

Cyber Early Warning & the Commonality of Cyber Warfare and Electronic Warfare

SESSION ID: TRM-T08

Dr. Nitzan Barkay & Mariana Gafni

Deputy Director, Research & Technology
IAI – Israel Aerospace Industries

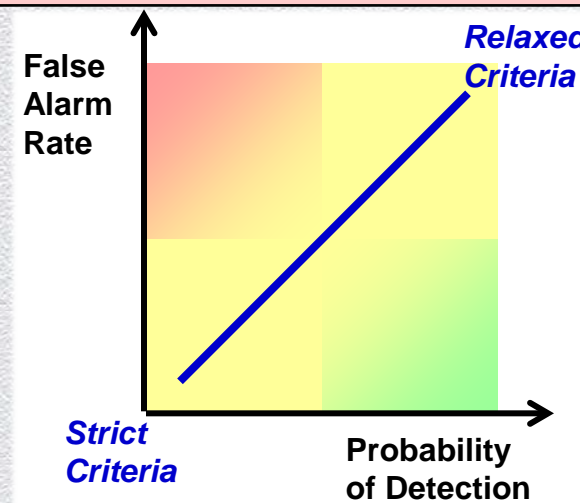

Cyber Early Warning Key Difficulty

The Goal: Early warning of cyber attacks

Currently: Many tools & techniques to detect “non-legitimate” activity or “abnormal” behavior

Suggested: A new layer to handle complex & sophisticated attacks

The Challenge: Too many False Alarms that cannot be handled;
OR:
Reduce false alerts by stricter criteria, while unfortunately masking out subtle events, typical to APT attacks

Towards Cyber Warfare

Electronic Warfare (EW)

Integrated SIGINT
(ELINT&COMINT) Solutions

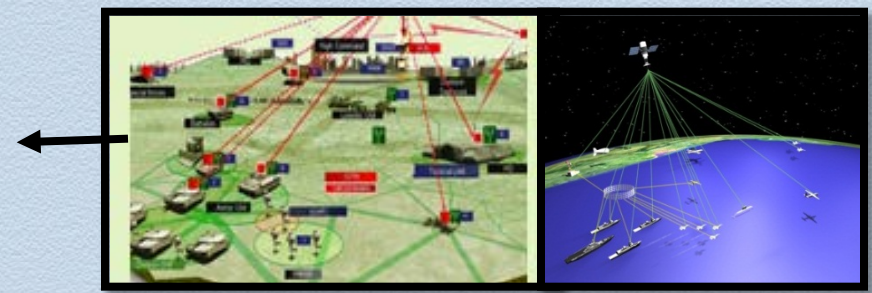

Electronic Protection (EP)
& Electronic Attack (EA)

Cyber Warfare
Intelligence & Situation Awareness

Communication & C4I

Cyber Warfare vs. Electronic Warfare

	Electronic Warfare	Cyber Warfare
Mission	<ul style="list-style-type: none"> ● Air-situation picture (surveillance) ● Guiding missiles ● Navigation ● C&C/data networks 	<ul style="list-style-type: none"> ● IT ● SCADA ● Business ● Government services
Intelligence	<ul style="list-style-type: none"> ● SIGINT (ELINT, COMINT) ● IMINT (Opt., Radar) 	<ul style="list-style-type: none"> ● Hacking ● Accessibility tools
Attack	<ul style="list-style-type: none"> ● Electronic Attack (EA) <ul style="list-style-type: none"> ● ECM (Victim: radars) ● ComJam (Victim: comm. links) 	<ul style="list-style-type: none"> ● Cyber attacks <ul style="list-style-type: none"> ● (Victim: network services & resources)
Attack type	<ul style="list-style-type: none"> ● Jamming <ul style="list-style-type: none"> ● Spoofing, noise ● Deception <ul style="list-style-type: none"> ● False targets, missile stealing 	<ul style="list-style-type: none"> ● Jamming <ul style="list-style-type: none"> ● DoS, DDoS ● Deception <ul style="list-style-type: none"> ● Identity theft, MITM, phishing, Trojan horses
Counter-measures	<ul style="list-style-type: none"> ● ECCM: <ul style="list-style-type: none"> ● Filters, guards, SLB&SLC,... ● Decoys,... ● Immunity <ul style="list-style-type: none"> ● LPI: waveform, agility,... 	<ul style="list-style-type: none"> ● Counter-measures <ul style="list-style-type: none"> ● FW, IPS,... ● Honeypots,... ● Immunity <ul style="list-style-type: none"> ● Encryption, virtualization

Cyber & EW Integration in Battlefield

- ◆ An example:
The US Army has published(*) the ICE (Integrated Cyber & Electronic Warfare) program
- ◆ Define common data contexts & mechanisms to allow Cyber & EW frameworks to communicate and combat the threats in an integrated fashion

(*) <http://www.army.mil/article/113678>

**Multi-Entity
Multi-Sensor
Scenario
&
Multi-Hypothesis
Tracking**

Cyber Early Warning Challenges

- ◆ **Huge amount of activity**
 - ◆ Data availability, especially in real time
 - ◆ Technical & regulatory difficulty to maintain effective coverage of everything
 - ◆ Derive insight from the mass of data
 - ◆ Data diversity
 - ◆ Data dynamics
- ◆ **Attacker/defender asymmetry**
 - ◆ Proliferation of attack types
 - ◆ Difficulty of "attribution" to actual actors
- ◆ **Attacks that involve subtle activities**
 - ◆ Eliminating false alarms: Discrimination between legitimate activity and cyber incidents
- ◆ **Attacks that involve multiple assets**
 - ◆ Identification based on the aggregated picture

Persistent Surveillance Challenges

- ◆ A multitude of entities, of various types
- ◆ Dynamic scenario
- ◆ Integration of different sensors
 - ◆ Each interprets the situation picture in its manner
 - ◆ Some get only a partial situation picture; Some overlap
- ◆ Discrimination between “innocent” entities (false) and “malicious” targets (real threats)
 - ◆ Threats attempt to avoid interception by hiding or behaving like legitimate entities

*quantity,
variability,
dynamics*

integration

discrimination

**Challenges are similar
to Cyber situation awareness;
Solutions can be similar, too...**

Multi-hypothesis Tracking for Cyber Situation Awareness

- ◆ **Multi-Hypothesis Tracking (MHT)** is a powerful means towards achieving **Cyber Situation Awareness**
- ◆ **Situation Awareness is a broader & better concept than Alert**
 - ◆ more information & comprehension
 - ◆ more threat assessment
 - ◆ more reliable & informative alerts

Cyber Multi-Hypothesis

- ◆ **Multi-Hypothesis Analysis is a method to handle the uncertainty**

- ◆ **An algorithmic methodology to handle complex & dynamic data**
 - ◆ Collected with various sources/sensors,
 - ◆ Involving many entities,
 - ◆ Information is partial and/or ambiguous,
 - ◆ Information is streaming & dynamically changing
- ◆ **For example:**
 - ◆ Physical situation awareness (e.g., air situation picture)
 - ◆ SIGINT-based order of battle (EOB)
- ◆ **Applicable to Cyber Situation Awareness**
 - ◆ Integrating the various security tools & techniques
 - ◆ Handling the uncertainty and supporting decision making

Multi-Sensor Multi-Entity Tracking

Tracking is the logical process of associating data of activity (including past data) of various entities into disjoint sets - tracks

- ◆ Examples:
 - ◆ Geographical data of platform entities into physical movement tracks
 - ◆ EW & SIGINT data of electromagnetic entities into threat interception tracks
- ◆ Logical tracks of data enable
 - ◆ Verification of data consistency
 - ◆ Identifying the past origin of the track
 - ◆ Predicting the future evolution of the track

Cyber Tracking

Tracking is the logical process of associating data of activity (including past data) of various entities into disjoint sets - tracks

- ◆ Examples:
 - ◆ Geographical data of platform entities into physical movement tracks
 - ◆ EW & SIGINT data of electromagnetic entities into threat interception tracks
- ◆ Logical tracks of data enable
 - ◆ Verification of data consistency
 - ◆ Identifying the past origin of the track
 - ◆ Predicting the future evolution of the track

Cyber events data

Cyber entities

Cyber Incident tracks!

Eliminate False!

Attribution!

Threat Alert!

Cyber Multi-Hypothesis Tracking (MHT)

- ◆ **MHT associates distinct cyber events to a single cyber incident**
 - ◆ When a new message from any sensor or information source is received, to which incident track does that message correspond?
- ◆ **Events may initially be distinct**
 - ◆ by “**time**”: evolution in time
 - ◆ by “**location**”: events detected at different items/hosts/etc.
 - ◆ by “**sensor**”: events detected by various sensor & security tools
 - ◆ by “**type**”: events of different type (a malicious file, illegitimate login, etc.)

Highlights of the MHT Algorithm

MHT Algorithm Main Modules

- ◆ **Hypothesis Management engine**
 - ◆ **A generic module**
 - ◆ Applicable to physical entities, electronic warfare signals or cyber events
 - ◆ Maintaining ambiguities, tracks, pictures, and history
- ◆ **Correlation & Scoring**
 - ◆ **Specific modules**
 - ◆ Depend on the application sensor characteristics
 - ◆ Correlating observations to system states and to previous data based on specific models

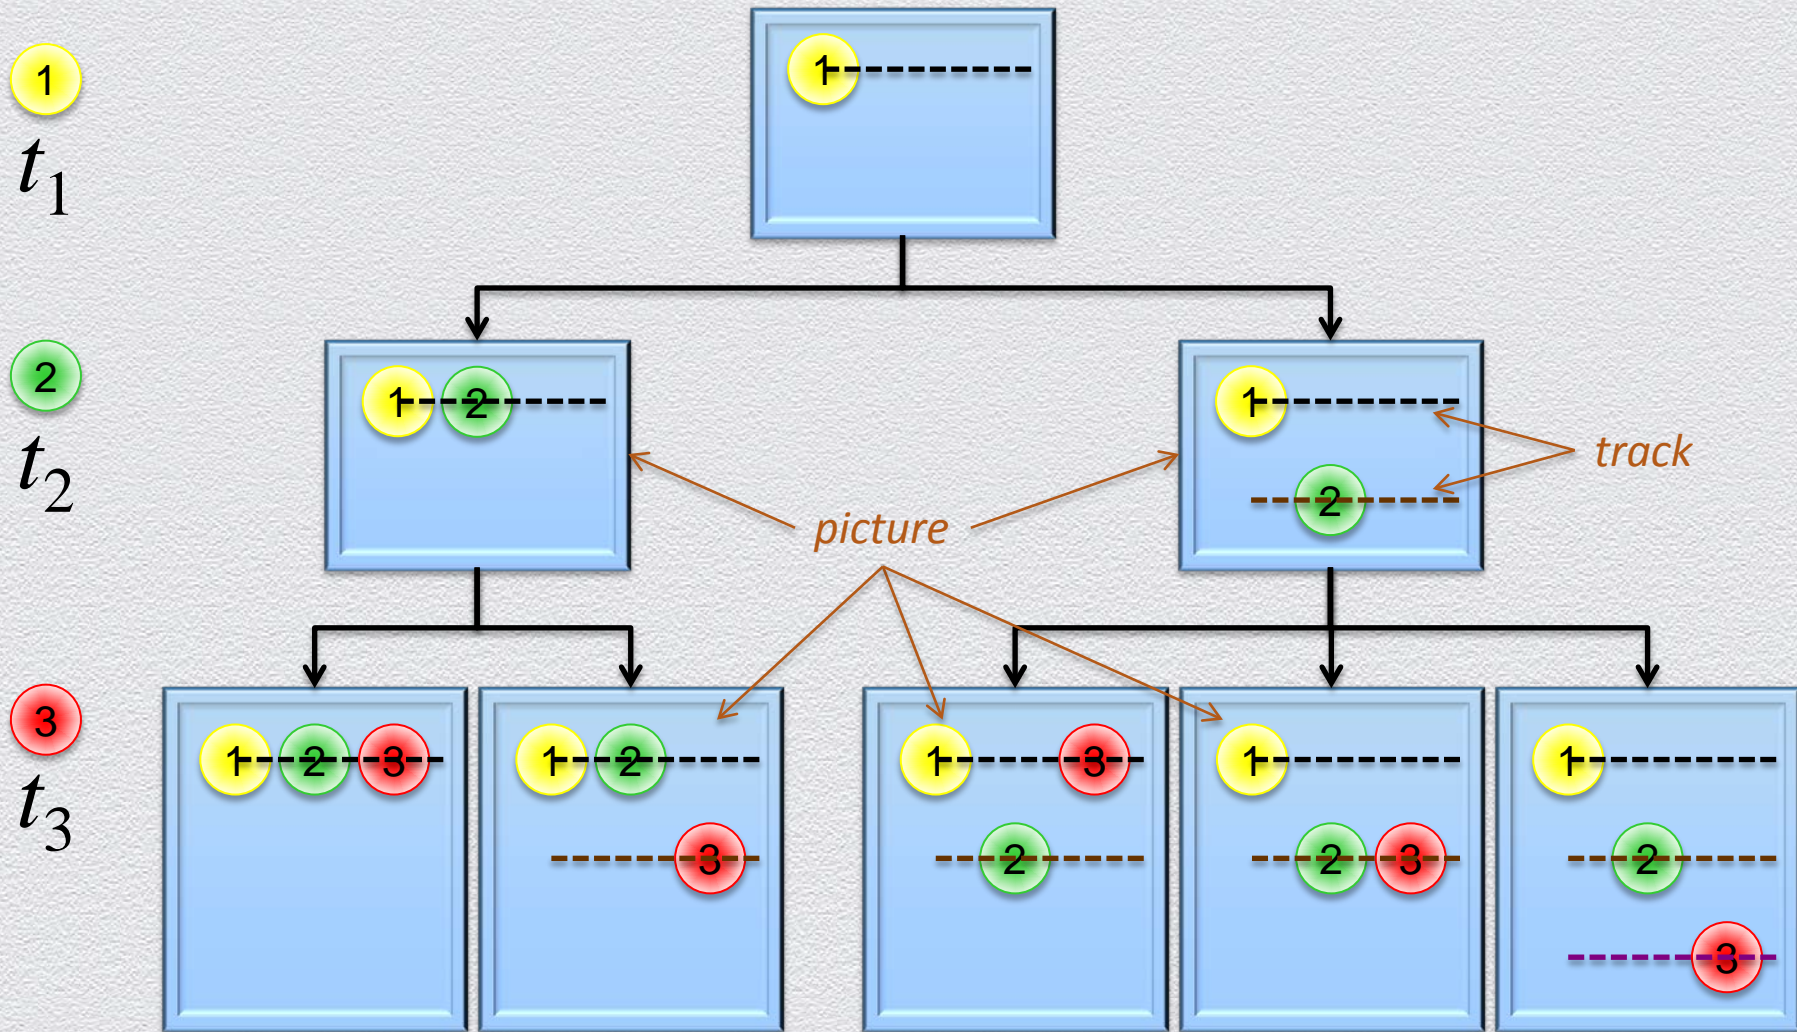

Tracks & Pictures

- ◆ A **Track** consists of set of data that may be associated with a single platform/system/incident
 - ◆ There can be alternative tracks to the same data
- ◆ A **Picture** includes a set of alternative tracks that are consistent with each other
 - ◆ There can be alternative pictures to the same data

- ◆ The "best" picture in any moment is the one which is selected for report, but many are maintained

Tracks & Pictures Schematic Example

Observations & Hidden States

- ◆ **States** describe the status, behavior or properties of a system
 - ◆ There are transition probabilities between system states
- ◆ **Observations** include the data streaming from the sensors
- ◆ **Observations relate to the system states, but the relationship may be ambiguous**
 - ◆ There may be several possible different observations (with some probabilities) to each state;
an observation may point to several possible alternative **hidden** states
- ◆ **Example in Electronic Warfare**
 - ◆ **Looking at the electronic order of battle (EOB) picture:**
The hidden states are the emitter/system type and the platform carrying it, while the observations are the intercepted electronic parameters
 - ◆ **Looking at the geographic situation picture:** The hidden states are the position & velocity of the platforms that should be estimated from observed bearings

Correlation & Tracking Models

- ◆ **Models** are used to correlate between the observations and the hidden-states of the system, based on the knowledge of expected processes & behavior
- ◆ **Model types**
 - ◆ **Kinematic** for continuous dynamics
 - ◆ e.g., platform trajectory based on direction observations
 - ◆ **Rule-based** for simple logic correlation
 - ◆ e.g., emitter type based on electronic parameters
 - ◆ Discrete **Markov chain** for discrete states
 - ◆ **Hidden Markov model (HMM)** when the states are not directly observable
 - ◆ **Ontology-based** analytics of related entities using patterns
- ◆ **In Cyber**
 - ◆ The **hidden states** can be individual host states (trusted, compromised, etc.)
 - ◆ The **observations** derive from firewalls, IDS sensors, server/network logs, etc. as well as context & intelligence
 - ◆ Relevant **models** are HMM and ontology-based with adaptation to attack types (worm, virus, DDOS, etc., and combinations)

More Aspects of MHT Algorithms

◆ Observability

- ◆ A state cannot always be estimated from a sequence of observations; necessary and sufficient conditions for observability should be evaluated
- ◆ In Cyber: The state of a host or network may not be identifiable from the reported events; the conditions can be estimated using attack models

◆ Hypotheses management

- ◆ The number of hypotheses may increase exponentially as observations arrive; consequently the computational complexity of maintaining the hypotheses and finding the optimal solution may grow too much
- ◆ Algorithms of clustering & pruning are employed to overcome the complexity of growing number of hypotheses
 - ◆ Deleting tracks, which have not been updated during a "purge time", which depends on estimated progress rate
 - ◆ Pruning the unlikely (low-score) hypotheses, with the risk of eliminating the future optimal hypothesis
- ◆ Clustering the tracks into independent sets and using scalability in the algorithms enable distributing the computational load

**MHT
&
Cyber Early Warning**

Cyber MHT Process (1)

- ◆ The **hidden states** can be individual states (trusted, compromised, etc.) of a host, a network, or a service
- ◆ The **observations** derive from firewalls, IDS sensors, server/network logs, etc., as well as context & intelligence
- ◆ Relevant **models** are HMM and ontology-based; Models are adapted to attack types (worm, virus, DDOS, etc., and their combinations)
- ◆ Each **picture** hypothesis represents a set of events associated to an independent cyber incident

Context & Intelligence

- ◆ **Context** refers to internal (organization) information
 - ◆ Structure, procedures, etc.
- ◆ **Intelligence** refers to relevant external data collected using WEBInt & accessibility tools
 - ◆ Hints to expected attackers, their behavior and their targets

Context & Intelligence are key factors for decision making

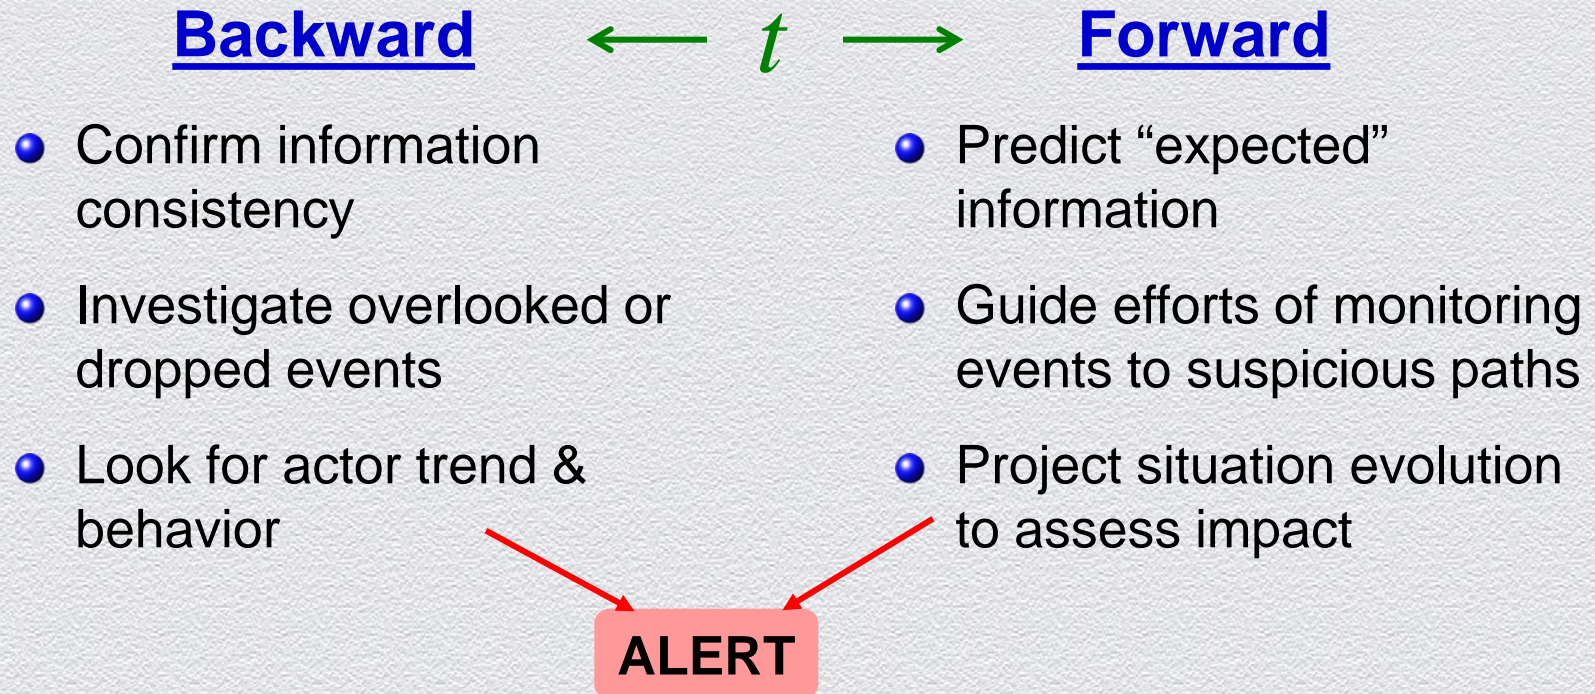

They add an important dimension to MHT scoring by allowing to judge events using adapted criteria

Cyber MHT Process (2)

- ◆ **Hypothesis score (track & picture) depends on**
 - ◆ Information **quality** & consistency
 - ◆ **Likelihood** as estimated by the tracking model
 - ◆ **Intelligence** & relevant context
 - ◆ **Impact** assessment
- ◆ **The hypothesis with the highest score is reported**
- ◆ **Many of the other hypotheses & tracks are maintained**
- ◆ **Each new event is checked against many hypotheses (not just the previously best)**
 - ◆ An updated set of hypotheses is formed with updated scoring
- ◆ **MHT keeps some history, in a special way of tracks & pictures, which is more efficient to utilize, when data is streaming and early response is required**
 - ◆ (All data is logged for later forensic research)

Multi-Hypothesis Tracking on Time

- ◆ MHT associates **events on a time scale** to follow cyber incident evolution backward & forward

Track Triggering

◆ In Electronic Warfare MHT

- ◆ Usually, any new intercept data is a possible trigger for tracking
 - ◆ For example: each plot of Radar, every signal in EW
- ◆ All entities (including legitimate) are tracked, to distinguish the hostile ones

◆ At a Cyber Warfare scenario

- ◆ The amount of data is enormous
- ◆ Tracking all legitimate activity is impossible
- ◆ However, analysis of known APT attacks, demonstrate that (eventually) suspect activity has been overlooked, resulting in miss of detection

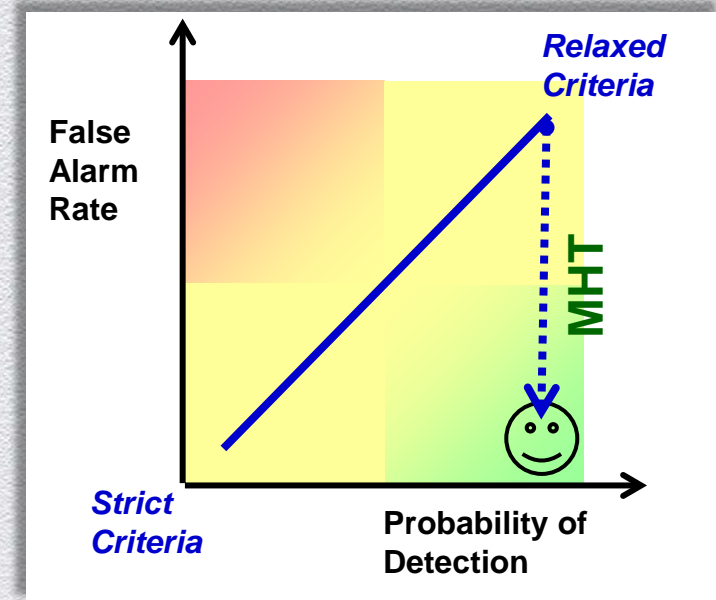

Track before Detect

- ◆ The approach is to track the events even before making the decision

IF an hypothesis track is consistent and has a high scoring, if its backward evolution suggests a threat actor and/or its forward projection indicates possible impact

THEN Report “Detection”

- ◆ And immediately get **Incident track details**
 - ◆ All associated events
 - ◆ Possible actor attribution
 - ◆ Estimated future impact

Research Challenges

- ◆ **Ongoing research to improve performance**
 - ◆ Flexible data modeling to handle all types of information, structured & unformatted, activity & intelligence
 - ◆ Best tracking models of events and attacks
 - ◆ Analytic engines & optimal hypothesis scoring
 - ◆ Efficient pruning & clustering
 - ◆ etc.
