6.37 Infinite sums

In this theory, we introduce the definition of infinite sums, i.e., sums ranging over an infinite, potentially uncountable index set with no particular

ordering. (This is different from series. Those are sums indexed by natural numbers, and the order of the index set matters.)

Our definition is quite standard: $s := \sum_{x \in A} f(x)$ is the limit of finite sums $s_F := \sum_{x \in F} f(x)$ for increasing F . That is, s is the limit of the net s_F where F are finite subsets of A ordered by inclusion. We believe that this is the standard definition for such sums. See, e.g., Definition 4.11 in [2]. This definition is quite general: it is well-defined whenever f takes values in some commutative monoid endowed with a Hausdorff topology. (Examples are reals, complex numbers, normed vector spaces, and more.)

The converse of *abs_summable_summable* does not hold: Consider the Hilbert space of square-summable sequences. Let e_i denote the sequence with 1 in the i th position and 0 elsewhere. Let $f(i) := e_i/i$ for $i \geq 1$. We have $\neg f \text{ abs\_summable\_on } UNIV$ because $\|f(i)\| = 1/i$ and thus the sum over $\|f(i)\|$ diverges. On the other hand, we have $f \text{ summable\_on } UNIV$; the limit is the sequence with $1/i$ in the i th position.

(We have not formalized this separating example here because to the best of our knowledge, this Hilbert space has not been formalized in Isabelle/HOL yet.)

lemma (in uniform_space) *cauchy_filter_complete_converges*:
assumes *cauchy_filter F complete A F ≤ principal A F ≠ bot*
shows $\exists c. F \leq \text{nhds } c$
using *assms unfolding complete_uniform by blast*

The following lemma indeed needs a complete space (as formalized by the premise *complete UNIV*). The following two counterexamples show this:

- Consider the real vector space V of sequences with finite support, and with the ℓ_2 -norm (sum of squares). Let e_i denote the sequence with a 1 at position i . Let $f : \mathbb{Z} \rightarrow V$ be defined as $f(n) := e_{|n|}/n$ (with $f(0) := 0$). We have that $\sum_{n \in \mathbb{Z}} f(n) = 0$ (it even converges absolutely). But $\sum_{n \in \mathbb{N}} f(n)$ does not exist (it would converge against a sequence with infinite support).
- Let f be a positive rational valued function such that $\sum_{x \in B} f(x)$ is $\sqrt{2}$ and $\sum_{x \in A} f(x)$ is 1 (over the reals, with $A \subseteq B$). Then $\sum_{x \in B} f(x)$ does not exist over the rationals. But $\sum_{x \in A} f(x)$ exists.

The lemma also requires uniform continuity of the addition. And example of a topological group with continuous but not uniformly continuous addition would be the positive reals with the usual multiplication as the addition. We do not know whether the lemma would also hold for such topological groups.

The lemmas *infsum_comm_additive_general* and *infsum_comm_additive* (and variants) below both state that the infinite sum commutes with a continuous additive function. *infsum_comm_additive_general* is stated more for more general type classes at the expense of a somewhat less compact formulation of the premises. E.g., by avoiding the constant *additive* which introduces an additional sort constraint (group instead of monoid). For example, extended reals (*ereal*, *ennreal*) are not covered by *infsum_comm_additive*.

```

lemma has_sum_comm_additive_general:
  fixes f :: 'b :: {comm_monoid_add, topological_space}  $\Rightarrow$  'c :: {comm_monoid_add, topological_space}
  assumes f_sum:  $\langle \bigwedge F.\ \text{finite}\ F \implies F \subseteq S \implies \text{sum}\ (f\ o\ g)\ F = f\ (\text{sum}\ g\ F) \rangle$ 

```

— Not using *additive* because it would add sort constraint *ab_group_add*
assumes *cont*: $\langle f -x \rightarrow f x \rangle$
 — For *t2_space*, this is equivalent to *isCont f x* by *isCont_def*.
assumes *infsum*: $\langle \text{has\_sum } g \ S \ x \rangle$

The following theorem relates (abs_summable_on) with $\text{Infinite\_Sum.abs\_summable\_on}$. Note that while this theorem expresses an equivalence, the notion on the lhs is more general nonetheless because it applies to a wider range of types. (The rhs requires second-countable Banach spaces while the lhs is well-defined on arbitrary real vector spaces.)

6.41 Absolute Retracts, Absolute Neighbourhood Retracts and Euclidean Neighbourhood Retracts

```

theory Retracts
imports
  Brouwer_Fixpoint
  Continuous_Extension
begin

```

Absolute retracts (AR), absolute neighbourhood retracts (ANR) and also Euclidean neighbourhood retracts (ENR). We define AR and ANR by specializing the standard definitions for a set to embedding in spaces of higher dimension.

John Harrison writes: "This turns out to be sufficient (since any set in $\mathbb{R}^n$ can be embedded as a closed subset of a convex subset of $\mathbb{R}^{n+1}$) to derive the usual definitions, but we need to split them into two implications because of the lack of type quantifiers. Then ENR turns out to be equivalent to ANR plus local compactness."

definition $AR :: 'a::topological\_space \text{ set} \Rightarrow \text{bool}$ **where**
 $AR\ S \equiv \forall U. \forall S': (a * \text{real}) \text{ set.}$

S homeomorphic $S' \wedge \text{closedin } (\text{top\_of\_set } U) S' \longrightarrow S' \text{ retract\_of } U$

definition $\text{ANR} :: 'a::\text{topological\_space} \text{ set} \Rightarrow \text{bool}$ **where**

$\text{ANR } S \equiv \forall U. \forall S'::('a * \text{real}) \text{ set.}$

$S \text{ homeomorphic } S' \wedge \text{closedin } (\text{top\_of\_set } U) S'$

$\longrightarrow (\exists T. \text{openin } (\text{top\_of\_set } U) T \wedge S' \text{ retract\_of } T)$

definition $\text{ENR} :: 'a::\text{topological\_space} \text{ set} \Rightarrow \text{bool}$ **where**

$\text{ENR } S \equiv \exists U. \text{open } U \wedge S \text{ retract\_of } U$

First, show that we do indeed get the "usual" properties of ARs and ANRs.

6.42.12 Upper and lower hemicontinuous functions

And relation in the case of preimage map to open and closed maps, and fact that upper and lower hemicontinuity together imply continuity in the sense of the Hausdorff metric (at points where the function gives a bounded and nonempty set).

Many similar proofs below.

lemma *upper_hemicontinuous*:

```

6.48.1 Local Lipschitz continuity

Given a function defined on a real interval, it is Lipschitz-continuous if and only if it is locally so, as proved in the following lemmas. It is useful especially for piecewise-defined functions: if each piece is Lipschitz, then so is

the whole function. The same goes for functions defined on geodesic spaces, or more generally on geodesic subsets in a metric space (for instance convex subsets in a real vector space), and this follows readily from the real case, but we will not prove it explicitly.

We give several variations around this statement. This is essentially a connectedness argument.

```

```

We deduce that if a function is Lipschitz on finitely many closed sets on the real line, then it is Lipschitz on any interval contained in their union. The difficulty in the proof is to show that any point z in this interval (except the maximum) has a point arbitrarily close to it on its right which is contained in a common initial closed set. Otherwise, we show that there is a small interval (z, T) which does not intersect any of the initial closed sets, a contradiction.

```

The case of division is more complicated and will therefore not be handled here. Handling division becomes much more easy using complex analysis, and we will do so once that is available.

6.50.5 Power series expansions of analytic functions

This predicate contains the notion that the given formal power series converges in some disc of positive radius around the origin and is equal to the given complex function there.

This relationship is unique in the sense that no complex function can have more than one formal power series to which it expands, and if two holomorphic functions that are holomorphic on a connected open set around the origin and have the same power series expansion, they must be equal on that set.

More concrete statements about the radius of convergence can usually be made, but for many purposes, the statement that the series converges to the function in some neighbourhood of the origin is enough, and that can be shown almost fully automatically in most cases, as there are straightforward introduction rules to show this.

In particular, when one wants to relate the coefficients of the power series to the values of the derivatives of the function at the origin, or if one wants to approximate the coefficients of the series with the singularities of the function, this predicate is enough.

6.54 Metrics on product spaces

```
theory Function_Metric
  imports
    Function_Topology
    Elementary_Metric_Spaces
begin
```

In general, the product topology is not metrizable, unless the index set is countable. When the index set is countable, essentially any (convergent) combination of the metrics on the factors will do. We use below the simplest one, based on L^1 , but L^2 would also work, for instance.

What is not completely trivial is that the distance thus defined induces the same topology as the product topology. This is what we have to prove to show that we have an instance of *metric_space*.

The proofs below would work verbatim for general countable products of metric spaces. However, since distances are only implemented in terms of type classes, we only develop the theory for countable products of the same space.

```
instantiation fun :: (countable, metric_space) metric_space
begin
```

```
definition dist_fun_def:
```

$$\text{dist } x \ y = (\sum n. (1/2)^n * \min (\text{dist } (x \text{ (from\_nat } n)) \ (y \text{ (from\_nat } n))) \ 1)$$

```
definition uniformity_fun_def:
```

$$(\text{uniformity}::('a \Rightarrow 'b) \times ('a \Rightarrow 'b)) \text{ filter} = (\text{INF } e \in \{0 < ..\}. \text{principal } \{(x, y). \text{dist } (x::('a \Rightarrow 'b)) \ y < e\})$$

Except for the first one, the auxiliary lemmas below are only useful when proving the instance: once it is proved, they become trivial consequences of the general theory of metric spaces. It would thus be desirable to hide them once the instance is proved, but I do not know how to do this.

```
lemma dist_fun_le_dist_first_terms:
```

$$\text{dist } x \ y \leq 2 * \text{Max } \{\text{dist } (x \text{ (from\_nat } n)) \ (y \text{ (from\_nat } n)) \mid n. n \leq N\} + (1/2)^N$$

```
proof -
```

$$\text{have } (\sum n. (1 / 2)^{(n+\text{Suc } N)} * \min (\text{dist } (x \text{ (from\_nat } (n+\text{Suc } N))) \ (y \text{ (from\_nat } (n+\text{Suc } N)))) \ 1)$$

$$= (\sum n. (1 / 2)^{(\text{Suc } N)} * ((1/2)^n * \min (\text{dist } (x \text{ (from\_nat } (n+\text{Suc } N))) \ (y \text{ (from\_nat } (n+\text{Suc } N)))) \ 1)$$

Finally, we show that the topology generated by the distance and the product topology coincide. This is essentially contained in Lemma *fun_open_ball_aux*, except that the condition to prove is expressed with filters. To deal with this, we copy some mumbo jumbo from Lemma *eventually_uniformity_metric* in `~/src/HOL/Real_Vector_Spaces.thy`

```

fix U::('a ⇒ 'b) set
have eventually P uniformity ⟷ (∃ e>0. ∀ x (y::('a ⇒ 'b)). dist x y < e ⟶
P (x, y)) for P
  unfolding uniformity_fun_def apply (subst eventually_INF_base)
  by (auto simp: eventually_principal subset_eq intro: bexI[of _ min _ _])
then show open U = (∀ x∈U. ∀_F (x', y) in uniformity. x' = x ⟶ y ∈ U)
  unfolding fun_open_ball_aux by simp
qed (simp add: uniformity_fun_def)

```

end

Nice properties of spaces are preserved under countable products. In addition to first countability, second countability and metrizability, as we have seen above, completeness is also preserved, and therefore being Polish.

```
