```

The next lemma shows that L^1 convergence of a sequence of functions follows from almost everywhere convergence and the weaker condition of the convergence of the integrated norms (or even just the nontrivial inequality about them). Useful in a lot of contexts! This statement (or its variations) are known as Scheffe lemma.

The formalization is more painful as one should jump back and forth between reals and ereals and justify all the time positivity or integrability (thankfully, measurability is handled more or less automatically).

proposition *Scheffe_lemma1:*

```

6.17.1 Abstract

The following document presents a proof that the Continuum is uncountable. It is formalised in the Isabelle/Isar theorem proving system.

Theorem: The Continuum $\mathbb{R}$ is not denumerable. In other words, there does not exist a function $f: \mathbb{N} \Rightarrow \mathbb{R}$ such that f is surjective.

Outline: An elegant informal proof of this result uses Cantor's Diagonalisation argument. The proof presented here is not this one.

First we formalise some properties of closed intervals, then we prove the Nested Interval Property. This property relies on the completeness of the Real numbers and is the foundation for our argument. Informally it states that an intersection of countable closed intervals (where each successive interval is a subset of the last) is non-empty. We then assume a surjective function $f: \mathbb{N} \Rightarrow \mathbb{R}$ exists and find a real x such that x is not in the range of f by generating a sequence of closed intervals then using the Nested Interval Property.

theorem *real_non_denum*: $\nexists f :: \text{nat} \Rightarrow \text{real}. \text{surj } f$

proof

assume $\exists f :: \text{nat} \Rightarrow \text{real}. \text{surj } f$

then obtain $f :: \text{nat} \Rightarrow \text{real}$ **where** $\text{surj } f$..

First we construct a sequence of nested intervals, ignoring *range f*.

have $a < b \implies \exists ka kb. ka < kb \wedge \{ka..kb\} \subseteq \{a..b\} \wedge c \notin \{ka..kb\}$ **for** $a b c :: \text{real}$

by (*auto simp add: not_le cong: conj_cong*)

(*metis dense le_less_linear less_linear less_trans order_refl*)

then obtain $i j$ **where** ij :

$a < b \implies i a b c < j a b c$

$a < b \implies \{i a b c .. j a b c\} \subseteq \{a .. b\}$

$a < b \implies c \notin \{i a b c .. j a b c\}$

for $a b c :: \text{real}$

by *metis*

define ivl **where** $ivl =$

$\text{rec\_nat } (f\ 0 + 1, f\ 0 + 2) (\lambda n x. (i\ (fst\ x)\ (snd\ x)\ (f\ n), j\ (fst\ x)\ (snd\ x)\ (f\ n)))$

define I **where** $I\ n = \{fst\ (ivl\ n) .. snd\ (ivl\ n)\}$ **for** n

have ivl [*simp*]:

$ivl\ 0 = (f\ 0 + 1, f\ 0 + 2)$

$\bigwedge n. ivl\ (Suc\ n) = (i\ (fst\ (ivl\ n))\ (snd\ (ivl\ n))\ (f\ n), j\ (fst\ (ivl\ n))\ (snd\ (ivl\ n))\ (f\ n))$

unfolding ivl_def **by** *simp_all*

This is a decreasing sequence of non-empty intervals.

```

have less: fst (ivl n) < snd (ivl n) for n
  by (induct n) (auto intro!: ij)

have decseq I
  unfolding I_def decseq_Suc_iff ivl fst_conv snd_conv
  by (intro ij allI less)

```

Now we apply the finite intersection property of compact sets.

```

have I 0  $\cap$  ( $\bigcap i. I i$ )  $\neq \{\}$

6.18.24 Contractible spaces

The definition (which agrees with "contractible" on subsets of Euclidean space) is a little cryptic because we don't in fact assume that the constant "a" is in the space. This forces the convention that the empty space / set is contractible, avoiding some special cases.

definition *contractible_space* where

contractible_space $X \equiv \exists a. \text{homotopic\_with } (\lambda x. \text{True}) X X \text{ id } (\lambda x. a)$

6.18.29 Nullhomotopic mappings

A mapping out of a sphere is nullhomotopic iff it extends to the ball. This even works out in the degenerate cases when the radius is ≤ 0 , and we also don't need to explicitly assume continuity since it's already implicit in both sides of the equivalence.

```

lemma nullhomotopic_from_lemma:
  assumes contg: continuous_on (cball a r - {a}) g
    and fa:  $\bigwedge e. 0 < e$ 
       $\implies \exists d. 0 < d \wedge (\forall x. x \neq a \wedge \text{norm}(x - a) < d \implies \text{norm}(g\ x - f\ a) < e)$ 
    and r:  $\bigwedge x. x \in \text{cball } a\ r \wedge x \neq a \implies f\ x = g\ x$

qed

This function returns the angle of a complex number from its representation in polar coordinates. Due to periodicity, its range is arbitrary. *Arg2pi* follows HOL Light in adopting the interval $[0, 2\pi)$. But we have the same periodicity issue with logarithms, and it is usual to adopt the same interval for the complex logarithm and argument functions. Further on down, we shall define both functions for the interval $(-\pi, \pi]$. The present version is provided for compatibility.

```

Several equivalent definitions of the Gamma function and its most important properties. Also contains the definition and some properties of the

log-Gamma function and the Digamma function and the other Polygamma functions.

Based on the Gamma function, we also prove the Weierstraß product form of the sin function and, based on this, the solution of the Basel problem (the sum over all $1 / \text{real } (n^2)$).

6.23.1 The Euler form and the logarithmic Gamma function

We define the Gamma function by first defining its multiplicative inverse $rGamma$. This is more convenient because $rGamma$ is entire, which makes proofs of its properties more convenient because one does not have to watch out for discontinuities. (e.g. $rGamma$ fulfils $rGamma \ z = z * rGamma \ (z + 1)$ everywhere, whereas the Γ function does not fulfil the analogous equation on the non-positive integers)

We define the Γ function (resp. its reciprocal) in the Euler form. This form has the advantage that it is a relatively simple limit that converges everywhere. The limit at the poles is 0 (due to division by 0). The functional equation $\Gamma \ (z + 1) = z * \Gamma \ z$ follows immediately from the definition.

definition $\Gamma\_series :: ('a :: \{banach, real\_normed\_field\}) \Rightarrow nat \Rightarrow 'a$ where
 $\Gamma\_series \ z \ n = \text{fact } n * \exp \ (z * \text{of\_real } (\ln \ (\text{of\_nat } n))) / \text{pochhammer } z \ (n+1)$

definition $\Gamma\_series' :: ('a :: \{banach, real\_normed\_field\}) \Rightarrow nat \Rightarrow 'a$

```

We now show that the series that defines the Γ function in the Euler form converges and that the function defined by it is continuous on the complex halfspace with positive real part.

We do this by showing that the logarithm of the Euler series is continuous and converges locally uniformly, which means that the log-Gamma function defined by its limit is also continuous.

This will later allow us to lift holomorphicity and continuity from the log-Gamma function to the inverse of the Gamma function, and from that to the Gamma function itself.

definition $\text{ln\_Gamma\_series} :: ('a :: \{\text{banach, real\_normed\_field}, \text{ln}\}) \Rightarrow \text{nat} \Rightarrow 'a$ **where**
 $\text{ln\_Gamma\_series } z n = z * \text{ln } (\text{of\_nat } n) - \text{ln } z - (\sum k=1..n. \text{ln } (z / \text{of\_nat } k + 1))$

definition $\text{ln\_Gamma\_series}' :: ('a :: \{\text{banach, real\_normed\_field}, \text{ln}\}) \Rightarrow \text{nat} \Rightarrow 'a$ **where**
 $\text{ln\_Gamma\_series}' z n =$
 $- \text{euler\_mascheroni} * z - \text{ln } z + (\sum k=1..n. z / \text{of\_nat } n - \text{ln } (z / \text{of\_nat } k + 1))$

definition $\text{ln\_Gamma} :: ('a :: \{\text{banach, real\_normed\_field}, \text{ln}\}) \Rightarrow 'a$ **where**
 $\text{ln\_Gamma } z = \text{lim } (\text{ln\_Gamma\_series } z)$

We now show that the log-Gamma series converges locally uniformly for all complex numbers except the non-positive integers. We do this by proving that the series is locally Cauchy.

We define a type class that captures all the fundamental properties of the inverse of the Gamma function and defines the Gamma function upon that. This allows us to instantiate the type class both for the reals and for the complex numbers with a minimal amount of proof duplication.

class *Gamma* = *real_normed_field* + *complete_space* +
fixes $r\text{Gamma} :: 'a \Rightarrow 'a$
assumes $r\text{Gamma\_eq\_zero\_iff\_aux}: r\text{Gamma } z = 0 \longleftrightarrow (\exists n. z = - \text{of\_nat } n)$
assumes *differentiable_rGamma_aux1*:
 $(\bigwedge n. z \neq - \text{of\_nat } n) \implies$
 $\text{let } d = (\text{THE } d. (\lambda n. \sum k < n. \text{inverse } (\text{of\_nat } (\text{Suc } k)) - \text{inverse } (z + \text{of\_nat } k)))$
 $\longrightarrow d) - \text{scaleR } \text{euler\_mascheroni } 1$
 $\text{in } \text{filterlim } (\lambda y. (r\text{Gamma } y - r\text{Gamma } z + r\text{Gamma } z * d * (y - z)) /_R$
 $\text{norm } (y - z)) (\text{nhds } 0) (\text{at } z)$
assumes *differentiable_rGamma_aux2*:
 $\text{let } z = - \text{of\_nat } n$
 $\text{in } \text{filterlim } (\lambda y. (r\text{Gamma } y - r\text{Gamma } z - (-1)^n * (\text{prod of\_nat } \{1..n\})$
 $* (y - z)) /_R$
 $\text{norm } (y - z)) (\text{nhds } 0) (\text{at } z)$
assumes $r\text{Gamma\_series\_aux}: (\bigwedge n. z \neq - \text{of\_nat } n) \implies$

6.23.7 The uniqueness of the real Gamma function

The following is a proof of the Bohr–Mollerup theorem, which states that any log-convex function G on the positive reals that fulfils $G(1) = 1$ and satisfies the functional equation $G(x + 1) = x G(x)$ must be equal to the Gamma function. In principle, if G is a holomorphic complex function, one could then extend this from the positive reals to the entire complex plane (minus the non-positive integers, where the Gamma function is not defined).

```

using *real_le_sqrt sqrt_le_D* **by** *blast*

Isabelle's type system makes it very difficult to do an induction over the dimension of a Euclidean space type, because the type would change in the inductive step. To avoid this problem, we instead formulate the problem in a more concrete way by unfolding the definition of the Euclidean norm.

6.26 Integral Test for Summability

theory *Integral_Test*

imports *Henstock_Kurzweil_Integration*

begin

The integral test for summability. We show here that for a decreasing non-negative function, the infinite sum over that function evaluated at the natural numbers converges iff the corresponding integral converges.

As a useful side result, we also provide some results on the difference between the integral and the partial sum. (This is useful e.g. for the definition of the Euler-Mascheroni constant)

```

An existence theorem for "improper" integrals. Hake's theorem implies that if the integrals over subintervals have a limit, the integral exists. We only need to assume that the integrals are bounded, and we get absolute integrability, but we also need a (rather weak) bound assumption on the function.

```

6.29.2 A differentiability-like property of the indefinite integral.

proposition *integrable_ccontinuous_explicit:*

fixes $f :: 'a::\text{euclidean\_space} \Rightarrow 'b::\text{euclidean\_space}$

assumes $\bigwedge a b::'a. f \text{ integrable\_on } \text{cbox } a \ b$

obtains N **where**

negligible N

$\bigwedge x e. \llbracket x \notin N; 0 < e \rrbracket \implies$

$\exists d > 0. \forall h. 0 < h \wedge h < d \longrightarrow$

$\text{norm}(\text{integral } (\text{cbox } x \ (x + h *_{\mathbb{R}} \text{One})) \ f \ /_{\mathbb{R}} h^{\wedge \text{DIM}('a)} - f$

$x) < e$

proof –

define BOX **where** $BOX \equiv \lambda h. \lambda x::'a. \text{cbox } x \ (x + h *_{\mathbb{R}} \text{One})$

define $BOX2$ **where** $BOX2 \equiv \lambda h. \lambda x::'a. \text{cbox } (x - h *_{\mathbb{R}} \text{One}) \ (x + h *_{\mathbb{R}} \text{One})$

define i **where** $i \equiv \lambda h x. \text{integral } (BOX \ h \ x) \ f \ /_{\mathbb{R}} h^{\wedge \text{DIM}('a)}$

define Ψ **where** $\Psi \equiv \lambda x r. \forall d > 0. \exists h. 0 < h \wedge h < d \wedge r \leq \text{norm}(i \ h \ x - f \ x)$

let $?N = \{x. \exists e > 0. \Psi \ x \ e\}$

have $\exists N. \text{negligible } N \wedge (\forall x e. x \notin N \wedge 0 < e \longrightarrow \neg \Psi \ x \ e)$

proof (*rule exI ; intro conjI allI impI*)

let $?M = \bigcup n. \{x. \Psi \ x \ (\text{inverse}(\text{real } n + 1))\}$

have *negligible* $(\{x. \Psi \ x \ \mu\} \cap \text{cbox } a \ b)$

if $\mu > 0$ **for** $a \ b \ \mu$

proof (*cases negligible(cbox a b)*)

case *True*

then show *?thesis*

by (*simp add: negligible_Int*)

next

case *False*

then have $\text{box } a \ b \neq \{\}$

by (*simp add: negligible_interval*)

then have $ab: \bigwedge i. i \in \text{Basis} \implies a \cdot i < b \cdot i$

by (*simp add: box_ne_empty*)

show *?thesis*

unfolding *negligible_outer_le*

proof (*intro allI impI*)

fix $e::\text{real}$

let $?ee = (e * \mu) / 2 / 6^{\wedge (\text{DIM}('a))}$

assume $e > 0$

then have *gt0: ?ee > 0*

using $\langle \mu > 0 \rangle$ **by** *auto*

have $f': f \text{ integrable\_on } \text{cbox } (a - \text{One}) \ (b + \text{One})$

using *assms* **by** *blast*

obtain γ **where** *gauge* γ

and $\gamma: \bigwedge p. \llbracket p \text{ tagged\_partial\_division\_of } (\text{cbox } (a - \text{One}) \ (b + \text{One})) ;$

$\gamma \text{ fine } p \rrbracket$

$\implies (\sum (x, k) \in p. \text{norm } (\text{content } k *_{\mathbb{R}} f \ x - \text{integral } k \ f)) < ?ee$

6.30 Embedding Measure Spaces with a Function

```

theory Embed_Measure
imports Binary_Product_Measure
begin

```

Given a measure space on some carrier set Ω and a function f , we can define a push-forward measure on the carrier set $f(\Omega)$ whose σ -algebra is the one generated by mapping f over the original sigma algebra.

This is useful e.g. when f is injective, i.e. it is some kind of “tagging” function. For instance, suppose we have some algebraic datatype of values with various constructors, including a constructor *RealVal* for real numbers. Then *embed_measure* allows us to lift a measure on real numbers to the appropriate subset of that algebraic datatype.

definition *embed_measure* :: *'a measure* $\Rightarrow$ (*'a* $\Rightarrow$ *'b*) $\Rightarrow$ *'b measure* **where**
embed_measure *M f* = *measure_of* (*f* ‘ *space M*) {*f* ‘ *A* | *A. A* $\in$ *sets M*}
