switches vs. few high-port-density switches
 - Requirements on switches: run fast and has programmable routing table
- Centralized load-balancing routing using real-time traffic matrix
 - Support for incremental and QoS-aware routing
- Fast fail-over using pre-computed primary/back routes
- Native support for network virtualization
 - Private IP address space reuse
 - Multi-tenancy VPN, NAT and traffic shaping
 - Intra-VDC or inter-VDC firewall

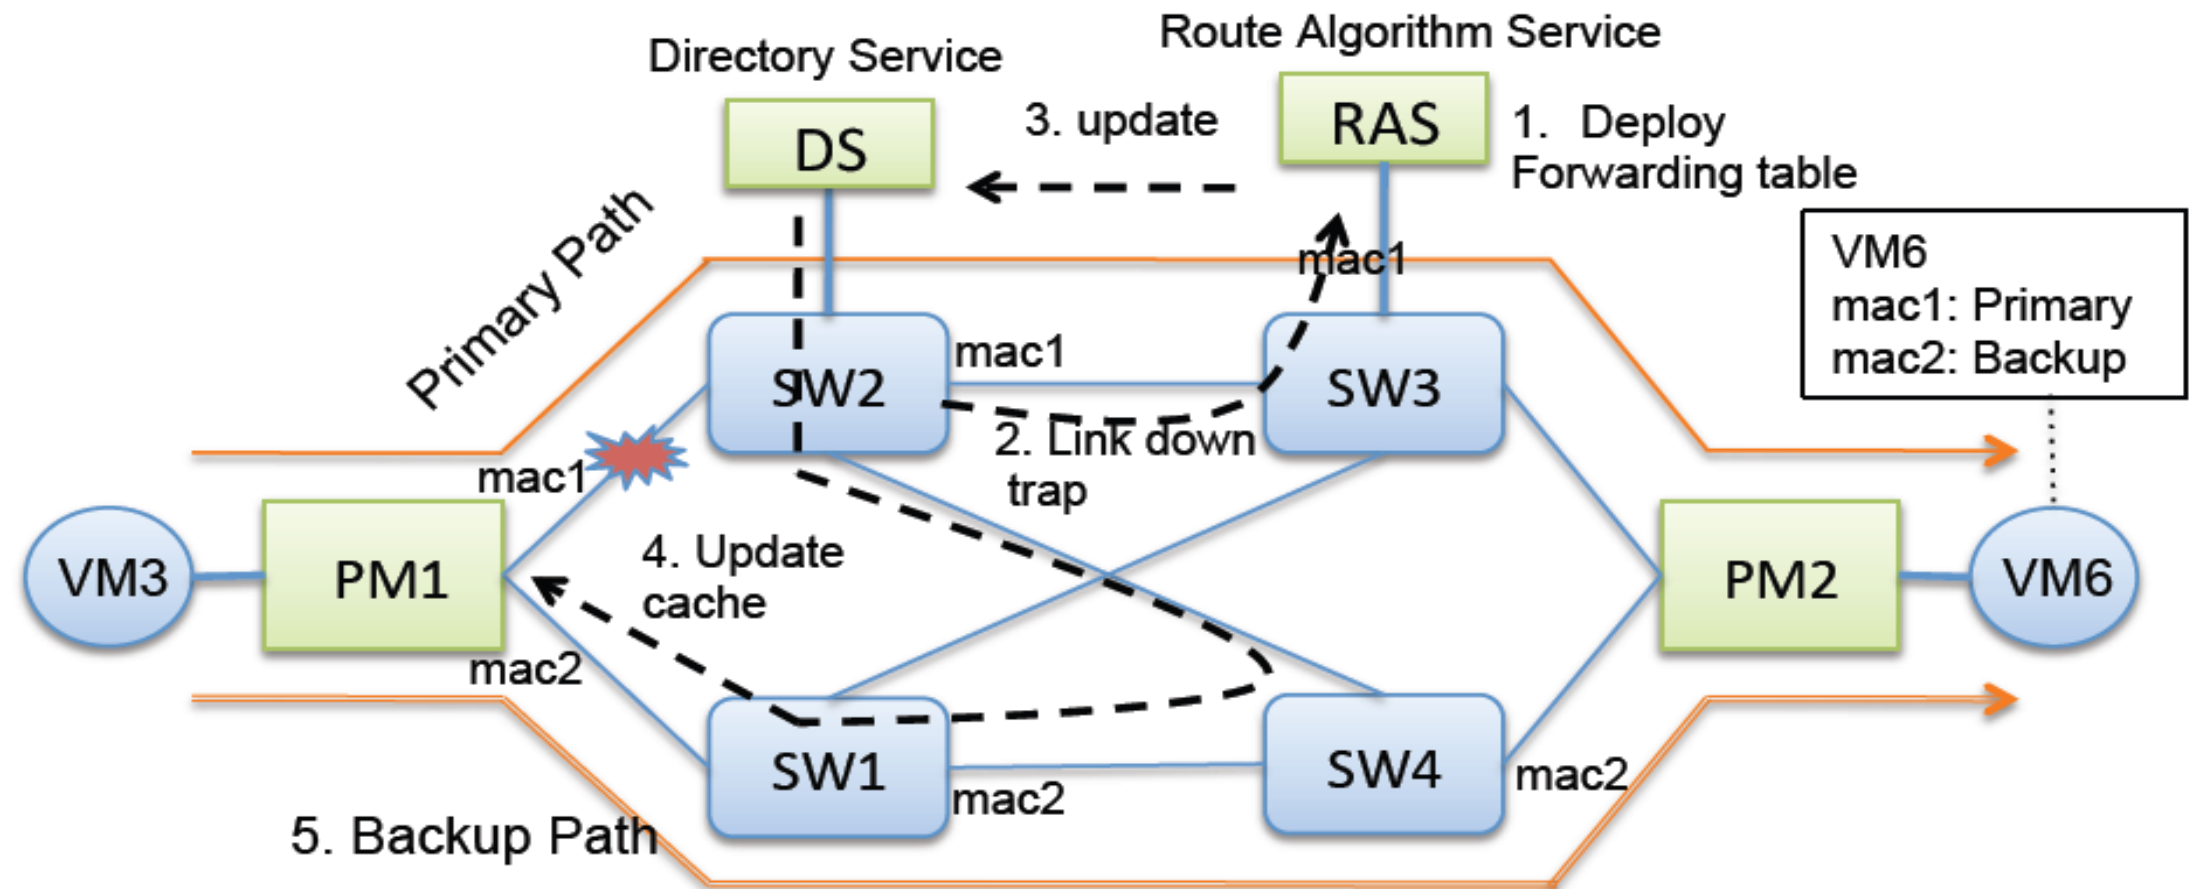

Software Architecture

Load Balancing Routing

- Collection of real-time traffic matrix
 - Traffic volume between each pair of VMs
 - Traffic volume between each pair of PMs
- Load balancing routing algorithm
 - Loads on the physical links
 - Number of hops
 - Forwarding table entries
 - Prioritization
- Computed routes are installed on switches

When a Network Link Fails

Private IP Address Space Reuse

- Requirement: Every VDC has a VDC ID and its own full 24-bit private IP address space (10.x.x.x), even though multiple VDCs run on top of the same data center network
- Two approaches:
 - Ethernet over TCP/UDP:
 - Every Ethernet packet is encapsulated inside an TCP/UDP packet or TCP/UDP connection as an Ethernet link
 - Needs to implement in software such Ethernet switch functions as source learning, flooding, VLAN, etc.
 - Can work with arbitrary IP networks
 - Multi-tenancy-aware IP-MAC mapping: our approach
 - Runs directly on L2 networks, no need for Ethernet switch emulation
 - Inter-virtual-data-center isolation

Peregrine Summary

- Peregrine is a **network system** technology, not a network device technology, and consists of
 - A hypervisor module running on every compute node
 - A route server and an ARP server
 - A VDC-aware VPN
- Runs **directly** on commodity Ethernet switches and NICs: fully leverages the benefit of **I/O virtualization**, which encourages direct NIC access from VM
- Under development: Refactor Peregrine as a Quantum plug-in

Conclusion

- Cloud computing is all about consolidation of IT infrastructures and usage-based resource allocation
 - Data center as a computer paradigm
- Cloud-scale data center industry is emerging
 - Integration is a real user pain point
 - An integrated solution with lesser components is much more desirable than an un-integrated set of more capable components
- ITRI's integrated data center solution, Container Computer 1.0 + Cloud OS 1.0, is expected to provide 70% of the functionalities at 1/3 cost of leading solutions from US
 - Virtual data center service abstraction

Thank You!
