

# NAME

Pod::Simple::PullParser -- a pull-parser interface to parsing Pod

# **SYNOPSIS**

```
my $parser = SomePodProcessor->new;
$parser->set_source( "whatever.pod" );
$parser->run;
```

## Or:

```
my $parser = SomePodProcessor->new;
$parser->set_source( $some_filehandle_object );
$parser->run;
```

## Or:

```
my $parser = SomePodProcessor->new;
$parser->set_source( \$document_source );
$parser->run;
```

## Or:

```
my $parser = SomePodProcessor->new;
$parser->set_source( \@document_lines );
$parser->run;
```

### And elsewhere:

```
require 5;
package SomePodProcessor;
use strict;
use base qw(Pod::Simple::PullParser);
sub run {
  my $self = shift;
Token:
  while(my $token = $self->get_token) {
   ...process each token...
  }
}
```

# DESCRIPTION

This class is for using Pod::Simple to build a Pod processor -- but one that uses an interface based on a stream of token objects, instead of based on events.

This is a subclass of *Pod::Simple* and inherits all its methods.

A subclass of Pod::Simple::PullParser should define a run method that calls \$token = \$parser->get\_token to pull tokens.

See the source for Pod::Simple::RTF for an example of a formatter that uses Pod::Simple::PullParser.

# METHODS

my \$token = \$parser->get\_token

This returns the next token object (which will be of a subclass of

# Perl

#### Perl version 5.20.1 documentation - Pod::Simple::PullParser

Pod::Simple::PullParserToken), or undef if the parser-stream has hit the end of the document.

\$parser->unget\_token( \$token )

\$parser->unget\_token( \$token1, \$token2, ... )

This restores the token object(s) to the front of the parser stream.

The source has to be set before you can parse anything. The lowest-level way is to call set\_source:

\$parser->set\_source( \$filename )

\$parser->set\_source( \$filehandle\_object )

\$parser->set\_source(\\$document\_source)

\$parser->set\_source(\@document\_lines)

Or you can call these methods, which Pod::Simple::PullParser has defined to work just like Pod::Simple's same-named methods:

\$parser->parse\_file(...)

\$parser->parse\_string\_document(...)

\$parser->filter(...)

\$parser->parse\_from\_file(...)

For those to work, the Pod-processing subclass of Pod::Simple::PullParser has to have defined a \$parser->run method -- so it is advised that all Pod::Simple::PullParser subclasses do so. See the Synopsis above, or the source for Pod::Simple::RTF.

Authors of formatter subclasses might find these methods useful to call on a parser object that you haven't started pulling tokens from yet:

my \$title\_string = \$parser->get\_title

This tries to get the title string out of \$parser, by getting some tokens, and scanning them for the title, and then ungetting them so that you can process the token-stream from the beginning.

For example, suppose you have a document that starts out:

=head1 NAME

Hoo::Boy::Wowza -- Stuff B<wow> yeah!

\$parser->get\_title on that document will return "Hoo::Boy::Wowza -- Stuff wow yeah!". If the
document starts with:

=head1 Name

Hoo::Boy::W00t -- Stuff B<w00t> yeah!

Then you'll need to pass the nocase option in order to recognize "Name":

\$parser->get\_title(nocase => 1);

In cases where get\_title can't find the title, it will return empty-string ("").

my \$title\_string = \$parser->get\_short\_title

This is just like get\_title, except that it returns just the modulename, if the title seems to be of the form "SomeModuleName -- description".

For example, suppose you have a document that starts out:

=head1 NAME

Hoo::Boy::Wowza -- Stuff B<wow> yeah!

then \$parser->get\_short\_title on that document will return "Hoo::Boy::Wowza".

But if the document starts out:

=head1 NAME

```
Hooboy, stuff B<wow> yeah!
```

then \$parser->get\_short\_title on that document will return "Hooboy, stuff wow yeah!". If the document starts with:

=head1 Name

Hoo::Boy::W00t -- Stuff B<w00t> yeah!

Then you'll need to pass the nocase option in order to recognize "Name":

\$parser->get\_short\_title(nocase => 1);

If the title can't be found, then get\_short\_title returns empty-string ("").

#### \$author\_name = \$parser->get\_author

This works like get\_title except that it returns the contents of the "=head1 AUTHOR\n\nParagraph...\n" section, assuming that that section isn't terribly long. To recognize a "=head1 Author\n\nParagraph\n" section, pass the nocase otpion:

```
$parser->get_author(nocase => 1);
```

(This method tolerates "AUTHORS" instead of "AUTHOR" too.)

#### \$description\_name = \$parser->get\_description

This works like get\_title except that it returns the contents of the "=head1 DESCRIPTION\n\nParagraph...\n" section, assuming that that section isn't terribly long. To recognize a "=head1 Description\n\nParagraph\n" section, pass the nocase otpion:

```
$parser->get_description(nocase => 1);
```

#### \$version\_block = \$parser->get\_version

This works like get\_title except that it returns the contents of the "=head1 VERSION\n\n[BIG BLOCK]\n" block. Note that this does NOT return the module's \$VERSION!! To recognize a "=head1 Version\n\n[BIG BLOCK]\n" section, pass the nocase otpion:

\$parser->get\_version(nocase => 1);

## NOTE

You don't actually *have* to define a run method. If you're writing a Pod-formatter class, you should define a run just so that users can call parse\_file etc, but you don't *have* to.

And if you're not writing a formatter class, but are instead just writing a program that does something simple with a Pod::PullParser object (and not an object of a subclass), then there's no reason to bother subclassing to add a run method.
