# config\_data - Query or change configuration of Perl modules

### **SYNOPSIS**

```
# Get config/feature values
config_data --module Foo::Bar --feature bazzable
config_data --module Foo::Bar --config magic_number
# Set config/feature values
config_data --module Foo::Bar --set_feature bazzable=1
config_data --module Foo::Bar --set_config magic_number=42
# Print a usage message
config_data --help
```

### DESCRIPTION

The config\_data tool provides a command-line interface to the configuration of Perl modules. By "configuration", we mean something akin to "user preferences" or "local settings". This is a formalization and abstraction of the systems that people like Andreas Koenig (CPAN::Config), Jon Swartz (HTML::Mason::Config), Andy Wardley (Template::Config), and Larry Wall (perl's own Config.pm) have developed independently.

The configuration system emplyed here was developed in the context of Module::Build. Under this system, configuration information for a module Foo, for example, is stored in a module called Foo::ConfigData) (I would have called it Foo::Config, but that was taken by all those other systems mentioned in the previous paragraph...). These ...::ConfigData modules contain the configuration data, as well as publically accessible methods for querying and setting (yes, actually re-writing) the configuration data. The config\_data script (whose docs you are currently reading) is merely a front-end for those methods. If you wish, you may create alternate front-ends.

The two types of data that may be stored are called config values and feature values. A config value may be any perl scalar, including references to complex data structures. It must, however, be serializable using Data::Dumper. A feature is a boolean (1 or 0) value.

### USAGE

This script functions as a basic getter/setter wrapper around the configuration of a single module. On the command line, specify which module's configuration you're interested in, and pass options to get or set config or feature values. The following options are supported:

#### module

Specifies the name of the module to configure (required).

#### feature

When passed the name of a feature, shows its value. The value will be 1 if the feature is enabled, 0 if the feature is not enabled, or empty if the feature is unknown. When no feature name is supplied, the names and values of all known features will be shown.

#### config

When passed the name of a config entry, shows its value. The value will be displayed using Data::Dumper (or similar) as perl code. When no config name is supplied, the names and values of all known config entries will be shown.

#### set\_feature

Sets the given feature to the given boolean value. Specify the value as either 1 or 0.

set\_config

Sets the given config entry to the given value.

eval

If the --eval option is used, the values in set\_config will be evaluated as perl code before being stored. This allows moderately complicated data structures to be stored. For really complicated structures, you probably shouldn't use this command-line interface, just use the Perl API instead.

help

Prints a help message, including a few examples, and exits.
