sage: W = WeylGroup(['A',4], implementation="permutation")
sage: W.simple_roots()
Finite family {1: (1, 0, 0, 0), 2: (0, 1, 0, 0),
                3: (0, 0, 1, 0), 4: (0, 0, 0, 1)}

```

5.1.252 Rooted (Unordered) Trees

AUTHORS:

- Florent Hivert (2011): initial version

```

class sage.combinat.rooted_tree.LabelledRootedTree (parent, children, label=None,
                                                    check=True)
Bases: sage.combinat.abstract_tree.AbstractLabelledClonableTree, sage.combinat.rooted_tree.RootedTree

```

Labelled rooted trees.

A labelled rooted tree is a rooted tree with a label attached at each node.

More formally: The *labelled rooted trees* are an inductive datatype defined as follows: A labelled rooted tree is a multiset of labelled rooted trees, endowed with a label (which can be any object, including `None`). The trees that belong to this multiset are said to be the *children* of the tree. (Notice that the labels of these children may and may not be of the same type as the label of the tree). A labelled rooted tree which has no children (so the only information it carries is its label) is said to be a *leaf*.

Every labelled rooted tree gives rise to an unlabelled rooted tree (*RootedTree*) by forgetting the labels. (This is implemented as a conversion.)

INPUT:

- `children` – a list or tuple or more generally any iterable of trees or objects convertible to trees
- `label` – any hashable Sage object (default is `None`)

EXAMPLES:

```
sage: x = LabelledRootedTree([], label = 3); x
3[]
sage: LabelledRootedTree([x, x, x], label = 2)
2[3[], 3[], 3[]]
sage: LabelledRootedTree((x, x, x), label = 2)
2[3[], 3[], 3[]]
sage: LabelledRootedTree([[], [], []], label = 3)
3[None[], None[None[], None[]]]
```

Children are reordered using the value of the `sort_key()` method:

```
sage: y = LabelledRootedTree([], label = 5); y
5[]
sage: xyy2 = LabelledRootedTree((x, y, y), label = 2); xyy2
2[3[], 5[], 5[]]
sage: yxy2 = LabelledRootedTree((y, x, y), label = 2); yxy2
2[3[], 5[], 5[]]
sage: xyy2 == yxy2
True
```

Converting labelled into unlabelled rooted trees by forgetting the labels, and back (the labels are initialized as None):

```
sage: yxy2crude = RootedTree(yxy2); yxy2crude
[[], [], []]
sage: LabelledRootedTree(yxy2crude)
None[None[], None[], None[]]
```

sort_key()

Return a tuple of nonnegative integers encoding the labelled rooted tree `self`.

The first entry of the tuple is a pair consisting of the number of children of the root and the label of the root. Then the rest of the tuple is obtained as follows: List the tuples corresponding to all children (we are regarding the children themselves as trees). Order this list (not the tuples!) in lexicographically increasing order, and flatten it into a single tuple.

This tuple characterizes the labelled rooted tree uniquely, and can be used to sort the labelled rooted trees provided that the labels belong to a type which is totally ordered.

Note: The tree `self` must be normalized before calling this method (see `normalize()`). This doesn't matter unless you are inside the `clone()` context manager, because outside of it every rooted tree is already normalized.

Note: This method overrides `RootedTree.sort_key()` and returns a result different from what the latter would return, as it wants to encode the whole labelled tree including its labelling rather than just the unlabelled tree. Therefore, be careful with using this method on subclasses of `RootedOrderedTree`; under some circumstances they could inherit it from another superclass instead of from `RootedTree`, which would cause the method to forget the labelling. See the docstrings of `RootedTree.sort_key()` and `sage.combinat.ordered_tree.OrderedTree.sort_key()`.

EXAMPLES:

```

sage: LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
sage: x = LRT([], label = 3); x
3[]
sage: x.sort_key()
((0, 3),)
sage: y = LRT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
sage: y.sort_key()
((3, 2), (0, 3), (0, 3), (0, 3))
sage: LRT.an_element().sort_key()
((3, 'alpha'), (0, 3), (1, 5), (0, None), (2, 42), (0, 3), (0, 3))
sage: lb = RootedTrees()([[], [], []]).canonical_labelling()
sage: lb.sort_key()
((2, 1), (0, 2), (2, 3), (0, 4), (0, 5))

```

class sage.combinat.rooted_tree.**LabelledRootedTrees**

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

This is a parent stub to serve as a factory class for labelled rooted trees.

EXAMPLES:

```

sage: LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
sage: x = LRT([], label = 3); x
3[]
sage: x.parent() is LRT
True
sage: y = LRT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
sage: y.parent() is LRT
True

```

Todo

Add the possibility to restrict the labels to a fixed set.

class sage.combinat.rooted_tree.**LabelledRootedTrees_all**(category=None)

Bases: *sage.combinat.rooted_tree.LabelledRootedTrees*

Class of all (unordered) labelled rooted trees.

See *LabelledRootedTree* for a definition.

Element

alias of *LabelledRootedTree*

labelled_trees()

Return the set of labelled trees associated to self.

EXAMPLES:

```

sage: LabelledRootedTrees().labelled_trees()
Labelled rooted trees

```

unlabelled_trees()

Return the set of unlabelled trees associated to self.

EXAMPLES:

```
sage: LabelledRootedTrees().unlabelled_trees()
Rooted trees
```

```
class sage.combinat.rooted_tree.RootedTree (parent=None, children=[], check=True)
Bases: sage.combinat.abstract_tree.AbstractClonableTree, sage.structure.
list_clone.NormalizedClonableList
```

The class for unordered rooted trees.

The *unordered rooted trees* are an inductive datatype defined as follows: An unordered rooted tree is a multiset of unordered rooted trees. The trees that belong to this multiset are said to be the *children* of the tree. The tree that has no children is called a *leaf*.

The *labelled rooted trees* (*LabelledRootedTree*) form a subclass of this class; they carry additional data.

One can create a tree from any list (or more generally iterable) of trees or objects convertible to a tree.

EXAMPLES:

```
sage: RootedTree([])
[]
sage: RootedTree([], [[]])
[[], [[]]]
sage: RootedTree([[]], [])
[[], [[]]]
sage: O = OrderedTree([[]], []); O
[[]], []
sage: RootedTree(O) # this is O with the ordering forgotten
[[], [[]]]
```

One can also enter any small rooted tree (“small” meaning that no vertex has more than 15 children) by using a simple numerical encoding of rooted trees, namely, the *from_hexacode()* function. (This function actually parametrizes ordered trees, and here we make it parametrize unordered trees by forgetting the ordering.)

```
sage: from sage.combinat.abstract_tree import from_hexacode
sage: RT = RootedTrees()
sage: from_hexacode('32001010', RT)
[[]], [[]], [[]], [[]]
```

Note: Unlike an ordered tree, an (unordered) rooted tree is a multiset (rather than a list) of children. That is, two ordered trees which differ from each other by switching the order of children are equal to each other as (unordered) rooted trees. Internally, rooted trees are encoded as `sage.structure.list_clone.NormalizedClonableList` instances, and instead of storing their children as an actual multiset, they store their children as a list which is sorted according to their *sort_key()* value. This is as good as storing them as multisets, since the *sort_key()* values are sortable and distinguish different (unordered) trees. However, if you wish to define a subclass of *RootedTree* which implements rooted trees with extra structure (say, a class of edge-colored rooted trees, or a class of rooted trees with a cyclic order on the list of children), then the inherited *sort_key()* method will no longer distinguish different trees (and, as a consequence, equal trees will be regarded as distinct). Thus, you will have to override the method by one that does distinguish different trees.

graft_list (*other*)

Return the list of trees obtained by grafting *other* on *self*.

Here grafting means that one takes the disjoint union of *self* and *other*, chooses a node of *self*, and

adds the root of *other* to the list of children of this node. The root of the resulting tree is the root of *self*. (This can be done for each node of *self*; this method returns the list of all results.)

This is useful for free pre-Lie algebras.

EXAMPLES:

```
sage: RT = RootedTree
sage: x = RT([])
sage: y = RT([x, x])
sage: x.graft_list(x)
[[[]]]
sage: l = y.graft_list(x); l
[[[], [], [], [], [], [], []]]
sage: [parent(i) for i in l]
[Rooted trees, Rooted trees, Rooted trees]
```

graft_on_root (*other*)

Return the tree obtained by grafting *other* on the root of *self*.

Here grafting means that one takes the disjoint union of *self* and *other*, and adds the root of *other* to the list of children of *self*. The root of the resulting tree is the root of *self*.

This is useful for free Nap algebras.

EXAMPLES:

```
sage: RT = RootedTree
sage: x = RT([])
sage: y = RT([x, x])
sage: x.graft_on_root(x)
[[[]]]
sage: y.graft_on_root(x)
[[[], [], []]]
sage: x.graft_on_root(y)
[[[], []]]
```

is_empty ()

Return if *self* is the empty tree.

For rooted trees, this always returns `False`.

Note: This is not the same as `bool(t)`, which returns whether *t* has some child or not.

EXAMPLES:

```
sage: t = RootedTrees(4) ([[], [[]]])
sage: t.is_empty()
False
sage: bool(t)
True
sage: t = RootedTrees(1) ([[]])
sage: t.is_empty()
False
sage: bool(t)
False
```

normalize ()

Normalize *self*.

This function is at the core of the implementation of rooted (unordered) trees. The underlying structure is provided by ordered rooted trees. Every rooted tree is represented by a normalized element in the set of its planar embeddings.

There should be no need to call `normalize` directly as it is called automatically upon creation and cloning or modification (by `NormalizedClonableList`).

The normalization has a recursive definition. It means first that every sub-tree is itself normalized, and also that sub-trees are sorted. Here the sort is performed according to the values of the `sort_key()` method.

EXAMPLES:

```
sage: RT = RootedTree
sage: RT([[[]],[[]]]) == RT([[[]],[[]]]) # indirect doctest
True
sage: rt1 = RT([[[]],[[]]])
sage: rt2 = RT([[[]],[[]]])
sage: rt1 is rt2
False
sage: rt1 == rt2
True
sage: rt1._get_list() == rt2._get_list()
True
```

`sort_key()`

Return a tuple of nonnegative integers encoding the rooted tree `self`.

The first entry of the tuple is the number of children of the root. Then the rest of the tuple is obtained as follows: List the tuples corresponding to all children (we are regarding the children themselves as trees). Order this list (not the tuples!) in lexicographically increasing order, and flatten it into a single tuple.

This tuple characterizes the rooted tree uniquely, and can be used to sort the rooted trees.

Note: The tree `self` must be normalized before calling this method (see `normalize()`). This doesn't matter unless you are inside the `clone()` context manager, because outside of it every rooted tree is already normalized.

Note: By default, this method does not encode any extra structure that `self` might have. If you have a subclass inheriting from `RootedTree` which allows for some extra structure, you need to override `sort_key()` in order to preserve this structure (for example, the `LabelledRootedTree` class does this in `LabelledRootedTree.sort_key()`). See the note in the docstring of `sage.combinat.ordered_tree.OrderedTree.sort_key()` for a pitfall.

EXAMPLES:

```
sage: RT = RootedTree
sage: RT([[[]],[[]]]).sort_key()
(2, 0, 1, 0)
sage: RT([[[]],[[]]]).sort_key()
(2, 0, 1, 0)
```

class `sage.combinat.rooted_tree.RootedTrees`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Factory class for rooted trees.

INPUT:

- `size` – (optional) an integer

OUTPUT:

the set of all rooted trees (of the given size `size` if specified)

EXAMPLES:

```
sage: RootedTrees()
Rooted trees

sage: RootedTrees(2)
Rooted trees with 2 nodes
```

class `sage.combinat.rooted_tree.RootedTrees_all`

Bases: `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`,
`sage.combinat.rooted_tree.RootedTrees`

Class of all (unordered, unlabelled) rooted trees.

See [RootedTree](#) for a definition.

Element

alias of [RootedTree](#)

labelled_trees()

Return the set of labelled trees associated to `self`.

EXAMPLES:

```
sage: RootedTrees().labelled_trees()
Labelled rooted trees
```

As a consequence:

```
sage: lb = RootedTrees()([[], [[]], [[]]]).canonical_labelling()
sage: lb
1[2[], 3[4[], 5[]]]
sage: lb.__class__
<class 'sage.combinat.rooted_tree.LabelledRootedTrees_all_with_category.
↳element_class'>
sage: lb.parent()
Labelled rooted trees
```

leaf()

Return a leaf tree with `self` as parent.

EXAMPLES:

```
sage: RootedTrees().leaf()
[]
```

unlabelled_trees()

Return the set of unlabelled trees associated to `self`.

EXAMPLES:

```
sage: RootedTrees().unlabelled_trees()
Rooted trees
```

class `sage.combinat.rooted_tree.RootedTrees_size(n)`

Bases: `sage.combinat.rooted_tree.RootedTrees`

The enumerated set of rooted trees with a given number of nodes.

The number of nodes of a rooted tree is defined recursively: The number of nodes of a rooted tree with a children is a plus the sum of the number of nodes of each of these children.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: RootedTrees(1).cardinality()
1
sage: RootedTrees(3).cardinality()
2
```

check_element(el, check=True)

Check that a given tree actually belongs to `self`.

This just checks the number of vertices.

EXAMPLES:

```
sage: RT3 = RootedTrees(3)
sage: RT3([[], []])      # indirect doctest
[[], []]
sage: RT3([[], [], []])  # indirect doctest
Traceback (most recent call last):
...
ValueError: wrong number of nodes
```

element_class()

`sage.combinat.rooted_tree.number_of_rooted_trees(n)`

Return the number of rooted trees with n nodes.

Compute the number $a(n)$ of rooted trees with n nodes using the recursive formula (*[SL000081]*):

$$a(n+1) = \frac{1}{n} \sum_{k=1}^n \left(\sum_{d|k} da(d) \right) a(n-k+1)$$

EXAMPLES:

```
sage: from sage.combinat.rooted_tree import number_of_rooted_trees
sage: [number_of_rooted_trees(i) for i in range(10)]
[0, 1, 1, 2, 4, 9, 20, 48, 115, 286]
```

5.1.253 Robinson-Schensted-Knuth correspondence

AUTHORS:

- Travis Scrimshaw (2012-12-07): Initial version

EXAMPLES:

We can perform RSK and the inverse on a variety of objects:

```

sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: gp = RSK_inverse(p, q); gp
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK(*gp)
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]
sage: m = RSK_inverse(p, q, 'matrix'); m
[0 1]
[1 0]
[0 2]
sage: RSK(m)
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]

```

REFERENCES:

`sage.combinat.rsk.RSK(obj1=None, obj2=None, insertion='RSK', check_standard=False, **options)`

Perform the Robinson-Schensted-Knuth (RSK) correspondence.

The Robinson-Schensted-Knuth (RSK) correspondence (also known as the RSK algorithm) is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semi-standard Young tableaux (P, Q) of identical shape. The tableau P is known as the insertion tableau, and Q is known as the recording tableau.

The basic operation is known as row insertion $P \leftarrow k$ (where P is a given semi-standard Young tableau, and k is an integer). Row insertion is a recursive algorithm which starts by setting $k_0 = k$, and in its i -th step inserts the number k_i into the i -th row of P (we start counting the rows at 0) by replacing the first integer greater than k_i in the row by k_i and defines k_{i+1} as the integer that has been replaced. If no integer greater than k_i exists in the i -th row, then k_i is simply appended to the row and the algorithm terminates at this point.

Now the RSK algorithm, applied to a generalized permutation $p = ((j_0, k_0), (j_1, k_1), \dots, (j_{\ell-1}, k_{\ell-1}))$ (encoded as a lexicographically sorted list of pairs) starts by initializing two semi-standard tableaux P_0 and Q_0 as empty tableaux. For each nonnegative integer t starting at 0, take the pair (j_t, k_t) from p and set $P_{t+1} = P_t \leftarrow k_t$, and define Q_{t+1} by adding a new box filled with j_t to the tableau Q_t at the same location the row insertion on P_t ended (that is to say, adding a new box with entry j_t such that P_{t+1} and Q_{t+1} have the same shape). The iterative process stops when t reaches the size of p , and the pair (P_t, Q_t) at this point is the image of p under the Robinson-Schensted-Knuth correspondence.

This correspondence has been introduced in [Knu1970], where it has been referred to as “Construction A”.

For more information, see Chapter 7 in [Sta-EC2].

We also note that integer matrices are in bijection with generalized permutations. Furthermore, we can convert any word w (and, in particular, any permutation) to a generalized permutation by considering the top line to be $(1, 2, \dots, n)$ where n is the length of w .

The optional argument `insertion` allows to specify an alternative insertion procedure to be used instead of the standard Robinson-Schensted-Knuth insertion. If the input is a reduced word of a permutation (i.e., an element of a type- A Coxeter group), one can set `insertion` to 'EG', which gives Edelman-Greene insertion, an algorithm defined in [EG1987] Definition 6.20 (where it is referred to as Coxeter-Knuth insertion). The Edelman-Greene insertion is similar to the standard row insertion except that if k_i and $k_i + 1$ both exist in row i , we *only* set $k_{i+1} = k_i + 1$ and continue.

One can also perform a “Hecke RSK algorithm”, defined using the Hecke insertion studied in [BKSTY06] (but using rows instead of columns). The algorithm proceeds similarly to the classical RSK algorithm. However, it is not clear in what generality it works; thus, following [BKSTY06], we shall assume that our biword p has top line $(1, 2, \dots, n)$ (or, at least, has its top line strictly increasing). The Hecke RSK algorithm returns a pair of an increasing tableau and a set-valued standard tableau. If $p = ((j_0, k_0), (j_1, k_1), \dots, (j_{\ell-1}, k_{\ell-1}))$, then the algorithm recursively constructs pairs $(P_0, Q_0), (P_1, Q_1), \dots, (P_\ell, Q_\ell)$ of tableaux. The construction of P_{t+1} and Q_{t+1} from P_t, Q_t, j_t and k_t proceeds as follows: Set $i = j_t$, $x = k_t$, $P = P_t$ and $Q = Q_t$. We are going to insert x into the increasing tableau P and update the set-valued “recording tableau” Q accordingly. As in the

classical RSK algorithm, we first insert x into row 1 of P , then into row 2 of the resulting tableau, and so on, until the construction terminates. The details are different: Suppose we are inserting x into row R of P . If (Case 1) there exists an entry y in row R such that $x < y$, then let y be the minimal such entry. We replace this entry y with x if the result is still an increasing tableau; in either subcase, we then continue recursively, inserting y into the next row of P . If, on the other hand, (Case 2) no such y exists, then we append x to the end of R if the result is an increasing tableau (Subcase 2.1), and otherwise (Subcase 2.2) do nothing. Furthermore, in Subcase 2.1, we add the box that we have just filled with x in P to the shape of Q , and fill it with the one-element set $\{x\}$. In Subcase 2.2, we find the bottommost box of the column containing the rightmost box of row R , and add x to the entry of Q in this box (this entry is a set, since Q is a set-valued). In either subcase, we terminate the recursion, and set $P_{t+1} = P$ and $Q_{t+1} = Q$.

Notice that set-valued tableaux are encoded as tableaux whose entries are tuples of positive integers; each such tuple is strictly increasing and encodes a set (namely, the set of its entries).

INPUT:

- `obj1, obj2` – Can be one of the following:
 - A word in an ordered alphabet
 - An integer matrix
 - Two lists of equal length representing a generalized permutation
 - Any object which has a method `_rsk_iter()` which returns an iterator over the object represented as generalized permutation or a pair of lists.
- `insertion` – (Default: 'RSK') The following types of insertion are currently supported:
 - 'RSK' – Robinson-Schensted-Knuth
 - 'EG' – Edelman-Greene (only for reduced words of permutations/elements of a type- A Coxeter group)
 - 'hecke' – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing)
- `check_standard` – (Default: False) Check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

EXAMPLES:

If we only give one line, we treat the top line as being $(1, 2, \dots, n)$:

```
sage: RSK([3, 3, 2, 4, 1])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([3, 3, 2, 4, 1]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([2, 3, 3, 2, 1, 3, 2, 3]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

With a generalized permutation:

```
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
sage: RSK(Word([1, 1, 3, 4, 4]), [1, 4, 2, 1, 3])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
sage: RSK([1, 3, 3, 4, 4], Word([6, 2, 2, 1, 7]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

If we give it a matrix:

```
sage: RSK(matrix([[0,1],[2,1]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

We can also give it something looking like a matrix:

```
sage: RSK([[0,1],[2,1]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

There are also variations of the insertion algorithm in RSK. Here we consider Edelman-Greene insertion:

```
sage: RSK([2,1,2,3,2], insertion='EG')
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
```

We reproduce figure 6.4 in [\[EG1987\]](#):

```
sage: RSK([2,3,2,1,2,3], insertion='EG')
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
```

Hecke insertion is also supported. We construct Example 2.1 in [Arxiv 0801.1319v2](#):

```
sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: RSK(w, insertion='hecke')
[[[1, 2, 4, 5], [2, 4, 5], [3, 5], [4], [5]],
 [[(1,),(4,),(5,),(7,)],
  [(2,),(9,),(11,13)],
  [(3,),(12,)],
  [(6,)],
  [(8,10)]]]
```

There is also `RSK_inverse()` which performs the inverse of the bijection on a pair of semistandard tableaux. We note that the inverse function takes 2 separate tableaux as inputs, so to compose with `RSK()`, we need to use the python `*` on the output:

```
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 1, 2]))
[[1, 2, 2, 2], [2, 1, 1, 2]]
sage: P,Q = RSK([1, 2, 2, 2], [2, 1, 1, 2])
sage: RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]
```

`sage.combinat.rsk.RSK_inverse(p,q,output='array',insertion='RSK')`

Return the generalized permutation corresponding to the pair of tableaux (p,q) under the inverse of the Robinson-Schensted-Knuth algorithm.

For more information on the bijection, see `RSK()`.

INPUT:

- p, q – Two semi-standard tableaux of the same shape, or (in the case when Hecke insertion is used) an increasing tableau and a set-valued tableau of the same shape (see the note below for the format of the set-valued tableau)
- `output` – (Default: 'array') if q is semi-standard:
 - 'array' – as a two-line array (i.e. generalized permutation or biword)
 - 'matrix' – as an integer matrix
 and if q is standard, we can have the output:
 - 'word' – as a word

and additionally if p is standard, we can also have the output:

- 'permutation' – as a permutation
- insertion – (Default: RSK) The insertion algorithm used in the bijection. Currently the following are supported:
 - 'RSK' – Robinson-Schensted-Knuth insertion
 - 'EG' – Edelman-Greene insertion
 - 'hecke' – Hecke insertion

Note: In the case of Hecke insertion, the input variable q should be a set-valued tableau, encoded as a tableau whose entries are strictly increasing tuples of positive integers. Each such tuple encodes the set of its entries.

EXAMPLES:

If both p and q are standard:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word')
word: 14532
sage: RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]
```

If the first tableau is semistandard:

```
sage: p = Tableau([[1, 2, 2], [3]]); q = Tableau([[1, 2, 4], [3]])
sage: ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
sage: RSK_inverse(p, q, 'word')
word: 1322
```

In general:

```
sage: p = Tableau([[1, 2, 2], [2]]); q = Tableau([[1, 3, 3], [2]])
sage: RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK_inverse(p, q, 'matrix')
[0 1]
[1 0]
[0 2]
```

Using Edelman-Greene insertion:

```
sage: pq = RSK([2,1,2,3,2], insertion='EG'); pq
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
sage: RSK_inverse(*pq, insertion='EG')
[2, 1, 2, 3, 2]
```

Using Hecke insertion:

```
sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: pq = RSK(w, insertion='hecke')
sage: RSK_inverse(*pq, insertion='hecke', output='list')
[5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
```

Note: The constructor of `Tableau` accepts not only semistandard tableaux, but also arbitrary lists that are fillings of a partition diagram. (And such lists are used, e.g., for the set-valued tableau q that is passed to `RSK_inverse(p, q, insertion='hecke')`.) The user is responsible for ensuring that the tableaux passed to `RSK_inverse` are of the right types (semistandard, standard, increasing, set-valued as needed).

`sage.combinat.rsk.hecke_insertion(obj1, obj2=None)`
 Return the Hecke insertion of the pair `[obj1, obj2]`.

See also:

[`RSK\(\)`](#)

EXAMPLES:

```
sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: RSK(w, insertion='hecke')
[[[1, 2, 4, 5], [2, 4, 5], [3, 5], [4], [5]],
 [[(1,), (4,), (5,), (7,)],
  [(2,), (9,), (11, 13)],
  [(3,), (12,)],
  [(6,)],
  [(8, 10)]]]
```

`sage.combinat.rsk.hecke_insertion_reverse(p, q, output='array')`
 Return the reverse Hecke insertion of `(p, q)`.

See also:

[`RSK\_inverse\(\)`](#)

EXAMPLES:

```
sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: P, Q = RSK(w, insertion='hecke')
sage: wp = RSK_inverse(P, Q, insertion='hecke', output='list'); wp
[5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: wp == w
True
```

`sage.combinat.rsk.robinson_schensted_knuth(obj1=None, obj2=None, insertion='RSK', check_standard=False, **options)`

Perform the Robinson-Schensted-Knuth (RSK) correspondence.

The Robinson-Schensted-Knuth (RSK) correspondence (also known as the RSK algorithm) is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of

semi-standard Young tableaux (P, Q) of identical shape. The tableau P is known as the insertion tableau, and Q is known as the recording tableau.

The basic operation is known as row insertion $P \leftarrow k$ (where P is a given semi-standard Young tableau, and k is an integer). Row insertion is a recursive algorithm which starts by setting $k_0 = k$, and in its i -th step inserts the number k_i into the i -th row of P (we start counting the rows at 0) by replacing the first integer greater than k_i in the row by k_i and defines k_{i+1} as the integer that has been replaced. If no integer greater than k_i exists in the i -th row, then k_i is simply appended to the row and the algorithm terminates at this point.

Now the RSK algorithm, applied to a generalized permutation $p = ((j_0, k_0), (j_1, k_1), \dots, (j_{\ell-1}, k_{\ell-1}))$ (encoded as a lexicographically sorted list of pairs) starts by initializing two semi-standard tableaux P_0 and Q_0 as empty tableaux. For each nonnegative integer t starting at 0, take the pair (j_t, k_t) from p and set $P_{t+1} = P_t \leftarrow k_t$, and define Q_{t+1} by adding a new box filled with j_t to the tableau Q_t at the same location the row insertion on P_t ended (that is to say, adding a new box with entry j_t such that P_{t+1} and Q_{t+1} have the same shape). The iterative process stops when t reaches the size of p , and the pair (P_t, Q_t) at this point is the image of p under the Robinson-Schensted-Knuth correspondence.

This correspondence has been introduced in [Knu1970], where it has been referred to as “Construction A”.

For more information, see Chapter 7 in [Sta-EC2].

We also note that integer matrices are in bijection with generalized permutations. Furthermore, we can convert any word w (and, in particular, any permutation) to a generalized permutation by considering the top line to be $(1, 2, \dots, n)$ where n is the length of w .

The optional argument `insertion` allows to specify an alternative insertion procedure to be used instead of the standard Robinson-Schensted-Knuth insertion. If the input is a reduced word of a permutation (i.e., an element of a type- A Coxeter group), one can set `insertion` to 'EG', which gives Edelman-Greene insertion, an algorithm defined in [EG1987] Definition 6.20 (where it is referred to as Coxeter-Knuth insertion). The Edelman-Greene insertion is similar to the standard row insertion except that if k_i and $k_i + 1$ both exist in row i , we *only* set $k_{i+1} = k_i + 1$ and continue.

One can also perform a “Hecke RSK algorithm”, defined using the Hecke insertion studied in [BKSTY06] (but using rows instead of columns). The algorithm proceeds similarly to the classical RSK algorithm. However, it is not clear in what generality it works; thus, following [BKSTY06], we shall assume that our biword p has top line $(1, 2, \dots, n)$ (or, at least, has its top line strictly increasing). The Hecke RSK algorithm returns a pair of an increasing tableau and a set-valued standard tableau. If $p = ((j_0, k_0), (j_1, k_1), \dots, (j_{\ell-1}, k_{\ell-1}))$, then the algorithm recursively constructs pairs $(P_0, Q_0), (P_1, Q_1), \dots, (P_{\ell}, Q_{\ell})$ of tableaux. The construction of P_{t+1} and Q_{t+1} from P_t, Q_t, j_t and k_t proceeds as follows: Set $i = j_t, x = k_t, P = P_t$ and $Q = Q_t$. We are going to insert x into the increasing tableau P and update the set-valued “recording tableau” Q accordingly. As in the classical RSK algorithm, we first insert x into row 1 of P , then into row 2 of the resulting tableau, and so on, until the construction terminates. The details are different: Suppose we are inserting x into row R of P . If (Case 1) there exists an entry y in row R such that $x < y$, then let y be the minimal such entry. We replace this entry y with x if the result is still an increasing tableau; in either subcase, we then continue recursively, inserting y into the next row of P . If, on the other hand, (Case 2) no such y exists, then we append x to the end of R if the result is an increasing tableau (Subcase 2.1), and otherwise (Subcase 2.2) do nothing. Furthermore, in Subcase 2.1, we add the box that we have just filled with x in P to the shape of Q , and fill it with the one-element set $\{x\}$. In Subcase 2.2, we find the bottommost box of the column containing the rightmost box of row R , and add i to the entry of Q in this box (this entry is a set, since Q is a set-valued). In either subcase, we terminate the recursion, and set $P_{t+1} = P$ and $Q_{t+1} = Q$.

Notice that set-valued tableaux are encoded as tableaux whose entries are tuples of positive integers; each such tuple is strictly increasing and encodes a set (namely, the set of its entries).

INPUT:

- obj1, obj2 – Can be one of the following:
 - A word in an ordered alphabet

- An integer matrix
- Two lists of equal length representing a generalized permutation
- Any object which has a method `_rsk_iter()` which returns an iterator over the object represented as generalized permutation or a pair of lists.
- `insertion` – (Default: 'RSK') The following types of insertion are currently supported:
 - 'RSK' – Robinson-Schensted-Knuth
 - 'EG' – Edelman-Greene (only for reduced words of permutations/elements of a type- A Coxeter group)
 - 'hecke' – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing)
- `check_standard` – (Default: `False`) Check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

EXAMPLES:

If we only give one line, we treat the top line as being $(1, 2, \dots, n)$:

```
sage: RSK([3, 3, 2, 4, 1])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([3, 3, 2, 4, 1]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([2, 3, 3, 2, 1, 3, 2, 3]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

With a generalized permutation:

```
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
sage: RSK(Word([1, 1, 3, 4, 4]), [1, 4, 2, 1, 3])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
sage: RSK([1, 3, 3, 4, 4], Word([6, 2, 2, 1, 7]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

If we give it a matrix:

```
sage: RSK(matrix([[0, 1], [2, 1]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

We can also give it something looking like a matrix:

```
sage: RSK([[0, 1], [2, 1]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

There are also variations of the insertion algorithm in RSK. Here we consider Edelman-Greene insertion:

```
sage: RSK([2, 1, 2, 3, 2], insertion='EG')
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
```

We reproduce figure 6.4 in [\[EG1987\]](#):

```
sage: RSK([2, 3, 2, 1, 2, 3], insertion='EG')
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
```

Hecke insertion is also supported. We construct Example 2.1 in [Arxiv 0801.1319v2](#):

```

sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: RSK(w, insertion='hecke')
[[[1, 2, 4, 5], [2, 4, 5], [3, 5], [4], [5]],
 [[(1,), (4,), (5,), (7,)],
  [(2,), (9,), (11, 13)],
  [(3,), (12,)],
  [(6,)],
  [(8, 10)]]]

```

There is also `RSK_inverse()` which performs the inverse of the bijection on a pair of semistandard tableaux. We note that the inverse function takes 2 separate tableaux as inputs, so to compose with `RSK()`, we need to use the python `*` on the output:

```

sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 1, 2]))
[[1, 2, 2, 2], [2, 1, 1, 2]]
sage: P, Q = RSK([1, 2, 2, 2], [2, 1, 1, 2])
sage: RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]

```

`sage.combinat.rsk.robinson_schensted_knuth_inverse(p, q, output='array', insertion='RSK')`

Return the generalized permutation corresponding to the pair of tableaux (p, q) under the inverse of the Robinson-Schensted-Knuth algorithm.

For more information on the bijection, see `RSK()`.

INPUT:

- p, q – Two semi-standard tableaux of the same shape, or (in the case when Hecke insertion is used) an increasing tableau and a set-valued tableau of the same shape (see the note below for the format of the set-valued tableau)
- `output` – (Default: 'array') if q is semi-standard:
 - 'array' – as a two-line array (i.e. generalized permutation or biword)
 - 'matrix' – as an integer matrix
 and if q is standard, we can have the output:
 - 'word' – as a word
 and additionally if p is standard, we can also have the output:
 - 'permutation' – as a permutation
- `insertion` – (Default: RSK) The insertion algorithm used in the bijection. Currently the following are supported:
 - 'RSK' – Robinson-Schensted-Knuth insertion
 - 'EG' – Edelman-Greene insertion
 - 'hecke' – Hecke insertion

Note: In the case of Hecke insertion, the input variable q should be a set-valued tableau, encoded as a tableau whose entries are strictly increasing tuples of positive integers. Each such tuple encodes the set of its entries.

EXAMPLES:

If both p and q are standard:

```

sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word')
word: 14532
sage: RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]

```

If the first tableau is semistandard:

```

sage: p = Tableau([[1, 2, 2], [3]]); q = Tableau([[1, 2, 4], [3]])
sage: ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
sage: RSK_inverse(p, q, 'word')
word: 1322

```

In general:

```

sage: p = Tableau([[1, 2, 2], [2]]); q = Tableau([[1, 3, 3], [2]])
sage: RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK_inverse(p, q, 'matrix')
[0 1]
[1 0]
[0 2]

```

Using Edelman-Greene insertion:

```

sage: pq = RSK([2, 1, 2, 3, 2], insertion='EG'); pq
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
sage: RSK_inverse(*pq, insertion='EG')
[2, 1, 2, 3, 2]

```

Using Hecke insertion:

```

sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: pq = RSK(w, insertion='hecke')
sage: RSK_inverse(*pq, insertion='hecke', output='list')
[5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]

```

Note: The constructor of `Tableau` accepts not only semistandard tableaux, but also arbitrary lists that are fillings of a partition diagram. (And such lists are used, e.g., for the set-valued tableau `q` that is passed to `RSK_inverse(p, q, insertion='hecke')`.) The user is responsible for ensuring that the tableaux

passed to `RSK_inverse` are of the right types (semistandard, standard, increasing, set-valued as needed).

`sage.combinat.rsk.to_matrix(t, b)`

Return the integer matrix corresponding to a two-line array.

INPUT:

- `t` – The top line of the array
- `b` – The bottom line of the array

OUTPUT:

An $m \times n$ -matrix (where m and n are the maximum entries in t and b respectively) whose (i, j) -th entry, for any i and j , is the number of all positions k satisfying $t_k = i$ and $b_k = j$.

EXAMPLES:

```
sage: from sage.combinat.rsk import to_matrix
sage: to_matrix([1, 1, 3, 3, 4], [2, 3, 1, 1, 3])
[0 1 1]
[0 0 0]
[2 0 0]
[0 0 1]
```

5.1.254 Schubert Polynomials

`sage.combinat.schubert_polynomial.SchubertPolynomialRing(R)`

Returns the Schubert polynomial ring over R on the X basis.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ); X
Schubert polynomial ring with X basis over Integer Ring
sage: X(1)
X[1]
sage: X([1, 2, 3]) * X([2, 1, 3])
X[2, 1]
sage: X([2, 1, 3]) * X([2, 1, 3])
X[3, 1, 2]
sage: X([2, 1, 3]) + X([3, 1, 2, 4])
X[2, 1] + X[3, 1, 2]
sage: a = X([2, 1, 3]) + X([3, 1, 2, 4])
sage: a^2
X[3, 1, 2] + 2*X[4, 1, 2, 3] + X[5, 1, 2, 3, 4]
```

class `sage.combinat.schubert_polynomial.SchubertPolynomialRing_xbasis(R)`

Bases: `sage.combinat.combinatorial_algebra.CombinatorialAlgebra`

EXAMPLES:

```
sage: X = SchubertPolynomialRing(QQ)
sage: X == loads(dumps(X))
True
```

Element

alias of `SchubertPolynomial_class`

class sage.combinat.schubert_polynomial.SchubertPolynomial_class

Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

divided_difference(*i*)

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,1])
sage: a.divided_difference(1)
X[2, 3, 1]
sage: a.divided_difference([3,2,1])
X[1]
```

expand()

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: X([2,1,3]).expand()
x0
sage: [X(p).expand() for p in Permutations(3)]
[1, x0 + x1, x0, x0*x1, x0^2, x0^2*x1]
```

```
sage: X = SchubertPolynomialRing(ZZ)
sage: f = X([1]); f
X[1]
sage: type(f.expand())
<type 'sage.rings.polynomial.multi_polynomial_libsingular.MPolynomial_
↳libsingular'>
sage: f.expand()
1
sage: f = X([1,2])
sage: type(f.expand())
<type 'sage.rings.polynomial.multi_polynomial_libsingular.MPolynomial_
↳libsingular'>
sage: f = X([1,3,2,4])
sage: type(f.expand())
<type 'sage.rings.polynomial.multi_polynomial_libsingular.MPolynomial_
↳libsingular'>
```

multiply_variable(*i*)

Returns the Schubert polynomial obtained by multiplying self by the variable x_i .

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.multiply_variable(0)
X[4, 2, 3, 1]
sage: a.multiply_variable(1)
X[3, 4, 2, 1]
sage: a.multiply_variable(2)
X[3, 2, 5, 1, 4] - X[3, 4, 2, 1] - X[4, 2, 3, 1]
sage: a.multiply_variable(3)
X[3, 2, 4, 5, 1]
```

scalar_product(*x*)

Returns the standard scalar product of self and *x*.

EXAMPLES:

```

sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.scalar_product(a)
0
sage: b = X([4,3,2,1])
sage: b.scalar_product(a)
X[1, 3, 4, 6, 2, 5]
sage: Permutation([1, 3, 4, 6, 2, 5, 7]).to_lehmer_code()
[0, 1, 1, 2, 0, 0, 0]
sage: s = SymmetricFunctions(ZZ).schur()
sage: c = s([2,1,1])
sage: b.scalar_product(a).expand()
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3 + x0^2*x2*x3 +
↪ 3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3 + x0*x1*x3^2 +
↪ x0*x2*x3^2 + x1*x2*x3^2
sage: c.expand(4)
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3 + x0^2*x2*x3 +
↪ 3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3 + x0*x1*x3^2 +
↪ x0*x2*x3^2 + x1*x2*x3^2

```

`sage.combinat.schubert_polynomial.is_SchubertPolynomial(x)`

Returns True if x is a Schubert polynomial and False otherwise.

EXAMPLES:

```

sage: from sage.combinat.schubert_polynomial import is_SchubertPolynomial
sage: X = SchubertPolynomialRing(ZZ)
sage: a = 1
sage: is_SchubertPolynomial(a)
False
sage: b = X(1)
sage: is_SchubertPolynomial(b)
True
sage: c = X([2,1,3])
sage: is_SchubertPolynomial(c)
True

```

5.1.255 Set Partitions

AUTHORS:

- Mike Hansen
- MuPAD-Combinat developers (for algorithms and design inspiration).
- Travis Scrimshaw (2013-02-28): Removed `CombinatorialClass` and added entry point through `SetPartition`.

This module defines a class for immutable partitioning of a set. For mutable version see `DisjointSet()`.

class `sage.combinat.set_partition.SetPartition` (*parent*, *s*)

Bases: `sage.structure.list_clone.ClonableArray`

A partition of a set.

A set partition p of a set S is a partition of S into subsets called parts and represented as a set of sets. By extension, a set partition of a nonnegative integer n is the set partition of the integers from 1 to n . The number of set partitions of n is called the n -th Bell number.

There is a natural integer partition associated with a set partition, namely the nonincreasing sequence of sizes of all its parts.

There is a classical lattice associated with all set partitions of n . The infimum of two set partitions is the set partition obtained by intersecting all the parts of both set partitions. The supremum is obtained by transitive closure of the relation i related to j if and only if they are in the same part in at least one of the set partitions.

We will use terminology from partitions, in particular the *length* of a set partition $A = \{A_1, \dots, A_k\}$ is the number of parts of A and is denoted by $|A| := k$. The *size* of A is the cardinality of S . We will also sometimes use the notation $[n] := \{1, 2, \dots, n\}$.

EXAMPLES:

There are 5 set partitions of the set $\{1, 2, 3\}$:

```
sage: SetPartitions(3).cardinality()
5
```

Here is the list of them:

```
sage: SetPartitions(3).list()
[{{1, 2, 3}},
 {{1}, {2, 3}},
 {{1, 3}, {2}},
 {{1, 2}, {3}},
 {{1}, {2}, {3}}]
```

There are 6 set partitions of $\{1, 2, 3, 4\}$ whose underlying partition is $[2, 1, 1]$:

```
sage: SetPartitions(4, [2, 1, 1]).list()
[{{1}, {2}, {3, 4}},
 {{1}, {2, 4}, {3}},
 {{1}, {2, 3}, {4}},
 {{1, 4}, {2}, {3}},
 {{1, 3}, {2}, {4}},
 {{1, 2}, {3}, {4}}]
```

Since [trac ticket #14140](#), we can create a set partition directly by *SetPartition*, which creates the base set by taking the union of the parts passed in:

```
sage: s = SetPartition([[1, 3], [2, 4]]); s
{{1, 3}, {2, 4}}
sage: s.parent()
Set partitions
```

apply_permutation(p)

Apply p to the underlying set of self.

INPUT:

•p – a permutation

EXAMPLES:

```
sage: x = SetPartition([[1, 2], [3, 5, 4]])
sage: p = Permutation([2, 1, 4, 5, 3])
sage: x.apply_permutation(p)
{{1, 2}, {3, 4, 5}}
sage: q = Permutation([3, 2, 1, 5, 4])
sage: x.apply_permutation(q)
{{1, 4, 5}, {2, 3}}
```

arcs()

Return `self` as a list of arcs.

Consider a set partition $X = \{X_1, X_2, \dots, X_n\}$, then the arcs are the pairs $i - j$ such that $i, j \in X_k$ for some k .

EXAMPLES:

```
sage: A = SetPartition([[1], [2, 3], [4]])
sage: A.arcs()
[(2, 3)]
sage: B = SetPartition([[1, 3, 6, 7], [2, 5], [4]])
sage: B.arcs()
[(1, 3), (3, 6), (6, 7), (2, 5)]
```

base_set()

Return the base set of `self`, which is the union of all parts of `self`.

EXAMPLES:

```
sage: SetPartition([[1], [2, 3], [4]]).base_set()
{1, 2, 3, 4}
sage: SetPartition([[1, 2, 3, 4]]).base_set()
{1, 2, 3, 4}
sage: SetPartition([]).base_set()
{}
```

base_set_cardinality()

Return the cardinality of the base set of `self`, which is the sum of the sizes of the parts of `self`.

This is also known as the *size* (sometimes the *weight*) of a set partition.

EXAMPLES:

```
sage: SetPartition([[1], [2, 3], [4]]).base_set_cardinality()
4
sage: SetPartition([[1, 2, 3, 4]]).base_set_cardinality()
4
```

cardinality()

Returns the len of `self`

EXAMPLES:

```
sage: from sage.structure.list_clone_demo import IncreasingArrays
sage: len(IncreasingArrays()([1, 2, 3]))
3
```

check()

Check that we are a valid ordered set partition.

EXAMPLES:

```
sage: OS = OrderedSetPartitions(4)
sage: s = OS([[1, 3], [2, 4]])
sage: s.check()
```

coarsenings()

Return a list of coarsenings of `self`.

See also:

`refinements()`

EXAMPLES:

```
sage: SetPartition([[1,3],[2,4]]).coarsenings()
[{{1, 2, 3, 4}}, {{1, 3}, {2, 4}}]
sage: SetPartition([[1],[2,4],[3]]).coarsenings()
[{{1, 2, 3, 4}},
 {{1}, {2, 3, 4}},
 {{1, 3}, {2, 4}},
 {{1, 2, 4}, {3}},
 {{1}, {2, 4}, {3}}]
sage: SetPartition([]).coarsenings()
[{}]
```

inf (*other*)

The product of the set partitions *self* and *other*.

The product of two set partitions *B* and *C* is defined as the set partition whose parts are the nonempty intersections between each part of *B* and each part of *C*. This product is also the infimum of *B* and *C* in the classical set partition lattice (that is, the coarsest set partition which is finer than each of *B* and *C*). Consequently, `inf` acts as an alias for this method.

See also:

`sup()`

EXAMPLES:

```
sage: x = SetPartition([ [1,2], [3,5,4] ])
sage: y = SetPartition([ (3,1,2), (5,4) ])
sage: x * y
{{1, 2}, {3}, {4, 5}}

sage: S = SetPartitions(4)
sage: sp1 = S([[2,3,4], [1]])
sage: sp2 = S([[1,3], [2,4]])
sage: s = S([[2,4], [3], [1]])
sage: sp1.inf(sp2) == s
True
```

is_atomic ()

Return if *self* is an atomic set partition.

A (standard) set partition *A* can be split if there exist $j < i$ such that $\max(A_j) < \min(A_i)$ where *A* is ordered by minimal elements. This means we can write $A = B|C$ for some nonempty set partitions *B* and *C*. We call a set partition *atomic* if it cannot be split and is nonempty. Here, the pipe symbol $|$ is as defined in method `pipe()`.

EXAMPLES:

```
sage: SetPartition([[1,3], [2]]).is_atomic()
True
sage: SetPartition([[1,3], [2], [4]]).is_atomic()
False
sage: SetPartition([[1], [2,4], [3]]).is_atomic()
False
sage: SetPartition([[1,2,3,4]]).is_atomic()
True
```

```
sage: SetPartition([[1, 4], [2], [3]]).is_atomic()
True
sage: SetPartition([]).is_atomic()
False
```

is_noncrossing()

Check if self is noncrossing.

EXAMPLES:

```
sage: x = SetPartition([[1, 2], [3, 4]])
sage: x.is_noncrossing()
True
sage: x = SetPartition([[1, 3], [2, 4]])
sage: x.is_noncrossing()
False
```

AUTHOR: Florent Hivert

latex_options()

Return the latex options for use in the `_latex_` function as a dictionary. The default values are set using the global options.

Options can be found in `set_latex_options()`

EXAMPLES:

```
sage: SP = SetPartition([[1, 6], [3, 5, 4]]); SP.latex_options()
{'angle': 0,
 'color': 'black',
 'fill': False,
 'plot': None,
 'radius': '1cm',
 'show_labels': True,
 'tikz_scale': 1}
```

ordered_set_partition_action(s)

Return the action of an ordered set partition s on self.

Let $A = \{A_1, A_2, \dots, A_k\}$ be a set partition of some set S and s be an ordered set partition (i.e., set composition) of a subset of $[k]$. Let $A^\downarrow$ denote the standardization of A , and $A_{\{i_1, i_2, \dots, i_m\}}$ denote the sub-partition $\{A_{i_1}, A_{i_2}, \dots, A_{i_m}\}$ for any subset $\{i_1, \dots, i_m\}$ of $\{1, \dots, k\}$. We define the set partition $s(A)$ by

$$s(A) = A_{s_1}^\downarrow | A_{s_2}^\downarrow | \dots | A_{s_q}^\downarrow.$$

where $s = (s_1, s_2, \dots, s_q)$. Here, the pipe symbol $|$ is as defined in method `pipe()`.

This is $s[A]$ in section 2.3 in [LM2011].

INPUT:

- s – an ordered set partition with base set a subset of $\{1, \dots, k\}$

EXAMPLES:

```
sage: A = SetPartition([[1], [2, 4], [3]])
sage: s = OrderedSetPartition([[1, 3], [2]])
sage: A.ordered_set_partition_action(s)
{{1}, {2}, {3, 4}}
```

```
sage: s = OrderedSetPartition([[2,3], [1]])
sage: A.ordered_set_partition_action(s)
{{1, 3}, {2}, {4}}
```

We create Figure 1 in [LM2011] (we note that there is a typo in the lower-left corner of the table in the published version of the paper, whereas the arXiv version gives the correct partition):

```
sage: A = SetPartition([[1,3], [2,9], [4,5,8], [7]])
sage: B = SetPartition([[1,3], [2,8], [4,5,6], [7]])
sage: C = SetPartition([[1,5], [2,8], [3,4,6], [7]])
sage: s = OrderedSetPartition([[1,3], [2]])
sage: t = OrderedSetPartition([[2], [3,4]])
sage: u = OrderedSetPartition([[1], [2,3,4]])
sage: A.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}
sage: A.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 6}, {5}}
sage: A.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 7}, {6}}
sage: B.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}
sage: B.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}
sage: B.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}
sage: C.ordered_set_partition_action(s)
{{1, 4}, {2, 3, 5}, {6, 7}}
sage: C.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}
sage: C.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}
```

REFERENCES:

pipe (*other*)

Return the pipe of the set partitions *self* and *other*.

The pipe of two set partitions is defined as follows:

For any integer k and any subset I of $\mathbf{Z}$, let $I + k$ denote the subset of $\mathbf{Z}$ obtained by adding k to every element of I .

If B and C are set partitions of $[n]$ and $[m]$, respectively, then the pipe of B and C is defined as the set partition

$$\{B_1, B_2, \dots, B_b, C_1 + n, C_2 + n, \dots, C_c + n\}$$

of $[n + m]$, where $B = \{B_1, B_2, \dots, B_b\}$ and $C = \{C_1, C_2, \dots, C_c\}$. This pipe is denoted by $B|C$.

EXAMPLES:

```
sage: SetPartition([[1,3], [2,4]]).pipe(SetPartition([[1,3], [2]]))
{{1, 3}, {2, 4}, {5, 7}, {6}}
sage: SetPartition([]).pipe(SetPartition([[1,2], [3,5], [4]]))
{{1, 2}, {3, 5}, {4}}
sage: SetPartition([[1,2], [3,5], [4]]).pipe(SetPartition([]))
{{1, 2}, {3, 5}, {4}}
sage: SetPartition([[1,2], [3]]).pipe(SetPartition([[1]]))
{{1, 2}, {3}, {4}}
```

plot (*angle=None*, *color='black'*, *base_set_dict=None*)

Return a plot of *self*.

INPUT:

- *angle* – (default: $\pi/4$) the angle at which the arcs take off (if angle is negative, the arcs are drawn below the horizontal line)
- *color* – (default: 'black') color of the arcs
- *base_set_dict* – (optional) dictionary with keys elements of *base_set()* and values as integer or float

EXAMPLES:

```
sage: p = SetPartition([[1,10,11],[2,3,7],[4,5,6],[8,9]])
sage: p.plot()
Graphics object consisting of 29 graphics primitives
```

```
sage: p = SetPartition([[1,3,4],[2,5]])
sage: print(p.plot().description())

  angle 0.0 inside the sector (0.785398163397,2.35619449019)

```

refinements()

Return a list of refinements of self.

See also:

coarsenings()

EXAMPLES:

```

sage: SetPartition([[1,3],[2,4]]).refinements()
[{{1, 3}, {2, 4}},
 {{1, 3}, {2}, {4}},
 {{1}, {2, 4}, {3}},
 {{1}, {2}, {3}, {4}}]
sage: SetPartition([[1],[2,4],[3]]).refinements()
[{{1}, {2, 4}, {3}}, {{1}, {2}, {3}, {4}}]
sage: SetPartition([]).refinements()
[{}]

```

restriction(I)

Return the restriction of `self` to a subset `I` (which is given as a set or list or any other iterable).

EXAMPLES:

```
sage: A = SetPartition([[1], [2,3]])
sage: A.restriction([1,2])
{{1}, {2}}
sage: A.restriction([2,3])
{{2, 3}}
sage: A.restriction([])
{}
sage: A.restriction([4])
{}
```

set_latex_options(kwargs)**

Set the latex options for use in the `_latex_` function

- `tikz_scale` – (default: 1) scale for use with tikz package
- `plot` – (default: None) None returns the set notation, `linear` returns a linear plot, `cyclic` returns a cyclic plot
- `color` – (default: 'black') the arc colors
- `fill` – (default: False) if True then fills color, else you can pass in a color to alter the fill color - *only works with cyclic plot*
- `show_labels` – (default: True) if True shows labels - *only works with plots*
- `radius` – (default: "1cm") radius of circle for cyclic plot - *only works with cyclic plot*
- `angle` – (default: 0) angle for linear plot

EXAMPLES:

```
sage: SP = SetPartition([[1,6], [3,5,4]])
sage: SP.set_latex_options(tikz_scale=2,plot='linear',fill=True,color='blue',
↪angle=45)
sage: SP.set_latex_options(plot='cyclic')
sage: SP.latex_options()
{'angle': 45,
 'color': 'blue',
 'fill': True,
 'plot': 'cyclic',
 'radius': '1cm',
 'show_labels': True,
 'tikz_scale': 2}
```

shape()

Return the integer partition whose parts are the sizes of the sets in `self`.

EXAMPLES:

```
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
sage: y.shape()
[2, 2, 1]
```

shape_partition()

Return the integer partition whose parts are the sizes of the sets in `self`.

EXAMPLES:

```
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
sage: y.shape()
[2, 2, 1]
```

size()

Return the cardinality of the base set of `self`, which is the sum of the sizes of the parts of `self`.

This is also known as the *size* (sometimes the *weight*) of a set partition.

EXAMPLES:

```
sage: SetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: SetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

standard_form()

Return `self` as a list of lists.

When the ground set is totally ordered, the elements of each block are listed in increasing order.

This is not related to standard set partitions (which simply means set partitions of $[n] = \{1, 2, \dots, n\}$ for some integer n) or standardization (`standardization()`).

EXAMPLES:

```
sage: [x.standard_form() for x in SetPartitions(4, [2,2])]
[[[1, 2], [3, 4]], [[1, 3], [2, 4]], [[1, 4], [2, 3]]]
```

standardization()

Return the standardization of `self`.

Given a set partition $A = \{A_1, \dots, A_n\}$ of an ordered set S , the standardization of A is the set partition of $\{1, 2, \dots, |S|\}$ obtained by replacing the elements of the parts of A by the integers $1, 2, \dots, |S|$ in such a way that their relative order is preserved (i. e., the smallest element in the whole set partition is replaced by 1, the next-smallest by 2, and so on).

EXAMPLES:

```
sage: SetPartition([[4], [1, 3]]).standardization()
{{1, 2}, {3}}
sage: SetPartition([[4], [6, 3]]).standardization()
{{1, 3}, {2}}
sage: SetPartition([]).standardization()
{}
```

strict_coarsenings()

Return all strict coarsenings of `self`.

Strict coarsening is the binary relation on set partitions defined as the transitive-and-reflexive closure of the relation $\prec$ defined as follows: For two set partitions A and B , we have $A \prec B$ if there exist parts A_i, A_j of A such that $\max(A_i) < \min(A_j)$ and $B = A \setminus \{A_i, A_j\} \cup \{A_i \cup A_j\}$.

EXAMPLES:

```
sage: A = SetPartition([[1],[2,3],[4]])
sage: A.strict_coarsenings()
[[{1}, {2, 3}, {4}], [{1, 2, 3}, {4}], [{1, 4}, {2, 3}],
 [{1}, {2, 3, 4}], [{1, 2, 3, 4}]]
sage: SetPartition([[1],[2,4],[3]]).strict_coarsenings()
[[{1}, {2, 4}, {3}], [{1, 2, 4}, {3}], [{1, 3}, {2, 4}]]
sage: SetPartition([]).strict_coarsenings()
[{}]
```

sup(*t*)

Return the supremum of *self* and *t* in the classical set partition lattice.

The supremum of two set partitions *B* and *C* is obtained as the transitive closure of the relation which relates *i* to *j* if and only if *i* and *j* are in the same part in at least one of the set partitions *B* and *C*.

See also:

`__mul__()`

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: sp1 = S([[2,3,4], [1]])
sage: sp2 = S([[1,3], [2,4]])
sage: s = S([[1,2,3,4]])
sage: sp1.sup(sp2) == s
True
```

to_partition()

Return the integer partition whose parts are the sizes of the sets in *self*.

EXAMPLES:

```
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
sage: y.shape()
[2, 2, 1]
```

to_permutation()

Convert a set partition of $\{1, \dots, n\}$ to a permutation by considering the blocks of the partition as cycles.

The cycles are such that the number of excedences is maximised, that is, each cycle is of the form $(a_1, a_2, \dots, a_k)$ with $a_1 < a_2 < \dots < a_k$.

EXAMPLES:

```
sage: s = SetPartition([[1,3],[2,4]])
sage: s.to_permutation()
[3, 4, 1, 2]
```

class sage.combinat.set_partition.**SetPartitions**

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

An (unordered) partition of a set *S* is a set of pairwise disjoint nonempty subsets with union *S*, and is represented by a sorted list of such subsets.

`SetPartitions(s)` returns the class of all set partitions of the set s , which can be given as a set or a string; if a string, each character is considered an element.

`SetPartitions(n)`, where n is an integer, returns the class of all set partitions of the set $\{1, 2, \dots, n\}$.

You may specify a second argument k . If k is an integer, `SetPartitions` returns the class of set partitions into k parts; if it is an integer partition, `SetPartitions` returns the class of set partitions whose block sizes correspond to that integer partition.

The Bell number B_n , named in honor of Eric Temple Bell, is the number of different partitions of a set with n elements.

EXAMPLES:

```
sage: S = [1,2,3,4]
sage: SetPartitions(S,2)
Set partitions of {1, 2, 3, 4} with 2 parts
sage: SetPartitions([1,2,3,4], [3,1]).list()
[{{1}, {2, 3, 4}}, {{1, 3, 4}, {2}}, {{1, 2, 4}, {3}}, {{1, 2, 3}, {4}}]
sage: SetPartitions(7, [3,3,1]).cardinality()
70
```

In strings, repeated letters are not considered distinct as of [trac ticket #14140](#):

```
sage: SetPartitions('abcde').cardinality()
52
sage: SetPartitions('aabcd').cardinality()
15
```

REFERENCES:

- [Wikipedia article Partition_of_a_set](#)

Element

alias of `SetPartition`

`is_less_than(s, t)`

Check if $s < t$ in the refinement ordering on set partitions.

This means that s is a refinement of t and satisfies $s \neq t$.

A set partition s is said to be a refinement of a set partition t of the same set if and only if each part of s is a subset of a part of t .

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1,3],[2,4]])
sage: t = S([[1],[2],[3],[4]])
sage: S.is_less_than(t, s)
True
sage: S.is_less_than(s, t)
False
sage: S.is_less_than(s, s)
False
```

`is_strict_refinement(s, t)`

Return True if s is a strict refinement of t and satisfies $s \neq t$.

A set partition s is said to be a strict refinement of a set partition t of the same set if and only if one can obtain t from s by repeatedly combining pairs of parts whose convex hulls don't intersect (i. e., whenever

we are combining two parts, the maximum of each of them should be smaller than the minimum of the other).

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1],[2],[3],[4]])
sage: t = S([[1,3],[2,4]])
sage: u = S([[1,2,3,4]])
sage: S.is_strict_refinement(s, t)
True
sage: S.is_strict_refinement(t, u)
False
sage: A = SetPartition([[1,3],[2,4]])
sage: B = SetPartition([[1,2,3,4]])
sage: S.is_strict_refinement(s, A)
True
sage: S.is_strict_refinement(t, B)
False
```

lt(s, t)

Check if $s < t$ in the refinement ordering on set partitions.

This means that s is a refinement of t and satisfies $s \neq t$.

A set partition s is said to be a refinement of a set partition t of the same set if and only if each part of s is a subset of a part of t .

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1,3],[2,4]])
sage: t = S([[1],[2],[3],[4]])
sage: S.is_less_than(t, s)
True
sage: S.is_less_than(s, t)
False
sage: S.is_less_than(s, s)
False
```

class sage.combinat.set_partition.**SetPartitions_all**
Bases: *sage.combinat.set_partition.SetPartitions*

All set partitions.

class sage.combinat.set_partition.**SetPartitions_set**(s)
Bases: *sage.combinat.set_partition.SetPartitions*

Set partitions of a fixed set S .

base_set()
Return the base set of self.

EXAMPLES:

```
sage: SetPartitions(3).base_set()
{1, 2, 3}
```

base_set_cardinality()
Return the cardinality of the base set of self.

EXAMPLES:

```
sage: SetPartitions(3).base_set_cardinality()
3
```

cardinality()

Return the number of set partitions of the set S .

The cardinality is given by the n -th Bell number where n is the number of elements in the set S .

EXAMPLES:

```
sage: SetPartitions([1,2,3,4]).cardinality()
15
sage: SetPartitions(3).cardinality()
5
sage: SetPartitions(3,2).cardinality()
3
sage: SetPartitions([]).cardinality()
1
```

class sage.combinat.set_partition.**SetPartitions_setn**(s, n)

Bases: *sage.combinat.set_partition.SetPartitions_set*

cardinality()

The Stirling number of the second kind is the number of partitions of a set of size n into k blocks.

EXAMPLES:

```
sage: SetPartitions(5, 3).cardinality()
25
sage: stirling_number2(5,3)
25
```

class sage.combinat.set_partition.**SetPartitions_setparts**($s, parts$)

Bases: *sage.combinat.set_partition.SetPartitions_set*

Class of all set partitions with fixed partition sizes corresponding to an integer partition λ .

cardinality()

Return the cardinality of *self*.

This algorithm counts for each block of the partition the number of ways to fill it using values from the set. Then, for each distinct value v of block size, we divide the result by the number of ways to arrange the blocks of size v in the set partition.

For example, if we want to count the number of set partitions of size 13 having $[3,3,3,2,2]$ as underlying partition we compute the number of ways to fill each block of the partition, which is $\binom{13}{3}\binom{10}{3}\binom{7}{3}\binom{4}{2}\binom{2}{2}$ and as we have three blocks of size 3 and two blocks of size 2, we divide the result by $3!2!$ which gives us 600600.

EXAMPLES:

```
sage: SetPartitions(3, [2,1]).cardinality()
3
sage: SetPartitions(13, Partition([3,3,3,2,2])).cardinality()
600600
```

sage.combinat.set_partition.**cyclic_permutations_of_set_partition**(*set_part*)

Returns all combinations of cyclic permutations of each cell of the set partition.

AUTHORS:

•Robert L. Miller

EXAMPLES:

```
sage: from sage.combinat.set_partition import cyclic_permutations_of_set_partition
sage: cyclic_permutations_of_set_partition([[1,2,3,4],[5,6,7]])
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```

`sage.combinat.set_partition.cyclic_permutations_of_set_partition_iterator`(*set_part*)
Iterates over all combinations of cyclic permutations of each cell of the set partition.

AUTHORS:

•Robert L. Miller

EXAMPLES:

```
sage: from sage.combinat.set_partition import cyclic_permutations_of_set_
      ↪partition_iterator
sage: list(cyclic_permutations_of_set_partition_iterator([[1,2,3,4],[5,6,7]]))
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```

5.1.256 Ordered Set Partitions

AUTHORS:

- Mike Hansen
- MuPAD-Combinat developers (for algorithms and design inspiration)
- Travis Scrimshaw (2013-02-28): Removed `CombinatorialClass` and added entry point through `OrderedSetPartition`.

class `sage.combinat.set_partition_ordered.OrderedSetPartition`(*parent*, *s*)
Bases: `sage.structure.list_clone.ClonableArray`

An ordered partition of a set.

An ordered set partition p of a set s is a list of pairwise disjoint nonempty subsets of s such that the union of these subsets is s . These subsets are called the parts of the partition. We represent an ordered set partition as a list of sets. By extension, an ordered set partition of a nonnegative integer n is the set partition of the integers from 1 to n . The number of ordered set partitions of n is called the n -th ordered Bell number.

There is a natural integer composition associated with an ordered set partition, that is the sequence of sizes of all its parts in order.

The number T_n of ordered set partitions of $\{1, 2, \dots, n\}$ is the so-called n -th *Fubini number* (also known as the n -th ordered Bell number; see [Wikipedia article Ordered Bell number](#)). Its exponential generating function is

$$\sum_n \frac{T_n}{n!} x^n = \frac{1}{2 - e^x}.$$

(See sequence A000670 in OEIS.)

EXAMPLES:

There are 13 ordered set partitions of $\{1, 2, 3\}$:

```
sage: OrderedSetPartitions(3).cardinality()
13
```

Here is the list of them:

```
sage: OrderedSetPartitions(3).list()
[[{1}, {2}, {3}],
 [{1}, {3}, {2}],
 [{2}, {1}, {3}],
 [{3}, {1}, {2}],
 [{2}, {3}, {1}],
 [{3}, {2}, {1}],
 [{1}, {2, 3}],
 [{2}, {1, 3}],
 [{3}, {1, 2}],
 [{1, 2}, {3}],
 [{1, 3}, {2}],
 [{2, 3}, {1}],
 [{1, 2, 3}]]
```

There are 12 ordered set partitions of $\{1, 2, 3, 4\}$ whose underlying composition is $[1, 2, 1]$:

```
sage: OrderedSetPartitions(4, [1, 2, 1]).list()
[[{1}, {2, 3}, {4}],
 [{1}, {2, 4}, {3}],
 [{1}, {3, 4}, {2}],
 [{2}, {1, 3}, {4}],
 [{2}, {1, 4}, {3}],
 [{3}, {1, 2}, {4}],
 [{4}, {1, 2}, {3}],
 [{3}, {1, 4}, {2}],
 [{4}, {1, 3}, {2}],
 [{2}, {3, 4}, {1}],
 [{3}, {2, 4}, {1}],
 [{4}, {2, 3}, {1}]]
```

Since [trac ticket #14140](#), we can create an ordered set partition directly by `OrderedSetPartition` which creates the parent object by taking the union of the partitions passed in. However it is recommended and (marginally) faster to create the parent first and then create the ordered set partition from that.

```

sage: s = OrderedSetPartition([[1,3],[2,4]]); s
[{1, 3}, {2, 4}]
sage: s.parent()
Ordered set partitions of {1, 2, 3, 4}

```

REFERENCES:

[Wikipedia article Ordered_partition_of_a_set](#)

check()

Check that we are a valid ordered set partition.

EXAMPLES:

```

sage: OS = OrderedSetPartitions(4)
sage: s = OS([[1, 3], [2, 4]])
sage: s.check()

```

to_composition()

Return the integer composition whose parts are the sizes of the sets in `self`.

EXAMPLES:

```

sage: S = OrderedSetPartitions(5)
sage: x = S([[3,5,4], [1, 2]])
sage: x.to_composition()
[3, 2]
sage: y = S([[3,1], [2], [5,4]])
sage: y.to_composition()
[2, 1, 2]

```

class `sage.combinat.set_partition_ordered.OrderedSetPartitions(s)`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Return the combinatorial class of ordered set partitions of `s`.

EXAMPLES:

```

sage: OS = OrderedSetPartitions([1,2,3,4]); OS
Ordered set partitions of {1, 2, 3, 4}
sage: OS.cardinality()
75
sage: OS.first()
[{1}, {2}, {3}, {4}]
sage: OS.last()
[{1, 2, 3, 4}]
sage: OS.random_element()
[{3}, {1}, {2}, {4}]

```

```

sage: OS = OrderedSetPartitions([1,2,3,4], [2,2]); OS
Ordered set partitions of {1, 2, 3, 4} into parts of size [2, 2]
sage: OS.cardinality()
6
sage: OS.first()
[{1, 2}, {3, 4}]
sage: OS.last()
[{3, 4}, {1, 2}]
sage: OS.list()

```

```
[[{1, 2}, {3, 4}],
 [{1, 3}, {2, 4}],
 [{1, 4}, {2, 3}],
 [{2, 3}, {1, 4}],
 [{2, 4}, {1, 3}],
 [{3, 4}, {1, 2}]]
```

```
sage: OS = OrderedSetPartitions("cat"); OS
Ordered set partitions of {'a', 'c', 't'}
sage: OS.list()
[[{'a'}, {'c'}, {'t'}],
 [{'a'}, {'t'}, {'c'}],
 [{'c'}, {'a'}, {'t'}],
 [{'t'}, {'a'}, {'c'}],
 [{'c'}, {'t'}, {'a'}],
 [{'t'}, {'c'}, {'a'}],
 [{'a'}, {'c', 't'}],
 [{'c'}, {'a', 't'}],
 [{'t'}, {'a', 'c'}],
 [{'a', 'c'}, {'t'}],
 [{'a', 't'}, {'c'}],
 [{'c', 't'}, {'a'}],
 [{'a', 'c', 't'}]]
```

Element

alias of *OrderedSetPartition*

class sage.combinat.set_partition_ordered.**OrderedSetPartitions_s**(*s*)
 Bases: *sage.combinat.set_partition_ordered.OrderedSetPartitions*

Class of ordered partitions of a set *S*.

cardinality()

EXAMPLES:

```
sage: OrderedSetPartitions(0).cardinality()
1
sage: OrderedSetPartitions(1).cardinality()
1
sage: OrderedSetPartitions(2).cardinality()
3
sage: OrderedSetPartitions(3).cardinality()
13
sage: OrderedSetPartitions([1,2,3]).cardinality()
13
sage: OrderedSetPartitions(4).cardinality()
75
sage: OrderedSetPartitions(5).cardinality()
541
```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions_scomp**(*s, comp*)
 Bases: *sage.combinat.set_partition_ordered.OrderedSetPartitions*

cardinality()

Return the cardinality of self.

The number of ordered set partitions of a set of length k with composition shape μ is equal to

$$\frac{k!}{\prod_{\mu_i \neq 0} \mu_i!}.$$

EXAMPLES:

```
sage: OrderedSetPartitions(5, [2, 3]).cardinality()
10
sage: OrderedSetPartitions(0, []).cardinality()
1
sage: OrderedSetPartitions(0, [0]).cardinality()
1
sage: OrderedSetPartitions(0, [0, 0]).cardinality()
1
sage: OrderedSetPartitions(5, [2, 0, 3]).cardinality()
10
```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions_sn**(s, n)

Bases: *sage.combinat.set_partition_ordered.OrderedSetPartitions*

cardinality()

Return the cardinality of self.

The number of ordered partitions of a set of size n into k parts is equal to $k!S(n, k)$ where $S(n, k)$ denotes the Stirling number of the second kind.

EXAMPLES:

```
sage: OrderedSetPartitions(4, 2).cardinality()
14
sage: OrderedSetPartitions(4, 1).cardinality()
1
```

class sage.combinat.set_partition_ordered.**SplitNK**($s, comp$)

Bases: *sage.combinat.set_partition_ordered.OrderedSetPartitions_scomp*

5.1.258 Symmetric function features that are imported by default in the interpreter namespace

5.1.259 Characters of the symmetric group as bases of the symmetric functions

Just as the Schur functions are the irreducible characters of Gl_n and form a basis of the symmetric functions, the irreducible symmetric group character basis are the irreducible characters of S_n when the group is realized as the permutation matrices.

REFERENCES:

class `sage.combinat.sf.character.character_basis` (*Sym, other_basis, bname, prefix*)

Bases: `sage.combinat.sf.character.generic_character`

General code for a character basis (irreducible and induced trivial).

This is a basis of the symmetric functions that has the property that `self(la).character_to_frobenius_image(n)` is equal to `other([n-sum(la)]+la)`.

It should also have the property that the (outer) structure constants are the analogue of the stable Kronecker coefficients on the other basis (where other is either the Schur or homogeneous bases).

These bases are introduced in [OZ2015].

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: ht = SymmetricFunctions(QQ).ht()
sage: st = SymmetricFunctions(QQ).st()
sage: ht(s[2,1])
ht[1, 1] + ht[2, 1] - ht[3]
sage: s(ht[2,1])
s[1] - 2*s[1, 1] - 2*s[2] + s[2, 1] + s[3]
sage: ht(h[2,1])
ht[1] + 2*ht[1, 1] + ht[2, 1]
```

```

sage: h(ht[2,1])
h[1] - 2*h[1, 1] + h[2, 1]
sage: st(ht[2,1])
st[] + 2*st[1] + st[1, 1] + 2*st[2] + st[2, 1] + st[3]
sage: ht(st[2,1])
ht[1] - ht[1, 1] + ht[2, 1] - ht[3]
sage: ht[2]*ht[1,1]
ht[1, 1] + 2*ht[1, 1, 1] + ht[2, 1, 1]
sage: h[4,2].kronecker_product(h[4,1,1])
h[2, 2, 1, 1] + 2*h[3, 1, 1, 1] + h[4, 1, 1]
sage: s(st[2,1])
3*s[1] - 2*s[1, 1] - 2*s[2] + s[2, 1]
sage: st(s[2,1])
st[] + 3*st[1] + 2*st[1, 1] + 2*st[2] + st[2, 1]
sage: st[2]*st[1]
st[1] + st[1, 1] + st[2] + st[2, 1] + st[3]
sage: s[4,2].kronecker_product(s[5,1])
s[3, 2, 1] + s[3, 3] + s[4, 1, 1] + s[4, 2] + s[5, 1]

```

class sage.combinat.sf.character.**generic_character**(Sym, basis_name=None, prefix=None, graded=True)
 Bases: *sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic*

Initializes the symmetric function algebra.

INPUT:

- Sym – the ring of symmetric functions
- basis_name – name of basis (default: None)
- prefix – prefix used to display basis
- graded – (default: True) if True, then the basis is considered to be graded, otherwise the basis is filtered

class sage.combinat.sf.character.**irreducible_character_basis**(Sym, prefix)
 Bases: *sage.combinat.sf.character.generic_character*

The irreducible symmetric group character basis of the symmetric functions.

This is a basis of the symmetric functions that has the property that `self(la).character_to_frobenius_image(n)` is equal to `s([n-sum(la)]+la)`.

It should also have the property that the (outer) structure constants are the analogue of the stable kronecker coefficients on the Schur basis (where other is either the Schur or homogeneous bases).

This basis is introduced in [OZ2015].

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: ht = SymmetricFunctions(QQ).ht()
sage: st = SymmetricFunctions(QQ).st()
sage: st(ht[2,1])
st[] + 2*st[1] + st[1, 1] + 2*st[2] + st[2, 1] + st[3]
sage: ht(st[2,1])
ht[1] - ht[1, 1] + ht[2, 1] - ht[3]
sage: s(st[2,1])
3*s[1] - 2*s[1, 1] - 2*s[2] + s[2, 1]

```

```

sage: st(s[2,1])
st[] + 3*st[1] + 2*st[1, 1] + 2*st[2] + st[2, 1]
sage: st[2]*st[1]
st[1] + st[1, 1] + st[2] + st[2, 1] + st[3]
sage: s[4,2].kronecker_product(s[5,1])
s[3, 2, 1] + s[3, 3] + s[4, 1, 1] + s[4, 2] + s[5, 1]
sage: st[1,1,1].counit()
-1
sage: all(sum(c*st(la)*st(mu).antipode() for
....:      ((la,mu),c) in st(ga).coproduct())==st(st(ga).counit())
....:      for ga in Partitions(3))
True

```

5.1.260 Classical symmetric functions.

```

class sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical(Sym,
                                                                    basis_name=None,
                                                                    pre-
                                                                    fix=None,
                                                                    graded=True)

```

Bases: *sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic*

The class of classical symmetric functions.

Todo

delete this class once all coercions will be handled by Sage's coercion model

class Element

Bases: *sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element*

A symmetric function.

```

sage.combinat.sf.classical.init()
Set up the conversion functions between the classical bases.

```

EXAMPLES:

```

sage: from sage.combinat.sf.classical import init
sage: sage.combinat.sf.classical.conversion_functions = {}
sage: init()
sage: sage.combinat.sf.classical.conversion_functions[('Schur', 'powersum')]
<built-in function t_SCHUR_POWSYM_symmetrica>

```

The following checks if the bug described in [trac ticket #15312](#) is fixed.:

```

sage: change = sage.combinat.sf.classical.conversion_functions[('powersum', 'Schur
↔')]
sage: hideme = change({Partition([1]*47):ZZ(1)}) # long time
sage: change({Partition([2,2]):QQ(1)})
s[1, 1, 1, 1] - s[2, 1, 1] + 2*s[2, 2] - s[3, 1] + s[4]

```

5.1.261 Generic dual bases symmetric functions

```
class sage.combinat.sf.dual.SymmetricFunctionAlgebra_dual (dual_basis, scalar,
                                                            scalar_name='', ba-
                                                            sis_name=None, pre-
                                                            fix=None)
```

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical`

Generic dual basis of a basis of symmetric functions.

INPUT:

- `dual_basis` – a basis of the ring of symmetric functions
- `scalar` – A function z on partitions which determines the scalar product on the power sum basis by $\langle p_\mu, p_\mu \rangle = z(\mu)$. (Independently on the function chosen, the power sum basis will always be orthogonal; the function `scalar` only determines the norms of the basis elements.) This defaults to the function `zee` defined in `sage.combinat.sf.sfa`, that is, the function is defined by:

$$\lambda \mapsto \prod_{i=1}^{\infty} m_i(\lambda)! i^{m_i(\lambda)},$$

where $m_i(\lambda)$ means the number of times i appears in λ . This default function gives the standard Hall scalar product on the ring of symmetric functions.

- `scalar_name` – (default: the empty string) a string giving a description of the scalar product specified by the parameter `scalar`
- `basis_name` – (optional) a string to serve as name for the basis to be generated (such as “forgotten” in “the forgotten basis”); don’t set it to any of the already existing basis names (such as `homogeneous`, `monomial`, `forgotten`, etc.).
- `prefix` – (default: ‘d’ and the prefix for `dual_basis`) a string to use as the symbol for the basis

OUTPUT:

The basis of the ring of symmetric functions dual to the basis `dual_basis` with respect to the scalar product determined by `scalar`.

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: f = e.dual_basis(prefix = "m", basis_name="Forgotten symmetric functions");
↪ f
Symmetric Functions over Rational Field in the Forgotten symmetric functions basis
sage: TestSuite(f).run(elements = [f[1,1]+2*f[2], f[1]+3*f[1,1]])
sage: TestSuite(f).run() # long time (11s on sage.math, 2011)
```

This class defines canonical coercions between `self` and `self^*`, as follow:

Lookup for the canonical isomorphism from `self` to P (=powersum), and build the adjoint isomorphism from P^* to `self^*`. Since P is self-adjoint for this scalar product, derive an isomorphism from P to `self^*`, and by composition with the above get an isomorphism from `self` to `self^*` (and similarly for the isomorphism `self^*` to `self`).

This should be striped down to just (auto?) defining canonical isomorphism by adjunction (as in MuPAD-Combinat), and let the coercion handle the rest.

Inversions may not be possible if the base ring is not a field:

```

sage: m = SymmetricFunctions(ZZ).m()
sage: h = m.dual_basis(lambda x: 1)
sage: h[2,1]
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer

```

By transitivity, this defines indirect coercions to and from all other bases:

```

sage: s = SymmetricFunctions(QQ['t'].fraction_field()).s()
sage: t = QQ['t'].fraction_field().gen()
sage: zee_h1 = lambda x: x.centralizer_size(t=t)
sage: S = s.dual_basis(zee_h1)
sage: S(s([2,1]))
(-t/(t^5-2*t^4+t^3-t^2+2*t-1))*d_s[1, 1, 1] + ((-t^2-1)/(t^5-2*t^4+t^3-t^2+2*t-
↪1))*d_s[2, 1] + (-t/(t^5-2*t^4+t^3-t^2+2*t-1))*d_s[3]

```

class Element (*A*, *dictionary=None*, *dual=None*)

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical.Element`

An element in the dual basis.

INPUT:

At least one of the following must be specified. The one (if any) which is not provided will be computed.

- *dictionary* – an internal dictionary for the monomials and coefficients of *self*
- *dual* – *self* as an element of the dual basis.

dual()

Return *self* in the dual basis.

OUTPUT:

- the element *self* expanded in the dual basis to *self.parent()*

EXAMPLES:

```

sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])
sage: a.parent()
Dual basis to Symmetric Functions over Rational Field in the monomial_
↪basis
sage: a.dual()
3*m[1, 1, 1] + 2*m[2, 1] + m[3]

```

expand (*n*, *alphabet='x'*)

Expand the symmetric function *self* as a symmetric polynomial in *n* variables.

INPUT:

- *n* – a nonnegative integer
- *alphabet* – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of *self* in the *n* variables labelled by *alphabet*.

EXAMPLES:

```

sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(zee)
sage: a = h([2,1]) + h([3])
sage: a.expand(2)
2*x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + 2*x1^3
sage: a.dual().expand(2)
2*x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + 2*x1^3
sage: a.expand(2, alphabet='y')
2*y0^3 + 3*y0^2*y1 + 3*y0*y1^2 + 2*y1^3
sage: a.expand(2, alphabet='x,y')
2*x^3 + 3*x^2*y + 3*x*y^2 + 2*y^3
sage: h([1]).expand(0)
0
sage: (3*h([])).expand(0)
3

```

omega()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the result of applying omega to `self`

EXAMPLES:

```

sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(zee)
sage: hh = SymmetricFunctions(QQ).homogeneous()
sage: hh([2,1]).omega()
h[1, 1, 1] - h[2, 1]
sage: h([2,1]).omega()
d_m[1, 1, 1] - d_m[2, 1]

```

omega_involution()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the result of applying omega to self

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(zee)
sage: hh = SymmetricFunctions(QQ).homogeneous()
sage: hh([2,1]).omega()
h[1, 1, 1] - h[2, 1]
sage: h([2,1]).omega()
d_m[1, 1, 1] - d_m[2, 1]
```

scalar(x)

Return the standard scalar product of self and x .

INPUT:

- x – element of the symmetric functions

OUTPUT:

- the scalar product between x and self

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])
sage: a.scalar(a)
2
```

scalar_hl(x)

Return the Hall-Littlewood scalar product of self and x .

INPUT:

- x – element of the same dual basis as self

OUTPUT:

- the Hall-Littlewood scalar product between x and self

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])
sage: a.scalar_hl(a)
(t + 2)/(-t^4 + 2*t^3 - 2*t + 1)
```

`SymmetricFunctionAlgebra_dual.transition_matrix`($basis, n$)

Returns the transition matrix between the n^{th} homogeneous components of self and basis.

INPUT:

- `basis` – a target basis of the ring of symmetric functions
- `n` – nonnegative integer

OUTPUT:

- A transition matrix from `self` to `basis` for the elements of degree `n`. The indexing order of the rows and columns is the order of `Partitions(n)`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: e = Sym.elementary()
sage: f = e.dual_basis()
sage: f.transition_matrix(s, 5)
[ 1 -1  0  1  0 -1  1]
[-2  1  1 -1 -1  1  0]
[-2  2 -1 -1  1  0  0]
[ 3 -1 -1  1  0  0  0]
[ 3 -2  1  0  0  0  0]
[-4  1  0  0  0  0  0]
[ 1  0  0  0  0  0  0]
sage: Partitions(5).list()
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: s(f[2,2,1])
s[3, 2] - 2*s[4, 1] + 3*s[5]
sage: e.transition_matrix(s, 5).inverse().transpose()
[ 1 -1  0  1  0 -1  1]
[-2  1  1 -1 -1  1  0]
[-2  2 -1 -1  1  0  0]
[ 3 -1 -1  1  0  0  0]
[ 3 -2  1  0  0  0  0]
[-4  1  0  0  0  0  0]
[ 1  0  0  0  0  0  0]
```

5.1.262 Elementary symmetric functions

class `sage.combinat.sf.elementary.SymmetricFunctionAlgebra_elementary` (*Sym*)

Bases: `sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative`

A class for methods for the elementary basis of the symmetric functions.

INPUT:

- `self` – an elementary basis of the symmetric functions
- `Sym` – an instance of the ring of symmetric functions

class `Element`

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical.Element`

expand (*n*, *alphabet*='x')

Expand the symmetric function `self` as a symmetric polynomial in `n` variables.

INPUT:

- `n` – a nonnegative integer
- `alphabet` – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the n variables labelled by `alphabet`.

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: e([2,1]).expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 3*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: e([1,1,1]).expand(2)
x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + x1^3
sage: e([3]).expand(2)
0
sage: e([2]).expand(3)
x0*x1 + x0*x2 + x1*x2
sage: e([3]).expand(4, alphabet='x,y,z,t')
x*y*z + x*y*t + x*z*t + y*z*t
sage: e([3]).expand(4, alphabet='y')
y0*y1*y2 + y0*y1*y3 + y0*y2*y3 + y1*y2*y3
sage: e([]).expand(2)
1
sage: e([]).expand(0)
1
sage: (3*e([])).expand(0)
3
```

`omega()`

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: a = e([2,1]); a
e[2, 1]
sage: a.omega()
e[1, 1, 1] - e[2, 1]
```

```
sage: h = SymmetricFunctions(QQ).h()
sage: h(e([2,1]).omega())
h[2, 1]
```

`omega_involution()`

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: a = e([2, 1]); a
e[2, 1]
sage: a.omega()
e[1, 1, 1] - e[2, 1]
```

```
sage: h = SymmetricFunctions(QQ).h()
sage: h(e([2, 1]).omega())
h[2, 1]
```

verschiebung(n)

Return the image of the symmetric function `self` under the n -th Verschiebung operator.

The n -th Verschiebung operator $\mathbf{V}_n$ is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n , and satisfies $V(h_r) = 0$ for every positive integer r not divisible by n . This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(h_r) = h_{r/n}, \quad \mathbf{V}_n(p_r) = np_{r/n}, \quad \mathbf{V}_n(e_r) = (-1)^{r-r/n}e_{r/n}$$

(where h is the complete homogeneous basis, p is the powersum basis, and e is the elementary basis). For every nonnegative integer r with $n \nmid r$, it satisfies

$$\mathbf{V}_n(h_r) = \mathbf{V}_n(p_r) = \mathbf{V}_n(e_r) = 0.$$

The n -th Verschiebung operator is also called the n -th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The n -th Verschiebung operator is adjoint to the n -th Frobenius operator (see `frobenius()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the n -th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley [STA].

Let λ be a partition. Let n be a positive integer. If the n -core of λ is nonempty, then $\mathbf{V}_n(s_\lambda) = 0$. Otherwise, the following method computes $\mathbf{V}_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, \dots, \lambda_{ns})$ for some nonnegative integer s . (If n does not divide the length of λ , then this is achieved by adding trailing zeroes to λ .) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \dots, ns\}$. Then, $(\beta_1, \beta_2, \dots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \dots, ns)$ in order of

(weakly) increasing remainder of $-1 - \beta_i$ modulo n . Let ξ be the sign of the permutation that is used for this sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo n . (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $V_n(s_\lambda) = \xi\psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \dots, \lambda^{(n-1)})$ is the n -quotient of λ .

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: e[3].verschiebung(2)
0
sage: e[4].verschiebung(4)
-e[1]
```

The Verschiebung endomorphisms are multiplicative:

```
sage: all( all( e(lam).verschiebung(2) * e(mu).verschiebung(2)
....:         == (e(lam) * e(mu)).verschiebung(2)
....:         for mu in Partitions(4) )
....:         for lam in Partitions(4) )
True
```

`SymmetricFunctionAlgebra_elementary.coproduct_on_generators(i)`

Returns the coproduct on `self[i]`.

INPUT:

- `self` – an elementary basis of the symmetric functions
- i – a nonnegative integer

OUTPUT:

- returns the coproduct on the elementary generator $e(i)$

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: e = Sym.elementary()
sage: e.coproduct_on_generators(2)
e[] # e[2] + e[1] # e[1] + e[2] # e[]
sage: e.coproduct_on_generators(0)
e[] # e[]
```

5.1.263 Hall-Littlewood Polynomials

Notation used in the definitions follows mainly [Mac1995].

REFERENCES:

```
class sage.combinat.sf.hall_littlewood.HallLittlewood(Sym, t='t')
    Bases: sage.structure.unique_representation.UniqueRepresentation
```

The family of Hall-Littlewood symmetric function bases.

The Hall-Littlewood symmetric functions are a family of symmetric functions that depend on a parameter t .

INPUT:

By default the parameter for these functions is t , and whatever the parameter is, it must be in the base ring.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).hall_littlewood(1)
Hall-Littlewood polynomials with t=1 over Rational Field
sage: SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood()
Hall-Littlewood polynomials over Fraction Field of Univariate Polynomial Ring in t
over Rational Field
```

P()

Return the algebra of symmetric functions in the Hall-Littlewood P basis. This is the same as the HL basis in John Stembridge's SF examples file.

INPUT:

- self – a class of Hall-Littlewood symmetric function bases

OUTPUT:

The class of the Hall-Littlewood P basis.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P(); HLP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
over Rational Field in the Hall-Littlewood P basis
sage: SP = Sym.hall_littlewood(t=-1).P(); SP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
over Rational Field in the Hall-Littlewood P with t=-1 basis
sage: s = Sym.schur()
sage: s(HLP([2,1]))
(-t^2-t)*s[1, 1, 1] + s[2, 1]
```

The Hall-Littlewood polynomials in the P basis at $t = 0$ are the Schur functions:

```
sage: Sym = SymmetricFunctions(QQ)
sage: HLP = Sym.hall_littlewood(t=0).P()
sage: s = Sym.schur()
sage: s(HLP([2,1])) == s([2,1])
True
```

The Hall-Littlewood polynomials in the P basis at $t = 1$ are the monomial symmetric functions:

```
sage: Sym = SymmetricFunctions(QQ)
sage: HLP = Sym.hall_littlewood(t=1).P()
sage: m = Sym.monomial()
sage: m(HLP([2,2,1])) == m([2,2,1])
True
```

We end with some examples of coercions between:

1. Hall-Littlewood P basis.
2. Hall-Littlewood polynomials in the Q basis
3. Hall-Littlewood polynomials in the Q' basis (via the Schurs)

4. Classical symmetric functions

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: s = Sym.schur()
sage: p = Sym.power()
sage: HLP(HLQ([2])) # indirect doctest
(-t+1)*HLP[2]
sage: HLP(HLQp([2]))
t*HLP[1, 1] + HLP[2]
sage: HLP(s([2]))
t*HLP[1, 1] + HLP[2]
sage: HLP(p([2]))
(t-1)*HLP[1, 1] + HLP[2]
sage: s = HLQp.symmetric_function_ring().s()
sage: HLQp.transition_matrix(s, 3)
[      1      0      0]
[      t      1      0]
[  t^3 t^2 + t      1]
sage: s.transition_matrix(HLP, 3)
[      1      t      t^3]
[      0      1 t^2 + t]
[      0      0      1]

```

The method `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element.hl_creation_operator()` is a creation operator for the Q basis:

```

sage: HLQp[1].hl_creation_operator([3]).hl_creation_operator([3])
HLQp[3, 3, 1]

```

Transitions between bases with the parameter t specialized:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['y', 'z']))
sage: (y, z) = Sym.base_ring().gens()
sage: HLy = Sym.hall_littlewood(t=y)
sage: HLz = Sym.hall_littlewood(t=z)
sage: Qpy = HLy.Qp()
sage: Qpz = HLz.Qp()
sage: s = Sym.schur()
sage: s( Qpy[3,1] + z*Qpy[2,2] )
z*s[2, 2] + (y*z+1)*s[3, 1] + (y^2*z+y)*s[4]
sage: s( Qpy[3,1] + y*Qpz[2,2] )
y*s[2, 2] + (y*z+1)*s[3, 1] + (y*z^2+y)*s[4]
sage: s( Qpy[3,1] + y*Qpy[2,2] )
y*s[2, 2] + (y^2+1)*s[3, 1] + (y^3+y)*s[4]

sage: Qy = HLy.Q()
sage: Qz = HLz.Q()
sage: Py = HLy.P()
sage: Pz = HLz.P()
sage: Pz(Qpy[2,1])
(y*z^3+z^2+z)*HLP[1, 1, 1] + (y*z+1)*HLP[2, 1] + y*HLP[3]
sage: Pz(Qz[2,1])
(z^2-2*z+1)*HLP[2, 1]
sage: Qz(Py[2])
((-y+z)/(z^3-z^2-z+1))*HLQ[1, 1] + (1/(-z+1))*HLQ[2]
sage: Qy(Pz[2])

```

```

((y-z)/(y^3-y^2-y+1))*HLQ[1, 1] + (1/(-y+1))*HLQ[2]
sage: Qy.hall_littlewood_family() == HLy
True
sage: Qy.hall_littlewood_family() == HLz
False
sage: Qz.symmetric_function_ring() == Qy.symmetric_function_ring()
True

sage: Sym = SymmetricFunctions(FractionField(QQ['q']))
sage: q = Sym.base_ring().gen()
sage: HL = Sym.hall_littlewood(t=q)
sage: HLQp = HL.Qp()
sage: HLQ = HL.Q()
sage: HLP = HL.P()
sage: s = Sym.schur()
sage: s(HLQp[3,2]).plethysm((1-q)*s[1])/(1-q)^2
(-q^5-q^4)*s[1, 1, 1, 1, 1] + (q^3+q^2)*s[2, 1, 1, 1] - q*s[2, 2, 1] - q*s[3, 1, 1] + s[3, 2]
sage: s(HLP[3,2])
(-q^5-q^4)*s[1, 1, 1, 1, 1] + (q^3+q^2)*s[2, 1, 1, 1] - q*s[2, 2, 1] - q*s[3, 1, 1] + s[3, 2]

```

The P and Q -Schur at $t = -1$ indexed by strict partitions are a basis for the space algebraically generated by the odd power sum symmetric functions:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q']))
sage: SP = Sym.hall_littlewood(t=-1).P()
sage: SQ = Sym.hall_littlewood(t=-1).Q()
sage: p = Sym.power()
sage: SP(SQ[3,2,1])
8*HLP[3, 2, 1]
sage: SP(SQ[2,2,1])
0
sage: p(SP[3,2,1])
1/45*p[1, 1, 1, 1, 1, 1] - 1/9*p[3, 1, 1, 1] - 1/9*p[3, 3] + 1/5*p[5, 1]
sage: SP(p[3,3])
-4*HLP[3, 2, 1] + 2*HLP[4, 2] - 2*HLP[5, 1] + HLP[6]
sage: SQ( SQ[1]*SQ[3] -2*(1-q)*SQ[4] )
HLQ[3, 1] + 2*q*HLQ[4]

```

$Q()$

Returns the algebra of symmetric functions in Hall-Littlewood Q basis. This is the same as the Q basis in John Stembridge's SF examples file.

More extensive examples can be found in the documentation for the Hall-Littlewood P basis.

INPUT:

- self – a class of Hall-Littlewood symmetric function bases

OUTPUT:

- returns the class of the Hall-Littlewood Q basis

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLQ = Sym.hall_littlewood().Q(); HLQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
over Rational Field in the Hall-Littlewood Q basis

```

```
sage: SQ = SymmetricFunctions(QQ).hall_littlewood(t=-1).Q(); SQ
Symmetric Functions over Rational Field in the Hall-Littlewood Q with t=-1
↪basis
```

Qp()

Returns the algebra of symmetric functions in Hall-Littlewood Q' (Qp) basis. This is dual to the Hall-Littlewood P basis with respect to the standard scalar product.

More extensive examples can be found in the documentation for the Hall-Littlewood P basis.

INPUT:

- self – a class of Hall-Littlewood symmetric function bases

OUTPUT:

- returns the class of the Hall-Littlewood Qp -basis

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLQp = Sym.hall_littlewood().Qp(); HLQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↪over Rational Field in the Hall-Littlewood Qp basis
```

base_ring()

Returns the base ring of the symmetric functions where the Hall-Littlewood symmetric functions live

INPUT:

- self – a class of Hall-Littlewood symmetric function bases

OUTPUT:

The base ring of the symmetric functions.

EXAMPLES

```
sage: HL = SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood(t=1)
sage: HL.base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

symmetric_function_ring()

The ring of symmetric functions associated to the class of Hall-Littlewood symmetric functions

INPUT:

- self – a class of Hall-Littlewood symmetric function bases

OUTPUT:

- returns the ring of symmetric functions

EXAMPLES

```
sage: HL = SymmetricFunctions(FractionField(QQ['t'])).hall_littlewood()
sage: HL.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↪over Rational Field
```

class sage.combinat.sf.hall_littlewood.**HallLittlewood_generic**(hall_littlewood)

Bases: *sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic*

A class with methods for working with Hall-Littlewood symmetric functions which are common to all bases.

INPUT:

- `self` – a Hall-Littlewood symmetric function basis
- `hall_littlewood` – a class of Hall-Littlewood bases

class Element

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`

Methods for elements of a Hall-Littlewood basis that are common to all bases.

expand (*n*, *alphabet*='x')

Expands the symmetric function as a symmetric polynomial in *n* variables.

INPUT:

- `self` – an element of a Hall-Littlewood basis
- *n* – a positive integer
- *alphabet* – a string representing a variable name (default: 'x')

OUTPUT:

- returns a symmetric polynomial of `self` in *n* variables

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLP([2]).expand(2)
x0^2 + (-t + 1)*x0*x1 + x1^2
sage: HLQ([2]).expand(2)
(-t + 1)*x0^2 + (t^2 - 2*t + 1)*x0*x1 + (-t + 1)*x1^2
sage: HLQp([2]).expand(2)
x0^2 + x0*x1 + x1^2
sage: HLQp([2]).expand(2, 'y')
y0^2 + y0*y1 + y1^2
sage: HLQp([2]).expand(1)
x^2
```

scalar (*x*, *zee*=None)

Returns standard scalar product between `self` and *x*.

This is the default implementation that converts both `self` and *x* into Schur functions and performs the scalar product that basis.

The Hall-Littlewood *P* basis is dual to the *Qp* basis with respect to this scalar product.

INPUT:

- `self` – an element of a Hall-Littlewood basis
- *x* – another symmetric element of the symmetric functions

OUTPUT:

- returns the scalar product between `self` and *x*

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLP([2]).scalar(HLQp([2]))
1
sage: HLP([2]).scalar(HLQp([1,1]))
0
```

```

sage: HLP([2]).scalar(HLQ([2]), lambda mu: mu.centralizer_size(t = HLP.t))
1
sage: HLP([2]).scalar(HLQ([1,1]), lambda mu: mu.centralizer_size(t = HLP.
↪t))
0

```

scalar_hl(*x*, *t=None*)

Returns the Hall-Littlewood (with parameter *t*) scalar product of *self* and *x*.

The Hall-Littlewood scalar product is defined in Macdonald's book [Mac1995]. The power sum basis is orthogonal and $\langle p_\mu, p_\mu \rangle = z_\mu \prod_i 1/(1 - t^{\mu_i})$

The Hall-Littlewood *P* basis is dual to the *Q* basis with respect to this scalar product.

INPUT:

- *self* – an element of a Hall-Littlewood basis
- *x* – another symmetric element of the symmetric functions
- *t* – an optional parameter, if this parameter is not specified then the value of the *t* from the basis is used in the calculation

OUTPUT:

- returns the Hall-Littlewood scalar product between *self* and *x*

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLP([2]).scalar_hl(HLQ([2]))
1
sage: HLP([2]).scalar_hl(HLQ([1,1]))
0
sage: HLQ([2]).scalar_hl(HLQ([2]))
-t + 1
sage: HLQ([2]).scalar_hl(HLQ([1,1]))
0
sage: HLP([2]).scalar_hl(HLP([2]))
1/(-t + 1)

```

HallLittlewood_generic.**hall_littlewood_family**()

The family of Hall-Littlewood bases associated to *self*

INPUT:

- *self* – a Hall-Littlewood symmetric function basis

OUTPUT:

- returns the class of Hall-Littlewood bases

EXAMPLES

```

sage: HLP = SymmetricFunctions(FractionField(QQ['t'])).hall_littlewood(1).P()
sage: HLP.hall_littlewood_family()
Hall-Littlewood polynomials with t=1 over Fraction Field of Univariate_
↪Polynomial Ring in t over Rational Field

```

HallLittlewood_generic.**transition_matrix**(*basis*, *n*)

Returns the transitions matrix between *self* and *basis* for the homogeneous component of degree *n*.

INPUT:

- *self* – a Hall-Littlewood symmetric function basis

- `basis` – another symmetric function basis
- `n` – a non-negative integer representing the degree

OUTPUT:

- Returns a $r \times r$ matrix of elements of the base ring of `self` where r is the number of partitions of n . The entry corresponding to row μ , column ν is the coefficient of `basis` (ν) in `self` (μ)

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: s = Sym.schur()
sage: HLP.transition_matrix(s, 4)
[      1      -t      0      t^2      -t^3]
[      0       1     -t     -t     t^3 + t^2]
[      0       0      1     -t     t^3]
[      0       0      0      1  -t^3 - t^2 - t]
[      0       0      0      0      1]
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQ.transition_matrix(s, 3)
[      -t + 1      t^2 - t]
↪ -t^3 + t^2]
[      0      t^2 - 2*t + 1      -t^4]
↪ + t^3 + t^2 - t]
[      0      0 -t^6 + t^5 + t^4 - t^2 - t + 1]
sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLQp.transition_matrix(s, 3)
[      1      0      0]
[      t      1      0]
[      t^3 t^2 + t      1]
```

class `sage.combinat.sf.hall_littlewood.HallLittlewood_p(hall_littlewood)`
 Bases: `sage.combinat.sf.hall_littlewood.HallLittlewood_generic`

A class representing the Hall-Littlewood P basis of symmetric functions

class `Element`

Bases: `sage.combinat.sf.hall_littlewood.HallLittlewood_generic.Element`

class `sage.combinat.sf.hall_littlewood.HallLittlewood_q(hall_littlewood)`
 Bases: `sage.combinat.sf.hall_littlewood.HallLittlewood_generic`

The Q basis is defined as a normalization of the P basis.

INPUT:

- `self` – an instance of the Hall-Littlewood P basis
- `hall_littlewood` – a class for the family of Hall-Littlewood bases

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: Q = Sym.hall_littlewood().Q()
sage: TestSuite(Q).run(skip=['_test_associativity', '_test_distributivity', '_test_prod']) # products are too expensive, long time (3s on sage.math, 2012)
sage: TestSuite(Q).run(elements = [Q.t*Q[1,1]+Q[2], Q[1]+(1+Q.t)*Q[1,1]]) # long time (depends on previous)
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
```

```

sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: s = Sym.schur(); p = Sym.power()
sage: HLQ( HLP([2,1]) + HLP([3]) )
(1/(t^2-2*t+1))*HLQ[2, 1] + (1/(-t+1))*HLQ[3]
sage: HLQ(HLQp([2])) # indirect doctest
(t/(t^3-t^2-t+1))*HLQ[1, 1] + (1/(-t+1))*HLQ[2]
sage: HLQ(s([2]))
(t/(t^3-t^2-t+1))*HLQ[1, 1] + (1/(-t+1))*HLQ[2]
sage: HLQ(p([2]))
(1/(t^2-1))*HLQ[1, 1] + (1/(-t+1))*HLQ[2]

```

class Element

Bases: `sage.combinat.sf.hall_littlewood.HallLittlewood_generic.Element`

class `sage.combinat.sf.hall_littlewood.HallLittlewood_qp(hall_littlewood)`

Bases: `sage.combinat.sf.hall_littlewood.HallLittlewood_generic`

The Hall-Littlewood Qp basis is calculated through the `symmetrica` library (see the function `HallLittlewood_qp._to_s()`).

INPUT:

- `self` – an instance of the Hall-Littlewood P basis
- `hall_littlewood` – a class for the family of Hall-Littlewood bases

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: Qp = Sym.hall_littlewood().Q()
sage: TestSuite(Qp).run(skip=['_test_passociativity', '_test_distributivity', '_test_prod']) # products are too expensive, long time (3s on sage.math, 2012)
sage: TestSuite(Qp).run(elements = [Qp.t*Qp[1,1]+Qp[2], Qp[1]+(1+Qp.t)*Qp[1,1]])
# long time (depends on previous)

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: s = Sym.schur(); p = Sym.power()
sage: HLQp(HLP([2])) # indirect doctest
-t*HLQp[1, 1] + (t^2+1)*HLQp[2]
sage: HLQp(s(HLQ([2]))) # work around bug reported in ticket #12969
(t^2-t)*HLQp[1, 1] + (-t^3+t^2-t+1)*HLQp[2]
sage: HLQp(s([2]))
HLQp[2]
sage: HLQp(p([2]))
-HLQp[1, 1] + (t+1)*HLQp[2]
sage: s = HLQp.symmetric_function_ring().s()
sage: HLQp.transition_matrix(s, 3)
[ 1 0 0]
[ t 1 0]
[ t^3 t^2 + t 1]
sage: s.transition_matrix(HLP, 3)
[ 1 t t^3]
[ 0 1 t^2 + t]
[ 0 0 1]

```

class Element

Bases: *sage.combinat.sf.hall_littlewood.HallLittlewood_generic.Element*

5.1.264 Homogeneous symmetric functions

By this we mean the basis formed of the complete homogeneous symmetric functions h_λ , not an arbitrary graded basis.

class *sage.combinat.sf.homogeneous.SymmetricFunctionAlgebra_homogeneous* (*Sym*)

Bases: *sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative*

A class of methods specific to the homogeneous basis of symmetric functions.

INPUT:

- *self* – a homogeneous basis of symmetric functions
- *Sym* – an instance of the ring of symmetric functions

class Element

Bases: *sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical.Element*

expand (*n*, *alphabet*='x')

Expand the symmetric function *self* as a symmetric polynomial in *n* variables.

INPUT:

- *n* – a nonnegative integer
- *alphabet* – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of *self* in the *n* variables labelled by *alphabet*.

EXAMPLES:

```
sage: h = SymmetricFunctions(QQ).h()
sage: h([3]).expand(2)
x0^3 + x0^2*x1 + x0*x1^2 + x1^3
sage: h([1,1,1]).expand(2)
x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + x1^3
sage: h([2,1]).expand(3)
x0^3 + 2*x0^2*x1 + 2*x0*x1^2 + x1^3 + 2*x0^2*x2 + 3*x0*x1*x2 + 2*x1^2*x2
↪ + 2*x0*x2^2 + 2*x1*x2^2 + x2^3
sage: h([3]).expand(2,alphabet='y')
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
sage: h([3]).expand(2,alphabet='x,y')
x^3 + x^2*y + x*y^2 + y^3
sage: h([3]).expand(3,alphabet='x,y,z')
x^3 + x^2*y + x*y^2 + y^3 + x^2*z + x*y*z + y^2*z + x*z^2 + y*z^2 + z^3
sage: (h([]) + 2*h([1])).expand(3)
2*x0 + 2*x1 + 2*x2 + 1
sage: h([1]).expand(0)
0
sage: (3*h([])).expand(0)
3
```

omega ()

Return the image of *self* under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the image of `self` under the omega automorphism

EXAMPLES:

```
sage: h = SymmetricFunctions(QQ).h()
sage: a = h([2,1]); a
h[2, 1]
sage: a.omega()
h[1, 1, 1] - h[2, 1]
sage: e = SymmetricFunctions(QQ).e()
sage: e(h([2,1]).omega())
e[2, 1]
```

`omega_involution()`

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the image of `self` under the omega automorphism

EXAMPLES:

```
sage: h = SymmetricFunctions(QQ).h()
sage: a = h([2,1]); a
h[2, 1]
sage: a.omega()
h[1, 1, 1] - h[2, 1]
```

```
sage: e = SymmetricFunctions(QQ).e()
sage: e(h([2,1]).omega())
e[2, 1]
```

`SymmetricFunctionAlgebra_homogeneous.coproduct_on_generators(i)`
Returns the coproduct on h_i .

INPUT:

- `self` – a homogeneous basis of symmetric functions
- `i` – a nonnegative integer

OUTPUT:

- the sum $\sum_{r=0}^i h_r \otimes h_{i-r}$

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: h = Sym.homogeneous()
sage: h.coproduct_on_generators(2)
h[] # h[2] + h[1] # h[1] + h[2] # h[]
sage: h.coproduct_on_generators(0)
h[] # h[]
```

5.1.265 Jack Symmetric Functions

Jack's symmetric functions appear in [Ma1995] Chapter VI, section 10. Zonal polynomials are the subject of [Ma1995] Chapter VII. The parameter α in that reference is the parameter t in this implementation in sage.

REFERENCES:

class `sage.combinat.sf.jack.Jack(Sym, t='t')`

Bases: `sage.structure.unique_representation.UniqueRepresentation`

The family of Jack symmetric functions including the P , Q , J , Qp bases. The default parameter is t .

INPUT:

- `self` – the family of Jack symmetric function bases
- `Sym` – a ring of symmetric functions
- `t` – an optional parameter (default : 't')

EXAMPLES:

```
sage: SymmetricFunctions(FractionField(QQ['t'])).jack()
Jack polynomials over Fraction Field of Univariate Polynomial Ring in t over
↳ Rational Field
sage: SymmetricFunctions(QQ).jack(1)
Jack polynomials with t=1 over Rational Field
```

J()

Returns the algebra of Jack polynomials in the J basis.

INPUT:

- `self` – the family of Jack symmetric function bases

OUTPUT: the J basis of the Jack symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JJ = Sym.jack().J(); JJ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳ over Rational Field in the Jack J basis
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.jack(t=-1).J()
Symmetric Functions over Rational Field in the Jack J with t=-1 basis
```

At $t = 1$, the Jack polynomials in the J basis are scalar multiples of the Schur functions with the scalar given by a Partition's `hook_product()` method at 1:

```
sage: Sym = SymmetricFunctions(QQ)
sage: JJ = Sym.jack(t=1).J()
sage: s = Sym.schur()
sage: p = Partition([3,2,1,1])
sage: s(JJ(p)) == p.hook_product(1)*s(p) # long time (4s on sage.math, 2012)
True
```

At $t = 2$, the Jack polynomials in the J basis are scalar multiples of the zonal polynomials with the scalar given by a Partition's `hook_product()` method at 2.

```
sage: Sym = SymmetricFunctions(QQ)
sage: JJ = Sym.jack(t=2).J()
sage: Z = Sym.zonal()
sage: p = Partition([2,2,1])
sage: Z(JJ(p)) == p.hook_product(2)*Z(p)
True
```

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JJ = Sym.jack().J()
sage: JP = Sym.jack().P()
sage: JJ(sum(JP(p) for p in Partitions(3)))
1/6*JackJ[1, 1, 1] + (1/(t+2))*JackJ[2, 1] + (1/(2*t^2+3*t+1))*JackJ[3]
```

```
sage: s = Sym.schur()
sage: JJ(s([3])) # indirect doctest
((t^2-3*t+2)/(6*t^2+18*t+12))*JackJ[1, 1, 1] + ((2*t-2)/(2*t^
↳ 2+5*t+2))*JackJ[2, 1] + (1/(2*t^2+3*t+1))*JackJ[3]
sage: JJ(s([2,1]))
((t-1)/(3*t+6))*JackJ[1, 1, 1] + (1/(t+2))*JackJ[2, 1]
sage: JJ(s([1,1,1]))
1/6*JackJ[1, 1, 1]
```

P()

Returns the algebra of Jack polynomials in the P basis.

INPUT:

- self – the family of Jack symmetric function bases

OUTPUT:

- the P basis of the Jack symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P(); JP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳over Rational Field in the Jack P basis
sage: Sym.jack(t=-1).P()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳over Rational Field in the Jack P with t=-1 basis

```

At $t = 1$, the Jack polynomials in the P basis are the Schur symmetric functions.

```

sage: Sym = SymmetricFunctions(QQ)
sage: JP = Sym.jack(t=1).P()
sage: s = Sym.schur()
sage: s(JP([2,2,1]))
s[2, 2, 1]
sage: JP(s([2,2,1]))
JackP[2, 2, 1]
sage: JP([2,1])^2
JackP[2, 2, 1, 1] + JackP[2, 2, 2] + JackP[3, 1, 1, 1] + 2*JackP[3, 2, 1] +
↳JackP[3, 3] + JackP[4, 1, 1] + JackP[4, 2]

```

At $t = 2$, the Jack polynomials in the P basis are the zonal polynomials.

```

sage: Sym = SymmetricFunctions(QQ)
sage: JP = Sym.jack(t=2).P()
sage: Z = Sym.zonal()
sage: Z(JP([2,2,1]))
Z[2, 2, 1]
sage: JP(Z[2, 2, 1])
JackP[2, 2, 1]
sage: JP([2])^2
64/45*JackP[2, 2] + 16/21*JackP[3, 1] + JackP[4]
sage: Z([2])^2
64/45*Z[2, 2] + 16/21*Z[3, 1] + Z[4]

```

```

sage: Sym = SymmetricFunctions(QQ['a','b'].fraction_field())
sage: (a,b) = Sym.base_ring().gens()
sage: Jacka = Sym.jack(t=a)
sage: Jackb = Sym.jack(t=b)
sage: m = Sym.monomial()
sage: JPa = Jacka.P()
sage: JPb = Jackb.P()
sage: m(JPa[2,1])
(6/(a+2))*m[1, 1, 1] + m[2, 1]
sage: m(JPb[2,1])
(6/(b+2))*m[1, 1, 1] + m[2, 1]
sage: m(a*JPb([2,1]) + b*JPa([2,1]))
((6*a^2+6*b^2+12*a+12*b)/(a*b+2*a+2*b+4))*m[1, 1, 1] + (a+b)*m[2, 1]
sage: JPa(JPb([2,1]))
((6*a-6*b)/(a*b+2*a+2*b+4))*JackP[1, 1, 1] + JackP[2, 1]

```

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JQ = Sym.jack().Q()
sage: JP = Sym.jack().P()
sage: JJ = Sym.jack().J()

```

```

sage: JP(JQ([2,1]))
((t+2)/(2*t^3+t^2))*JackP[2, 1]
sage: JP(JQ([3]))
(2*t^2+3*t+1)/(6*t^3)*JackP[3]
sage: JP(JQ([1,1,1]))
(6/(t^3+3*t^2+2*t))*JackP[1, 1, 1]

```

```

sage: JP(JJ([3]))
(2*t^2+3*t+1)*JackP[3]
sage: JP(JJ([2,1]))
(t+2)*JackP[2, 1]
sage: JP(JJ([1,1,1]))
6*JackP[1, 1, 1]

```

```

sage: s = Sym.schur()
sage: JP(s([2,1]))
((2*t-2)/(t+2))*JackP[1, 1, 1] + JackP[2, 1]
sage: s(_)
s[2, 1]

```

Q()

Returns the algebra of Jack polynomials in the Q basis.

INPUT:

- self – the family of Jack symmetric function bases

OUTPUT:

- the Q basis of the Jack symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JQ = Sym.jack().Q()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳over Rational Field in the Jack Q basis
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.jack(t=-1).Q()
Symmetric Functions over Rational Field in the Jack Q with t=-1 basis

```

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JQ = Sym.jack().Q()
sage: JP = Sym.jack().P()
sage: JQ(sum(JP(p) for p in Partitions(3)))
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] +
↳(6*t^3/(2*t^2+3*t+1))*JackQ[3]

```

```

sage: s = Sym.schur()
sage: JQ(s([3])) # indirect doctest
(1/6*t^3-1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3-2*t^2)/(t+2))*JackQ[2, 1] +
↳(6*t^3/(2*t^2+3*t+1))*JackQ[3]
sage: JQ(s([2,1]))
(1/3*t^3-1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1]
sage: JQ(s([1,1,1]))
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1]

```

Qp()

Returns the algebra of Jack polynomials in the Qp , which is dual to the P basis with respect to the standard scalar product.

INPUT:

- self – the family of Jack symmetric function bases

OUTPUT:

- the Q' basis of the Jack symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P()
sage: JQp = Sym.jack().Qp(); JQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↪over Rational Field in the Jack Qp basis
sage: a = JQp([2])
sage: a.scalar(JP([2]))
1
sage: a.scalar(JP([1,1]))
0
sage: JP(JQp([2]))                                # todo: missing auto normalization
((t-1)/(t+1))*JackP[1, 1] + JackP[2]
sage: JP._normalize(JP(JQp([2])))
((t-1)/(t+1))*JackP[1, 1] + JackP[2]
```

base_ring()

Returns the base ring of the symmetric functions in which the Jack symmetric functions live

INPUT:

- self – the family of Jack symmetric function bases

OUTPUT:

- the base ring of the symmetric functions ring of self

EXAMPLES:

```
sage: J2 = SymmetricFunctions(QQ).jack(t=2)
sage: J2.base_ring()
Rational Field
```

symmetric_function_ring()

Returns the base ring of the symmetric functions of the Jack symmetric function bases

INPUT:

- self – the family of Jack symmetric function bases

OUTPUT:

- the symmetric functions ring of self

EXAMPLES:

```
sage: Jacks = SymmetricFunctions(FractionField(QQ['t'])).jack()
sage: Jacks.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↪over Rational Field
```

class `sage.combinat.sf.jack.JackPolynomials_generic` (*jack*)
 Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`

A class of methods which are common to all Jack bases of the symmetric functions

INPUT:

- *self* – a Jack basis of the symmetric functions
- *jack* – a family of Jack symmetric function bases

EXAMPLES

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P(); JP.base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
sage: Sym = SymmetricFunctions(QQ)
sage: JP = Sym.jack(t=2).P(); JP.base_ring()
Rational Field
```

class `Element`

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`

scalar_jack (*x*, *t=None*)

A scalar product where the power sums are orthogonal and $\langle p_\mu, p_\mu \rangle = z_\mu t^{\text{length}(\mu)}$

INPUT:

- *self* – an element of a Jack basis of the symmetric functions
- *x* – an element of the symmetric functions
- *t* – an optional parameter (default [None uses the parameter from] the basis)

OUTPUT:

- returns the Jack scalar product between *x* and *self*

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P()
sage: JQ = Sym.jack().Q()
sage: p = Partitions(3).list()
sage: matrix([[JP(a).scalar_jack(JQ(b)) for a in p] for b in p])
[1 0 0]
[0 1 0]
[0 0 1]
```

`JackPolynomials_generic.c1` (*part*)

Returns the *t*-Jack scalar product between *J* (*part*) and *P* (*part*).

INPUT:

- *self* – a Jack basis of the symmetric functions
- *part* – a partition
- *t* – an optional parameter (default: uses the parameter *t* from the Jack basis)

OUTPUT:

- a polynomial in the parameter *t* which is equal to the scalar product of *J* (*part*) and *P* (*part*)

EXAMPLES

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: JP.c1(Partition([2,1]))
t + 2
```

JackPolynomials_generic.**c2**(part)

Returns the t -Jack scalar product between $J(\text{part})$ and $Q(\text{part})$.

INPUT:

- self – a Jack basis of the symmetric functions
- part – a partition
- t – an optional parameter (default: uses the parameter t from the Jack basis)

OUTPUT:

- a polynomial in the parameter t which is equal to the scalar product of $J(\text{part})$ and $Q(\text{part})$

EXAMPLES:

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: JP.c2(Partition([2,1]))
2*t^3 + t^2
```

JackPolynomials_generic.**coproduct_by_coercion**(elt)

Returns the coproduct of the element elt by coercion to the Schur basis.

INPUT:

- self – a Jack symmetric function basis
- elt – an instance of this basis

OUTPUT:

- The coproduct acting on elt , the result is an element of the tensor squared of the Jack symmetric function basis

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: Sym.jack().P()[2,2].coproduct() #indirect doctest
JackP[] # JackP[2, 2] + (2/(t+1))*JackP[1] # JackP[2, 1] + ((8*t+4)/(t^3+4*t^
↪ 2+5*t+2))*JackP[1, 1] # JackP[1, 1] + JackP[2] # JackP[2] + (2/
↪ (t+1))*JackP[2, 1] # JackP[1] + JackP[2, 2] # JackP[]
```

JackPolynomials_generic.**jack_family**()

Returns the family of Jack bases associated to the basis self

INPUT:

- self – a Jack basis of the symmetric functions

OUTPUT:

- the family of Jack symmetric functions associated to self

EXAMPLES:

```
sage: JackP = SymmetricFunctions(QQ).jack(t=2).P()
sage: JackP.jack_family()
Jack polynomials with t=2 over Rational Field
```

class sage.combinat.sf.jack.**JackPolynomials_j**(jack)

Bases: *sage.combinat.sf.jack.JackPolynomials_generic*

The J basis is a defined as a normalized form of the P basis

INPUT:

- self – an instance of the Jack P basis of the symmetric functions
- jack – a family of Jack symmetric function bases

EXAMPLES:

```
sage: J = SymmetricFunctions(FractionField(QQ['t'])).jack().J()
sage: TestSuite(J).run(skip=['_test_associativity', '_test_distributivity', '_
↳test_prod']) # products are too expensive
sage: TestSuite(J).run(elements = [J.t*J[1,1]+J[2], J[1]+(1+J.t)*J[1,1]]) # long_
↳time (3s on sage.math, 2012)
```

class Element

Bases: `sage.combinat.sf.jack.JackPolynomials_generic.Element`

class `sage.combinat.sf.jack.JackPolynomials_p(jack)`

Bases: `sage.combinat.sf.jack.JackPolynomials_generic`

The P basis is uni-triangularly related to the monomial basis and orthogonal with respect to the Jack scalar product.

INPUT:

- self – an instance of the Jack P basis of the symmetric functions
- jack – a family of Jack symmetric function bases

EXAMPLES:

```
sage: P = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: TestSuite(P).run(skip=['_test_associativity', '_test_distributivity', '_
↳test_prod']) # products are too expensive
sage: TestSuite(P).run(elements = [P.t*P[1,1]+P[2], P[1]+(1+P.t)*P[1,1]])
```

class Element

Bases: `sage.combinat.sf.jack.JackPolynomials_generic.Element`

scalar_jack ($x, t=None$)

The scalar product on the symmetric functions where the power sums are orthogonal and $\langle p_\mu, p_\mu \rangle = z_\mu t^{\text{length}(\mu)}$ where the t parameter from the Jack symmetric function family.

INPUT:

- self – an element of the Jack P basis
- x – an element of the P basis

EXAMPLES

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: l = [JP(p) for p in Partitions(3)]
sage: matrix([[a.scalar_jack(b) for a in l] for b in l])
[ 6*t^3/(2*t^2 + 3*t + 1) 0
↳ 0]
[ 0 (2*t^3 + t^2)/(t + 2)
↳ 0]
[ 0 0 1/6*t^3 + 1/2*t^2 +
↳ 1/3*t]
```

`JackPolynomials_p.scalar_jack_basis(part1, part2=None)`

Returns the scalar product of $P(\text{part1})$ and $P(\text{part2})$.

This is equation (10.16) of [Mc1995] on page 380.

INPUT:

- self – an instance of the Jack P basis of the symmetric functions
- part1 – a partition
- part2 – an optional partition (default : None)

OUTPUT:

- the scalar product between $P(\text{part1})$ and $P(\text{part2})$ (or itself if part2 is None)

REFERENCES:

EXAMPLES:

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: JJ = SymmetricFunctions(FractionField(QQ['t'])).jack().J()
sage: JP.scalar_jack_basis(Partition([2,1]), Partition([1,1,1]))
0
sage: JP._normalize_coefficients(JP.scalar_jack_basis(Partition([3,2,1]),
↳ Partition([3,2,1])))
(12*t^6 + 20*t^5 + 11*t^4 + 2*t^3)/(2*t^3 + 11*t^2 + 20*t + 12)
sage: JJ(JP[3,2,1]).scalar_jack(JP[3,2,1])
(12*t^6 + 20*t^5 + 11*t^4 + 2*t^3)/(2*t^3 + 11*t^2 + 20*t + 12)
```

With a single argument, takes $\text{part2} = \text{part1}$:

```
sage: JP.scalar_jack_basis(Partition([2,1]), Partition([2,1]))
(2*t^3 + t^2)/(t + 2)
sage: JJ(JP[2,1]).scalar_jack(JP[2,1])
(2*t^3 + t^2)/(t + 2)
```

class sage.combinat.sf.jack.**JackPolynomials_q**(jack)

Bases: *sage.combinat.sf.jack.JackPolynomials_generic*

The Q basis is defined as a normalized form of the P basis

INPUT:

- self – an instance of the Jack Q basis of the symmetric functions
- jack – a family of Jack symmetric function bases

EXAMPLES:

```
sage: Q = SymmetricFunctions(FractionField(QQ['t'])).jack().Q()
sage: TestSuite(Q).run(skip=['_test_associativity', '_test_distributivity', '_
↳ test_prod']) # products are too expensive
sage: TestSuite(Q).run(elements = [Q.t*Q[1,1]+Q[2], Q[1]+(1+Q.t)*Q[1,1]]) # long_
↳ time (3s on sage.math, 2012)
```

class **Element**

Bases: *sage.combinat.sf.jack.JackPolynomials_generic.Element*

class sage.combinat.sf.jack.**JackPolynomials_qp**(jack)

Bases: *sage.combinat.sf.jack.JackPolynomials_generic*

The Qp basis is the dual basis to the P basis with respect to the standard scalar product

INPUT:

- self – an instance of the Jack Qp basis of the symmetric functions
- jack – a family of Jack symmetric function bases

EXAMPLES:

```
sage: Qp = SymmetricFunctions(FractionField(QQ['t'])).jack().Qp()
sage: TestSuite(Qp).run(skip=['_test_associativity', '_test_distributivity', '_
↳test_prod']) # products are too expensive
sage: TestSuite(Qp).run(elements = [Qp.t*Qp[1,1]+Qp[2], Qp[1]+(1+Qp.t)*Qp[1,1]])
↳# long time (3s on sage.math, 2012)
```

class Element

Bases: `sage.combinat.sf.jack.JackPolynomials_generic.Element`

`JackPolynomials_qp.coproduct_by_coercion(elt)`

Returns the coproduct of the element `elt` by coercion to the Schur basis.

INPUT:

- `elt` – an instance of the `Qp` basis

OUTPUT:

- The coproduct acting on `elt`, the result is an element of the tensor squared of the `Qp` symmetric function basis

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t']).fraction_field()
sage: JQp = Sym.jack().Qp()
sage: JQp[2,2].coproduct() #indirect doctest
JackQp[] # JackQp[2, 2] + (2*t/(t+1))*JackQp[1] # JackQp[2, 1] + JackQp[1, 1]
↳# JackQp[1, 1] + ((4*t^3+8*t^2)/(2*t^3+5*t^2+4*t+1))*JackQp[2] # JackQp[2]
↳+ (2*t/(t+1))*JackQp[2, 1] # JackQp[1] + JackQp[2, 2] # JackQp[]
```

class `sage.combinat.sf.jack.SymmetricFunctionAlgebra_zonal(Sym)`

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`

Returns the algebra of zonal polynomials.

INPUT:

- `self` – a zonal basis of the symmetric functions
- `Sym` – a ring of the symmetric functions

EXAMPLES

```
sage: Z = SymmetricFunctions(QQ).zonal()
sage: Z([2])^2
64/45*Z[2, 2] + 16/21*Z[3, 1] + Z[4]
sage: Z = SymmetricFunctions(QQ).zonal()
sage: TestSuite(Z).run(skip=['_test_associativity', '_test_distributivity', '_
↳test_prod']) # products are too expensive
sage: TestSuite(Z).run(elements = [Z[1,1]+Z[2], Z[1]+2*Z[1,1]])
```

class Element

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`

scalar_zonal(`x`)

The zonal scalar product has the power sum basis and the zonal symmetric functions are orthogonal. In particular, $\langle p_\mu, p_\mu \rangle = z_\mu 2^{\text{length}(\mu)}$.

INPUT:

- `self` – an element of the zonal basis
- `x` – an element of the symmetric function

OUTPUT:

- the scalar product between `self` and `x`

EXAMPLES

```
sage: Sym = SymmetricFunctions(QQ)
sage: Z = Sym.zonal()
sage: parts = Partitions(3).list()
sage: matrix([[Z(a).scalar_zonal(Z(b)) for a in parts] for b in parts])
[16/5  0  0]
[  0  5  0]
[  0  0  4]
sage: p = Z.symmetric_function_ring().power()
sage: matrix([[Z(p(a)).scalar_zonal(p(b)) for a in parts] for b in parts])
[ 6  0  0]
[ 0  8  0]
[ 0  0 48]
```

`sage.combinat.sf.jack.c1(part, t)`

Returns the t -Jack scalar product between $J(\text{part})$ and $P(\text{part})$.

INPUT:

- `part` – a partition
- `t` – an optional parameter (default: uses the parameter t from the Jack basis)

OUTPUT:

- a polynomial in the parameter t which is equal to the scalar product of $J(\text{part})$ and $P(\text{part})$

EXAMPLES:

```
sage: from sage.combinat.sf.jack import c1
sage: t = QQ['t'].gen()
sage: [c1(p,t) for p in Partitions(3)]
[2*t^2 + 3*t + 1, t + 2, 6]
```

`sage.combinat.sf.jack.c2(part, t)`

Returns the t -Jack scalar product between $J(\text{part})$ and $Q(\text{part})$.

INPUT:

- `self` – a Jack basis of the symmetric functions
- `part` – a partition
- `t` – an optional parameter (default: uses the parameter t from the Jack basis)

OUTPUT:

- a polynomial in the parameter t which is equal to the scalar product of $J(\text{part})$ and $Q(\text{part})$

EXAMPLES:

```
sage: from sage.combinat.sf.jack import c2
sage: t = QQ['t'].gen()
sage: [c2(p,t) for p in Partitions(3)]
[6*t^3, 2*t^3 + t^2, t^3 + 3*t^2 + 2*t]
```

`sage.combinat.sf.jack.normalize_coefficients(self, c)`

If our coefficient ring is the field of fractions over a univariate polynomial ring over the rationals, then we should clear both the numerator and denominator of the denominators of their coefficients.

INPUT:

- `self` – a Jack basis of the symmetric functions
- `c` – a coefficient in the base ring of `self`

OUTPUT:

- divide numerator and denominator by the greatest common divisor

EXAMPLES:

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: t = JP.base_ring().gen()
sage: a = 2/(1/2*t+1/2)
sage: JP._normalize_coefficients(a)
4/(t + 1)
sage: a = 1/(1/3+1/6*t)
sage: JP._normalize_coefficients(a)
6/(t + 2)
sage: a = 24/(4*t^2 + 12*t + 8)
sage: JP._normalize_coefficients(a)
6/(t^2 + 3*t + 2)
```

`sage.combinat.sf.jack.part_scalar_jack(part1, part2, t)`

Returns the Jack scalar product between $p(\text{part1})$ and $p(\text{part2})$ where p is the power-sum basis.

INPUT:

- `part1, part2` – two partitions
- `t` – a parameter

OUTPUT:

- returns the scalar product between the power sum indexed by `part1` and `part2`

EXAMPLES:

```
sage: Q.<t> = QQ[]
sage: from sage.combinat.sf.jack import part_scalar_jack
sage: matrix([[part_scalar_jack(p1,p2,t) for p1 in Partitions(4)] for p2 in_
↪Partitions(4)])
[ 4*t      0      0      0      0]
[  0 3*t^2      0      0      0]
[  0      0 8*t^2      0      0]
[  0      0      0 4*t^3      0]
[  0      0      0      0 24*t^4]
```

5.1.266 Quotient of symmetric function space by ideal generated by Hall-Littlewood symmetric functions

The quotient of symmetric functions by the ideal generated by the Hall-Littlewood P symmetric functions indexed by partitions with first part greater than k . When $t = 1$ this space is the quotient of the symmetric functions by the ideal generated by the monomial symmetric functions indexed by partitions with first part greater than k .

AUTHORS:

- Chris Berg (2012-12-01)
- Mike Zabrocki - k -bounded Hall Littlewood P and dual k -Schur functions (2012-12-02)

class `sage.combinat.sf.k_dual.AffineSchurFunctions` (*kBoundedRing*)

Bases: `sage.combinat.sf.k_dual.KBoundedQuotientBasis`

This basis is dual to the k -Schur functions at $t = 1$. This realization follows the monomial expansion given by Lam [Lam2006].

REFERENCES:

class `sage.combinat.sf.k_dual.DualkSchurFunctions` (*kBoundedRing*)

Bases: `sage.combinat.sf.k_dual.KBoundedQuotientBasis`

This basis is dual to the k -Schur functions. The expansion is given in Section 4.12 of [LLMSSZ]. When $t = 1$ this basis is equal to the `AffineSchurFunctions` and that basis is more efficient in this case.

REFERENCES:

class `sage.combinat.sf.k_dual.KBoundedQuotient` (*Sym, k, t='t'*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Initialization of the ring of Symmetric functions modulo the ideal of monomial symmetric functions which are indexed by partitions whose first part is greater than k .

INPUT:

- `Sym` – an element of class `sage.combinat.sf.sf.SymmetricFunctions`
- `k` – a positive integer
- `R` – a ring

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Q = Sym.kBoundedQuotient(3,t=1)
sage: Q
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1
sage: km = Q.km()
sage: km

↪+ (2*t+2)*dks3[3, 2, 1] + (t+1)*dks3[3, 3]

```

AffineGrothendieckPolynomial(*la*, *m*)

Returns the affine Grothendieck polynomial indexed by the partition *la*. Because this belongs to the completion of the algebra, and hence is an infinite sum, it computes only up to those symmetric functions of degree at most *m*. See `_AffineGrothendieckPolynomial()` for the code.

INPUT:

- *la* – A *k*-bounded partition
- *m* – An integer

EXAMPLES:

```

sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.AffineGrothendieckPolynomial([2,1],4)
2*m3[1, 1, 1] - 8*m3[1, 1, 1, 1] + m3[2, 1] - 3*m3[2, 1, 1] - m3[2, 2]

```

F()

The affine Schur basis of the *k*-bounded quotient of symmetric functions, indexed by *k*-bounded partitions. This is also equal to the affine Stanley symmetric functions (see `WeylGroups.ElementMethods.stanley_symmetric_function()`) indexed by an affine Grassmannian permutation.

EXAMPLES:

```

sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).affineSchur()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the
↪2-bounded affine Schur basis

```

a_realization()

Returns a particular realization of `self` (the basis of k -bounded monomials if $t = 1$ and the basis of k -bounded Hall-Littlewood functions otherwise).

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Q = Sym.kBoundedQuotient(3,t=1)
sage: Q.a_realization()
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the
↪3-bounded monomial basis
sage: Q = Sym.kBoundedQuotient(3,t=2)
sage: Q.a_realization()
3-Bounded Quotient of Symmetric Functions over Rational Field with t=2 in the
↪3-bounded Hall-Littlewood P basis
```

affineSchur()

The affine Schur basis of the k -bounded quotient of symmetric functions, indexed by k -bounded partitions. This is also equal to the affine Stanley symmetric functions (see `WeylGroups.ElementMethods.stanley_symmetric_function()`) indexed by an affine Grassmannian permutation.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).affineSchur()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the
↪2-bounded affine Schur basis
```

ambient()

Returns the Symmetric Functions over the same ring as `self`. This is needed to realize our ring as a quotient.

an_element()

Returns an element of the quotient ring of k -bounded symmetric functions. This method is here to make the TestSuite run properly.

EXAMPLES:

```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.an_element()
2*m3[] + 2*m3[1] + 3*m3[2]
```

dks()

The dual k -Schur basis of the k -bounded quotient of symmetric functions, indexed by k -bounded partitions. At $t = 1$ this is also equal to the affine Schur basis and calculations will be faster using elements in the `affineSchur()` basis.

EXAMPLES:

```
sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).dual_k_
↪Schur()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate
↪Polynomial Ring in t over Rational Field in the dual 2-Schur basis
```

dual_k_Schur()

The dual k -Schur basis of the k -bounded quotient of symmetric functions, indexed by k -bounded partitions. At $t = 1$ this is also equal to the affine Schur basis and calculations will be faster using elements in the `affineSchur()` basis.

EXAMPLES:

```

sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).dual_k_
↪Schur()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
↪Polynomial Ring in t over Rational Field in the dual 2-Schur basis

```

kHLP()

The Hall-Littlewood P basis of the k -bounded quotient of symmetric functions, indexed by k -bounded partitions. At $t = 1$ this basis is equal to the k -bounded monomial basis and calculations will be faster using elements in the k -bounded monomial basis (see `kmonomial()`).

EXAMPLES:

```

sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).
↪kHallLittlewoodP()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
↪Polynomial Ring in t over Rational Field in the 2-bounded Hall-Littlewood P_
↪basis

```

kHallLittlewoodP()

The Hall-Littlewood P basis of the k -bounded quotient of symmetric functions, indexed by k -bounded partitions. At $t = 1$ this basis is equal to the k -bounded monomial basis and calculations will be faster using elements in the k -bounded monomial basis (see `kmonomial()`).

EXAMPLES:

```

sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).
↪kHallLittlewoodP()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
↪Polynomial Ring in t over Rational Field in the 2-bounded Hall-Littlewood P_
↪basis

```

km()

The monomial basis of the k -bounded quotient of symmetric functions, indexed by k -bounded partitions.

EXAMPLES:

```

sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).kmonomial()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the_
↪2-bounded monomial basis

```

kmonomial()

The monomial basis of the k -bounded quotient of symmetric functions, indexed by k -bounded partitions.

EXAMPLES:

```

sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).kmonomial()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the_
↪2-bounded monomial basis

```

lift(la)

Gives the lift map from the quotient ring of k -bounded symmetric functions to the symmetric functions. This method is here to make the TestSuite run properly.

INPUT:

- `la` – A k -bounded partition

OUTPUT:

- The monomial element or a Hall-Littlewood P element of the symmetric functions indexed by the partition λ .

EXAMPLES:

```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.lift([2,1])
m[2, 1]
sage: Q = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3)
sage: Q.lift([2,1])
HLP[2, 1]
```

one()

Returns the unit of the quotient ring of k -bounded symmetric functions. This method is here to make the TestSuite run properly.

EXAMPLES:

```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.one()
m3[]
```

realizations()

A list of realizations of the k -bounded quotient.

EXAMPLES:

```
sage: kQ = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3)
sage: kQ.realizations()
[3-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
↪Polynomial Ring in t over Rational Field in the 3-bounded monomial basis, 3-
↪Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
↪Polynomial Ring in t over Rational Field in the 3-bounded Hall-Littlewood P_
↪basis, 3-Bounded Quotient of Symmetric Functions over Fraction Field of_
↪Univariate Polynomial Ring in t over Rational Field in the 3-bounded affine_
↪Schur basis, 3-Bounded Quotient of Symmetric Functions over Fraction Field_
↪of Univariate Polynomial Ring in t over Rational Field in the dual 3-Schur_
↪basis]
sage: HLP = kQ.ambient().hall_littlewood().P()
sage: all( rzn(HLP[3,2,1]).lift() == HLP[3,2,1] for rzn in kQ.realizations())
True
sage: kQ = SymmetricFunctions(QQ).kBoundedQuotient(3,1)
sage: kQ.realizations()
[3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in_
↪the 3-bounded monomial basis, 3-Bounded Quotient of Symmetric Functions_
↪over Rational Field with t=1 in the 3-bounded Hall-Littlewood P basis, 3-
↪Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the_
↪3-bounded affine Schur basis, 3-Bounded Quotient of Symmetric Functions_
↪over Rational Field with t=1 in the dual 3-Schur basis]
sage: m = kQ.ambient().m()
sage: all( rzn(m[3,2,1]).lift() == m[3,2,1] for rzn in kQ.realizations())
True
```

retract(λ)

Gives the retract map from the symmetric functions to the quotient ring of k -bounded symmetric functions. This method is here to make the TestSuite run properly.

INPUT:

- λ – A partition

OUTPUT:

- The monomial element of the k -bounded quotient indexed by $1a$.

EXAMPLES:

```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.retract([2,1])
m3[2, 1]
```

```
class sage.combinat.sf.k_dual.KBoundedQuotientBases(base)
    Bases: sage.categories.realizations.Category_realization_of_parent
```

The category of bases for the k -bounded subspace of symmetric functions.

class ElementMethods

class KBoundedQuotientBases.ParentMethods

ambient()

Returns the symmetric functions.

EXAMPLES:

```
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.ambient()
Symmetric Functions over Rational Field
```

antipode(element)

Return the antipode of *element* via lifting to the symmetric functions and then retracting into the k -bounded quotient basis.

INPUT:

- element* – an element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: dks3 = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).dual_k_Schur()
sage: dks3[3,2].antipode()
-dks3[1, 1, 1, 1, 1]
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km[3,2].antipode()
m3[3, 2]
sage: km.antipode(km[3,2])
m3[3, 2]
sage: m = SymmetricFunctions(QQ).m()
sage: m[3,2].antipode()
m[3, 2] + 2*m[5]
```

```
sage: km = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3).
↳ km()
sage: km[1,1,1,1].antipode()
(t^3-3*t^2+3*t)*m3[1, 1, 1, 1] + (-t^2+2*t)*m3[2, 1, 1] + t*m3[2, 2] +
↳ t*m3[3, 1]
sage: kHP = SymmetricFunctions(FractionField(QQ['t'])).
↳ kBoundedQuotient(3).kHLP()
sage: kHP[2,2].antipode()
(t^9-t^6-t^5+t^2)*HLP3[1, 1, 1, 1] + (t^6-t^3-t^2+t)*HLP3[2, 1, 1] + (t^5-
↳ t^2+1)*HLP3[2, 2] + (t^4-t)*HLP3[3, 1]
sage: dks = SymmetricFunctions(FractionField(QQ['t'])).
↳ kBoundedQuotient(3).dks()
```

```

sage: dks[2,2].antipode()
dks3[2, 2]
sage: dks[3,2].antipode()
-t^2*dks3[1, 1, 1, 1, 1] + (t^2-1)*dks3[2, 2, 1] + (-t^5+t)*dks3[3, 2]

```

coproduct (*element*)

Return the coproduct of *element* via lifting to the symmetric functions and then returning to the k -bounded quotient basis. This method is implemented for all t but is (weakly) conjectured to not be the correct operation for arbitrary t because the coproduct on dual- k -Schur functions does not have a positive expansion.

INPUT:

- *element* – an element in a basis of the ring of symmetric functions

EXAMPLES:

```

sage: Q3 = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: km = Q3.km()
sage: km[3,2].coproduct()
m3[] # m3[3, 2] + m3[2] # m3[3] + m3[3] # m3[2] + m3[3, 2] # m3[]
sage: dks3 = Q3.dual_k_Schur()
sage: dks3[2,2].coproduct()
dks3[] # dks3[2, 2] + dks3[1] # dks3[2, 1] + dks3[1, 1] # dks3[1, 1] +
↳ dks3[2] # dks3[2] + dks3[2, 1] # dks3[1] + dks3[2, 2] # dks3[]

```

```

sage: Q3t = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3)
sage: km = Q3t.km()
sage: km[3,2].coproduct()
m3[] # m3[3, 2] + m3[2] # m3[3] + m3[3] # m3[2] + m3[3, 2] # m3[]
sage: dks = Q3t.dks()
sage: dks[2,1,1].coproduct()
dks3[] # dks3[2, 1, 1] + (-t+1)*dks3[1] # dks3[1, 1, 1] + dks3[1] #
↳ dks3[2, 1] + (-t+1)*dks3[1, 1] # dks3[1, 1] + dks3[1, 1] # dks3[2] + (-
↳ t+1)*dks3[1, 1, 1] # dks3[1] + dks3[2] # dks3[1, 1] + dks3[2, 1] #
↳ dks3[1] + dks3[2, 1, 1] # dks3[]
sage: kHLP = Q3t.kHLP()
sage: kHLP[2,1].coproduct()
HLP3[] # HLP3[2, 1] + (-t^2+1)*HLP3[1] # HLP3[1, 1] + HLP3[1] # HLP3[2] +
↳ (-t^2+1)*HLP3[1, 1] # HLP3[1] + HLP3[2] # HLP3[1] + HLP3[2, 1] # HLP3[]
sage: km.coproduct(km[3,2])
m3[] # m3[3, 2] + m3[2] # m3[3] + m3[3] # m3[2] + m3[3, 2] # m3[]

```

counit (*element*)

Return the counit of *element*.

The counit is the constant term of *element*.

INPUT:

- *element* – an element in a basis

EXAMPLES:

```

sage: km = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3).
↳ km()
sage: f = 2*km[2,1] - 3*km[]
sage: f.counit()
-3
sage: km.counit(f)
-3

```

degree_on_basis(*b*)

Return the degree of the basis element indexed by *b*.

INPUT:

- *b* – a partition

EXAMPLES:

```
sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).affineSchur()
sage: F.degree_on_basis(Partition([3,2]))
5
```

indices()

The set of *k*-bounded partitions of all non-negative integers.

EXAMPLES:

```
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.indices()
3-Bounded Partitions
```

lift(*la*)

Implements the lift map from the basis *self* to the monomial basis of symmetric functions.

INPUT:

- *la* – A *k*-bounded partition.

OUTPUT:

- A symmetric function in the monomial basis.

EXAMPLES:

```
sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).affineSchur()
sage: F.lift([3,1])
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1]
sage: Sym = SymmetricFunctions(QQ['t']).fraction_field()
sage: dks = Sym.kBoundedQuotient(3).dual_k_Schur()
sage: dks.lift([3,1])
t^5*HLP[1, 1, 1, 1] + t^2*HLP[2, 1, 1] + t*HLP[2, 2] + HLP[3, 1]
sage: dks = Sym.kBoundedQuotient(3,t=1).dual_k_Schur()
sage: dks.lift([3,1])
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1]
```

one_basis()

Return the basis element indexing 1.

EXAMPLES:

```
sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).affineSchur()
sage: F.one() # indirect doctest
F3[]
```

product(*x*, *y*)

Returns the product of two elements *x* and *y*.

INPUT:

- *x*, *y* – Elements of the *k*-bounded quotient of symmetric functions.

OUTPUT:

- A *k*-bounded symmetric function in the dual *k*-Schur function basis

EXAMPLES:

```

sage: dks3 = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).dual_k_Schur()
sage: dks3.product(dks3[2,1],dks3[1,1])
2*dks3[1, 1, 1, 1, 1] + 2*dks3[2, 1, 1, 1] + 2*dks3[2, 2, 1] + dks3[3, 1, 1] + dks3[3, 2]
sage: dks3.product(dks3[2,1]+dks3[1,1], dks3[1,1])
dks3[1, 1, 1, 1, 1] + 2*dks3[1, 1, 1, 1, 1] + dks3[2, 1] + 2*dks3[2, 1, 1, 1] + 2*dks3[2, 2, 1] + dks3[3, 1, 1] + dks3[3, 2]
sage: dks3.product(dks3[2,1]+dks3[1,1], dks3([]))
dks3[1] + dks3[2, 1]
sage: dks3.product(dks3([]), dks3([]))
dks3[]
sage: dks3.product(dks3([]), dks3([4,1]))
Traceback (most recent call last):

↪ m3[3, 2]

```

retract (*la*)

Gives the retract map from the symmetric functions to the quotient ring of k -bounded symmetric functions. This method is here to make the TestSuite run properly.

INPUT:

- *la* – A partition

OUTPUT:

- The monomial element of the k -bounded quotient indexed by *la*.

EXAMPLES:

```

sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.retract([2,1])
m3[2, 1]

```

`KBoundedQuotientBases.super_categories()`

The super categories of self.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ['t'])
sage: from sage.combinat.sf.k_dual import KBoundedQuotientBases
sage: Q = Sym.kBoundedQuotient(3,t=1)
sage: KQB = KBoundedQuotientBases(Q)
sage: KQB.super_categories()
[Category of realizations of 3-Bounded Quotient of Symmetric Functions over
↪ Univariate Polynomial Ring in t over Rational Field with t=1,
Join of Category of graded hopf algebras with basis over Univariate
↪ Polynomial Ring in t over Rational Field and
Category of quotients of algebras over Univariate Polynomial Ring in
↪ t over Rational Field]

```

class `sage.combinat.sf.k_dual.KBoundedQuotientBasis` (*kBoundedRing*, *prefix*)

Bases: `sage.combinat.free_module.CombinatorialFreeModule`

Abstract base class for the bases of the k -bounded quotient.

class `sage.combinat.sf.k_dual.kMonomial` (*kBoundedRing*)
 Bases: `sage.combinat.sf.k_dual.KBoundedQuotientBasis`

The basis of monomial symmetric functions indexed by partitions with first part less than or equal to k .

lift (*la*)

Implements the lift function on the monomial basis. Given a k -bounded partition la , the lift will return the corresponding monomial basis element.

INPUT:

- la – A k -bounded partition

OUTPUT:

- A monomial symmetric function.

EXAMPLES:

```
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.lift(Partition([3,1]))
m[3, 1]
sage: km.lift([])
m[]
sage: km.lift(Partition([4,1]))
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 1]) an element of self (=3-
↳Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the
↳3-bounded monomial basis)
```

retract (*la*)

Implements the retract function on the monomial basis. Given a partition la , the retract will return the corresponding k -bounded monomial basis element if la is k -bounded; zero otherwise.

INPUT:

- la – A partition

OUTPUT:

- A k -bounded monomial symmetric function in the k -quotient of symmetric functions.

EXAMPLES:

```
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.retract(Partition([3,1]))
m3[3, 1]
sage: km.retract(Partition([4,1]))
0
sage: km.retract([])
m3[]
sage: m = SymmetricFunctions(QQ).m()
sage: km(m[3, 1])
m3[3, 1]
sage: km(m[4, 1])
0
```

```
sage: km = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3).km()
sage: km.retract(Partition([3,1]))
m3[3, 1]
sage: km.retract(Partition([4,1]))
0
```

```

(t^4+t^3-9*t^2+11*t-4)*m3[1, 1, 1, 1, 1] + (-3*t^2+6*t-3)*m3[2, 1, 1, 1] + (-
↪t^2+3*t-2)*m3[2, 2, 1] + (2*t-2)*m3[3, 1, 1] + (t-1)*m3[3, 2]

↪t^2+3*t-2)*m3[2, 2, 1] + (2*t-2)*m3[3, 1, 1] + (t-1)*m3[3, 2]

```

class `sage.combinat.sf.k_dual.kbounded_HallLittlewoodP` (*kBoundedRing*)

Bases: `sage.combinat.sf.k_dual.KBoundedQuotientBasis`

The basis of P Hall-Littlewood symmetric functions indexed by partitions with first part less than or equal to k .

lift (*la*)

Implements the lift function on the Hall-Littlewood P basis. Given a k -bounded partition la , the lift will return the corresponding Hall-Littlewood P basis element.

INPUT:

- la – A k -bounded partition

OUTPUT:

- A Hall-Littlewood symmetric function.

EXAMPLES:

```

sage: kHLP = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3).
↪kHallLittlewoodP()
sage: kHLP.lift(Partition([3,1]))
HLP[3, 1]
sage: kHLP.lift([])
HLP[]
sage: kHLP.lift(Partition([4,1]))
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 1]) an element of self (=3-
↪Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
↪Polynomial Ring in t over Rational Field in the 3-bounded Hall-Littlewood P_
↪basis)

```

retract (*la*)

Implements the retract function on the Hall-Littlewood P basis. Given a partition la , the retract will return the corresponding k -bounded Hall-Littlewood P basis element if la is k -bounded; zero otherwise.

INPUT:

- la – A partition

OUTPUT:

- A k -bounded Hall-Littlewood P symmetric function in the k -quotient of symmetric functions.

EXAMPLES:

```

sage: kHLP = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3).
↪kHallLittlewoodP()
sage: kHLP.retract(Partition([3,1]))
HLP3[3, 1]
sage: kHLP.retract(Partition([4,1]))
0

```

```

sage: kHLP.retract([])
HLP3[]
sage: m = kHLP.realization_of().ambient().m()
sage: kHLP(m[2,2])
(t^4-t^3-t+1)*HLP3[1, 1, 1, 1] + (t-1)*HLP3[2, 1, 1] + HLP3[2, 2]

```

5.1.267 Kostka-Foulkes Polynomials

Based on the algorithms in John Stembridge's SF package for Maple which can be found at <http://www.math.lsa.umich.edu/~jrs/maple.html>.

`sage.combinat.sf.kfpoly.KostkaFoulkesPolynomial(mu, nu, t=None)`

Returns the Kostka-Foulkes polynomial $K_{\mu,\nu}(t)$.

INPUT:

- `mu, nu` – partitions
- `t` – an optional parameter (default: `None`)

OUTPUT:

- the Kostka-Foulkes polynomial indexed by partitions `mu` and `nu` and evaluated at the parameter `t`. If `t` is `None` the resulting polynomial is in the polynomial ring $\mathbb{Z}\mathbb{Z}[t]$.

EXAMPLES:

```

sage: KostkaFoulkesPolynomial([2,2],[2,2])
1
sage: KostkaFoulkesPolynomial([2,2],[4])
0
sage: KostkaFoulkesPolynomial([2,2],[1,1,1,1])
t^4 + t^2
sage: KostkaFoulkesPolynomial([2,2],[2,1,1])
t
sage: q = PolynomialRing(QQ,'q').gen()
sage: KostkaFoulkesPolynomial([2,2],[2,1,1],q)
q

```

`sage.combinat.sf.kfpoly.compat(n, mu, nu)`

Generate all possible partitions of `n` that can precede μ, ν in a rigging sequence.

INPUT:

- `n` – a positive integer
- `mu, nu` – partitions

OUTPUT:

- a list of partitions

EXAMPLES:

```

sage: from sage.combinat.sf.kfpoly import *
sage: compat(4, [1], [2,1])
[[1, 1, 1, 1], [2, 1, 1], [2, 2], [3, 1], [4]]
sage: compat(3, [1], [2,1])
[[1, 1, 1], [2, 1], [3]]
sage: compat(2, [1], [])
[[2]]

```

```

sage: compat(3, [1], [])
[[2, 1], [3]]
sage: compat(3, [2], [1])
[[3]]
sage: compat(4, [1,1], [])
[[2, 2], [3, 1], [4]]
sage: compat(4, [2], [])
[[4]]

```

`sage.combinat.sf.kfpoly.dom(mu, snu)`

Returns True if $\text{sum}(\text{mu}[i+1]) \geq \text{snu}[i]$ for all $0 \leq i < \text{len}(\text{snu})$; otherwise, it returns False.

INPUT:

- `mu` – a partition
- `snu` – a sequence of positive integers

OUTPUT:

- a boolean value

EXAMPLES:

```

sage: from sage.combinat.sf.kfpoly import *
sage: dom([3,2,1], [2,4,5])
True
sage: dom([3,2,1], [2,4,7])
False
sage: dom([3,2,1], [2,6,5])
False
sage: dom([3,2,1], [4,4,4])
False

```

`sage.combinat.sf.kfpoly.kfpoly(mu, nu, t=None)`

Returns the Kostka-Foulkes polynomial $K_{\mu,\nu}(t)$ by generating all rigging sequences for the shape μ , and then selecting those of content ν .

INPUT:

- `mu, nu` – partitions
- `t` – an optional parameter (default: None)

OUTPUT:

- the Kostka-Foulkes polynomial indexed by partitions `mu` and `nu` and evaluated at the parameter `t`. If `t` is None the resulting polynomial is in the polynomial ring $\mathbb{Z}[t]$.

EXAMPLES:

```

sage: from sage.combinat.sf.kfpoly import kfpoly
sage: kfpoly([2,2], [2,1,1])
t
sage: kfpoly([4], [2,1,1])
t^3
sage: kfpoly([4], [2,2])
t^2
sage: kfpoly([1,1,1,1], [2,2])
0

```

`sage.combinat.sf.kfpoly.riggings(part)`

Generate all possible rigging sequences for a fixed `sage.combinat.partition`.

INPUT:

- `part` – a partition

OUTPUT:

- returns a list of riggings associated to the partition `part`

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: riggings([3])
[[[1, 1, 1]], [[2, 1]], [[3]]]
sage: riggings([2,1])
[[[2, 1], [1]], [[3], [1]]]
sage: riggings([1,1,1])
[[[3], [2], [1]]]
sage: riggings([2,2])
[[[2, 2], [1, 1]], [[3, 1], [1, 1]], [[4], [1, 1]], [[4], [2]]]
sage: riggings([2,2,2])
[[[3, 3], [2, 2], [1, 1]],
 [[4, 2], [2, 2], [1, 1]],
 [[5, 1], [2, 2], [1, 1]],
 [[6], [2, 2], [1, 1]],
 [[5, 1], [3, 1], [1, 1]],
 [[6], [3, 1], [1, 1]],
 [[6], [4], [2]]]
```

`sage.combinat.sf.kfpoly.schur_to_hl(mu, t=None)`

Returns a dictionary corresponding to s_μ in Hall-Littlewood P basis.

INPUT:

- `mu` – a partition
- `t` – an optional parameter (default : the generator from $\mathbb{Z}[t]$)

OUTPUT:

- a dictionary with the coefficients $K_{\mu\nu}(t)$ for ν smaller in dominance order than μ

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: schur_to_hl([1,1,1])
{[1, 1, 1]: 1}
sage: a = schur_to_hl([2,1])
sage: for mc in sorted(six.iteritems(a)): print(mc)
([1, 1, 1], t^2 + t)
([2, 1], 1)
sage: a = schur_to_hl([3])
sage: for mc in sorted(six.iteritems(a)): print(mc)
([1, 1, 1], t^3)
([2, 1], t)
([3], 1)
sage: a = schur_to_hl([4])
sage: for mc in sorted(six.iteritems(a)): print(mc)
([1, 1, 1, 1], t^6)
([2, 1, 1], t^3)
```

```

([2, 2], t^2)
([3, 1], t)
([4], 1)
sage: a = schur_to_hl([3,1])
sage: for mc in sorted(six.iteritems(a)): print(mc)
([1, 1, 1, 1], t^5 + t^4 + t^3)
([2, 1, 1], t^2 + t)
([2, 2], t)
([3, 1], 1)
sage: a = schur_to_hl([2,2])
sage: for mc in sorted(six.iteritems(a)): print(mc)
([1, 1, 1, 1], t^4 + t^2)
([2, 1, 1], t)
([2, 2], 1)
sage: a = schur_to_hl([2,1,1])
sage: for mc in sorted(six.iteritems(a)): print(mc)
([1, 1, 1, 1], t^3 + t^2 + t)
([2, 1, 1], 1)
sage: a = schur_to_hl([1,1,1,1])
sage: for mc in sorted(six.iteritems(a)): print(mc)
([1, 1, 1, 1], 1)
sage: a = schur_to_hl([2,2,2])
sage: for mc in sorted(six.iteritems(a)): print(mc)
([1, 1, 1, 1, 1, 1], t^9 + t^7 + t^6 + t^5 + t^3)
([2, 1, 1, 1, 1], t^4 + t^2)
([2, 2, 1, 1], t)
([2, 2, 2], 1)

```

`sage.combinat.sf.kfpoly.weight` (*rg*, *t=None*)
Returns the weight of a rigging.

INPUT:

- *rg* – a rigging, a list of partitions
- *t* – an optional parameter, (default : uses the generator from $\mathbb{Z}\mathbb{Z}[t']$)

OUTPUT:

- a polynomial in the parameter *t*

EXAMPLES:

```

sage: from sage.combinat.sf.kfpoly import weight
sage: weight([[2,1], [1]])
1
sage: weight([[3], [1]])
t^2 + t
sage: weight([[2,1], [3]])
t^4
sage: weight([[2, 2], [1, 1]])
1
sage: weight([[3, 1], [1, 1]])
t
sage: weight([[4], [1, 1]], 2)
16
sage: weight([[4], [2]], t=2)
4

```

5.1.268 LLT symmetric functions

REFERENCES:

class `sage.combinat.sf.llt.LLT_class(Sym, k, t='t')`
 Bases: `sage.structure.unique_representation.UniqueRepresentation`

A class for working with LLT symmetric functions.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: L3 = Sym.llt(3); L3
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in t
↳ over Rational Field
sage: L3.cospin([3,2,1])
(t+1)*m[1, 1] + m[2]
sage: HC3 = L3.hcospin(); HC3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳ Rational Field in the level 3 LLT cospin basis
sage: m = Sym.monomial()
sage: m( HC3[1,1] )
(t+1)*m[1, 1] + m[2]
```

We require that the parameter t must be in the base ring:

```
sage: Symxt = SymmetricFunctions(QQ['x', 't'].fraction_field())
sage: (x,t) = Symxt.base_ring().gens()
sage: LLT3x = Symxt.llt(3,t=x)
sage: LLT3 = Symxt.llt(3)
sage: HS3x = LLT3x.hspin()
sage: HS3t = LLT3.hspin()
sage: s = Symxt.schur()
sage: s(HS3x[2,1])
s[2, 1] + x*s[3]
sage: s(HS3t[2,1])
s[2, 1] + t*s[3]
sage: HS3x(HS3t[2,1])
HSp3[2, 1] + (-x+t)*HSp3[3]
sage: s(HS3x(HS3t[2,1]))
s[2, 1] + t*s[3]
sage: LLT3t2 = Symxt.llt(3,t=2)
sage: HC3t2 = LLT3t2.hcospin()
sage: HS3x(HC3t2[3,1])
2*HSp3[3, 1] + (-2*x+1)*HSp3[4]
```

base_ring()

Returns the base ring of `self`.

INPUT:

- `self` – a family of LLT symmetric functions bases

OUTPUT:

- returns the base ring of the symmetric function ring associated to `self`

EXAMPLES:

```
sage: SymmetricFunctions(FractionField(QQ['t'])).llt(3).base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

cospin(*skp*)

Calculates a single instance of the cospin symmetric functions. These are the functions defined in [\[LLT1997\]](#) equation (26).

INPUT:

- *self* – a family of LLT symmetric functions bases
- *skp* – a partition or a list of partitions or a list of skew partitions

OUTPUT:

- returns the monomial expansion of the LLT symmetric function cospin functions indexed by *skp*

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: L3 = Sym.llt(3)
sage: L3.cospin([2,1])
m[1]
sage: L3.cospin([3,2,1])
(t+1)*m[1, 1] + m[2]
sage: s = Sym.schur()
sage: s(L3.cospin([2], [1], [2]))
t^4*s[2, 2, 1] + t^3*s[3, 1, 1] + (t^3+t^2)*s[3, 2] + (t^2+t)*s[4, 1] + s[5]
```

hcospin()

Returns the HCospin basis. This basis is defined [\[LLT1997\]](#) equation (27).

INPUT:

- *self* – a family of LLT symmetric functions bases

OUTPUT:

- returns the h-cospin basis of the LLT symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HCosp3 = Sym.llt(3).hcospin(); HCosp3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t_
↳ over Rational Field in the level 3 LLT cospin basis
sage: HCosp3([1])^2
1/t*HCosp3[1, 1] + ((t-1)/t)*HCosp3[2]

sage: s = Sym.schur()
sage: HCosp3(s([2]))
HCosp3[2]
sage: HCosp3(s([1,1]))
1/t*HCosp3[1, 1] - 1/t*HCosp3[2]
sage: s(HCosp3([2,1]))
t*s[2, 1] + s[3]
```

hspin()

Returns the HSpin basis. This basis is defined [\[LLT1997\]](#) equation (28).

INPUT:

- *self* – a family of LLT symmetric functions bases

OUTPUT:

- returns the h-spin basis of the LLT symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HSp3 = Sym.llt(3).hspin(); HSp3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t_
↳ over Rational Field in the level 3 LLT spin basis
sage: HSp3([1])^2
HSp3[1, 1] + (-t+1)*HSp3[2]

sage: s = Sym.schur()
sage: HSp3(s([2]))
HSp3[2]
sage: HSp3(s([1,1]))
HSp3[1, 1] - t*HSp3[2]
sage: s(HSp3([2,1]))
s[2, 1] + t*s[3]
```

level()

Returns the level of `self`.

INPUT:

- `self` – a family of LLT symmetric functions bases

OUTPUT:

- the level is the parameter of k in the basis

EXAMPLES:

```
sage: SymmetricFunctions(FractionField(QQ['t'])).llt(3).level()
3
```

spin_square(*skp*)

Calculates a single instance of a spin squared LLT symmetric function associated with a partition, list of partitions, or a list of skew partitions. This family of symmetric functions is defined in [\[LT2000\]](#) equation (43).

INPUT:

- `self` – a family of LLT symmetric functions bases
- `skp` – a partition of a list of partitions or a list of skew partitions

OUTPUT:

- returns the monomial expansion of the LLT symmetric function spin-square functions indexed by `skp`

EXAMPLES:

```
sage: L3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3)
sage: L3.spin_square([2,1])
t*m[1]
sage: L3.spin_square([3,2,1])
(t^3+t)*m[1, 1] + t^3*m[2]
sage: L3.spin_square([[1],[1],[1]])
(t^6+2*t^4+2*t^2+1)*m[1, 1, 1] + (t^6+t^4+t^2)*m[2, 1] + t^6*m[3]
sage: L3.spin_square([[2,2],[1]],[[2,1],[1]])
(2*t^4+3*t^2+1)*m[1, 1, 1, 1] + (t^4+t^2)*m[2, 1, 1] + t^4*m[2, 2]
```

symmetric_function_ring()

The symmetric function algebra associated to the family of LLT symmetric function bases

INPUT:

- self – a family of LLT symmetric functions bases

OUTPUT:

- returns the symmetric function ring associated to self.

EXAMPLES

```
sage: L3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3)
sage: L3.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳over Rational Field
```

```
class sage.combinat.sf.llt.LLT_cospin(llt)
    Bases: sage.combinat.sf.llt.LLT_generic
```

A class of methods for the h-cospin LLT basis of the symmetric functions.

INPUT:

- self – an instance of the LLT hcospin basis
- llt – a family of LLT symmetric function bases

```
sage: HC3t2 = SymmetricFunctions(QQ).llt(3,t=2).hcospin()
sage: TestSuite(HC3t2).run() # products are too expensive, long time (6s on sage.
↳math, 2012)
```

```
sage: HC3x = SymmetricFunctions(FractionField(QQ['x'])).llt(3,t=x).hcospin()
sage: TestSuite(HC3x).run(skip = ["_test_associativity", "_test_distributivity",
↳"_test_prod"]) # products are too expensive, long time (5s on sage.math, 2012)
sage: TestSuite(HC3x).run(elements = [HC3x.t*HC3x[1,1]+HC3x.t*HC3x[2],
↳HC3x[1]+(1+HC3x.t)*HC3x[1,1]]) # long time (depends on previous)
```

```
class Element
```

```
    Bases: sage.combinat.sf.llt.LLT_generic.Element
```

```
class sage.combinat.sf.llt.LLT_generic(llt, prefix)
    Bases: sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic
```

A class of methods which are common to both the hspin and hcospin of the LLT symmetric functions.

INPUT:

- self – an instance of the LLT hspin or hcospin basis
- llt – a family of LLT symmetric functions

EXAMPLES:

```
sage: SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the level 3 LLT spin basis
sage: SymmetricFunctions(QQ).llt(3,t=2).hspin()
Symmetric Functions over Rational Field in the level 3 LLT spin with t=2 basis
sage: QQz = FractionField(QQ['z']); z = QQz.gen()
sage: SymmetricFunctions(QQz).llt(3,t=z).hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in z over
↳Rational Field in the level 3 LLT spin with t=z basis
```

class ElementBases: *sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element***LLT_generic.level()**

Returns the level of self.

INPUT:

- self – an instance of the LLT hspin or hcospin basis

OUTPUT:

- returns the level associated to the basis self.

EXAMPLES:

```
sage: HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
sage: HSp3.level()
3
```

LLT_generic.llt_family()

The family of the llt bases of the symmetric functions.

INPUT:

- self – an instance of the LLT hspin or hcospin basis

OUTPUT:

- returns an instance of the family of LLT bases associated to self.

EXAMPLES:

```
sage: HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
sage: HSp3.llt_family()
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in
↪t over Rational Field
```

class sage.combinat.sf.llt.LLT_spin(lt)Bases: *sage.combinat.sf.llt.LLT_generic*

A class of methods for the h-spin LLT basis of the symmetric functions.

INPUT:

- self – an instance of the LLT hcospin basis
- llt – a family of LLT symmetric function bases

```
sage: HS3t2 = SymmetricFunctions(QQ).llt(3,t=2).hspin()
sage: TestSuite(HS3t2).run() # products are too expensive, long time (7s on sage.
↪math, 2012)
```

```
sage: HS3x = SymmetricFunctions(FractionField(QQ['x'])).llt(3,t=x).hspin()
sage: TestSuite(HS3x).run(skip = ["_test_associativity", "_test_distributivity",
↪"_test_prod"]) # products are too expensive, long time (4s on sage.math, 2012)
sage: TestSuite(HS3x).run(elements = [HS3x.t*HS3x[1,1]+HS3x.t*HS3x[2],
↪HS3x[1]+(1+HS3x.t)*HS3x[1,1]]) # long time (depends on previous)
```

class ElementBases: *sage.combinat.sf.llt.LLT_generic.Element*

5.1.269 Macdonald Polynomials

Notation used in the definitions follows mainly [Macdonald1995].

The integral forms of the bases H and Ht do not appear in Macdonald's book. They correspond to the two bases $H_\mu[X; q, t] = \sum_\nu K_{\nu\mu}(q, t) s_\mu[X]$ and $\tilde{H}_\mu[X; q, t] = t^{n(\mu)} \sum_\nu K_{\nu\mu}(q, 1/t) s_\nu[X]$ where $K_{\mu\nu}(q, t)$ are the Macdonald q, t -Koskta coefficients.

The Ht in this case is short for $\tilde{H}$ and is the basis which is the graded Frobenius image of the Garsia-Haiman modules [GH1993].

REFERENCES:

class sage.combinat.sf.macdonald.**Macdonald**(Sym, q='q', t='t')

Bases: sage.structure.unique_representation.UniqueRepresentation

Macdonald Symmetric functions including P, Q, J, H, Ht bases also including the S basis which is the plethystic transformation of the Schur basis (that which is dual to the Schur basis with respect to the Macdonald q, t -scalar product)

INPUT:

- self – a family of Macdonald symmetric function bases

EXAMPLES

```
sage: t = QQ['t'].gen(); SymmetricFunctions(QQ['t'].fraction_field()).
↳macdonald(q=t,t=1)
Macdonald polynomials with q=t and t=1 over Fraction Field of Univariate_
↳Polynomial Ring in t over Rational Field
sage: Sym = SymmetricFunctions(FractionField(QQ['t'])).macdonald()
Traceback (most recent call last):
...
TypeError: unable to evaluate 'q' in Fraction Field of Univariate Polynomial Ring_
↳in t over Rational Field
```

H()

Returns the Macdonald polynomials on the H basis. When the H basis is expanded on the Schur basis, the coefficients are the qt -Kostka numbers.

INPUT:

- self – a family of Macdonald symmetric function bases

OUTPUT:

- returns the H Macdonald basis of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: H = Sym.macdonald().H(); H
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,
↳t over Rational Field in the Macdonald H basis
sage: s = Sym.schur()
sage: s(H([2]))
q*s[1, 1] + s[2]
sage: s(H([1, 1]))
s[1, 1] + t*s[2]
```

Coercions to/from the Schur basis are implemented:

```

sage: H = Sym.macdonald().H()
sage: s = Sym.schur()
sage: H(s([2]))
(q/(q*t-1))*McdH[1, 1] - (1/(q*t-1))*McdH[2]

```

Ht()

Returns the Macdonald polynomials on the Ht basis. The elements of the Ht basis are eigenvectors of the $nabla$ operator. When expanded on the Schur basis, the coefficients are the modified qt -Kostka numbers.

INPUT:

- self – a family of Macdonald symmetric function bases

OUTPUT:

- returns the Ht Macdonald basis of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Ht = Sym.macdonald().Ht(); Ht
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
over Rational Field in the Macdonald Ht basis
sage: [Ht(p).nabla() for p in Partitions(3)]
[q^3*McdHt[3], q*t*McdHt[2, 1], t^3*McdHt[1, 1, 1]]

```

```

sage: s = Sym.schur()
sage: from sage.combinat.sf.macdonald import qt_kostka
sage: q,t = Ht.base_ring().gens()
sage: s(Ht([2,1]))
q*t*s[1, 1, 1] + (q+t)*s[2, 1] + s[3]
sage: qt_kostka([1,1,1],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
q*t
sage: qt_kostka([2,1],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
q + t
sage: qt_kostka([3],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
1

```

Coercions to/from the Schur basis are implemented:

```

sage: Ht = Sym.macdonald().Ht()
sage: s = Sym.schur()
sage: Ht(s([2,1]))
((-q)/(-q*t^2+t^3+q^2-q*t))*McdHt[1, 1, 1] + ((q^2+q*t+t^2)/(-q^2*t^2+q^3+t^3-q*t))*McdHt[2, 1] + (t/(-q^3+q^2*t+q*t-t^2))*McdHt[3]
sage: Ht(s([2]))
((-q)/(-q+t))*McdHt[1, 1] + (t/(-q+t))*McdHt[2]

```

J()

Returns the Macdonald polynomials on the J basis also known as the integral form of the Macdonald polynomials. These are scalar multiples of both the P and Q bases. When expressed in the P or Q basis, the scaling coefficients are polynomials in q and t rather than rational functions.

The J basis is calculated using determinantal formulas of Lapointe-Lascoux-Morse giving the action on the S -basis [LLM1998].

INPUT:

- self – a family of Macdonald symmetric function bases

OUTPUT:

- returns the J Macdonald basis of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: J = Sym.macdonald().J(); J
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
over Rational Field in the Macdonald J basis
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: P(J([2]))
(q*t^2-q*t-t+1)*McdP[2]
sage: P(J([1,1]))
(t^3-t^2-t+1)*McdP[1, 1]
sage: Q(J([2]))
(q^3-q^2-q+1)*McdQ[2]
sage: Q(J([1,1]))
(q^2*t-q*t-q+1)*McdQ[1, 1]
```

Coercions from the Q and J basis (proportional) and to/from the Schur basis are implemented:

```
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: J = Sym.macdonald().J()
sage: s = Sym.schur()
```

```
sage: J(P([2]))
(1/(q*t^2-q*t-t+1))*McdJ[2]
```

```
sage: J(Q([2]))
(1/(q^3-q^2-q+1))*McdJ[2]
```

```
sage: s(J([2]))
(-q*t+t^2+q-t)*s[1, 1] + (q*t^2-q*t-t+1)*s[2]
sage: J(s([2]))
((q-t)/(q*t^4-q*t^3-q*t^2-t^3+q*t+t^2+t-1))*McdJ[1, 1] + (1/(q*t^2-q*t-
t+1))*McdJ[2]
```

P()

Returns Macdonald polynomials in P basis. The P basis is defined here as a normalized form of the J basis.

INPUT:

- self – a family of Macdonald symmetric function bases

OUTPUT:

- returns the P Macdonald basis of symmetric functions

EXAMPLES

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
over Rational Field in the Macdonald P basis
sage: P[2]
McdP[2]
```

The P Macdonald basis is upper triangularly related to the monomial symmetric functions and are orthogonal with respect to the qt -Hall scalar product:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
over Rational Field in the Macdonald P basis
sage: m = Sym.monomial()
sage: P.transition_matrix(m, 2)
[      1 (q*t - q + t - 1)/(q*t - 1)]
[      0                               1]
sage: P([1, 1]).scalar_qt(P([2]))
0
sage: P([2]).scalar_qt(P([2]))
(-q^3 + q^2 + q - 1)/(-q*t^2 + q*t + t - 1)
sage: P([1, 1]).scalar_qt(P([1, 1]))
(-q^2*t + q*t + q - 1)/(-t^3 + t^2 + t - 1)
```

When $q = 0$, the Macdonald polynomials on the P basis are the same as the Hall-Littlewood polynomials on the P basis.

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: P = Sym.macdonald(q=0).P(); P
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
over Rational Field in the Macdonald P with q=0 basis
sage: P([2])^2
(t+1)*McdP[2, 2] + (-t+1)*McdP[3, 1] + McdP[4]
sage: HLP = Sym.hall_littlewood().P()
sage: HLP([2])^2
(t+1)*HLP[2, 2] + (-t+1)*HLP[3, 1] + HLP[4]
```

Coercions from the Q and J basis (proportional) are implemented:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: J = Sym.macdonald().J()
sage: s = Sym.schur()
```

```
sage: P(Q([2]))
((q*t^2-q*t-t+1)/(q^3-q^2-q+1))*McdP[2]
sage: P(Q([2, 1]))
((-q*t^4+2*q*t^3-q*t^2+t^2-2*t+1)/(-q^4*t+2*q^3*t-q^2*t+q^2-2*q+1))*McdP[2, 1]
```

```
sage: P(J([2]))
(q*t^2-q*t-t+1)*McdP[2]
sage: P(J([2, 1]))
(-q*t^4+2*q*t^3-q*t^2+t^2-2*t+1)*McdP[2, 1]
```

By transitivity, one get coercions from the classical bases:

```
sage: P(s([2]))
((q-t)/(q*t-1))*McdP[1, 1] + McdP[2]
sage: P(s([2, 1]))
((q*t-t^2+q-t)/(q*t^2-1))*McdP[1, 1, 1] + McdP[2, 1]
```

```

sage: Sym = SymmetricFunctions(QQ['x', 'y', 'z'].fraction_field())
sage: (x, y, z) = Sym.base_ring().gens()
sage: Macxy = Sym.macdonald(q=x, t=y)
sage: Macyz = Sym.macdonald(q=y, t=z)
sage: Maczx = Sym.macdonald(q=z, t=x)
sage: P1 = Macxy.P()
sage: P2 = Macyz.P()
sage: P3 = Maczx.P()
sage: m(P1[2, 1])
((-2*x*y^2+x*y-y^2+x-y+2)/(-x*y^2+1))*m[1, 1] + m[2, 1]
sage: m(P2[2, 1])
((-2*y*z^2+y*z-z^2+y-z+2)/(-y*z^2+1))*m[1, 1] + m[2, 1]
sage: m(P1(P2(P3[2, 1])))
((-2*x^2*z-x^2+x*z-x+z+2)/(-x^2*z+1))*m[1, 1] + m[2, 1]
sage: P1(P2[2])
((-x*y^2+2*x*y*z-y^2*z-x+2*y-z)/(x*y^2*z-x*y-y*z+1))*McdP[1, 1] + McdP[2]
sage: m(z*P1[2]+x*P2[2])
((x^2*y^2*z+x*y^2*z^2-x^2*y^2+x^2*y*z-x*y*z^2+y^2*z^2-x^2*y-2*x*y*z-y*z^2+x*y-
↪ y*z+x+z)/(x*y^2*z-x*y-y*z+1))*m[1, 1] + (x+z)*m[2]

```

Q()

Returns the Macdonald polynomials on the Q basis. These are dual to the Macdonald polynomials on the P basis with respect to the qt -Hall scalar product. The Q basis is defined to be a normalized form of the J basis.

INPUT:

- self – a family of Macdonald symmetric function bases

OUTPUT:

- returns the Q Macdonald basis of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: Q = Sym.macdonald().Q(); Q
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
↪ over Rational Field in the Macdonald Q basis
sage: P = Sym.macdonald().P()
sage: Q([2]).scalar_qt(P([2]))
1
sage: Q([2]).scalar_qt(P([1, 1]))
0
sage: Q([1, 1]).scalar_qt(P([2]))
0
sage: Q([1, 1]).scalar_qt(P([1, 1]))
1
sage: Q(P([2]))
((q^3-q^2-q+1)/(q*t^2-q*t-t+1))*McdQ[2]
sage: Q(P([1, 1]))
((q^2*t-q*t-q+1)/(t^3-t^2-t+1))*McdQ[1, 1]

```

Coercions from the P and J basis (proportional) are implemented:

```

sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: J = Sym.macdonald().J()
sage: s = Sym.schur()

```

```
sage: Q(J([2]))
(q^3-q^2-q+1)*McdQ[2]
```

```
sage: Q(P([2]))
((q^3-q^2-q+1)/(q*t^2-q*t-t+1))*McdQ[2]
sage: P(Q(P([2])))
McdP[2]
sage: Q(P(Q([2])))
McdQ[2]
```

By transitivity, one gets coercions from the classical bases:

```
sage: Q(s([2]))
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdQ[1, 1] + ((q^3-q^2-q+1)/(q*t^2-q*t-
↪t+1))*McdQ[2]
```

S()

Returns the modified Schur functions defined by the plethystic substitution $S_\mu = s_\mu[X(1-t)/(1-q)]$. When the Macdonald polynomials in the J basis are expressed in terms of the modified Schur functions at $q = 0$, the coefficients are qt -Kostka numbers.

INPUT:

- self – a family of Macdonald symmetric function bases

OUTPUT:

- returns the S Macdonald basis of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: S = Sym.macdonald().S(); S
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
↪t over Rational Field in the Macdonald S basis
sage: p = Sym.power()
sage: p(S[2,1])
((1/3*t^3-t^2+t-1/3)/(q^3-3*q^2+3*q-1))*p[1, 1, 1] + ((-1/3*t^3+1/3)/(q^3-
↪1))*p[3]
sage: J = Sym.macdonald().J()
sage: S(J([2]))
(q^3-q^2-q+1)*McdS[2]
sage: S(J([1,1]))
(q^2*t-q*t-q+1)*McdS[1, 1] + (q^2-q*t-q+t)*McdS[2]
sage: S = Sym.macdonald(q=0).S()
sage: S(J[1,1])
McdS[1, 1] + t*McdS[2]
sage: S(J[2])
q*McdS[1, 1] + McdS[2]
sage: p(S[2,1])
(-1/3*t^3+t^2-t+1/3)*p[1, 1, 1] + (1/3*t^3-1/3)*p[3]

sage: from sage.combinat.sf.macdonald import qt_kostka
sage: qt_kostka([2],[1,1])
t
sage: qt_kostka([1,1],[2])
q
```

Coercions to/from the Schur basis are implemented:

```

sage: S = Sym.macdonald().S()
sage: s = Sym.schur()
sage: S(s([2]))
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdS[1, 1] + ((-q^2*t+q*t+q-1)/(-t^3+t^2+t-
↪1))*McdS[2]
sage: s(S([1,1]))
((-q*t^2+q*t+t-1)/(-q^3+q^2+q-1))*s[1, 1] + ((q*t-t^2-q+t)/(-q^3+q^2+q-
↪1))*s[2]

```

base_ring()

Returns the base ring of the symmetric functions where the Macdonald symmetric functions live

INPUT:

- self – a family of Macdonald symmetric function bases

OUTPUT:

- the base ring associated to the corresponding symmetric function ring

EXAMPLES

```

sage: Sym = SymmetricFunctions(QQ['q'].fraction_field())
sage: Mac = Sym.macdonald(t=0)
sage: Mac.base_ring()
Fraction Field of Univariate Polynomial Ring in q over Rational Field

```

symmetric_function_ring()

Returns the base ring of the symmetric functions where the Macdonald symmetric functions live

INPUT:

- self – a family of Macdonald symmetric function bases

OUTPUT:

- the symmetric function ring associated to the Macdonald bases

EXAMPLES

```

sage: Mac = SymmetricFunctions(QQ['q'].fraction_field()).macdonald(t=0)
sage: Mac.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in q
↪over Rational Field

```

class sage.combinat.sf.macdonald.**MacdonaldPolynomials_generic**(macdonald)

Bases: *sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic*

A class for methods for one of the Macdonald bases of the symmetric functions

INPUT:

- self – a Macdonald basis
- macdonald – a family of Macdonald symmetric function bases

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q,t'])); Sym.rename("Sym"); Sym
Sym
sage: Sym.macdonald().P()
Sym in the Macdonald P basis
sage: Sym.macdonald(t=2).P()

```

```
Sym in the Macdonald P with t=2 basis
sage: Sym.rename()
```

class Element

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`

nabla (*q=None, t=None, power=1*)

Return the value of the nabla operator applied to `self`.

The eigenvectors of the nabla operator are the Macdonald polynomials in the Ht basis. For more information see: [\[BGHT1999\]](#).

The operator nabla acts on symmetric functions and has the Macdonald Ht basis as eigenfunctions and the eigenvalues are $q^{n(\mu')}t^{n(\mu)}$ where $n(\mu) = \sum_i (i-1)\mu_i$ and μ' is the conjugate shape of μ .

If the parameter `power` is an integer then it calculates nabla to that integer. The default value of `power` is 1.

INPUT:

- `self` – an element of a Macdonald basis
- `q, t` – optional parameters to specialize
- `power` – an integer (default: 1)

OUTPUT:

- returns the symmetric function of ∇ acting on `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P([1,1]).nabla()
((q^2*t+q*t^2-2*t)/(q*t-1))*McdP[1, 1] + McdP[2]
sage: P([1,1]).nabla(t=1)
((q^2*t+q*t-t-1)/(q*t-1))*McdP[1, 1] + McdP[2]
sage: H = Sym.macdonald().H()
sage: H([1,1]).nabla()
t*McdH[1, 1] + (-t^2+1)*McdH[2]
sage: H([1,1]).nabla(q=1)
((t^2+q-t-1)/(q*t-1))*McdH[1, 1] + ((-t^3+t^2+t-1)/(q*t-1))*McdH[2]
sage: H(0).nabla()
0
sage: H([2,2,1]).nabla(t=1/H.t)
((-q^2)/(-t^4))*McdH[2, 2, 1]
sage: H([2,2,1]).nabla(t=1/H.t,power=-1)
((-t^4)/(-q^2))*McdH[2, 2, 1]
```

MacdonaldPolynomials_generic.c1 (*part*)

Returns the qt -Hall scalar product between `J(part)` and `P(part)`.

INPUT:

- `self` – a Macdonald basis
- `part` – a partition

OUTPUT:

- returns the qt -Hall scalar product between `J(part)` and `P(part)`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
```

```
sage: P.c1(Partition([2,1]))
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
```

MacdonaldPolynomials_generic.**c2**(part)

Returns the qt -Hall scalar product between $J(\text{part})$ and $Q(\text{part})$.

INPUT:

- self – a Macdonald basis
- part – a partition

OUTPUT:

- returns the qt -Hall scalar product between $J(\text{part})$ and $Q(\text{part})$

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P.c2(Partition([2,1]))
-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1
```

MacdonaldPolynomials_generic.**macdonald_family**()

Returns the family of Macdonald bases associated to the basis self

INPUT:

- self – a Macdonald basis

OUTPUT:

- the family of Macdonald symmetric functions associated to self

EXAMPLES

```
sage: MacP = SymmetricFunctions(QQ['q'].fraction_field()).macdonald(t=0).P()
sage: MacP.macdonald_family()
Macdonald polynomials with t=0 over Fraction Field of Univariate Polynomial_
↪Ring in q over Rational Field
```

class sage.combinat.sf.macdonald.**MacdonaldPolynomials_h**(macdonald)

Bases: [sage.combinat.sf.macdonald.MacdonaldPolynomials_generic](#)

The H basis is defined as $H_\mu = \sum_\lambda K_{\lambda\mu}(q, t) s_\lambda$ where $K_{\lambda\mu}(q, t)$ are the Macdonald Kostka coefficients.

In this implementation, it is calculated by using the Macdonald Ht basis and substituting $t \rightarrow 1/t$ and multiplying by $t^{n(\mu)}$.

INPUT:

- self – a Macdonald H basis
- macdonald – a family of Macdonald bases

class **Element**

Bases: [sage.combinat.sf.macdonald.MacdonaldPolynomials_generic.Element](#)

class sage.combinat.sf.macdonald.**MacdonaldPolynomials_ht**(macdonald)

Bases: [sage.combinat.sf.macdonald.MacdonaldPolynomials_generic](#)

The Ht basis is defined as $\tilde{H}_\mu = t^{n(\mu)} \sum_\lambda K_{\lambda\mu}(q, t^{-1}) s_\lambda$ where $K_{\lambda\mu}(q, t)$ are the Macdonald (q, t) -Kostka coefficients and $n(\mu) = \sum_i (i-1)\mu_i$.

It is implemented here by using a Pieri formula due to F. Bergeron and M. Haiman [BH2013].

INPUT:

- `self` – a Macdonald Ht basis
- `macdonald` – a family of Macdonald bases

class Element

Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic.Element`

nabla ($q=None, t=None, power=1$)

Returns the value of the nabla operator applied to `self`. The eigenvectors of the *nabla* operator are the Macdonald polynomials in the Ht basis. For more information see: [\[BGHT1999\]](#).

The operator *nabla* acts on symmetric functions and has the Macdonald Ht basis as eigenfunctions and the eigenvalues are $q^{n(\mu')}t^{n(\mu)}$ where $n(\mu) = \sum_i (i-1)\mu_i$.

If the parameter `power` is an integer then it calculates nabla to that integer. The default value of `power` is 1.

INPUT:

- `self` – an element of the Macdonald Ht basis
- `q, t` – optional parameters to specialize
- `power` – an integer (default: 1)

OUTPUT:

- returns the symmetric function of ∇ acting on `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: Ht = Sym.macdonald().Ht()
sage: t = Ht.t; q = Ht.q;
sage: s = Sym.schur()
sage: a = sum(Ht(p) for p in Partitions(3))
sage: Ht(0).nabla()
0
sage: a.nabla() == t^3*Ht([1, 1, 1]) + q*t*Ht([2, 1]) + q^3*Ht([3])
True
sage: a.nabla(t=3) == 27*Ht([1, 1, 1]) + 3*q*Ht([2, 1]) + q^3*Ht([3])
True
sage: a.nabla(q=3) == t^3*Ht([1, 1, 1]) + 3*t*Ht([2, 1]) + 27*Ht([3])
True
sage: Ht[2, 1].nabla(power=-1)
1/(q*t)*McdHt[2, 1]
sage: Ht[2, 1].nabla(power=4)
q^4*t^4*McdHt[2, 1]
sage: s(a.nabla(q=3))
(t^6+27*q^3+3*q*t^2)*s[1, 1, 1] + (t^5+t^4+27*q^2+3*q*t+3*t^2+27*q)*s[2, 1]
+ (t^3+3*t+27)*s[3]
sage: Ht = Sym.macdonald(q=3).Ht()
sage: a = sum(Ht(p) for p in Partitions(3))
sage: s(a.nabla())
(t^6+9*t^2+729)*s[1, 1, 1] + (t^5+t^4+3*t^2+9*t+324)*s[2, 1] + (t^3+3*t+27)*s[3]
```

class `sage.combinat.sf.macdonald.MacdonaldPolynomials_j` (*macdonald*)

Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic`

The J basis is calculated using determinantal formulas of Lapointe-Lascoux-Morse giving the action on the S -basis.

INPUT:

- self – a Macdonald J basis
- macdonald – a family of Macdonald bases

class Element

Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic.Element`

class `sage.combinat.sf.macdonald.MacdonaldPolynomials_p`(*macdonald*)

Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic`

The P basis is defined here as the J basis times a normalizing coefficient c_2 .

INPUT:

- self – a Macdonald P basis
- macdonald – a family of Macdonald bases

class Element

Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic.Element`

`MacdonaldPolynomials_p.scalar_qt_basis`(*part1*, *part2*=None)

Returns the scalar product of $P(\text{part1})$ and $P(\text{part2})$. This scalar product formula is given in equation (4.11) p.323 and (6.19) p.339 of Macdonald's book [Macdonald1995].

INPUT:

- self – a Macdonald P basis
- part1, part2 – partitions

OUTPUT:

- returns the scalar product of $P(\text{part1})$ and $P(\text{part2})$

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P.scalar_qt_basis(Partition([2,1]), Partition([1,1,1]))
0
sage: f = P.scalar_qt_basis(Partition([3,2,1]), Partition([3,2,1]))
sage: factor(f.numerator())
(q - 1)^3 * (q^2*t - 1)^2 * (q^3*t^2 - 1)
sage: factor(f.denominator())
(t - 1)^3 * (q*t^2 - 1)^2 * (q^2*t^3 - 1)
```

With a single argument, takes $\text{part2} = \text{part1}$:

```
sage: P.scalar_qt_basis(Partition([2,1]), Partition([2,1]))
(-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1)/(-q*t^4 + 2*q*t^3 - q*t^2 + t^2 -
↪ 2*t + 1)
```

class `sage.combinat.sf.macdonald.MacdonaldPolynomials_q`(*macdonald*)

Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic`

The Q basis is defined here as the J basis times a normalizing coefficient.

INPUT:

- self – a Macdonald Q basis
- macdonald – a family of Macdonald bases

class ElementBases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic.Element`**class** `sage.combinat.sf.macdonald.MacdonaldPolynomials_s` (`macdonald`)Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic`An implementation of the basis $s_\lambda[(1-t)X/(1-q)]$

This is perhaps misnamed as a ‘Macdonald’ basis for the symmetric functions but is used in the calculation of the Macdonald J basis (see method ‘creation’ below) but does use both of the two parameters and can be specialized to $s_\lambda[(1-t)X]$ and $s_\lambda[X/(1-t)]$.

INPUT:

- `self` – a Macdonald S basis
- `macdonald` – a family of Macdonald bases

class ElementBases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic.Element`**creation** (`k`)

This function is a creation operator for the J -basis for which the action is known on the ‘Macdonald’ S -basis by formula from [LLM1998].

INPUT:

- `self` – an element of the Macdonald S basis
- `k` – a positive integer

OUTPUT:

- returns the column adding operator on the J basis on `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: S = Sym.macdonald().S()
sage: a = S(1)
sage: a.creation(1)
(-q+1)*McdS[1]
sage: a.creation(2)
(q^2*t-q*t-q+1)*McdS[1, 1] + (q^2-q*t-q+t)*McdS[2]
```

`sage.combinat.sf.macdonald.c1` (`part`, `q`, `t`)

This function returns the qt -Hall scalar product between $J(\text{part})$ and $P(\text{part})$.

This coefficient is c_λ in equation (8.1') p. 352 of Macdonald's book [Macdonald1995].

INPUT:

- `part` – a partition
- `q, t` – parameters

OUTPUT:

- returns a polynomial of the scalar product between the J and P bases

EXAMPLES:

```
sage: from sage.combinat.sf.macdonald import c1
sage: R.<q,t> = QQ[]
sage: c1(Partition([2,1]),q,t)
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
sage: c1(Partition([1,1]),q,t)
q^2*t - q*t - q + 1
```

`sage.combinat.sf.macdonald.c2(part, q, t)`

This function returns the qt-Hall scalar product between $J(\text{part})$ and $Q(\text{part})$.

This coefficient is c_λ in equation (8.1) p. 352 of Macdonald's book [\[Macdonald1995\]](#).

INPUT:

- `part` – a partition
- `q, t` – parameters

OUTPUT:

- returns a polynomial of the scalar product between the J and P bases

EXAMPLES:

```
sage: from sage.combinat.sf.macdonald import c2
sage: R.<q,t> = QQ[]
sage: c2(Partition([1,1]),q,t)
t^3 - t^2 - t + 1
sage: c2(Partition([2,1]),q,t)
-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1
```

`sage.combinat.sf.macdonald.cmunu(mu, nu)`

Return the coefficient of $\tilde{H}_\nu$ in $h_r^\perp \tilde{H}_\mu$.

Proposition 5 of F. Bergeron and M. Haiman [\[BH2013\]](#) states

$$c_{\mu\nu} = \sum_{\alpha \leftarrow \nu} c_{\mu\alpha} c_{\alpha\nu} B_{\alpha/\nu} / B_{\mu/\nu}$$

where $c_{\mu\nu}$ is the coefficient of $\tilde{H}_\nu$ in $h_r^\perp \tilde{H}_\mu$ and $B_{\mu/\nu}$ is the bi-exponent generator implemented in the function `sage.combinat.sf.macdonald.Bmu()`.

INPUT:

- `mu, nu` – partitions with `nu` contained in `mu`

OUTPUT:

- an element of the fraction field of polynomials in q and t

EXAMPLES:

```
sage: from sage.combinat.sf.macdonald import cmunu
sage: cmunu(Partition([2,1]),Partition([1]))
q + t + 1
sage: cmunu(Partition([2,2]),Partition([1,1]))
(-q^3 - q^2 + q*t + t)/(-q + t)
sage: Sym = SymmetricFunctions(QQ['q','t'].fraction_field())
sage: h = Sym.h()
sage: Ht = Sym.macdonald().Ht()
sage: all(Ht[2,2].skew_by(h[r]).coefficient(nu)
....:      == cmunu(Partition([2,2]),nu)
....:      for r in range(1,5) for nu in Partitions(4-r))
True
```

`sage.combinat.sf.macdonald.cmunu1(mu, nu)`

Return the coefficient of $\tilde{H}_\nu$ in $h_1^\perp \tilde{H}_\mu$.

INPUT:

- `mu, nu` – partitions with `nu` preceeds `mu`

OUTPUT:

- an element of the fraction field of polynomials in q and t

EXAMPLES:

```
sage: from sage.combinat.sf.macdonald import cmunul
sage: cmunul(Partition([2,1]),Partition([2]))
(-t^2 + q)/(q - t)
sage: cmunul(Partition([2,1]),Partition([1,1]))
(-q^2 + t)/(-q + t)
sage: Sym = SymmetricFunctions(QQ['q','t'].fraction_field())
sage: h = Sym.h()
sage: Ht = Sym.macdonald().Ht()
sage: all(Ht[3,2,1].skew_by(h[1]).coefficient(nu)
....:      == cmunul(Partition([3,2,1]),nu)
....:      for nu in Partition([3,2,1]).down_list())
True
```

`sage.combinat.sf.macdonald.qt_kostka(lam, mu)`

Returns the $K_{\lambda\mu}(q, t)$ by computing the change of basis from the Macdonald H basis to the Schurs.

INPUT:

- lam, mu – partitions of the same size

OUTPUT:

- returns the q, t -Kostka polynomial indexed by the partitions lam and mu

EXAMPLES:

```
sage: from sage.combinat.sf.macdonald import qt_kostka
sage: qt_kostka([2,1,1],[1,1,1,1])
t^3 + t^2 + t
sage: qt_kostka([1,1,1,1],[2,1,1])
q

5.1.270 Monomial symmetric functions

`class sage.combinat.sf.monomial.SymmetricFunctionAlgebra_monomial(Sym)`

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical`

A class for methods related to monomial symmetric functions

INPUT:

- `self` – a monomial symmetric function basis
- `Sym` – an instance of the ring of the symmetric functions

class `Element`

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical.Element`

expand (*n*, *alphabet*='x')

Expand the symmetric function `self` as a symmetric polynomial in *n* variables.

INPUT:

- *n* – a nonnegative integer
- *alphabet* – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the *n* variables labelled by *alphabet*.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: m([2,1]).expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: m([1,1,1]).expand(2)
0
sage: m([2,1]).expand(3,alphabet='z')
z0^2*z1 + z0*z1^2 + z0^2*z2 + z1^2*z2 + z0*z2^2 + z1*z2^2
sage: m([2,1]).expand(3,alphabet='x,y,z')
x^2*y + x*y^2 + x^2*z + y^2*z + x*z^2 + y*z^2
sage: m([1]).expand(0)
0
sage: (3*m([])).expand(0)
3
```

`SymmetricFunctionAlgebra_monomial.antipode_by_coercion` (*element*)

The antipode of *element* via coercion to and from the power-sum basis or the Schur basis (depending on whether the power sums really form a basis over the given ground ring).

INPUT:

- *element* – element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: m[3,2].antipode()
m[3, 2] + 2*m[5]
sage: m.antipode_by_coercion(m[3,2])
m[3, 2] + 2*m[5]

sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.monomial()
sage: m[3,2].antipode()
m[3, 2] + 2*m[5]
sage: m.antipode_by_coercion(m[3,2])
m[3, 2] + 2*m[5]
```

Todo

Is there a not too difficult way to get the power-sum computations to work over any ring, not just one with coercion from $\mathbb{Q}$?

`SymmetricFunctionAlgebra_monomial.from_polynomial(f, check=True)`

Returns the symmetric function in the monomial basis corresponding to the polynomial f .

INPUT:

- `self` – a monomial symmetric function basis
- `f` – a polynomial in finitely many variables over the same base ring as `self`. It is assumed that this polynomial is symmetric.
- `check` – boolean (default: `True`), checks whether the polynomial is indeed symmetric

OUTPUT:

- This function converts a symmetric polynomial f in a polynomial ring in finitely many variables to a symmetric function in the monomial basis of the ring of symmetric functions over the same base ring.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: m.from_polynomial(f)
m[1]
sage: f = x[0]**2+x[1]**2+x[2]**2
sage: m.from_polynomial(f)
m[2]
sage: f=x[0]^2+x[1]
sage: m.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0^2 + x1 is not a symmetric polynomial
sage: f = (m[2,1]+m[1,1]).expand(3)
sage: m.from_polynomial(f)
m[1, 1] + m[2, 1]
sage: f = (2*m[2,1]+m[1,1]+3*m[3]).expand(3)
sage: m.from_polynomial(f)
m[1, 1] + 2*m[2, 1] + 3*m[3]
```

`SymmetricFunctionAlgebra_monomial.from_polynomial_exp(p)`

Conversion from polynomial in exponential notation

INPUT:

- `self` – a monomial symmetric function basis
- `p` – a multivariate polynomial over the same base ring as `self`

OUTPUT:

- This returns a symmetric function by mapping each monomial of p with exponents exp into m_λ where λ is the partition with exponential notation exp .

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: P = PolynomialRing(QQ, 'x', 5)
sage: x = P.gens()
```

The exponential notation of the partition (5, 5, 5, 3, 1, 1) is:

```
sage: Partition([5, 5, 5, 3, 1, 1]).to_exp()
[2, 0, 1, 0, 3]
```

Therefore, the monomial:

```
sage: f = x[0]^2 * x[2] * x[4]^3
```

is mapped to:

```
sage: m.from_polynomial_exp(f)
m[5, 5, 5, 3, 1, 1]
```

Furthermore, this function is linear:

```
sage: f = 3 * x[3] + 2 * x[0]^2 * x[2] * x[4]^3
sage: m.from_polynomial_exp(f)
3*m[4] + 2*m[5, 5, 5, 3, 1, 1]
```

See also:

Partition(), Partition.to_exp()

5.1.271 Multiplicative symmetric functions

A realization h of the ring of symmetric functions is multiplicative if for a partition $\lambda = (\lambda_1, \lambda_2, \dots)$ we have $h_\lambda = h_{\lambda_1} h_{\lambda_2} \dots$.

class sage.combinat.sf.multiplicative.**SymmetricFunctionAlgebra_multiplicative** (Sym, basis_name=None, prefix=None, graded=True)

Bases: *sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical*

The class of multiplicative bases of the ring of symmetric functions.

A realization q of the ring of symmetric functions is multiplicative if for a partition $\lambda = (\lambda_1, \lambda_2, \dots)$ we have $q_\lambda = q_{\lambda_1} q_{\lambda_2} \dots$ (with q_0 meaning 1).

Examples of multiplicative realizations are the elementary symmetric basis, the complete homogeneous basis, the powersum basis (if the base ring is a $\mathbf{Q}$ -algebra), and the Witt basis (but not the Schur basis or the monomial basis).

coproduct_on_basis (*mu*)

Return the coproduct on a basis element for multiplicative bases.

INPUT:

- *mu* – a partition

OUTPUT:

- the image of `self[mu]` under comultiplication; this is an element of the tensor square of `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.powersum()
sage: p.coproduct_on_basis([2,1])
p[] # p[2, 1] + p[1] # p[2] + p[2] # p[1] + p[2, 1] # p[]

sage: e = Sym.elementary()
sage: e.coproduct_on_basis([3,1])
e[] # e[3, 1] + e[1] # e[2, 1] + e[1] # e[3] + e[1, 1] # e[2] + e[2] # e[1, 1]
↪ 1] + e[2, 1] # e[1] + e[3] # e[1] + e[3, 1] # e[]

sage: h = Sym.homogeneous()
sage: h.coproduct_on_basis([3,1])
h[] # h[3, 1] + h[1] # h[2, 1] + h[1] # h[3] + h[1, 1] # h[2] + h[2] # h[1, 1]
↪ 1] + h[2, 1] # h[1] + h[3] # h[1] + h[3, 1] # h[]
```

5.1.272 k -Schur Functions

class `sage.combinat.sf.new_kschur.KBoundedSubspace` (*Sym*, *k*, *t='t'*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

This class implements the subspace of the ring of symmetric functions spanned by $\{s_\lambda[X/(1-t)]\}_{\lambda_1 \leq k} = \{s_\lambda^{(k)}[X;t]\}_{\lambda_1 \leq k}$ over the base ring $\mathbb{Q}[t]$. When $t = 1$, this space is in fact a subring of the ring of symmetric functions generated by the complete homogeneous symmetric functions h_i for $1 \leq i \leq k$.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: KB = Sym.kBoundedSubspace(3,1); KB
3-bounded Symmetric Functions over Rational Field with t=1

sage: Sym = SymmetricFunctions(QQ['t'])
sage: KB = Sym.kBoundedSubspace(3); KB
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational_
↪ Field
```

The k -Schur function basis can be constructed as follows:

```
sage: ks = KB.kschur(); ks
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational_
↪ Field in the 3-Schur basis
```

K_kschur ()

Returns the k -bounded basis called the K- k -Schur basis. See [Morse11] and [LamSchillingShimozono10].

REFERENCES:

EXAMPLES:

```
sage: kB = SymmetricFunctions(QQ).kBoundedSubspace(3,1)
sage: g = kB.K_kschur()
sage: g
3-bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur_
↪ basis
```

```

sage: kB = SymmetricFunctions(QQ['t']).kBoundedSubspace(3)
sage: g = kB.K_kschur()
Traceback (most recent call last):
...
ValueError: This basis only exists for t=1

```

khomogeneous()

The homogeneous basis of this algebra.

See also:

kHomogeneous()

EXAMPLES:

```

sage: kh3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).khomogeneous()
sage: TestSuite(kh3).run()

```

kschur()

The k -Schur basis of this algebra.

See also:

kSchur()

EXAMPLES:

```

sage: ks3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).kschur()
sage: TestSuite(ks3).run()

```

ksplit()

The k -split basis of this algebra.

See also:

kSplit()

EXAMPLES:

```

sage: ksp3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).ksplit()
sage: TestSuite(ksp3).run()

```

realizations()

A list of realizations of this algebra.

EXAMPLES:

```

sage: SymmetricFunctions(QQ).kBoundedSubspace(3,1).realizations()
[3-bounded Symmetric Functions over Rational Field with t=1 in the 3-Schur_
↪basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the 3-split_
↪basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the 3-bounded_
↪homogeneous basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur_
↪basis]
sage: SymmetricFunctions(QQ['t']).kBoundedSubspace(3).realizations()
[3-bounded Symmetric Functions over Univariate Polynomial Ring in t over_
↪Rational Field in the 3-Schur basis,
 3-bounded Symmetric Functions over Univariate Polynomial Ring in t over_
↪Rational Field in the 3-split basis]

```

retract (*sym*)

Return the retract of *sym* from the ring of symmetric functions to *self*.

INPUT:

- *sym* – a symmetric function

OUTPUT:

- the analogue of the symmetric function in the k -bounded subspace (if possible)

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: KB = Sym.kBoundedSubspace(3,1); KB
3-bounded Symmetric Functions over Rational Field with t=1
sage: KB.retract(s[2]+s[3])
ks3[2] + ks3[3]
sage: KB.retract(s[2,1,1])
Traceback (most recent call last):
...
ValueError: s[2, 1, 1] is not in the image
```

class sage.combinat.sf.new_kschur.**KBoundedSubspaceBases** (*base, t='t'*)
 Bases: sage.categories.realizations.Category_realization_of_parent

The category of bases for the k -bounded subspace of symmetric functions.

class **ElementMethods**

expand (**args, **kwargs*)

Returns the monomial expansion of *self* in n variables.

INPUT:

- n – positive integer

OUTPUT: monomial expansion of *self* in n variables

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: ks[3,1].expand(2)
x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
sage: s = Sym.schur()
sage: ks[3,1].expand(2) == s(ks[3,1]).expand(2)
True

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks = Sym.kschur(3)
sage: f = ks[3,2]-ks[1]
sage: f.expand(2)
t^2*x0^5 + (t^2 + t)*x0^4*x1 + (t^2 + t + 1)*x0^3*x1^2 + (t^2 + t + 1)*x0^
↪ 2*x1^3 + (t^2 + t)*x0*x1^4 + t^2*x1^5 - x0 - x1
```

hl_creation_operator (*nu, t=None*)

This is the vertex operator that generalizes Jing's operator.

It is a linear operator that raises the degree by $|\nu|$. This creation operator is a t -analogue of multiplication by $s(\nu)$.

See also:

Proposition 5 in [SZ.2001].

INPUT:

- `nu` – a partition
- `t` – a parameter (default: None, in this case t is used)

REFERENCES:**EXAMPLES:**

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(4)
sage: s = Sym.schur()
sage: s(ks([3,1,1]).hl_creation_operator([1]))
(t-1)*s[2, 2, 1, 1] + t^2*s[3, 1, 1, 1] + (t^3+t^2-t)*s[3, 2, 1] + (t^3-t^
↪2)*s[3, 3] + (t^4+t^3)*s[4, 1, 1] + t^4*s[4, 2] + t^5*s[5, 1]
sage: ks([3,1,1]).hl_creation_operator([1])
(t-1)*ks4[2, 2, 1, 1] + t^2*ks4[3, 1, 1, 1] + t^3*ks4[3, 2, 1] + (t^3-t^
↪2)*ks4[3, 3] + t^4*ks4[4, 1, 1]

sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(4,t=1)
sage: ks([3,1,1]).hl_creation_operator([1])
ks4[3, 1, 1, 1] + ks4[3, 2, 1] + ks4[4, 1, 1]
```

is_schur_positive(*args, **kwargs)

Returns whether `self` is Schur positive.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: f = ks[3,2]+ks[1]
sage: f.is_schur_positive()
True
sage: f = ks[3,2]-ks[1]
sage: f.is_schur_positive()
False

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks = Sym.kschur(3)
sage: f = ks[3,2]+ks[1]
sage: f.is_schur_positive()
True
sage: f = ks[3,2]-ks[1]
sage: f.is_schur_positive()
False
```

omega()

Returns the ω operator on `self`.

At $t = 1$, ω maps the k -Schur function $s_{\lambda}^{(k)}$ to $s_{\lambda^{(k)}}^{(k)}$, where $\lambda^{(k)}$ is the k -conjugate of the partition λ .

See also:

[`k\_conjugate\(\)`](#).

For generic t , ω sends $s_{\lambda}^{(k)}[X; t]$ to $t^d s_{\lambda^{(k)}}^{(k)}[X; 1/t]$, where d is the size of the core of λ minus the size of λ . Most of the time, this result is not in the k -bounded subspace.

See also:

`omega_t_inverse()`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: ks[2,2,1,1].omega()
ks3[2, 2, 2]
sage: kh = Sym.khomogeneous(3)
sage: kh[3].omega()
h3[1, 1, 1] - 2*h3[2, 1] + h3[3]

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(3)
sage: ks[3,1,1].omega()
Traceback (most recent call last):
...
ValueError: t*s[2, 1, 1, 1] + s[3, 1, 1] is not in the image
```

omega_t_inverse()

Returns the map $t \rightarrow 1/t$ composed with ω on self.

Unlike the map `omega()`, the result of `omega_t_inverse()` lives in the k -bounded subspace and hence will return an element even for generic t . For $t = 1$, `omega()` and `omega_t_inverse()` return the same result.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(3)
sage: ks[3,1,1].omega_t_inverse()
1/t*ks3[2, 1, 1, 1]
sage: ks[3,2].omega_t_inverse()
1/t^2*ks3[1, 1, 1, 1, 1]
```

scalar(x , $zee=None$)

Return standard scalar product between self and x .

INPUT:

- x – element of the ring of symmetric functions over the same base ring as self
- zee – an optional function on partitions giving the value for the scalar product between p_μ and p_ν (default is to use the standard `zee()` function)

See also:

`scalar()`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks3 = Sym.kschur(3)
sage: ks3[3,2,1].scalar( ks3[2,2,2] )
t^3 + t
sage: dks3 = Sym.kBoundedQuotient(3).dks()
sage: [ks3[3,2,1].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
[0, 1, 0, 0, 0, 0, 0]
sage: dks3 = Sym.kBoundedQuotient(3,t=1).dks()
sage: [ks3[2,2,2].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
[0, t - 1, 0, 1, 0, 0, 0]
```

```

sage: ks3 = Sym.kschur(3,t=1)
sage: [ks3[2,2,2].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
[0, 0, 0, 1, 0, 0, 0]
sage: kH = Sym.khomogeneous(4)
sage: kH([2,2,1]).scalar(ks3[2,2,1])
3

```

class KBoundedSubspaceBases.**ParentMethods**

an_element()

Return an element of `self`.

EXAMPLES:

```

sage: SymmetricFunctions(QQ['t']).kschur(3).an_element()
2*ks3[] + 2*ks3[1] + 3*ks3[2]

```

antipode (*element*)

Return the antipode on `self` by lifting to the space of symmetric functions, computing the antipode, and then converting to `self.parent()`. This is only the antipode for $t = 1$ and for other values of t the result may not be in the space where the k -Schur functions live.

INPUT:

- `element` – an element in a basis of the ring of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: ks3 = Sym.kschur(3,1)
sage: ks3[3,2].antipode()
-ks3[1, 1, 1, 1, 1]
sage: ks3.antipode(ks3[3,2])
-ks3[1, 1, 1, 1, 1]

```

coproduct (*element*)

Return the coproduct operation on `element`.

The coproduct is first computed on the homogeneous basis if $t = 1$ and on the Hall-Littlewood Qp basis otherwise. The result is computed then converted to the tensor squared of `self.parent()`.

INPUT:

- `element` – an element in a basis of the ring of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: ks3 = Sym.kschur(3,1)
sage: ks3[2,1].coproduct()
ks3[] # ks3[2, 1] + ks3[1] # ks3[1, 1] + ks3[1] # ks3[2] + ks3[1, 1] #
↪ ks3[1] + ks3[2] # ks3[1] + ks3[2, 1] # ks3[]
sage: h3 = Sym.khomogeneous(3)
sage: h3[2,1].coproduct()
h3[] # h3[2, 1] + h3[1] # h3[1, 1] + h3[1] # h3[2] + h3[1, 1] # h3[1] +
↪ h3[2] # h3[1] + h3[2, 1] # h3[]
sage: ks3t = SymmetricFunctions(FractionField(QQ['t'])).kschur(3)
sage: ks3t[2,1].coproduct()
ks3[] # ks3[2, 1] + ks3[1] # ks3[1, 1] + ks3[1] # ks3[2] + ks3[1, 1] #
↪ ks3[1] + ks3[2] # ks3[1] + ks3[2, 1] # ks3[]
sage: ks3t[3,1].coproduct()
ks3[] # ks3[3, 1] + ks3[1] # ks3[2, 1] + (t+1)*ks3[1] # ks3[3] + ks3[1,
↪ 1] # ks3[2] + ks3[2] # ks3[1, 1]

```

```

+ (t+1)*ks3[2] # ks3[2] + ks3[2, 1] # ks3[1] + (t+1)*ks3[3] # ks3[1] +
↪ks3[3, 1] # ks3[]
sage: h3.coproduct(h3[2,1])
h3[] # h3[2, 1] + h3[1] # h3[1, 1] + h3[1] # h3[2] + h3[1, 1] # h3[1] +
↪h3[2] # h3[1] + h3[2, 1] # h3[]

```

counit (*element*)

Return the counit of *element*.

The counit is the constant term of *element*.

INPUT:

- *element* – an element in a basis of the ring of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: ks3 = Sym.kschur(3,1)
sage: f = 2*ks3[2,1] + 3*ks3[[]]
sage: f.counit()
3
sage: ks3.counit(f)
3

```

degree_on_basis (*b*)

Return the degree of the basis element indexed by *b*.

INPUT: - *b* – a partition

EXAMPLES:

```

sage: ks3 = SymmetricFunctions(QQ).kschur(3,1)
sage: ks3.degree_on_basis(Partition([3,2]))
5

```

one_basis ()

Return the basis element indexing 1.

EXAMPLES:

```

sage: ks3 = SymmetricFunctions(QQ).kschur(3,1)
sage: ks3.one() # indirect doctest
ks3[]

```

transition_matrix (*other, n*)

Return the degree *n* transition matrix between *self* and *other*.

INPUT:

- *other* – a basis in the ring of symmetric functions
- *n* – a positive integer

The entry in the i^{th} row and j^{th} column is the coefficient obtained by writing the i^{th} element of the basis of *self* in terms of the basis *other*, and extracting the j^{th} coefficient.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ); s = Sym.schur()
sage: ks3 = Sym.kschur(3,1)
sage: ks3.transition_matrix(s,5)
[1 1 1 0 0 0 0]
[0 1 0 1 0 0 0]

```

```

[0 0 1 0 1 0 0]
[0 0 0 1 0 1 0]
[0 0 0 0 1 1 1]

sage: Sym = SymmetricFunctions(QQ['t'])
sage: s = Sym.schur()
sage: ks = Sym.kschur(3)
sage: ks.transition_matrix(s, 5)
[t^2  t  1  0  0  0  0]
[ 0  t  0  1  0  0  0]
[ 0  0  t  0  1  0  0]
[ 0  0  0  t  0  1  0]
[ 0  0  0  0 t^2  t  1]

```

`KBoundedSubspaceBases.super_categories()`

The super categories of self.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ['t'])
sage: from sage.combinat.sf.new_kschur import KBoundedSubspaceBases
sage: KB = Sym.kBoundedSubspace(3)
sage: KBB = KBoundedSubspaceBases(KB); KBB
Category of k bounded subspace bases of 3-bounded Symmetric Functions over
↳ Univariate Polynomial Ring in t over Rational Field
sage: KBB.super_categories()
[Category of realizations of 3-bounded Symmetric Functions over Univariate
↳ Polynomial Ring in t over Rational Field,
Join of Category of graded modules with basis over Univariate Polynomial
↳ Ring in t over Rational Field
and Category of coalgebras with basis over Univariate Polynomial Ring in
↳ t over Rational Field
and Category of subobjects of sets]

```

class `sage.combinat.sf.new_kschur.K_kSchur(kBoundedRing)`
 Bases: `sage.combinat.free_module.CombinatorialFreeModule`

This class implements the basis of the k -bounded subspace called the K- k -Schur basis. See [Morse2011], [LamSchillingShimozono2010].

REFERENCES:

K_k_Schur_non_commutative_variables(la)

Returns the K- k -Schur function, as embedded inside the affine zero Hecke algebra.

INPUT:

- `la` – A k -bounded Partition

OUTPUT:

- An element of the affine zero Hecke algebra.

EXAMPLES:

```

sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: g.K_k_Schur_non_commutative_variables([2,1])
T[3,1,0] + T[1,2,0] + T[3,2,0] + T[0,1,0] + T[2,0,1] + T[0,3,0] + T[2,0,3] +
↳ T[0,3,1] + T[2,3,2] + T[2,3,1] + T[3,1,2] + T[1,2,1] - T[2,0] - T[3,1]
sage: g.K_k_Schur_non_commutative_variables([])
1

```

```
sage: g.K_k_Schur_non_commutative_variables([4,1])
Traceback (most recent call last):
...
ValueError: Partition should be 3-bounded
```

homogeneous_basis_noncommutative_variables_zero_Hecke (*la*)

Returns the homogeneous basis element indexed by *la*, viewed as an element inside the affine zero Hecke algebra. For the code, see method `_homogeneous_basis`.

INPUT:

- *la* – A *k*-bounded partition

OUTPUT:

- An element of the affine zero Hecke algebra.

EXAMPLES:

```
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: g.homogeneous_basis_noncommutative_variables_zero_Hecke([2,1])
T[2,1,0] + T[3,1,0] + T[1,2,0] + T[3,2,0] + T[0,1,0] + T[2,0,1] + T[1,0,3] +
↪ T[0,3,0] + T[2,0,3] + T[0,3,2] + T[0,3,1] + T[2,3,2] + T[3,2,1] + T[2,3,1]
↪ + T[3,1,2] + T[1,2,1] - T[1,0] - 2*T[2,0] - T[0,3] - T[3,2] - 2*T[3,1] -
↪ T[2,1]
sage: g.homogeneous_basis_noncommutative_variables_zero_Hecke([])
1
```

lift (*x*)

Returns the lift of a *k*-bounded symmetric function.

INPUT:

- ***x*** – An expression in the **K-*k*-Schur basis**. Equivalently, ***x*** can be a *k*-bounded partition (then *x* corresponds to the basis element indexed by *x*)

OUTPUT:

- A symmetric function.

EXAMPLES:

```
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: g.lift([2,1])
h[2] + h[2, 1] - h[3]
sage: g.lift([])
h[]
sage: g.lift([4,1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 1]) an element of self (=3-
↪ bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur
↪ basis)
```

product (*x, y*)

Returns the product of the two **K-*k*-Schur functions**.

INPUT:

- *x, y* – elements of the *k*-bounded subspace, in the **K-*k*-Schur basis**.

OUTPUT:

- An element of the k -bounded subspace, in the K - k -Schur basis

EXAMPLES:

```
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: g.product(g([2,1]), g[1])
-2*Kks3[2, 1] + Kks3[2, 1, 1] + Kks3[2, 2]
sage: g.product(g([2,1]), g([]))
Kks3[2, 1]
```

retract (x)

Returns the retract of a symmetric function.

INPUT:

- x – A symmetric function.

OUTPUT:

- A k -bounded symmetric function in the K - k -Schur basis.

EXAMPLES:

```
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: m = SymmetricFunctions(QQ).m()
sage: g.retract(m[2,1])
-2*Kks3[1] + 4*Kks3[1, 1] - 2*Kks3[1, 1, 1] - Kks3[2] + Kks3[2, 1]
sage: g.retract(m([]))
Kks3[]
```

class sage.combinat.sf.new_kschur.**kHomogeneous** ($kBoundedRing$)

Bases: *sage.combinat.free_module.CombinatorialFreeModule*

Space of k -bounded homogeneous symmetric functions.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: kH = Sym.khomogeneous(3)
sage: kH[2]
h3[2]
sage: kH[2].lift()
h[2]
```

class sage.combinat.sf.new_kschur.**kSchur** ($kBoundedRing$)

Bases: *sage.combinat.free_module.CombinatorialFreeModule*

Space of k -Schur functions.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'])
sage: KB = Sym.kBoundedSubspace(3); KB
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational_
↪Field
```

The k -Schur function basis can be constructed as follows:

```
sage: ks3 = KB.kschur(); ks3
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational_
↪Field in the 3-Schur basis
```

We can convert to any basis of the ring of symmetric functions and, whenever it makes sense, also the other way round:

```
sage: s = Sym.schur()
sage: s(ks3([3,2,1]))
s[3, 2, 1] + t*s[4, 1, 1] + t*s[4, 2] + t^2*s[5, 1]
sage: t = Sym.base_ring().gen()
sage: ks3(s([3, 2, 1]) + t*s([4, 1, 1]) + t*s([4, 2]) + t^2*s([5, 1]))
ks3[3, 2, 1]
sage: s(ks3[2, 1, 1])
s[2, 1, 1] + t*s[3, 1]
sage: ks3(s[2, 1, 1] + t*s[3, 1])
ks3[2, 1, 1]
```

k -Schur functions are indexed by partitions with first part $\leq k$. Constructing a k -Schur function for a larger partition raises an error:

```
sage: ks3([4,3,2,1]) #
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 3, 2, 1]) an element of self (=3-
↳bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational_
↳Field in the 3-Schur basis)
```

Similarly, attempting to convert a function that is not in the linear span of the k -Schur functions raises an error:

```
sage: ks3(s([4]))
Traceback (most recent call last):
...
ValueError: s[4] is not in the image
```

Note that the product of k -Schur functions is not guaranteed to be in the space spanned by the k -Schurs. In general, we only have that a k -Schur times a j -Schur function is in the $(k+j)$ -bounded subspace. The multiplication of two k -Schur functions thus generally returns the product of the lift of the functions to the ambient symmetric function space. If the result happens to lie in the k -bounded subspace, then the result is cast into the k -Schur basis:

```
sage: ks2 = Sym.kBoundedSubspace(2).kschur()
sage: ks2[1] * ks2[1]
ks2[1, 1] + ks2[2]
sage: ks2[1] * ks2[2]
s[2, 1] + s[3]
```

Because the target space of the product of a k -Schur and a j -Schur has several possibilities, the product of a k -Schur and j -Schur function is not implemented for distinct k and j . Let us show how to get around this ‘manually’:

```
sage: ks3 = Sym.kBoundedSubspace(3).kschur()
sage: ks2([2,1]) * ks3([3,1])
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for *: '2-bounded Symmetric Functions_
↳over Univariate Polynomial Ring in t over Rational Field in the 2-Schur basis'_
↳and '3-bounded Symmetric Functions over Univariate Polynomial Ring in t over_
↳Rational Field in the 3-Schur basis'
```

The workaround:

```
sage: f = s(ks2([2,1])) * s(ks3([3,1])); f # Convert to Schur functions first and
↳multiply there.
s[3, 2, 1, 1] + s[3, 2, 2] + (t+1)*s[3, 3, 1] + s[4, 1, 1, 1]
+ (2*t+2)*s[4, 2, 1] + (t^2+t+1)*s[4, 3] + (2*t+1)*s[5, 1, 1]
+ (t^2+2*t+1)*s[5, 2] + (t^2+2*t)*s[6, 1] + t^2*s[7]
```

or:

```
sage: f = ks2[2,1].lift() * ks3[3,1].lift()
sage: ks5 = Sym.kBoundedSubspace(5).kschur()
sage: ks5(f) # The product of a 'ks2' with a 'ks3' is a 'ks5'.
ks5[3, 2, 1, 1] + ks5[3, 2, 2] + (t+1)*ks5[3, 3, 1] + ks5[4, 1, 1, 1]
+ (t+2)*ks5[4, 2, 1] + (t^2+t+1)*ks5[4, 3] + (t+1)*ks5[5, 1, 1] + ks5[5, 2]
```

For other technical reasons, taking powers of k -Schur functions is not implemented, even when the answer is still in the k -bounded subspace:

```
sage: ks2([1])^2
Traceback (most recent call last):
...
TypeError: unsupported operand type(s) for ** or pow(): 'kSchur_with_category.
↳element_class' and 'int'
```

Todo

Get rid of said technical “reasons”.

However, at $t = 1$, the product of k -Schur functions is in the span of the k -Schur functions always. Below are some examples at $t = 1$

```
sage: ks3 = Sym.kBoundedSubspace(3, t=1).kschur(); ks3
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational
↳Field with t=1 in the 3-Schur basis
sage: s = SymmetricFunctions(ks3.base_ring()).schur()
sage: ks3(s([3]))
ks3[3]
sage: s(ks3([3,2,1]))
s[3, 2, 1] + s[4, 1, 1] + s[4, 2] + s[5, 1]
sage: ks3([2,1])^2 # taking powers works for t=1
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
```

product (left, right)

Take the product of two k -Schur functions.

If $t \neq 1$, then take the product by lifting to the Schur functions and then retracting back into the k -bounded subspace (if possible).

If $t = 1$, then the product is done using `_product_from_combinatorial_algebra_multiply()` and this method calls `_multiply_basis()`.

INPUT:

- left, right – elements of the k -Schur functions

OUTPUT:

- an element of the k -Schur functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks3 = Sym.kschur(3,1)
sage: kH = Sym.khomogeneous(3)
sage: ks3(kH[2,1,1])
ks3[2, 1, 1] + ks3[2, 2] + ks3[3, 1]
sage: ks3([])*kH[2,1,1]
ks3[2, 1, 1] + ks3[2, 2] + ks3[3, 1]
sage: ks3([3,3,3,2,2,1,1,1])^2
ks3[3, 3, 3, 3, 3, 3, 2, 2, 2, 2, 1, 1, 1, 1, 1, 1]
sage: ks3([3,3,3,2,2,1,1,1])*ks3([2,2,2,2,2,1,1,1])
ks3[3, 3, 3, 2, 2, 2, 2, 2, 2, 2, 1, 1, 1, 1, 1, 1]
sage: ks3([2,2,1,1,1,1])*ks3([2,2,2,1,1,1])
ks3[2, 2, 2, 2, 2, 2, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1] + ks3[2, 2, 2, 2, 2, 2, 2, 1, 1, 1, 1, 1, 1, 1, 1, 1]
↪ 1, 1]
sage: ks3[2,1]^2
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
sage: ks3 = Sym.kschur(3)
sage: ks3[2,1]*ks3[2,1]
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1, 1]
↪ 1] + s[4, 2]

```

class `sage.combinat.sf.new_kschur.kSplit` (*kBoundedRing*)
 Bases: `sage.combinat.free_module.CombinatorialFreeModule`

The k -split basis of the space of k -bounded-symmetric functions

Fix k a positive integer and t an element of the base ring.

The k -split functions are a basis for the space of k -bounded symmetric functions that also have the bases

$$\{Q'_\lambda[X; t]\}_{\lambda_1 \leq k} = \{s_\lambda^{(k)}[X; t]\}_{\lambda_1 \leq k}$$

where $Q'_\lambda[X; t]$ are the Hall-Littlewood symmetric functions (using the notation of [MAC]) and $s_\lambda^{(k)}[X; t]$ are the k -Schur functions. If t is not a root of unity, then

$$\{s_\lambda[X/(1-t)]\}_{\lambda_1 \leq k}$$

is also a basis of this space.

The k -split basis has the property that $Q'_\lambda[X; t]$ expands positively in the k -split basis and the k -split basis conjecturally expands positively in the k -Schur functions. See [LLMSSZ] p. 81.

The k -split basis is defined recursively using the Hall-Littlewood creation operator defined in [SZ.2001]. If a partition $\mathbf{1a}$ is the concatenation (as lists) of a partition $\mathbf{mu}$ and $\mathbf{nu}$ where $\mathbf{mu}$ has maximal hook length equal to k then $\text{ksp}(\mathbf{1a}) = \text{ksp}(\mathbf{nu}).\text{hl\_creation\_operator}(\mathbf{mu})$. If the hook length of $\mathbf{1a}$ is less than or equal to k , then $\text{ksp}(\mathbf{1a})$ is equal to the Schur function indexed by $\mathbf{1a}$.

EXAMPLES:

```

sage: Symt = SymmetricFunctions(QQ['t']).fraction_field()
sage: kBS3 = Symt.kBoundedSubspace(3)
sage: ks3 = kBS3.kschur()
sage: ksp3 = kBS3.ksplit()
sage: ks3(ksp3[2,1,1])
ks3[2, 1, 1] + t*ks3[2, 2]
sage: ksp3(ks3[2,1,1])
ksp3[2, 1, 1] - t*ksp3[2, 2]
sage: ksp3[2,1]*ksp3[1]

```

```

s[2, 1, 1] + s[2, 2] + s[3, 1]
sage: ksp3[2,1].hl_creation_operator([1])
t*ksp3[2, 1, 1] + (-t^2+t)*ksp3[2, 2]

sage: Qp = Symt.hall_littlewood().Qp()
sage: ksp3(Qp[3,2,1])
ksp3[3, 2, 1] + t*ksp3[3, 3]

sage: kBS4 = Symt.kBoundedSubspace(4)
sage: ksp4 = kBS4.ksplit()
sage: ksp4(ksp3([3,2,1]))
ksp4[3, 2, 1] - t*ksp4[3, 3] + t*ksp4[4, 1, 1]
sage: ks4 = kBS4.kschur()
sage: ks4(ksp4[3,2,2,1])
ks4[3, 2, 2, 1] + t*ks4[3, 3, 1, 1] + t*ks4[3, 3, 2]

```

5.1.273 Non-symmetric Macdonald Polynomials

class sage.combinat.sf.ns_macdonald.**AugmentedLatticeDiagramFilling** (*l, pi=None*)
 Bases: *sage.combinat.combinat.CombinatorialObject*

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a == loads(dumps(a))
True
sage: pi = Permutation([2,3,1]).to_permutation_group_element()
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]],pi)
sage: a == loads(dumps(a))
True

```

are_attacking (*i, j, ii, jj*)

Return True if the boxes (*i, j*) and (*ii, jj*) in *self* are attacking.

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: all( a.are_attacking(i,j,ii,jj) for (i,j),(ii,jj) in a.attacking_
↪boxes() )
True
sage: a.are_attacking(1,1,3,2)
False

```

attacking_boxes ()

Returns a list of pairs of boxes in *self* that are attacking.

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.attacking_boxes()[:5]
[((1, 1), (2, 1)),
 ((1, 1), (3, 1)),
 ((1, 1), (6, 1)),
 ((1, 1), (2, 0)),
 ((1, 1), (3, 0))]

```

boxes()

Return a list of the coordinates of the boxes of `self`, including the ‘basement row’.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.boxes()
[(1, 1),
 (1, 2),
 (2, 1),
 (3, 1),
 (3, 2),
 (3, 3),
 (6, 1),
 (6, 2),
 (1, 0),
 (2, 0),
 (3, 0),
 (4, 0),
 (5, 0),
 (6, 0)]
```

coeff(*q*,*t*)

Return the coefficient in front of `self` in the HHL formula for the expansion of the non-symmetric Macdonald polynomial $E(\text{self.shape}())$.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: q,t = var('q,t')
sage: a.coeff(q,t)
(t - 1)^4 / ((q^2*t^3 - 1)^2*(q*t^2 - 1)^2)
```

coeff_integral(*q*,*t*)

Return the coefficient in front of `self` in the HHL formula for the expansion of the integral non-symmetric Macdonald polynomial $E(\text{self.shape}())$

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: q,t = var('q,t')
sage: a.coeff_integral(q,t)
(q^2*t^3 - 1)^2*(q*t^2 - 1)^2*(t - 1)^4
```

coinv()

Return `self`’s co-inversion statistic.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.coinv()
2
```

descents()

Return a list of the descents of `self`.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.descents()
[(1, 2), (3, 2)]
```

inv()

Return self's inversion statistic.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.inv()
15
```

inversions()

Return a list of the inversions of self.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.inversions()[ :5]
[((6, 2), (3, 2)),
 ((1, 2), (6, 1)),
 ((1, 2), (3, 1)),
 ((1, 2), (2, 1)),
 ((6, 1), (3, 1))]
sage: len(a.inversions())
25
```

is_non_attacking()

Return True if self is non-attacking.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.is_non_attacking()
True
sage: a = AugmentedLatticeDiagramFilling([[1, 1, 1], [2, 3], [3]])
sage: a.is_non_attacking()
False
sage: a = AugmentedLatticeDiagramFilling([[2,2],[1]])
sage: a.is_non_attacking()
False
sage: pi = Permutation([2,1]).to_permutation_group_element()
sage: a = AugmentedLatticeDiagramFilling([[2,2],[1]],pi)
sage: a.is_non_attacking()
True
```

maj()

Return the major index of self.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.maj()
3
```

permuted_filling(*sigma*)

EXAMPLES:

```

sage: pi=Permutation([2,1,4,3]).to_permutation_group_element()
sage: fill=[[2],[1,2,3],[],[3,1]]
sage: AugmentedLatticeDiagramFilling(fill).permuted_filling(pi)
[[2, 1], [1, 2, 1, 4], [4], [3, 4, 2]]

```

reading_order()

Return a list of coordinates of the boxes in `self`, starting from the top right, and reading from right to left. Note that this includes the ‘basement row’ of `self`.

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[[5,5]])
sage: a.reading_order()
[(3, 3),
 (6, 2),
 (3, 2),
 (1, 2),
 (6, 1),
 (3, 1),
 (2, 1),
 (1, 1),
 (6, 0),
 (5, 0),
 (4, 0),
 (3, 0),
 (2, 0),
 (1, 0)]

```

reading_word()

Return the reading word of `self`, obtained by reading the boxes entries of `self` from right to left, starting in the upper right.

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[[5,5]])
sage: a.reading_word()
word: 25465321

```

shape()

Return the shape of `self`.

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[[5,5]])
sage: a.shape()
[2, 1, 3, 0, 0, 2]

```

weight()

Return the weight of `self`.

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[[5,5]])
sage: a.weight()
[1, 2, 1, 1, 2, 1]

```

`sage.combinat.sf.ns_macdonald.E(mu, q=None, t=None, pi=None)`

Returns the non-symmetric Macdonald polynomial in type A corresponding to a shape `mu`, with basement permuted according to `pi`.

Note that if both q and t are specified, then they must have the same parent.

REFERENCE:

- J. Haglund, M. Haiman, N. Loehr. *A combinatorial formula for non-symmetric Macdonald polynomials*. Arxiv math/0601693v3.

See also:

`NonSymmetricMacdonaldPolynomials` for a type free implementation where the polynomials are constructed recursively by the application of intertwining operators.

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import E
sage: E([0,0,0])
1
sage: E([1,0,0])
x0
sage: E([0,1,0])
((-t + 1)/(-q*t^2 + 1))*x0 + x1
sage: E([0,0,1])
((-t + 1)/(-q*t + 1))*x0 + ((-t + 1)/(-q*t + 1))*x1 + x2
sage: E([1,1,0])
x0*x1
sage: E([1,0,1])
((-t + 1)/(-q*t^2 + 1))*x0*x1 + x0*x2
sage: E([0,1,1])
((-t + 1)/(-q*t + 1))*x0*x1 + ((-t + 1)/(-q*t + 1))*x0*x2 + x1*x2
sage: E([2,0,0])
x0^2 + ((-q*t + q)/(-q*t + 1))*x0*x1 + ((-q*t + q)/(-q*t + 1))*x0*x2
sage: E([0,2,0])
((-t + 1)/(-q^2*t^2 + 1))*x0^2 + ((-q^2*t^3 + q^2*t^2 - q*t^2 + 2*q*t - q + t - 1)/(-q^3*t^3 + q^2*t^2 + q*t - 1))*x0*x1 + (q*t^2 - 2*q*t + q)/(q^3*t^3 - q^2*t^2 - q*t + 1))*x0*x2 + ((-q*t + q)/(-q*t + 1))*x1*x2
```

`sage.combinat.sf.ns_macdonald.E_integral(mu, q=None, t=None, pi=None)`

Returns the integral form for the non-symmetric Macdonald polynomial in type A corresponding to a shape μ .

Note that if both q and t are specified, then they must have the same parent.

REFERENCE:

- J. Haglund, M. Haiman, N. Loehr. *A combinatorial formula for non-symmetric Macdonald polynomials*. Arxiv math/0601693v3.

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import E_integral
sage: E_integral([0,0,0])
1
sage: E_integral([1,0,0])
(-t + 1)*x0
sage: E_integral([0,1,0])
(-q*t^2 + 1)*x0 + (-t + 1)*x1
sage: E_integral([0,0,1])
(-q*t + 1)*x0 + (-q*t + 1)*x1 + (-t + 1)*x2
sage: E_integral([1,1,0])
(t^2 - 2*t + 1)*x0*x1
sage: E_integral([1,0,1])
(q*t^3 - q*t^2 - t + 1)*x0*x1 + (t^2 - 2*t + 1)*x0*x2
```

```

sage: E_integral([0,1,1])
(q^2*t^3 + q*t^4 - q*t^3 - q*t^2 - q*t - t^2 + t + 1)*x0*x1 + (q*t^2 - q*t - t + 1)*x0*x2 + (t^2 - 2*t + 1)*x1*x2
sage: E_integral([2,0,0])
(t^2 - 2*t + 1)*x0^2 + (q^2*t^2 - q^2*t - q*t + q)*x0*x1 + (q^2*t^2 - q^2*t - q*t + q)*x0*x2
sage: E_integral([0,2,0])
(q^2*t^3 - q^2*t^2 - t + 1)*x0^2 + (q^4*t^3 - q^3*t^2 - q^2*t + q*t^2 - q*t + q - t + 1)*x0*x1 + (t^2 - 2*t + 1)*x1^2 + (q^4*t^3 - q^3*t^2 - q^2*t + q)*x0*x2 + (q^2*t^2 - q^2*t - q*t + q)*x1*x2

```

`sage.combinat.sf.ns_macdonald.Ht(mu, q=None, t=None, pi=None)`

Returns the symmetric Macdonald polynomial using the Haiman, Haglund, and Loehr formula.

Note that if both q and t are specified, then they must have the same parent.

REFERENCE:

•J. Haglund, M. Haiman, N. Loehr. *A combinatorial formula for non-symmetric Macdonald polynomials.* [Arxiv math/0601693v3](https://arxiv.org/abs/math/0601693v3).

EXAMPLES:

```

sage: from sage.combinat.sf.ns_macdonald import Ht
sage: HHt = SymmetricFunctions(QQ['q','t'].fraction_field()).macdonald().Ht()
sage: Ht([0,0,1])
x0 + x1 + x2
sage: HHt([1]).expand(3)
x0 + x1 + x2
sage: Ht([0,0,2])
x0^2 + (q + 1)*x0*x1 + x1^2 + (q + 1)*x0*x2 + (q + 1)*x1*x2 + x2^2
sage: HHt([2]).expand(3)
x0^2 + (q + 1)*x0*x1 + x1^2 + (q + 1)*x0*x2 + (q + 1)*x1*x2 + x2^2

```

class `sage.combinat.sf.ns_macdonald.LatticeDiagram(l, copy=True)`

Bases: `sage.combinat.combinat.CombinatorialObject`

`CombinatorialObject` provides a thin wrapper around a list. The main differences are that `__setitem__` is disabled so that `CombinatorialObjects` are shallowly immutable, and the intention is that they are semantically immutable.

Because of this, `CombinatorialObjects` provide a `__hash__` function which computes the hash of the string representation of a list and the hash of its parent's class. Thus, each `CombinatorialObject` should have a unique string representation.

See also:

`CombinatorialElement` if you want a combinatorial object which is an element of a parent.

Warning: This class is slowly being deprecated. Use `ClonableList` instead.

INPUT:

- `l` – a list or any object that can be converted to a list by calling `list()`.
- `copy` – (boolean, default `True`) if `False`, then `l` must be a list, which is assigned to `self._list` without copying.

EXAMPLES:

```

sage: c = CombinatorialObject([1,2,3])
sage: c == loads(dumps(c))
True
sage: c._list
[1, 2, 3]
sage: c._hash is None
True

```

For efficiency, you can specify `copy=False` if you know what you are doing:

```

sage: from sage.combinat.combinat import CombinatorialObject
sage: x = [3, 2, 1]
sage: C = CombinatorialObject(x, copy=False)
sage: C
[3, 2, 1]
sage: x[0] = 5
sage: C
[5, 2, 1]

```

a(i,j)

Return the length of the arm of the box (i, j) in self.

EXAMPLES:

```

sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.a(5,2)
3

```

arm(i,j)

Return the arm of the box (i, j) in self.

EXAMPLES:

```

sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.arm(5,2)
[(1, 2), (3, 2), (8, 1)]

```

arm_left(i,j)

Return the left arm of the box (i, j) in self.

EXAMPLES:

```

sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.arm_left(5,2)
[(1, 2), (3, 2)]

```

arm_right(i,j)

Return the right arm of the box (i, j) in self.

EXAMPLES:

```

sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.arm_right(5,2)
[(8, 1)]

```

boxes()

EXAMPLES:

```

sage: a = LatticeDiagram([3,0,2])
sage: a.bboxes()
[(1, 1), (1, 2), (1, 3), (3, 1), (3, 2)]
sage: a = LatticeDiagram([2, 1, 3, 0, 0, 2])
sage: a.bboxes()
[(1, 1), (1, 2), (2, 1), (3, 1), (3, 2), (3, 3), (6, 1), (6, 2)]

```

boxes_same_and_lower_right (*ii, jj*)

Return a list of the boxes of `self` that are in row `jj` but not identical with `(ii, jj)`, or lie in the row `jj - 1` (the row directly below `jj`; this might be the basement) and strictly to the right of `(ii, jj)`.

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a = a.shape()
sage: a.bboxes_same_and_lower_right(1,1)
[(2, 1), (3, 1), (6, 1), (2, 0), (3, 0), (4, 0), (5, 0), (6, 0)]
sage: a.bboxes_same_and_lower_right(1,2)
[(3, 2), (6, 2), (2, 1), (3, 1), (6, 1)]
sage: a.bboxes_same_and_lower_right(3,3)
[(6, 2)]
sage: a.bboxes_same_and_lower_right(2,3)
[(3, 3), (3, 2), (6, 2)]

```

flip ()

Return the flip of `self`, where flip is defined as follows. Let $r = \max(\text{self})$. Then `self.flip()[i] = r - self[i]`.

EXAMPLES:

```

sage: a = LatticeDiagram([3,0,2])
sage: a.flip()
[0, 3, 1]

```

l (*i, j*)

Return `self[i] - j`.

EXAMPLES:

```

sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.l(5,2)
1

```

leg (*i, j*)

Return the leg of the box `(i, j)` in `self`.

EXAMPLES:

```

sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.leg(5,2)
[(5, 3)]

```

size ()

Return the number of boxes in `self`.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.size()
22
```

class `sage.combinat.sf.ns_macdonald.NonattackingBacktracker` (*shape, pi=None*)
 Bases: `sage.combinat.backtrack.GenericBacktracker`

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
sage: n = NonattackingBacktracker(LatticeDiagram([0,1,2]))
sage: n._ending_position
(3, 2)
sage: n._initial_state
(2, 1)
```

`get_next_pos(ii,jj)`

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: n = NonattackingBacktracker(a.shape())
sage: n.get_next_pos(1, 1)
(2, 1)
sage: n.get_next_pos(6, 1)
(1, 2)
sage: n = NonattackingBacktracker(LatticeDiagram([2,2,2]))
sage: n.get_next_pos(3, 1)
(1, 2)
```

`sage.combinat.sf.ns_macdonald.NonattackingFillings` (*shape, pi=None*)

Returning the combinatorial class of nonattacking fillings of a given shape.

EXAMPLES:

```
sage: NonattackingFillings([0,1,2])
Nonattacking fillings of [0, 1, 2]
sage: NonattackingFillings([0,1,2]).list()
[[[1], [2, 1], [3, 2, 1]],
 [[1], [2, 1], [3, 2, 2]],
 [[1], [2, 1], [3, 2, 3]],
 [[1], [2, 1], [3, 3, 1]],
 [[1], [2, 1], [3, 3, 2]],
 [[1], [2, 1], [3, 3, 3]],
 [[1], [2, 2], [3, 1, 1]],
 [[1], [2, 2], [3, 1, 2]],
 [[1], [2, 2], [3, 1, 3]],
 [[1], [2, 2], [3, 3, 1]],
 [[1], [2, 2], [3, 3, 2]],
 [[1], [2, 2], [3, 3, 3]]]
```

class `sage.combinat.sf.ns_macdonald.NonattackingFillings_shape` (*shape, pi=None*)

Bases: `sage.combinat.combinat.CombinatorialClass`

EXAMPLES:

```
sage: n = NonattackingFillings([0,1,2])
sage: n == loads(dumps(n))
True
```

flip()

Return the nonattacking fillings of the flipped shape.

EXAMPLES:

```
sage: NonattackingFillings([0,1,2]).flip()
Nonattacking fillings of [2, 1, 0]
```

5.1.274 Orthogonal Symmetric Functions

AUTHORS:

- Travis Scrimshaw (2013-11-10): Initial version

class `sage.combinat.sf.orthogonal.SymmetricFunctionAlgebra_orthogonal` (*Sym*)

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`

The orthogonal symmetric function basis (or orthogonal basis, to be short).

The orthogonal basis $\{o_\lambda\}$ where λ is taken over all partitions is defined by the following change of basis with the Schur functions:

$$s_\lambda = \sum_{\mu} \left(\sum_{\nu \in H} c_{\mu\nu}^\lambda \right) o_\mu$$

where H is the set of all partitions with even-width rows and $c_{\mu\nu}^\lambda$ is the usual Littlewood-Richardson (LR) coefficients. By the properties of LR coefficients, this can be shown to be a upper unitriangular change of basis.

Note: This is only a filtered basis, not a $\mathbf{Z}$ -graded basis. However this does respect the induced $(\mathbf{Z}/2\mathbf{Z})$ -grading.

INPUT:

- *Sym* – an instance of the ring of the symmetric functions

REFERENCES:

- [\[ChariKleber2000\]](#)
- [\[KoikeTerada1987\]](#)
- [\[ShimozonoZabrocki2006\]](#)

EXAMPLES:

Here are the first few orthogonal symmetric functions, in various bases:

```
sage: Sym = SymmetricFunctions(QQ)
sage: o = Sym.o()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: p(o([1]))
p[1]
```

```

sage: m(o([1]))
m[1]
sage: e(o([1]))
e[1]
sage: h(o([1]))
h[1]
sage: s(o([1]))
s[1]

sage: p(o([2]))
-p[] + 1/2*p[1, 1] + 1/2*p[2]
sage: m(o([2]))
-m[] + m[1, 1] + m[2]
sage: e(o([2]))
-e[] + e[1, 1] - e[2]
sage: h(o([2]))
-h[] + h[2]
sage: s(o([2]))
-s[] + s[2]

sage: p(o([3]))
-p[1] + 1/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3]
sage: m(o([3]))
-m[1] + m[1, 1, 1] + m[2, 1] + m[3]
sage: e(o([3]))
-e[1] + e[1, 1, 1] - 2*e[2, 1] + e[3]
sage: h(o([3]))
-h[1] + h[3]
sage: s(o([3]))
-s[1] + s[3]

sage: Sym = SymmetricFunctions(ZZ)
sage: o = Sym.o()
sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: p = Sym.p()
sage: m(o([4]))
-m[1, 1] + m[1, 1, 1, 1] - m[2] + m[2, 1, 1] + m[2, 2] + m[3, 1] + m[4]
sage: e(o([4]))
-e[1, 1] + e[1, 1, 1, 1] + e[2] - 3*e[2, 1, 1] + e[2, 2] + 2*e[3, 1] - e[4]
sage: h(o([4]))
-h[2] + h[4]
sage: s(o([4]))
-s[2] + s[4]

```

Some examples of conversions the other way:

```

sage: o(h[3])
o[1] + o[3]
sage: o(e[3])
o[1, 1, 1]
sage: o(m[2, 1])
o[1] - 2*o[1, 1, 1] + o[2, 1]
sage: o(p[3])
o[1, 1, 1] - o[2, 1] + o[3]

```

Some multiplication:

```
sage: o([2]) * o([1,1])
o[1, 1] + o[2] + o[2, 1, 1] + o[3, 1]
sage: o([2,1,1]) * o([2])
o[1, 1] + o[1, 1, 1, 1] + 2*o[2, 1, 1] + o[2, 2] + o[2, 2, 1, 1]
+ o[3, 1] + o[3, 1, 1, 1] + o[3, 2, 1] + o[4, 1, 1]
sage: o([1,1]) * o([2,1])
o[1] + o[1, 1, 1] + 2*o[2, 1] + o[2, 1, 1, 1] + o[2, 2, 1]
+ o[3] + o[3, 1, 1] + o[3, 2]
```

Examples of the Hopf algebra structure:

```
sage: o([1]).antipode()
-o[1]
sage: o([2]).antipode()
-o[] + o[1, 1]
sage: o([1]).coproduct()
o[] # o[1] + o[1] # o[]
sage: o([2]).coproduct()
o[] # o[] + o[] # o[2] + o[1] # o[1] + o[2] # o[]
sage: o([1]).counit()
0
sage: o.one().counit()
1
```

5.1.275 Symmetric functions defined by orthogonality and triangularity.

One characterization of Schur functions is that they are upper triangularly related to the monomial symmetric functions and orthogonal with respect to the Hall scalar product. We can use the class `SymmetricFunctionAlgebra_orthotriang` to obtain the Schur functions from this definition.

```
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur functions')
sage: s([2,1])^2
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1] +
↪s[4, 2]
```

```
sage: s2 = SymmetricFunctions(QQ).s()
sage: s2([2,1])^2
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1] +
↪s[4, 2]
```

```
class sage.combinat.sf.orthotriang.SymmetricFunctionAlgebra_orthotriang(Sym,
                                                                           base,
                                                                           scalar,
                                                                           prefix,
                                                                           ba-
                                                                           sis_name,
                                                                           lead-
                                                                           ing_coeff=None)

Bases: sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic
```

Initialization of the symmetric function algebra defined via orthotriangular rules.

INPUT:

- `self` – a basis determined by an orthotriangular definition
- `Sym` – ring of symmetric functions
- `base` – an instance of a basis of the ring of symmetric functions (e.g. the Schur functions)
- `scalar` – a function `zee` on partitions. The function `zee` determines the scalar product on the power sum basis with normalization $\langle p_\mu, p_\mu \rangle = \text{zee}(\mu)$.
- `prefix` – the prefix used to display the basis
- `basis_name` – the name used for the basis

Note: The base ring is required to be a $\mathbb{Q}$ -algebra for this method to be useable, since the scalar product is defined by its values on the power sum basis.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_
      ↪ orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur'); s
Symmetric Functions over Rational Field in the Schur basis
```

class Element

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`

5.1.276 Power sum symmetric functions

class `sage.combinat.sf.powersum.SymmetricFunctionAlgebra_power(Sym)`

Bases: `sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative`

A class for methods associated to the power sum basis of the symmetric functions

INPUT:

- `self` – the power sum basis of the symmetric functions
- `Sym` – an instance of the ring of symmetric functions

class Element

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical.Element`

adams_operation(*n*)

Return the image of the symmetric function `self` under the *n*-th Frobenius operator.

The *n*-th Frobenius operator $\mathbf{f}_n$ is defined to be the map from the ring of symmetric functions to itself that sends every symmetric function $P(x_1, x_2, x_3, \dots)$ to $P(x_1^n, x_2^n, x_3^n, \dots)$. This operator $\mathbf{f}_n$ is a Hopf algebra endomorphism, and satisfies

$$\mathbf{f}_n m_{(\lambda_1, \lambda_2, \lambda_3, \dots)} = m_{(n\lambda_1, n\lambda_2, n\lambda_3, \dots)}$$

for every partition $(\lambda_1, \lambda_2, \lambda_3, \dots)$ (where m means the monomial basis). Moreover, $\mathbf{f}_n(p_r) = p_{nr}$ for every positive integer r (where p_k denotes the k -th powersum symmetric function).

The n -th Frobenius operator is also called the n -th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The n -th Frobenius operator is also the n -th Adams operator of the Λ -ring of symmetric functions over the integers.

The n -th Frobenius operator can also be described via plethysm: Every symmetric function P satisfies $\mathbf{f}_n(P) = p_n \circ P = P \circ p_n$, where p_n is the n -th powersum symmetric function, and $\circ$ denotes (outer) plethysm.

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Frobenius operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: p[3].frobenius(2)
p[6]
sage: p[4, 2, 1].frobenius(3)
p[12, 6, 3]
sage: p[[]].frobenius(4)
p[[]]
sage: p[3].frobenius(1)
p[3]
sage: (p[[3]] - p[[2]] + p[[]]).frobenius(3)
p[[]] - p[6] + p[9]
```

See also:

[*plethysm\(\)*](#)

eval_at_permutation_roots(*rho*)

Evaluate at eigenvalues of a permutation matrix.

Evaluate an element of the power sum basis at the eigenvalues of a permutation matrix with cycle structure ρ .

This function evaluates an element at the roots of unity

$$\Xi_{\rho_1}, \Xi_{\rho_2}, \dots, \Xi_{\rho_\ell}$$

where

$$\Xi_m = 1, \zeta_m, \zeta_m^2, \dots, \zeta_m^{m-1}$$

and ζ_m is an m root of unity. These roots of unity represent the eigenvalues of permutation matrix with cycle structure ρ .

INPUT:

- *rho* – a partition or a list of non-negative integers

OUTPUT:

- an element of the base ring

EXAMPLES:

```

sage: p = SymmetricFunctions(QQ).p()
sage: p([3,3]).eval_at_permutation_roots([6])
0
sage: p([3,3]).eval_at_permutation_roots([3])
9
sage: p([3,3]).eval_at_permutation_roots([1])
1
sage: p([3,3]).eval_at_permutation_roots([3,3])
36
sage: p([3,3]).eval_at_permutation_roots([1,1,1,1,1])
25
sage: (p[1]+p[2]+p[3]).eval_at_permutation_roots([3,2])
5

```

expand(*n*, *alphabet*='x')

Expand the symmetric function `self` as a symmetric polynomial in *n* variables.

INPUT:

- *n* – a nonnegative integer
- *alphabet* – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the *n* variables labelled by *alphabet*.

EXAMPLES:

```

sage: p = SymmetricFunctions(QQ).p()
sage: a = p([2])
sage: a.expand(2)
x0^2 + x1^2
sage: a.expand(3, alphabet=['a', 'b', 'c'])
a^2 + b^2 + c^2
sage: p([2,1,1]).expand(2)
x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
sage: p([7]).expand(4)
x0^7 + x1^7 + x2^7 + x3^7
sage: p([7]).expand(4, alphabet='t')
t0^7 + t1^7 + t2^7 + t3^7
sage: p([7]).expand(4, alphabet='x,y,z,t')
x^7 + y^7 + z^7 + t^7
sage: p(1).expand(4)
1
sage: p(0).expand(4)
0
sage: (p([]) + 2*p([1])).expand(3)
2*x0 + 2*x1 + 2*x2 + 1
sage: p([1]).expand(0)
0
sage: (3*p([])).expand(0)
3

```

frobenius(*n*)

Return the image of the symmetric function `self` under the *n*-th Frobenius operator.

The *n*-th Frobenius operator $\mathbf{f}_n$ is defined to be the map from the ring of symmetric functions to itself that sends every symmetric function $P(x_1, x_2, x_3, \dots)$ to $P(x_1^n, x_2^n, x_3^n, \dots)$. This operator $\mathbf{f}_n$ is a Hopf algebra endomorphism, and satisfies

$$\mathbf{f}_n m_{(\lambda_1, \lambda_2, \lambda_3, \dots)} = m_{(n\lambda_1, n\lambda_2, n\lambda_3, \dots)}$$

for every partition $(\lambda_1, \lambda_2, \lambda_3, \dots)$ (where m means the monomial basis). Moreover, $f_n(p_r) = p_{nr}$ for every positive integer r (where p_k denotes the k -th powersum symmetric function).

The n -th Frobenius operator is also called the n -th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The n -th Frobenius operator is also the n -th Adams operator of the Λ -ring of symmetric functions over the integers.

The n -th Frobenius operator can also be described via plethysm: Every symmetric function P satisfies $f_n(P) = p_n \circ P = P \circ p_n$, where p_n is the n -th powersum symmetric function, and $\circ$ denotes (outer) plethysm.

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Frobenius operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()

`omega()`

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the image of `self` under the omega automorphism

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: a = p([2,1]); a
p[2, 1]
sage: a.omega()
-p[2, 1]
sage: p([]).omega()
p[]
sage: p(0).omega()
0
sage: p = SymmetricFunctions(ZZ).p()
sage: (p([3,1,1]) - 2 * p([2,1])).omega()
2*p[2, 1] + p[3, 1, 1]
```

omega_involution()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the image of `self` under the omega automorphism

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: a = p([2,1]); a
p[2, 1]
sage: a.omega()
-p[2, 1]
sage: p([]).omega()
p[]
sage: p(0).omega()
0
sage: p = SymmetricFunctions(ZZ).p()
sage: (p([3,1,1]) - 2 * p([2,1])).omega()
2*p[2, 1] + p[3, 1, 1]
```

scalar(`x`, `zee=None`)

Return the standard scalar product of `self` and `x`.

INPUT:

- `x` – a power sum symmetric function
- `zee` – (default: uses standard `zee` function) optional input specifying the scalar product on the power sum basis with normalization $\langle p_\mu, p_\mu \rangle = zee(\mu)$. `zee` should be a function on partitions.

Note that the power-sum symmetric functions are orthogonal under this scalar product. With the default value of `zee`, the value of $\langle p_\lambda, p_\lambda \rangle$ is given by the size of the centralizer in S_n of a permutation of cycle type λ .

OUTPUT:

- the standard scalar product between `self` and `x`, or, if the optional parameter `zee` is specified, then the scalar product with respect to the normalization $\langle p_\mu, p_\mu \rangle = \text{zee}(\mu)$ with the power sum basis elements being orthogonal

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: p4 = Partitions(4)
sage: matrix([ [p(a).scalar(p(b)) for a in p4] for b in p4])
[ 4  0  0  0  0]
[ 0  3  0  0  0]
[ 0  0  8  0  0]
[ 0  0  0  4  0]
[ 0  0  0  0 24]
sage: p(0).scalar(p(1))
0
sage: p(1).scalar(p(2))
2

sage: zee = lambda x : 1
sage: matrix([ [p[la].scalar(p[mu], zee) for la in Partitions(3)] for mu
↪ in Partitions(3)])
[1 0 0]
[0 1 0]
[0 0 1]
```

verschiebung(*n*)

Return the image of the symmetric function `self` under the n -th Verschiebung operator.

The n -th Verschiebung operator $\mathbf{V}_n$ is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n , and satisfies $V(h_r) = 0$ for every positive integer r not divisible by n . This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(h_r) = h_{r/n}, \quad \mathbf{V}_n(p_r) = np_{r/n}, \quad \mathbf{V}_n(e_r) = (-1)^{r-r/n} e_{r/n}$$

(where h is the complete homogeneous basis, p is the powersum basis, and e is the elementary basis). For every nonnegative integer r with $n \nmid r$, it satisfies

$$\mathbf{V}_n(h_r) = \mathbf{V}_n(p_r) = \mathbf{V}_n(e_r) = 0.$$

The n -th Verschiebung operator is also called the n -th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The n -th Verschiebung operator is adjoint to the n -th Frobenius operator (see `frobenius()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the n -th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let λ be a partition. Let n be a positive integer. If the n -core of λ is nonempty, then $\mathbf{V}_n(s_\lambda) = 0$. Otherwise, the following method computes $\mathbf{V}_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, \dots, \lambda_{ns})$ for some nonnegative integer s . (If n does not divide the length of λ , then this is achieved by adding trailing zeroes to λ .) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \dots, ns\}$. Then, $(\beta_1, \beta_2, \dots, \beta_{ns})$ is

a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo n . Let ξ be the sign of the permutation that is used for this sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo n . (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $V_n(s_\lambda) = \xi\psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \dots, \lambda^{(n-1)})$ is the n -quotient of λ .

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: p[3].verschiebung(2)
0
sage: p[4].verschiebung(4)
4*p[1]
```

The Verschiebung endomorphisms are multiplicative:

```
sage: all( all( p(lam).verschiebung(2) * p(mu).verschiebung(2)
....:         == (p(lam) * p(mu)).verschiebung(2)
....:         for mu in Partitions(4) )
....:         for lam in Partitions(4) )
True
```

Testing the adjointness between the Frobenius operators f_n and the Verschiebung operators V_n :

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: all( all( p(lam).verschiebung(2).scalar(p(mu))
....:         == p(lam).scalar(p(mu)).frobenius(2)
....:         for mu in Partitions(2) )
....:         for lam in Partitions(4) )
True
```

`SymmetricFunctionAlgebra_power.antipode_on_basis(partition)`

Return the antipode of `self[partition]`.

The antipode on the generator p_i (for $i > 0$) is $-p_i$, and the antipode on p_μ is $(-1)^{\text{length}(\mu)} p_\mu$.

INPUT:

- `self` – the power sum basis of the symmetric functions
- `partition` – a partition

OUTPUT:

- the result of the antipode on `self(partition)`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: p.antipode_on_basis([2])
-p[2]
sage: p.antipode_on_basis([3])
```

```

-p[3]
sage: p.antipode_on_basis([2,2])
p[2, 2]
sage: p.antipode_on_basis([])
p[]

```

`SymmetricFunctionAlgebra_power.bottom_schur_function` (*partition*, *degree=None*)

Return the least-degree component of $s[\text{partition}]$, where s denotes the Schur basis of the symmetric functions, and the grading is not the usual grading on the symmetric functions but rather the grading which gives every p_i degree 1.

This least-degree component has its degree equal to the Frobenius rank of *partition*, while the degree with respect to the usual grading is still the size of *partition*.

This method requires the base ring to be a (commutative) $\mathbf{Q}$ -algebra. This restriction is unavoidable, since the least-degree component (in general) has noninteger coefficients in all classical bases of the symmetric functions.

The optional keyword *degree* allows taking any homogeneous component rather than merely the least-degree one. Specifically, if *degree* is set, then the *degree*-th component will be returned.

REFERENCES:

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: p.bottom_schur_function([2,2,1])
-1/6*p[3, 2] + 1/4*p[4, 1]
sage: p.bottom_schur_function([2,1])
-1/3*p[3]
sage: p.bottom_schur_function([3])
1/3*p[3]
sage: p.bottom_schur_function([1,1,1])
1/3*p[3]
sage: p.bottom_schur_function(Partition([1,1,1]))
1/3*p[3]
sage: p.bottom_schur_function([2,1], degree=1)
-1/3*p[3]
sage: p.bottom_schur_function([2,1], degree=2)
0
sage: p.bottom_schur_function([2,1], degree=3)
1/3*p[1, 1, 1]
sage: p.bottom_schur_function([2,2,1], degree=3)
1/8*p[2, 2, 1] - 1/6*p[3, 1, 1]

```

`SymmetricFunctionAlgebra_power.coproduct_on_generators` (*i*)

Return coproduct on generators for power sums p_i (for $i > 0$).

The elements p_i are primitive elements.

INPUT:

- *self* – the power sum basis of the symmetric functions
- *i* – a positive integer

OUTPUT:

- the result of the coproduct on the generator $p(i)$

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.powersum()
sage: p.coproduct_on_generators(2)
p[] # p[2] + p[2] # p[]
```

`SymmetricFunctionAlgebra_power.eval_at_permutation_roots_on_generators` (k , ρ)

Evaluate p_k at eigenvalues of permutation matrix.

This function evaluates a symmetric function $p([k])$ at the eigenvalues of a permutation matrix with cycle structure ρ .

This function evaluates a p_k at the roots of unity

$$\Xi_{\rho_1}, \Xi_{\rho_2}, \dots, \Xi_{\rho_\ell}$$

where

$$\Xi_m = 1, \zeta_m, \zeta_m^2, \dots, \zeta_m^{m-1}$$

and ζ_m is an m root of unity. This is characterized by $p_k[A, B] = p_k[A] + p_k[B]$ and $p_k[\Xi_m] = 0$ unless m divides k and $p_{rm}[\Xi_m] = m$.

INPUT:

- k – a non-negative integer
- ρ – a partition or a list of non-negative integers

OUTPUT:

- an element of the base ring

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: p.eval_at_permutation_roots_on_generators(3, [6])
0
sage: p.eval_at_permutation_roots_on_generators(3, [3])
3
sage: p.eval_at_permutation_roots_on_generators(3, [1])
1
sage: p.eval_at_permutation_roots_on_generators(3, [3, 3])
6
sage: p.eval_at_permutation_roots_on_generators(3, [1, 1, 1, 1, 1])
5
```

5.1.277 Schur symmetric functions

class `sage.combinat.sf.schur.SymmetricFunctionAlgebra_schur` (*Sym*)

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical`

A class for methods related to the Schur symmetric function basis

INPUT:

- *self* – a Schur symmetric function basis
- *Sym* – an instance of the ring of the symmetric functions

class Element

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical.Element`

expand (*n*, *alphabet*='x')

Expand the symmetric function `self` as a symmetric polynomial in *n* variables.

INPUT:

- *n* – a nonnegative integer
- *alphabet* – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the *n* variables labelled by *alphabet*.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2, 1])
sage: a.expand(2)
x0^2*x1 + x0*x1^2
sage: a.expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: a.expand(4)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 +
↪ x0^2*x3 + 2*x0*x1*x3 + x1^2*x3 + 2*x0*x2*x3 + 2*x1*x2*x3 + x2^2*x3 +
↪ x0*x3^2 + x1*x3^2 + x2*x3^2
sage: a.expand(2, alphabet='y')
y0^2*y1 + y0*y1^2
sage: a.expand(2, alphabet=['a', 'b'])
a^2*b + a*b^2
sage: s([1, 1, 1, 1]).expand(3)
0
sage: (s([]) + 2*s([1])).expand(3)
2*x0 + 2*x1 + 2*x2 + 1
sage: s([1]).expand(0)
0
sage: (3*s([])).expand(0)
3
```

omega ()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers *k* (where e_k stands for the *k*-th elementary symmetric function, and h_k stands for the *k*-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer *k*.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the image of `self` under the omega automorphism

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([2, 1]).omega()
s[2, 1]
sage: s([2, 1, 1]).omega()
s[3, 1]
```

`omega_involution()`

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the image of `self` under the omega automorphism

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([2, 1]).omega()
s[2, 1]
sage: s([2, 1, 1]).omega()
s[3, 1]
```

`scalar(x, zee=None)`

Return the standard scalar product between `self` and x .

Note that the Schur functions are self-dual with respect to this scalar product. They are also lower-triangularly related to the monomial symmetric functions with respect to this scalar product.

INPUT:

- x – element of the ring of symmetric functions over the same base ring as `self`
- `zee` – an optional function on partitions giving the value for the scalar product between the power-sum symmetric function p_μ and itself (the default value is the standard `zee()` function)

OUTPUT:

- the scalar product between `self` and x

EXAMPLES:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2, 1])
sage: b = s([1, 1, 1])
sage: c = 2*s([1, 1, 1])
sage: d = a + b
sage: a.scalar(a)
```

```

1
sage: b.scalar(b)
1
sage: b.scalar(a)
0
sage: b.scalar(c)
2
sage: c.scalar(c)
4
sage: d.scalar(a)
1
sage: d.scalar(b)
1
sage: d.scalar(c)
2

```

```

sage: m = SymmetricFunctions(ZZ).monomial()
sage: p4 = Partitions(4)
sage: l = [ [s(p).scalar(m(q)) for q in p4] for p in p4]
sage: matrix(l)
[ 1  0  0  0  0]
[-1  1  0  0  0]
[ 0 -1  1  0  0]
[ 1 -1 -1  1  0]
[-1  2  1 -3  1]

```

verschiebung(*n*)

Return the image of the symmetric function `self` under the n -th Verschiebung operator.

The n -th Verschiebung operator V_n is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n , and satisfies $V(h_r) = 0$ for every positive integer r not divisible by n . This operator V_n is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$V_n(h_r) = h_{r/n}, \quad V_n(p_r) = np_{r/n}, \quad V_n(e_r) = (-1)^{r-r/n} e_{r/n}$$

(where h is the complete homogeneous basis, p is the powersum basis, and e is the elementary basis). For every nonnegative integer r with $n \nmid r$, it satisfies

$$V_n(h_r) = V_n(p_r) = V_n(e_r) = 0.$$

The n -th Verschiebung operator is also called the n -th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The n -th Verschiebung operator is adjoint to the n -th Frobenius operator (see `frobenius()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the n -th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let λ be a partition. Let n be a positive integer. If the n -core of λ is nonempty, then $V_n(s_\lambda) = 0$. Otherwise, the following method computes $V_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, \dots, \lambda_{ns})$ for some nonnegative integer s . (If n does not divide the length of λ , then this is achieved by adding trailing zeroes to λ .) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \dots, ns\}$. Then, $(\beta_1, \beta_2, \dots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo n . Let ξ be the sign of the permutation that is used for this sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \dots, ns)$

in order of (weakly) increasing remainder of $i - 1$ modulo n . (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $V_n(s_\lambda) = \xi^\psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \dots, \lambda^{(n-1)})$ is the n -quotient of λ .

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.s()
sage: s[5].verschiebung(2)
0
sage: s[6].verschiebung(6)
s[1]
sage: s[6, 3].verschiebung(3)
s[2, 1] + s[3]
sage: s[6, 3, 1].verschiebung(2)
-s[3, 2]
sage: s[3, 2, 1].verschiebung(1)
s[3, 2, 1]
sage: s[[]].verschiebung(1)
s[]
sage: s[[]].verschiebung(4)
s[]
```

`SymmetricFunctionAlgebra_schur.coproduct_on_basis(mu)`

Returns the coproduct of `self(mu)`.

Here `self` is the basis of Schur functions in the ring of symmetric functions.

INPUT:

- `self` – a Schur symmetric function basis
- `mu` – a partition

OUTPUT:

- the image of the `mu`-th Schur function under the comultiplication of the Hopf algebra of symmetric functions; this is an element of the tensor square of the Schur basis

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: s.coproduct_on_basis([2])
s[] # s[2] + s[1] # s[1] + s[2] # s[]
```

5.1.278 Symplectic Symmetric Functions

AUTHORS:

- Travis Scrimshaw (2013-11-10): Initial version

class `sage.combinat.sf.symplectic.SymmetricFunctionAlgebra_symplectic(Sym)`

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`

The symplectic symmetric function basis (or symplectic basis, to be short).

The symplectic basis $\{sp_\lambda\}$ where λ is taken over all partitions is defined by the following change of basis with the Schur functions:

$$s_\lambda = \sum_{\mu} \left(\sum_{\nu \in V} c_{\mu\nu}^\lambda \right) sp_\mu$$

where V is the set of all partitions with even-height columns and $c_{\mu\nu}^\lambda$ is the usual Littlewood-Richardson (LR) coefficients. By the properties of LR coefficients, this can be shown to be an upper unitriangular change of basis.

Note: This is only a filtered basis, not a $\mathbf{Z}$ -graded basis. However this does respect the induced $(\mathbf{Z}/2\mathbf{Z})$ -grading.

INPUT:

- Sym – an instance of the ring of the symmetric functions

REFERENCES:

EXAMPLES:

Here are the first few symplectic symmetric functions, in various bases:

```
sage: Sym = SymmetricFunctions(QQ)
sage: sp = Sym.sp()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: p(sp([1]))

sage: e(sp([3]))
e[1, 1, 1] - 2*e[2, 1] + e[3]
```

```

sage: h(sp([3]))
h[3]
sage: s(sp([3]))
s[3]

sage: Sym = SymmetricFunctions(ZZ)
sage: sp = Sym.sp()
sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: p = Sym.p()
sage: m(sp([4]))
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1] + m[4]
sage: e(sp([4]))
e[1, 1, 1, 1] - 3*e[2, 1, 1] + e[2, 2] + 2*e[3, 1] - e[4]
sage: h(sp([4]))
h[4]
sage: s(sp([4]))
s[4]

```

Some examples of conversions the other way:

```

sage: sp(h[3])
sp[3]
sage: sp(e[3])
sp[1] + sp[1, 1, 1]
sage: sp(m[2, 1])
-sp[1] - 2*sp[1, 1, 1] + sp[2, 1]
sage: sp(p[3])
sp[1, 1, 1] - sp[2, 1] + sp[3]

```

Some multiplication:

```

sage: sp([2]) * sp([1, 1])
sp[1, 1] + sp[2] + sp[2, 1, 1] + sp[3, 1]
sage: sp([2, 1, 1]) * sp([2])
sp[1, 1] + sp[1, 1, 1, 1] + 2*sp[2, 1, 1] + sp[2, 2] + sp[2, 2, 1, 1]
+ sp[3, 1] + sp[3, 1, 1, 1] + sp[3, 2, 1] + sp[4, 1, 1]
sage: sp([1, 1]) * sp([2, 1])
sp[1] + sp[1, 1, 1] + 2*sp[2, 1] + sp[2, 1, 1, 1] + sp[2, 2, 1]
+ sp[3] + sp[3, 1, 1] + sp[3, 2]

```

Examples of the Hopf algebra structure:

```

sage: sp([1]).antipode()
-sp[1]
sage: sp([2]).antipode()
sp[] + sp[1, 1]
sage: sp([1]).coproduct()
sp[] # sp[1] + sp[1] # sp[]
sage: sp([2]).coproduct()
sp[] # sp[2] + sp[1] # sp[1] + sp[2] # sp[]
sage: sp([1]).counit()
0
sage: sp.one().counit()
1

```

5.1.279 Symmetric functions, with their multiple realizations

```
class sage.combinat.sf.sf.SymmetricFunctions(R)
    Bases:      sage.structure.unique_representation.UniqueRepresentation,      sage.
               structure.parent.Parent
```

The abstract algebra of commutative symmetric functions

Symmetric Functions in Sage

This document is an introduction to working with symmetric function theory in Sage. It is not intended to be an introduction to the theory of symmetric functions ([\[MAC\]](#) and [\[STA\]](#), Chapter 7, are two excellent references.) The reader is also expected to be familiar with Sage.

The algebra of symmetric functions

The algebra of symmetric functions is the unique free commutative graded connected algebra over the given ring, with one generator in each degree. It can also be thought of as the inverse limit (in the category of graded algebras) of the algebra of symmetric polynomials in n variables as $n \rightarrow \infty$. Sage allows us to construct the algebra of symmetric functions over any ring. We will use a base ring of rational numbers in these first examples:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Sym
Symmetric Functions over Rational Field
```

Sage knows certain categorical information about this algebra:

```
sage: Sym.category()
Join of Category of hopf algebras over Rational Field
      and Category of graded algebras over Rational Field
      and Category of monoids with realizations
      and Category of coalgebras over Rational Field with realizations
```

Notice that `Sym` is an *abstract* algebra. This reflects the fact that there are multiple natural bases. To work with specific elements, we need a *realization* of this algebra. In practice, this means we need to specify a basis.

An example basis - power sums

Here is an example of how one might use the power sum realization:

```
sage: p = Sym.powersum()
sage: p
Symmetric Functions over Rational Field in the powersum basis
```

`p` now represents the realization of the symmetric function algebra on the power sum basis. The basis itself is accessible through:

```
sage: p.basis()
Lazy family (Term map from Partitions to Symmetric Functions over Rational Field,
             ↦ in the powersum basis(i))_{i in Partitions}
sage: p.basis().keys()
Partitions
```

This last line means that `p.basis()` is an association between the set of Partitions and the basis elements of the algebra `p`. To construct a specific element one can therefore do:

```
sage: p.basis()[Partition([2,1,1])]
p[2, 1, 1]
```

As this is rather cumbersome, realizations of the symmetric function algebra allow for the following abuses of notation:

```
sage: p[Partition([2, 1, 1])]
p[2, 1, 1]
sage: p[[2, 1, 1]]
p[2, 1, 1]
sage: p[2, 1, 1]
p[2, 1, 1]
```

or even:

```
sage: p[(i for i in [2, 1, 1])]
p[2, 1, 1]
```

In the special case of the empty partition, due to a limitation in Python syntax, one cannot use:

```
sage: p[]      # todo: not implemented
```

Please use instead:

```
sage: p[[]]
p[]
```

Note: When elements are constructed using the `p[something]` syntax, an error will be raised if the input cannot be interpreted as a partition. This is *not* the case when `p.basis()` is used:

```
sage: p['something']
Traceback (most recent call last):
...
ValueError: ['s', 'o', 'm', 'e', 't', 'h', 'i', 'n', 'g'] is not an element of_
↪Partitions
sage: p.basis()['something']
p'something'
```

Elements of `p` are linear combinations of such compositions:

```
sage: p.an_element()
2*p[] + 2*p[1] + 3*p[2]
```

Algebra structure

Algebraic combinations of basis elements can be entered in a natural way:

```
sage: p[2,1,1] + 2 * p[1] * (p[4] + p[2,1])
3*p[2, 1, 1] + 2*p[4, 1]
```

Let us explore the other operations of `p`. We can ask for the mathematical properties of `p`:

```
sage: p.categories()
[Category of graded bases of Symmetric Functions over Rational Field,
Category of filtered bases of Symmetric Functions over Rational Field,
Category of bases of Symmetric Functions over Rational Field,
Category of graded hopf algebras with basis over Rational Field,
...]
```

To start with, p is a graded algebra, the grading being induced by the size of the partitions. Due to this, the one is the basis element indexed by the empty partition:

```
sage: p.one()
p[]
```

The p basis is multiplicative; that is, multiplication is induced by linearity from the (nonincreasingly sorted) concatenation of partitions:

```
sage: p[3,1] * p[2,1]
p[3, 2, 1, 1]

sage: (p.one() + 2 * p[3,1]) * p[4, 2]
p[4, 2] + 2*p[4, 3, 2, 1]
```

The classical bases

In addition to the power sum basis, other classical bases of the symmetric function algebra include the elementary, complete homogeneous, monomial, and Schur bases:

```
sage: e = Sym.elementary()
sage: h = Sym.homogeneous()
sage: m = Sym.monomial()
sage: s = Sym.schur()
```

These and others can be defined all at once with the single command:

```
sage: Sym.inject_shorthands()
Defining e as shorthand for Symmetric Functions over Rational Field in the
↳elementary basis
Defining f as shorthand for Symmetric Functions over Rational Field in the
↳forgotten basis
Defining h as shorthand for Symmetric Functions over Rational Field in the
↳homogeneous basis
Defining m as shorthand for Symmetric Functions over Rational Field in the
↳monomial basis
Defining p as shorthand for Symmetric Functions over Rational Field in the
↳powersum basis
Defining s as shorthand for Symmetric Functions over Rational Field in the Schur
↳basis
```

We can then do conversions from one basis to another:

```
sage: s(p[2,1])
-s[1, 1, 1] + s[3]

sage: m(p[3])
m[3]
```

```
sage: m(p[3,2])
m[3, 2] + m[5]
```

For computations which mix bases, Sage will return a result with respect to a single (not necessarily predictable) basis:

```
sage: p[2] * s[2] - m[4]
1/2*p[2, 1, 1] + 1/2*p[2, 2] - p[4]

sage: p( m[1] * ( e[3]*s[2] + 1 ))
p[1] + 1/12*p[1, 1, 1, 1, 1, 1] - 1/6*p[2, 1, 1, 1, 1] - 1/4*p[2, 2, 1, 1] + 1/
↪6*p[3, 1, 1, 1] + 1/6*p[3, 2, 1]
```

The one for different bases such as the power sum and Schur function is the same:

```
sage: s.one() == p.one()
True
```

Basic computations

In this section, we explore some of the many methods that can be applied to an arbitrary symmetric function:

```
sage: f = s[2]^2; f
s[2, 2] + s[3, 1] + s[4]
```

For more methods than discussed here, create a symmetric function as above, and use `f.<tab>`.

Representation theory of the symmetric group

The Schur functions s_λ can also be interpreted as irreducible characters of the symmetric group S_n , where n is the size of the partition λ . Since the Schur functions of degree n form a basis of the symmetric functions of degree n , it follows that an arbitrary symmetric function (homogeneous of degree n) may be interpreted as a function on the symmetric group. In this interpretation the power sum symmetric function p_λ is the characteristic function of the conjugacy class with shape λ , multiplied by the order of the centralizer of an element. Hence the irreducible characters can be computed as follows:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: p = Sym.power()
sage: P = Partitions(5).list()
sage: P = [P[i] for i in range(len(P)-1,-1,-1)]
sage: M = matrix([[s[P[i]].scalar(p[P[j]]) for j in range(len(P))] for i in
↪range(len(P))])
sage: M
[ 1 -1  1  1 -1 -1  1]
[ 4 -2  0  1  1  0 -1]
[ 5 -1  1 -1 -1  1  0]
[ 6  0 -2  0  0  0  1]
[ 5  1  1 -1  1 -1  0]
[ 4  2  0  1 -1  0 -1]
[ 1  1  1  1  1  1  1]
```

We can indeed check that this agrees with the character table of S_5 :

```
sage: SymmetricGroup(5).character_table() == M
True
```

In this interpretation of symmetric functions as characters on the symmetric group, the multiplication and co-multiplication are interpreted as induction (from $S_n \times S_m$ to S_{n+m}) and restriction, respectively. The Schur functions can also be interpreted as characters of GL_n , see Partitions and Schur functions.

The omega involution

The ω involution is the linear extension of the map which sends e_λ to h_λ :

```
sage: h(f)
h[2, 2]
sage: e(f.omega())
e[2, 2]
```

The Hall scalar product

The Hall scalar product on the algebra of symmetric functions makes the Schur functions into an orthonormal basis:

```
sage: f.scalar(f)
3
```

Skewing

Skewing is the adjoint operation to multiplication with respect to this scalar product:

```
sage: f.skew_by(s[1])
2*s[2, 1] + 2*s[3]
```

In general, `s[la].skew_by(s[mu])` is the symmetric function typically denoted $s_{\lambda \setminus \mu}$ or $s_{\lambda/\mu}$.

Expanding into variables

We can expand a symmetric function into a symmetric polynomial in a specified number of variables:

```
sage: f.expand(2)
x0^4 + 2*x0^3*x1 + 3*x0^2*x1^2 + 2*x0*x1^3 + x1^4
```

See the documentation for `expand` for more examples.

The Kronecker product

As in the section on the *Representation theory of the symmetric group*, a symmetric function may be considered as a class function on the symmetric group where the elements p_μ/z_μ are the indicators of a permutation having cycle structure μ . The Kronecker product of two symmetric functions corresponds to the pointwise product of these class functions.

Since the Schur functions are the irreducible characters of the symmetric group under this identification, the Kronecker product of two Schur functions corresponds to the internal tensor product of two irreducible symmetric group representations.

Under this identification, the Kronecker product of p_μ/z_μ and p_ν/z_ν is p_μ/z_μ if $\mu = \nu$, and the result is equal to 0 otherwise.

`internal_product`, `kronecker_product`, `inner_tensor` and `itensor` are different names for the same function.

```
sage: f.kronecker_product(f)
s[1, 1, 1, 1] + 3*s[2, 1, 1] + 4*s[2, 2] + 5*s[3, 1] + 3*s[4]
```

Plethysm

The *plethysm* of symmetric functions is the operation corresponding to composition of representations of the general linear group. See [STA] Chapter 7, Appendix 2 for details.

```
sage: s[2].plethysm(s[2])
s[2, 2] + s[4]
```

Plethysm can also be written as a composition of functions:

```
sage: s[2]( s[2] )
s[2, 2] + s[4]
```

If the coefficient ring contains degree 1 elements, these are handled properly by plethysm:

```
sage: R.<t> = QQ[]; s = SymmetricFunctions(R).schur()
sage: s[2]( (1-t)*s[1] )
(t^2-t)*s[1, 1] + (-t+1)*s[2]
```

See the documentation for `plethysm` for more information.

Inner plethysm

The operation of inner plethysm `f.inner_plethysm(g)` models the composition of the S_n representation represented by g with the GL_m representation whose character is f . See the documentation of `inner_plethysm`, [ST94] or [STA], exercise 7.74 solutions for more information:

```
sage: s = SymmetricFunctions(QQ).schur()
sage: f = s[2]^2
sage: f.inner_plethysm(s[2])
s[2]
```

Hopf algebra structure

The ring of symmetric functions is further endowed with a coalgebra structure. The coproduct is an algebra morphism, and therefore determined by its values on the generators; the power sum generators are primitive:

```
sage: p[1].coproduct()
p[] # p[1] + p[1] # p[]
sage: p[2].coproduct()
p[] # p[2] + p[2] # p[]
```

The coproduct, being cocommutative on the generators, is cocommutative everywhere:

```
sage: p[2, 1].coproduct()
p[] # p[2, 1] + p[1] # p[2] + p[2] # p[1] + p[2, 1] # p[]
```

This coproduct, along with the counit which sends every symmetric function to its 0-th homogeneous component, makes the ring of symmetric functions into a graded connected bialgebra. It is known that every graded connected bialgebra has an antipode. For the ring of symmetric functions, the antipode can be characterized explicitly: The antipode is an anti-algebra morphism (thus an algebra morphism, since our algebra is commutative) which sends p_λ to $(-1)^{\text{length}(\lambda)} p_\lambda$ for every partition λ . Thus, in particular, it sends the generators on the p basis to their opposites:

```
sage: p[3].antipode()
-p[3]
sage: p[3, 2, 1].antipode()
-p[3, 2, 1]
```

The graded connected bialgebra of symmetric functions over a $\mathbf{Q}$ -algebra has a rather simply-understood structure: It is (isomorphic to) the symmetric algebra of its space of primitives (which is spanned by the power-sum symmetric functions).

Here are further examples:

```
sage: f = s[2]^2
sage: f.antipode()
s[1, 1, 1, 1] + s[2, 1, 1] + s[2, 2]
sage: f.coproduct()
s[] # s[2, 2] + s[] # s[3, 1] + s[] # s[4] + 2*s[1] # s[2, 1] + 2*s[1] # s[3] +
↪ s[1, 1] # s[1, 1]
+ s[1, 1] # s[2] + s[2] # s[1, 1] + 3*s[2] # s[2] + 2*s[2, 1] # s[1] + s[2, 2] #
↪ s[] + 2*s[3] # s[1]
+ s[3, 1] # s[] + s[4] # s[]
sage: f.coproduct().apply_multilinear_morphism( lambda x,y: x*y.antipode() )
0
```

Transformations of symmetric functions

There are many methods in Sage which make it easy to manipulate symmetric functions. For example, if we have some function which acts on partitions (say, conjugation), it is a simple matter to apply it to the support of a symmetric function. Here is an example:

```
sage: conj = lambda mu: mu.conjugate()
sage: f = h[4] + 2*h[3, 1]
sage: f.map_support(conj)
h[1, 1, 1, 1] + 2*h[2, 1, 1]
```

We can also easily modify the coefficients:

```
sage: def foo(mu, coeff): return mu.conjugate(), -coeff
sage: f.map_item(foo)
-h[1, 1, 1, 1] - 2*h[2, 1, 1]
```

See also `map_coefficients`.

There are also methods for building functions directly:

```

sage: s.sum_of_monomials(mu for mu in Partitions(3))
s[1, 1, 1] + s[2, 1] + s[3]
sage: s.sum_of_monomials(Partitions(3))
s[1, 1, 1] + s[2, 1] + s[3]
sage: s.sum_of_terms( (mu, mu[0]) for mu in Partitions(3))
s[1, 1, 1] + 2*s[2, 1] + 3*s[3]

```

These are the preferred way to build elements within a program; the result will usually be faster than using `sum()`. It also guarantees that empty sums yields the zero of `s` (see also `s.sum`).

Note also that it is a good idea to use:

```

sage: s.one()
s[]
sage: s.zero()
0

```

instead of `s(1)` and `s(0)` within programs where speed is important, in order to prevent unnecessary coercions.

Different base rings

Depending on the base ring, the different realizations of the symmetric function algebra may not span the same space:

```

sage: SZ = SymmetricFunctions(ZZ)
sage: p = SZ.power(); s = SZ.schur()
sage: p(s[1,1,1])
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer

```

Because of this, some functions may not behave as expected when working over the integers, even though they make mathematical sense:

```

sage: s[1,1,1].plethysm(s[1,1,1])
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer

```

It is possible to work over different base rings simultaneously:

```

sage: s = SymmetricFunctions(QQ).schur()
sage: p = SymmetricFunctions(QQ).power()
sage: sz = SymmetricFunctions(ZZ).schur(); sz._prefix = 'sz'
sage: pz = SymmetricFunctions(ZZ).power(); pz._prefix = 'pz'
sage: p(sz[1,1,1])
1/6*p[1, 1, 1] - 1/2*p[2, 1] + 1/3*p[3]
sage: sz( 1/6*p[1, 1, 1] - 1/2*p[2, 1] + 1/3*p[3] )
sz[1, 1, 1]

```

As shown in this example, if you are working over multiple base rings simultaneously, it is a good idea to change the prefix in some cases, so that you can tell from the output which realization your result is in.

Let us change the notation back for the remainder of this tutorial:

```

sage: sz._prefix = 's'
sage: pz._prefix = 'p'

```

One can also use the Sage standard renaming idiom to get shorter outputs:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.rename("Sym")
sage: Sym
Sym
sage: Sym.rename()
```

And we name it back:

```
sage: Sym.rename("Symmetric Functions over Rational Field"); Sym
Symmetric Functions over Rational Field
```

Other bases

There are two additional basis of the symmetric functions which are not considered as classical bases:

- forgotten basis
- Witt basis

The forgotten basis is the dual basis of the elementary symmetric functions basis with respect to the Hall scalar product. The Witt basis can be constructed by

$$\prod_{d=1}^{\infty} (1 - w_d t^d)^{-1} = \sum_{n=0}^{\infty} h_n t^n$$

where t is a formal variable.

There are further bases of the ring of symmetric functions, in general over fields with parameters such as q and t :

- Hall-Littlewood bases
- Jack bases
- Macdonald bases
- k -Schur functions

We briefly demonstrate how to access these bases. For more information, see the documentation of the individual bases.

The *Jack polynomials* can be obtained as:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: Jack = Sym.jack()
sage: P = Jack.P(); J = Jack.J(); Q = Jack.Q()
sage: J(P[2,1])
(1/(t+2))*JackJ[2, 1]
```

The parameter t can be specialized as follows:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Jack = Sym.jack(t = 1)
sage: P = Jack.P(); J = Jack.J(); Q = Jack.Q()
sage: J(P[2,1])
1/3*JackJ[2, 1]
```

Similarly one can access the Hall-Littlewood and Macdonald polynomials, etc:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Mcd = Sym.macdonald()
sage: P = Mcd.P(); J = Mcd.J(); Q = Mcd.Q()
sage: J(P[2,1])
(1/(-q*t^4+2*q*t^3-q*t^2+t^2-2*t+1))*McdJ[2, 1]

```

k -Schur functions

The k -Schur functions live in the k -bounded subspace of the ring of symmetric functions. It is possible to compute in the k -bounded subspace directly:

```

sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: f = ks[2,1]*ks[2,1]; f
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]

```

or to lift to the ring of symmetric functions:

```

sage: f.lift()
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1]
↪+ s[4, 2]

```

However, it is not always possible to convert a symmetric function to the k -bounded subspace:

```

sage: s = Sym.schur()
sage: ks(s[2,1,1])
Traceback (most recent call last):
...
ValueError: s[2, 1, 1] is not in the image

```

The k -Schur functions are more generally defined with a parameter t and they are a basis of the subspace spanned by the Hall-Littlewood Q_p symmetric functions indexed by partitions whose first part is less than or equal to k :

```

sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: SymS3 = Sym.kBoundedSubspace(3) # default t='t'
sage: ks = SymS3.kschur()
sage: Qp = Sym.hall_littlewood().Qp()
sage: ks(Qp[2,1,1,1])
ks3[2, 1, 1, 1] + (t^2+t)*ks3[2, 2, 1] + (t^3+t^2)*ks3[3, 1, 1] + t^4*ks3[3, 2]

```

The subspace spanned by the k -Schur functions with a parameter t are not known to form a natural algebra. However it is known that the product of a k -Schur function and an ℓ -Schur function is in the linear span of the $k + \ell$ -Schur functions:

```

sage: ks(ks[2,1]*ks[1,1])
Traceback (most recent call last):
...
ValueError: s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] is not in the image
sage: ks[2,1]*ks[1,1]
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2]
sage: ks6 = Sym.kBoundedSubspace(6).kschur()
sage: ks6(ks[3,1,1]*ks[3])
ks6[3, 3, 1, 1] + ks6[4, 2, 1, 1] + (t+1)*ks6[4, 3, 1] + t*ks6[4, 4]
+ ks6[5, 1, 1, 1] + ks6[5, 2, 1] + t*ks6[5, 3] + ks6[6, 1, 1]

```

The k -split basis is a second basis of the ring spanned by the k -Schur functions with a parameter t . The k -split basis has the property that $Q'_\lambda[X; t]$ expands positively in the k -split basis and the k -split basis conjecturally expands positively in the k -Schur functions. The definition can be found in [LLMSSZ] p. 81.:

```
sage: ksp3 = SymS3.ksplit()
sage: ksp3(Qp[2,1,1,1])
ksp3[2, 1, 1, 1] + t^2*ksp3[2, 2, 1] + (t^3+t^2)*ksp3[3, 1, 1] + t^4*ksp3[3, 2]
sage: [ks(ksp3(la)) for la in ksp3(Qp[2,1,1,1]).support()]
[ks3[2, 2, 1], ks3[2, 1, 1, 1] + t*ks3[2, 2, 1], ks3[3, 2], ks3[3, 1, 1]]
```

dual k -Schur functions

The dual space to the subspace spanned by the k -Schur functions is most naturally realized as a quotient of the ring of symmetric functions by an ideal. When $t = 1$ the ideal is generated by the monomial symmetric functions indexed by partitions whose first part is greater than k .

```
sage: Sym = SymmetricFunctions(QQ)
sage: SymQ3 = Sym.kBoundedQuotient(3,t=1)
sage: km = SymQ3.kmonomial()
sage: km[2,1]*km[2,1]
4*m3[2, 2, 1, 1] + 6*m3[2, 2, 2] + 2*m3[3, 2, 1] + 2*m3[3, 3]
sage: F = SymQ3.affineSchur()
sage: F[2,1]*F[2,1]
2*F3[1, 1, 1, 1, 1, 1] + 4*F3[2, 1, 1, 1, 1] + 4*F3[2, 2, 1, 1] + 4*F3[2, 2, 2]
+ 2*F3[3, 1, 1, 1] + 4*F3[3, 2, 1] + 2*F3[3, 3]
```

When t is not equal to 1, the subspace spanned by the k -Schur functions is realized as a quotient of the ring of symmetric functions by the ideal generated by the Hall-Littlewood symmetric functions in the P basis indexed by partitions with first part greater than k .

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: SymQ3 = Sym.kBoundedQuotient(3)
sage: kHLP = SymQ3.kHallLittlewoodP()
sage: kHLP[2,1]*kHLP[2,1]
(t^2+2*t+1)*HLP3[2, 2, 1, 1] + (t^3+2*t^2+2*t+1)*HLP3[2, 2, 2]
+ (-t^4-t^3+t+1)*HLP3[3, 1, 1, 1] + (-t^2+t+2)*HLP3[3, 2, 1] + (t+1)*HLP3[3, 3]
sage: HLP = Sym.hall_littlewood().P()
sage: kHLP(HLP[3,1])
HLP3[3, 1]
sage: kHLP(HLP[4])
0
```

In this space, the basis which is dual to the k -Schur functions conjecturally expands positively in the k -bounded Hall-Littlewood functions and has positive structure coefficients.:

```
sage: dks = SymQ3.dual_k_Schur()
sage: kHLP(dks[2,2])
(t^4+t^2)*HLP3[1, 1, 1, 1] + t*HLP3[2, 1, 1] + HLP3[2, 2]
sage: dks[2,1]*dks[1,1]
(t^2+t)*dks3[1, 1, 1, 1, 1] + (t+1)*dks3[2, 1, 1, 1] + (t+1)*dks3[2, 2, 1]
+ dks3[3, 1, 1] + dks3[3, 2]
```

At $t = 1$ the k -bounded Hall-Littlewood basis is equal to the k -bounded monomial basis and the dual k -Schur elements are equal to the affine Schur basis. The k -bounded monomial basis and affine Schur functions are faster and should be used instead of the k -bounded Hall-Littlewood P basis and dual k -Schur functions when $t = 1$.

```

sage: SymQ3 = Sym.kBoundedQuotient(3,t=1)
sage: dks = SymQ3.dual_k_Schur()
sage: F = SymQ3.affineSchur()
sage: F[3,1]==dks[3,1]
True

```

Implementing new bases

In order to implement a new symmetric function basis, Sage will need to know at a minimum how to change back and forth between at least one other basis (although they do not necessarily have to be the same basis). All of the standard functions associated with the basis will have a default implementation (although a more specific implementation may be more efficient).

To present an idea of how this is done, we will create here the example of how to implement the basis $s_\mu[X(1-t)]$.

To begin, we import the class `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic()`. Our new basis will inherit all of the default methods from this class:

```

sage: from sage.combinat.sf.sfa import SymmetricFunctionAlgebra_generic as SFA_
      ↪generic

```

Now the basis we are creating has a parameter t which is possible to specialize. In this example we will convert to and from the Schur basis. For this we implement methods `_self_to_s` and `_s_to_self`. By registering these two functions as coercions, Sage then knows automatically how it possible to change between any two bases for which there is a path of changes of bases.

```

sage: from sage.categories.morphism import SetMorphism
sage: class SFA_st(SFA_generic):
.....:     def __init__(self, Sym, t):
.....:         SFA_generic.__init__(self, Sym, basis_name=
.....:             "Schur functions with a plethystic substitution of X -> X(1-t)",
.....:             prefix='st')
.....:         self._s = Sym.s()
.....:         self.t = Sym.base_ring()(t)
.....:         cat = HopfAlgebras(Sym.base_ring()).WithBasis()
.....:         self.register_coercion(
.....:             SetMorphism(Hom(self._s, self, cat), self._s_to_self))
.....:         self._s.register_coercion(
.....:             SetMorphism(Hom(self, self._s, cat), self._self_to_s))
.....:     def _s_to_self(self, f):
.....:         # f is a Schur function and the output is in the st basis
.....:         return self._from_dict(f.theta_qt(0,self.t)._monomial_coefficients)
.....:     def _self_to_s(self, f):
.....:         # f is in the st basis and the output is in the Schur basis
.....:         return self._s.sum(cmu*self._s(mu).theta_qt(self.t,0) for mu,cmu in_
      ↪f)
.....:     class Element(SFA_generic.Element):
.....:         pass

```

An instance of this basis is created by calling it with a symmetric function ring `Sym` and a parameter `t` which is in the base ring of `Sym`. The `Element` class inherits all of the methods from `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`.

In the reference [MAC] on page 354, this basis is denoted $S_\lambda(x; t)$ and the change of basis coefficients of the Macdonald $\mathcal{J}$ basis are the coefficients $K_{\lambda\mu}(q, t)$. Here is an example of its use:

```

sage: QQqt = QQ['q', 't'].fraction_field()
sage: (q, t) = QQqt.gens()
sage: st = SFA_st(SymmetricFunctions(QQqt), t)
sage: st
Symmetric Functions over Fraction Field of Multivariate Polynomial
Ring in q, t over Rational Field in the Schur functions with a
plethystic substitution of X -> X(1-t) basis
sage: st[2, 1] * st[1]
st[2, 1, 1] + st[2, 2] + st[3, 1]
sage: st([2]).coproduct()
st[] # st[2] + st[1] # st[1] + st[2] # st[]
sage: J = st.symmetric_function_ring().macdonald().J()
sage: st(J[2, 1])
q*st[1, 1, 1] + (q*t+1)*st[2, 1] + t*st[3]

```

Acknowledgements

The design is heavily inspired from the implementation of symmetric functions in MuPAD-Combinat (see [\[HT04\]](#) and [\[FD06\]](#)).

REFERENCES:

Further tests

Todo

- Introduce fields with degree 1 elements as in MuPAD-Combinat, to get proper plethysm.
- Use UniqueRepresentation to get rid of all the manual cache handling for the bases
- Devise a mechanism so that pickling bases of symmetric functions pickles the coercions which have a cache.

Schur()

The Schur basis of the Symmetric Functions

EXAMPLES:

```

sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis

```

Witt (coerce_h=True, coerce_e=False, coerce_p=False)

The Witt basis of the symmetric functions.

EXAMPLES:

```

sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_h=False, coerce_e=True, coerce_
↪ p=True)
Symmetric Functions over Rational Field in the Witt basis

```

a_realization()

Return a particular realization of `self` (the Schur basis).

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.a_realization()
Symmetric Functions over Rational Field in the Schur basis
```

complete()

The complete basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

e()

The elementary basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).elementary()
Symmetric Functions over Rational Field in the elementary basis
```

elementary()

The elementary basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).elementary()
Symmetric Functions over Rational Field in the elementary basis
```

f()

The forgotten basis of the Symmetric Functions (or the basis dual to the elementary basis with respect to the Hall scalar product).

EXAMPLES:

```
sage: SymmetricFunctions(QQ).forgotten()
Symmetric Functions over Rational Field in the forgotten basis
```

forgotten()

The forgotten basis of the Symmetric Functions (or the basis dual to the elementary basis with respect to the Hall scalar product).

EXAMPLES:

```
sage: SymmetricFunctions(QQ).forgotten()
Symmetric Functions over Rational Field in the forgotten basis
```

from_polynomial(f)

Converts a symmetric polynomial f to a symmetric function.

INPUT:

- f – a symmetric polynomial

This function converts a symmetric polynomial f in a polynomial ring in finitely many variables to a symmetric function in the monomial basis of the ring of symmetric functions over the same base ring.

EXAMPLES:

```
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: S = SymmetricFunctions(QQ)
sage: S.from_polynomial(f)
m[1]

sage: f = x[0] + 2*x[1] + x[2]
sage: S.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0 + 2*x1 + x2 is not a symmetric polynomial
```

h()

The complete basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

hall_littlewood($t='t'$)

Returns the entry point for the various Hall-Littlewood bases.

INPUT:

- t – parameter

Hall-Littlewood symmetric functions including bases P , Q , Qp . The Hall-Littlewood P and Q functions at $t = -1$ are the Schur-P and Schur-Q functions when indexed by strict partitions.

The parameter t must be in the base ring of parent.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: P = Sym.hall_littlewood().P(); P
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳ over Rational Field in the Hall-Littlewood P basis
sage: P[2]
HLP[2]
sage: Q = Sym.hall_littlewood().Q(); Q
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳ over Rational Field in the Hall-Littlewood Q basis
sage: Q[2]
HLQ[2]
sage: Qp = Sym.hall_littlewood().Qp(); Qp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳ over Rational Field in the Hall-Littlewood Qp basis
sage: Qp[2]
HLQp[2]
```

homogeneous()

The complete basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

ht()

The induced trivial character basis of the Symmetric Functions.

The trivial character of

$$S_{n-|\lambda|} \times S_{\lambda_1} \times S_{\lambda_2} \times \cdots \times S_{\lambda_\ell(\lambda)}$$

induced to the group S_n is a symmetric function in the eigenvalues of a permutation matrix. This basis is that character.

It has the property that if the element indexed by the partition λ is evaluated at the roots of a permutation of cycle structure ρ then the value is the coefficient $\langle h_{(n-|\lambda|, \lambda)}, p_\rho \rangle$.

In terms of methods that are implemented in Sage, if n is a sufficiently large integer, then `ht(lam).character_to_frobenius_image(n)` is equal the complete function indexed by `[n-sum(lam)]+lam`.

This basis is introduced in [OZ2015].

See also:

`character_to_frobenius_image()`, `eval_at_permutation_roots()`

EXAMPLES:

```
sage: SymmetricFunctions(QQ).induced_trivial_character()
Symmetric Functions over Rational Field in the induced trivial character basis
sage: ht = SymmetricFunctions(QQ).ht()
sage: h = SymmetricFunctions(QQ).h()
sage: h(ht([3,2]).character_to_frobenius_image(9))
h[4, 3, 2]
sage: h(ht([3,2]).character_to_frobenius_image(7))
h[3, 2, 2]
sage: h(ht([3,2]).character_to_frobenius_image(5))
h[3, 2]
sage: h(ht([3,2]).character_to_frobenius_image(4))
0
sage: p = SymmetricFunctions(QQ).p()
sage: [h([4,1]).scalar(p(rho)) for rho in Partitions(5)]
[0, 1, 0, 2, 1, 3, 5]
sage: [ht([1]).eval_at_permutation_roots(rho) for rho in Partitions(5)]
[0, 1, 0, 2, 1, 3, 5]
```

induced_trivial_character()

The induced trivial character basis of the Symmetric Functions.

The trivial character of

$$S_{n-|\lambda|} \times S_{\lambda_1} \times S_{\lambda_2} \times \cdots \times S_{\lambda_\ell(\lambda)}$$

induced to the group S_n is a symmetric function in the eigenvalues of a permutation matrix. This basis is that character.

It has the property that if the element indexed by the partition λ is evaluated at the roots of a permutation of cycle structure ρ then the value is the coefficient $\langle h_{(n-|\lambda|, \lambda)}, p_\rho \rangle$.

In terms of methods that are implemented in Sage, if n is a sufficiently large integer, then `ht(lam).character_to_frobenius_image(n)` is equal the complete function indexed by `[n-sum(lam)]+lam`.

This basis is introduced in [OZ2015].

See also:

`character_to_frobenius_image()`, `eval_at_permutation_roots()`

EXAMPLES:

```
sage: SymmetricFunctions(QQ).induced_trivial_character()
Symmetric Functions over Rational Field in the induced trivial character basis
sage: ht = SymmetricFunctions(QQ).ht()
sage: h = SymmetricFunctions(QQ).h()
sage: h(ht([3,2]).character_to_frobenius_image(9))
h[4, 3, 2]
sage: h(ht([3,2]).character_to_frobenius_image(7))
h[3, 2, 2]
sage: h(ht([3,2]).character_to_frobenius_image(5))
h[3, 2]
sage: h(ht([3,2]).character_to_frobenius_image(4))
0
sage: p = SymmetricFunctions(QQ).p()
sage: [h([4,1]).scalar(p(rho)) for rho in Partitions(5)]
[0, 1, 0, 2, 1, 3, 5]
sage: [ht([1]).eval_at_permutation_roots(rho) for rho in Partitions(5)]
[0, 1, 0, 2, 1, 3, 5]
```

`irreducible_symmetric_group_character()`

The irreducible S_n character basis of the Symmetric Functions.

This basis has the property that if the element indexed by the partition λ is evaluated at the roots of a permutation of cycle structure ρ then the value is the irreducible character $\chi^{(|\rho| - |\lambda|, \lambda)}(\rho)$.

In terms of methods that are implemented in Sage, if n is a sufficiently large integer, then `st(lam).character_to_frobenius_image(n)` is equal the Schur function indexed by `[n-sum(lam)]+lam`.

This basis is introduced in [OZ2015].

See also:

`character_to_frobenius_image()`, `eval_at_permutation_roots()`

EXAMPLES:

```
sage: SymmetricFunctions(QQ).irreducible_symmetric_group_character()
Symmetric Functions over Rational Field in the irreducible symmetric group_
↪character basis
sage: st = SymmetricFunctions(QQ).st()
sage: s = SymmetricFunctions(QQ).s()
sage: s(st([3,2]).character_to_frobenius_image(9))
s[4, 3, 2]
sage: s(st([3,2]).character_to_frobenius_image(7))
0
sage: s(st([3,2]).character_to_frobenius_image(6))
-s[2, 2, 2]
sage: list(SymmetricGroup(5).character_table()[-2])
[4, 2, 0, 1, -1, 0, -1]
sage: list(reversed([st([1]).eval_at_permutation_roots(rho) \
....:   for rho in Partitions(5)]))
[4, 2, 0, 1, -1, 0, -1]
```

`jack(t='t')`

Returns the entry point for the various Jack bases.

INPUT:

- t – parameter

Jack symmetric functions including bases P , Q , Qp .

The parameter t must be in the base ring of parent.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P(); JP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳over Rational Field in the Jack P basis
sage: JQ = Sym.jack().Q(); JQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳over Rational Field in the Jack Q basis
sage: JJ = Sym.jack().J(); JJ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳over Rational Field in the Jack J basis
sage: JQp = Sym.jack().Qp(); JQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳over Rational Field in the Jack Qp basis
```

kBoundedQuotient ($k, t='t'$)

Returns the k -bounded quotient space of the ring of symmetric functions.

INPUT:

- k - a positive integer

The quotient of the ring of symmetric functions ...

See also:

`sage.combinat.sf.k_dual.KBoundedQuotient()`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: KQ = Sym.kBoundedQuotient(3); KQ
Traceback (most recent call last):
...
TypeError: unable to convert 't' to a rational
sage: KQ = Sym.kBoundedQuotient(3,t=1); KQ
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1
sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: KQ = Sym.kBoundedQuotient(3); KQ
3-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate
↳Polynomial Ring in t over Rational Field
```

kBoundedSubspace ($k, t='t'$)

Return the k -bounded subspace of the ring of symmetric functions.

INPUT:

- k - a positive integer
- t a formal parameter; $t = 1$ yields a subring

The subspace of the ring of symmetric functions spanned by $\{s_\lambda[X/(1-t)]\}_{\lambda_1 \leq k} = \{s_\lambda^{(k)}[X, t]\}_{\lambda_1 \leq k}$ over the base ring $\mathbb{Q}[t]$. When $t = 1$, this space is in fact a subalgebra of the ring of symmetric functions generated by the complete homogeneous symmetric functions h_i for $1 \leq i \leq k$.

See also:

`sage.combinat.sf.new_kschur.KBoundedSubspace()`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: KB = Sym.kBoundedSubspace(3,1); KB
3-bounded Symmetric Functions over Rational Field with t=1

sage: Sym = SymmetricFunctions(QQ['t'])
sage: Sym.kBoundedSubspace(3)
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over
↪ Rational Field

sage: Sym = SymmetricFunctions(QQ['z'])
sage: z = Sym.base_ring().gens()[0]
sage: Sym.kBoundedSubspace(3,t=z)
3-bounded Symmetric Functions over Univariate Polynomial Ring in z over
↪ Rational Field with t=z
```

khomogeneous (k)

Returns the homogeneous symmetric functions in the k -bounded subspace.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: kh = Sym.khomogeneous(4)
sage: kh[3]*kh[4]
h4[4, 3]
sage: kh[4].lift()
h[4]
```

kschur ($k, t='t'$)

Returns the k -Schur functions.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: ks[2]*ks[2]
ks3[2, 2] + ks3[3, 1]
sage: ks[2,1,1].lift()
s[2, 1, 1] + s[3, 1]

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks = Sym.kschur(3)
sage: ks[2,2,1].lift()
s[2, 2, 1] + t*s[3, 2]
```

ksplit ($k, t='t'$)

Returns the k -split basis of the k -bounded subspace.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ksp = Sym.ksplit(3,1)
sage: ksp[2]*ksp[2]
ksp3[2, 2] + ksp3[3, 1]
sage: ksp[2,1,1].lift()
```

```
s[2, 1, 1] + s[2, 2] + s[3, 1]

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ksp = Sym.ksplit(3)
sage: ksp[2,1,1].lift()
s[2, 1, 1] + t*s[2, 2] + t*s[3, 1]
```

llt ($k, t='t'$)

The LLT symmetric functions.

INPUT:

- k – a positive integer indicating the level
- t – a parameter (default: t)

LLT polynomials in *hspin* and *hcospin* bases.

EXAMPLES:

```
sage: llt3 = SymmetricFunctions(QQ['t'].fraction_field()).llt(3); llt3
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in t
↳ over Rational Field
sage: llt3.hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳ over Rational Field in the level 3 LLT spin basis
sage: llt3.hcospin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳ over Rational Field in the level 3 LLT cospin basis
sage: llt3.hcospin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
↳ over Rational Field in the level 3 LLT cospin basis
```

m ()

The monomial basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).monomial()
Symmetric Functions over Rational Field in the monomial basis
```

macdonald ($q='q', t='t'$)

Returns the entry point for the various Macdonald bases.

INPUT:

- q, t – parameters

Macdonald symmetric functions including bases P, Q, J, H, Ht . This also contains the S basis which is dual to the Schur basis with respect to the q, t scalar product.

The parameters q and t must be in the `base_ring` of parent.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
↳ over Rational Field in the Macdonald P basis
sage: P[2]
McdP[2]
```

```

sage: Q = Sym.macdonald().Q(); Q
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,
↪ t over Rational Field in the Macdonald Q basis
sage: S = Sym.macdonald().S()
sage: s = Sym.schur()
sage: matrix([[S(la).scalar_qt(s(mu)) for la in Partitions(3)] for mu in
↪ Partitions(3)])
[1 0 0]
[0 1 0]
[0 0 1]
sage: H = Sym.macdonald().H()
sage: s(H[2,2])
q^2*s[1, 1, 1, 1] + (q^2*t+q*t+q)*s[2, 1, 1] + (q^2*t^2+1)*s[2, 2] + (q*t^
↪ 2+q*t+t)*s[3, 1] + t^2*s[4]

sage: Sym = SymmetricFunctions(QQ['z','q'].fraction_field())
sage: (z,q) = Sym.base_ring().gens()
sage: Hzq = Sym.macdonald(q=z,t=q).H()
sage: H1z = Sym.macdonald(q=1,t=z).H()
sage: s = Sym.schur()
sage: s(H1z([2,2]))
s[1, 1, 1, 1] + (2*z+1)*s[2, 1, 1] + (z^2+1)*s[2, 2] + (z^2+2*z)*s[3, 1] + z^
↪ 2*s[4]
sage: s(Hzq[2,2])
z^2*s[1, 1, 1, 1] + (z^2*q+z*q+z)*s[2, 1, 1] + (z^2*q^2+1)*s[2, 2] + (z*q^
↪ 2+z*q+q)*s[3, 1] + q^2*s[4]
sage: s(H1z(Hzq[2,2]))
z^2*s[1, 1, 1, 1] + (z^2*q+z*q+z)*s[2, 1, 1] + (z^2*q^2+1)*s[2, 2] + (z*q^
↪ 2+z*q+q)*s[3, 1] + q^2*s[4]

```

monomial()

The monomial basis of the Symmetric Functions

EXAMPLES:

```

sage: SymmetricFunctions(QQ).monomial()
Symmetric Functions over Rational Field in the monomial basis

```

o()

The orthogonal basis of the symmetric functions.

See also:

[*SymmetricFunctionAlgebra_orthogonal*](#)

EXAMPLES:

```

sage: SymmetricFunctions(QQ).orthogonal()
Symmetric Functions over Rational Field in the orthogonal basis

```

orthogonal()

The orthogonal basis of the symmetric functions.

See also:

[*SymmetricFunctionAlgebra_orthogonal*](#)

EXAMPLES:

```
sage: SymmetricFunctions(QQ).orthogonal()
Symmetric Functions over Rational Field in the orthogonal basis
```

p()

The power sum basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

power()

The power sum basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

powersum()

The power sum basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

register_isomorphism(morphism, only_conversion=False)

Register an isomorphism between two bases of self, as a canonical coercion (unless the optional keyword only_conversion is set to True, in which case the isomorphism is registered as conversion only).

EXAMPLES:

We override the canonical coercion from the Schur basis to the powersum basis by a (stupid!) map $s_\lambda \mapsto 2p_\lambda$.

```
sage: Sym = SymmetricFunctions(QQ['zorglub']) # make sure we are not going to
↪screw up later tests
sage: s = Sym.s(); p = Sym.p().dual_basis()
sage: phi = s.module_morphism(diagonal = lambda t: 2, codomain = p)
sage: phi(s[2, 1])
2*d_p[2, 1]
sage: Sym.register_isomorphism(phi)
sage: p(s[2, 1])
2*d_p[2, 1]
```

The map is supposed to implement the canonical isomorphism between the two bases. Otherwise, the results will be mathematically wrong, as above. Use with care!

s()

The Schur basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

schur()

The Schur basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

sp()

The symplectic basis of the symmetric functions.

See also:

SymmetricFunctionAlgebra_symplectic

EXAMPLES:

```
sage: SymmetricFunctions(QQ).symplectic()
Symmetric Functions over Rational Field in the symplectic basis
```

st()

The irreducible S_n character basis of the Symmetric Functions.

This basis has the property that if the element indexed by the partition λ is evaluated at the roots of a permutation of cycle structure ρ then the value is the irreducible character $\chi^{(|\rho| - |\lambda|, \lambda)}(\rho)$.

In terms of methods that are implemented in Sage, if n is a sufficiently large integer, then `st(lam).character_to_frobenius_image(n)` is equal the Schur function indexed by `[n - sum(lam)] + lam`.

This basis is introduced in [OZ2015].

See also:

character_to_frobenius_image(), eval_at_permutation_roots()

EXAMPLES:

```
sage: SymmetricFunctions(QQ).irreducible_symmetric_group_character()
Symmetric Functions over Rational Field in the irreducible symmetric group_
↪character basis
sage: st = SymmetricFunctions(QQ).st()
sage: s = SymmetricFunctions(QQ).s()
sage: s(st([3,2]).character_to_frobenius_image(9))
s[4, 3, 2]
sage: s(st([3,2]).character_to_frobenius_image(7))
0
sage: s(st([3,2]).character_to_frobenius_image(6))
-s[2, 2, 2]
sage: list(SymmetricGroup(5).character_table()[-2])
[4, 2, 0, 1, -1, 0, -1]
sage: list(reversed([st([1]).eval_at_permutation_roots(rho) \
....:   for rho in Partitions(5)]))
[4, 2, 0, 1, -1, 0, -1]
```

symplectic()

The symplectic basis of the symmetric functions.

See also:

SymmetricFunctionAlgebra_symplectic

EXAMPLES:

```
sage: SymmetricFunctions(QQ).symplectic()
Symmetric Functions over Rational Field in the symplectic basis
```

w (*coerce_h=True, coerce_e=False, coerce_p=False*)

The Witt basis of the symmetric functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_h=False, coerce_e=True, coerce_
↪p=True)
Symmetric Functions over Rational Field in the Witt basis
```

witt (*coerce_h=True, coerce_e=False, coerce_p=False*)

The Witt basis of the symmetric functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_h=False, coerce_e=True, coerce_
↪p=True)
Symmetric Functions over Rational Field in the Witt basis
```

zonal ()

The zonal basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).zonal()
Symmetric Functions over Rational Field in the zonal basis
```

class sage.combinat.sf.sf.**SymmetriconConversionOnBasis** (*t, domain, codomain*)

Initialization of self.

INPUT:

- **t** – a function taking a monomial in **CombinatorialFreeModule(QQ, Partitions())**, and returning a (partition, coefficient) list.
- domain, codomain – parents

Construct a function mapping a partition to an element of codomain.

This is a temporary quick hack to wrap around the existing symmetricon conversions, without changing their specs.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['x'])
sage: p = Sym.p(); s = Sym.s()
sage: def t(x) : [(p,c)] = x; return [ (p,2*c), (p.conjugate(), c) ]
sage: f = sage.combinat.sf.sf.SymmetriconConversionOnBasis(t, p, s)
sage: f(Partition([3,1]))
s[2, 1, 1] + 2*s[3, 1]
```

5.1.280 Symmetric Functions

For a comprehensive tutorial on how to use symmetric functions in Sage

See also:

`SymmetricFunctions()`

We define the algebra of symmetric functions in the Schur and elementary bases:

```
sage: s = SymmetricFunctions(QQ).schur()
sage: e = SymmetricFunctions(QQ).elementary()
```

Each is actually a graded Hopf algebra whose basis is indexed by integer partitions:

```
sage: s.category()
Category of graded bases of Symmetric Functions over Rational Field
sage: s.basis().keys()
Partitions
```

Let us compute with some elements in different bases:

```
sage: f1 = s([2,1]); f1
s[2, 1]
sage: f2 = e(f1); f2 # basis conversion
e[2, 1] - e[3]
sage: f1 == f2
True
sage: f1.expand(3, alphabet=['x','y','z'])
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
sage: f2.expand(3, alphabet=['x','y','z'])
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
```

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: m([3,1])
m[3, 1]
sage: m(4) # This is the constant 4, not the partition 4.
4*m[]
sage: m([4]) # This is the partition 4.
m[4]
sage: 3*m([3,1]) - 1/2*m([4])
3*m[3, 1] - 1/2*m[4]
```

```
sage: p = SymmetricFunctions(QQ).power()
sage: f = p(3)
sage: f
3*p[]
sage: f.parent()
Symmetric Functions over Rational Field in the powersum basis
sage: f + p([3,2])
3*p[] + p[3, 2]
```

One can convert symmetric functions to symmetric polynomials and vice versa:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.powersum()
sage: h = Sym.homogeneous()
sage: f = h[2,1] + 2*p[3,1]
sage: poly = f.expand(3); poly
```

```

2*x0^4 + 2*x0^3*x1 + 2*x0*x1^3 + 2*x1^4 + 2*x0^3*x2 + 2*x1^3*x2 + 2*x0*x2^3 + 2*x1*x2^
↪ 3 + 2*x2^4
+ x0^3 + 2*x0^2*x1 + 2*x0*x1^2 + x1^3 + 2*x0^2*x2 + 3*x0*x1*x2 + 2*x1^2*x2 + 2*x0*x2^
↪ 2 + 2*x1*x2^2 + x2^3
sage: Sym.from_polynomial(poly)
3*m[1, 1, 1] + 2*m[2, 1] + m[3] + 2*m[3, 1] + 2*m[4]
sage: Sym.from_polynomial(poly) == f
True
sage: g = h[1,1,1,1]
sage: poly = g.expand(3)
sage: Sym.from_polynomial(poly) == g
False

```

```

sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: p = Sym.p()
sage: e = Sym.e()
sage: m = Sym.m()
sage: a = s([3,1])
sage: s(a)
s[3, 1]
sage: h(a)
h[3, 1] - h[4]
sage: p(a)
1/8*p[1, 1, 1, 1] + 1/4*p[2, 1, 1] - 1/8*p[2, 2] - 1/4*p[4]
sage: e(a)
e[2, 1, 1] - e[2, 2] - e[3, 1] + e[4]
sage: m(a)
3*m[1, 1, 1, 1] + 2*m[2, 1, 1] + m[2, 2] + m[3, 1]
sage: a.expand(4)
x0^3*x1 + x0^2*x1^2 + x0*x1^3 + x0^3*x2 + 2*x0^2*x1*x2 + 2*x0*x1^2*x2 + x1^3*x2 + x0^
↪ 2*x2^2 + 2*x0*x1*x2^2 + x1^2*x2^2 + x0*x2^3 + x1*x2^3 + x0^3*x3 + 2*x0^2*x1*x3 +
↪ 2*x0*x1^2*x3 + x1^3*x3 + 2*x0^2*x2*x3 + 3*x0*x1*x2*x3 + 2*x1^2*x2*x3 + 2*x0*x2^2*x3
↪ + 2*x1*x2^2*x3 + x2^3*x3 + x0^2*x3^2 + 2*x0*x1*x3^2 + x1^2*x3^2 + 2*x0*x2*x3^2 +
↪ 2*x1*x2*x3^2 + x2^2*x3^2 + x0*x3^3 + x1*x3^3 + x2*x3^3

```

Here are further examples:

```

sage: h(m([1]))
h[1]
sage: h( m([2]) + m([1,1]) )
h[2]
sage: h( m([3]) + m([2,1]) + m([1,1,1]) )
h[3]
sage: h( m([4]) + m([3,1]) + m([2,2]) + m([2,1,1]) + m([1,1,1,1]) )
h[4]
sage: k = 5
sage: h( sum([ m(part) for part in Partitions(k)]) )
h[5]
sage: k = 10
sage: h( sum([ m(part) for part in Partitions(k)]) )
h[10]

```

```

sage: P3 = Partitions(3)
sage: P3.list()
[[3], [2, 1], [1, 1, 1]]

```

```

sage: m = SymmetricFunctions(QQ).monomial()
sage: f = sum([m(p) for p in P3])
sage: m.get_print_style()
'lex'
sage: f
m[1, 1, 1] + m[2, 1] + m[3]
sage: m.set_print_style('length')
sage: f
m[3] + m[2, 1] + m[1, 1, 1]
sage: m.set_print_style('maximal_part')
sage: f
m[1, 1, 1] + m[2, 1] + m[3]
sage: m.set_print_style('lex')

```

```

sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: m = Sym.m()
sage: m([3])*s([2,1])
2*m[3, 1, 1, 1] + m[3, 2, 1] + 2*m[4, 1, 1] + m[4, 2] + m[5, 1]
sage: s(m([3])*s([2,1]))
s[2, 1, 1, 1, 1] - s[2, 2, 2] - s[3, 3] + s[5, 1]
sage: s(s([2,1])*m([3]))
s[2, 1, 1, 1, 1] - s[2, 2, 2] - s[3, 3] + s[5, 1]
sage: e = Sym.e()
sage: e([4])*e([3])*e([1])
e[4, 3, 1]

```

```

sage: s = SymmetricFunctions(QQ).s()
sage: z = s([2,1]) + s([1,1,1])
sage: z.coefficient([2,1])
1
sage: z.length()
2
sage: z.support()
[[1, 1, 1], [2, 1]]
sage: z.degree()
3

```

AUTHORS:

class sage.combinat.sf.sfa.**FilteredSymmetricFunctionsBases** (*parent_with_realization*)
 Bases: sage.categories.realizations.Category_realization_of_parent

The category of filtered bases of the ring of symmetric functions.

super_categories()
 The super categories of self.

EXAMPLES:

```

sage: from sage.combinat.sf.sfa import FilteredSymmetricFunctionsBases
sage: Sym = SymmetricFunctions(QQ)

```

```

sage: bases = FilteredSymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of bases of Symmetric Functions over Rational Field,
Join of Category of hopf algebras with basis over Rational Field
and Category of filtered algebras with basis over Rational Field
and Category of commutative algebras over Rational Field]

```

class sage.combinat.sf.sfa.**GradedSymmetricFunctionsBases** (*parent_with_realization*)
 Bases: sage.categories.realizations.Category_realization_of_parent

The category of graded bases of the ring of symmetric functions.

These are further required to have the property that the basis element indexed by the empty partition is 1.

class ElementMethods

degree_negation()

Return the image of `self` under the degree negation automorphism of the ring of symmetric functions.

The degree negation is the automorphism which scales every homogeneous element of degree k by $(-1)^k$ (for all k).

Calling `degree_negation(self)` is equivalent to calling `self.parent().degree_negation(self)`.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 4*m[1,1] - 5*m[1] - 3*m[[]]
sage: f.degree_negation()
-3*m[] + 5*m[1] + 4*m[1, 1] - 2*m[2, 1]
sage: x = m.zero().degree_negation(); x
0
sage: parent(x) is m
True

```

degree_zero_coefficient()

Returns the degree zero coefficient of `self`.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 3*m[[]]
sage: f.degree_zero_coefficient()
3

```

class GradedSymmetricFunctionsBases.**ParentMethods**

antipode_by_coercion (*element*)

The antipode of `element`.

INPUT:

- `element` – element in a basis of the ring of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: s = Sym.s()
sage: e = Sym.e()
sage: h = Sym.h()
sage: (h([]) + h([1])).antipode() # indirect doctest
h[] - h[1]
sage: (s([]) + s([1]) + s[2]).antipode()
s[] - s[1] + s[1, 1]
sage: (p([2]) + p([3])).antipode()
-p[2] - p[3]
sage: (e([2]) + e([3])).antipode()
e[1, 1] - e[1, 1, 1] - e[2] + 2*e[2, 1] - e[3]
sage: f = Sym.f()
sage: f([3, 2, 1]).antipode()
-f[3, 2, 1] - 4*f[3, 3] - 2*f[4, 2] - 2*f[5, 1] - 6*f[6]

```

The antipode is an involution:

```

sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.s()
sage: all( s[u].antipode().antipode() == s[u] for u in Partitions(4) )
True

```

The antipode is an algebra homomorphism:

```

sage: Sym = SymmetricFunctions(FiniteField(23))
sage: h = Sym.h()
sage: all( all( (s[u] * s[v]).antipode() == s[u].antipode() * s[v].
↪ antipode()
....:         for u in Partitions(3) )
....:         for v in Partitions(3) )
True

```

counit (*element*)

Return the counit of *element*.

The counit is the constant term of *element*.

INPUT:

- *element* – element in a basis of the ring of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: f = 2*m[2, 1] + 3*m[[]]
sage: f.counit()
3

```

degree_negation (*element*)

Return the image of *element* under the degree negation automorphism of the ring of symmetric functions.

The degree negation is the automorphism which scales every homogeneous element of degree k by $(-1)^k$ (for all k).

INPUT:

- *element* – symmetric function written in *self*

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 4*m[1,1] - 5*m[1] - 3*m[[]]
sage: m.degree_negation(f)
-3*m[] + 5*m[1] + 4*m[1, 1] - 2*m[2, 1]
```

`GradedSymmetricFunctionsBases.super_categories()`

The super categories of self.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import GradedSymmetricFunctionsBases
sage: Sym = SymmetricFunctions(QQ)
sage: bases = GradedSymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of filtered bases of Symmetric Functions over Rational Field,
Category of commutative graded hopf algebras with basis over Rational Field]
```

```
class sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic(Sym,          ba-
                                                             sis_name=None,
                                                             prefix=None,
                                                             graded=True)
```

Bases: `sage.combinat.free_module.CombinatorialFreeModule`

Abstract base class for symmetric function algebras.

Todo

Most of the methods in this class are generic (manipulations of morphisms, ...) and should be generalized (or removed)

Element

alias of `SymmetricFunctionAlgebra_generic_Element`

basis_name()

Return the name of the basis of self.

This is used for output and, for the classical bases of symmetric functions, to connect this basis with Symmetriza.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: s.basis_name()
'Schur'
sage: p = Sym.p()
sage: p.basis_name()
'powersum'
sage: h = Sym.h()
sage: h.basis_name()
'homogeneous'
sage: e = Sym.e()
sage: e.basis_name()
'elementary'
sage: m = Sym.m()
sage: m.basis_name()
```

```
'monomial'
sage: f = Sym.f()
sage: f.basis_name()
'forgotten'
```

coproduct_by_coercion(*elt*)

Return the coproduct of the element *elt* by coercion to the Schur basis.

INPUT:

- *elt* – an instance of this basis

OUTPUT:

- The image of *elt* under the comultiplication (=coproduct) of the coalgebra of symmetric functions. The result is an element of the tensor squared of the basis *self*.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: m[3,1,1].coproduct()
m[] # m[3, 1, 1] + m[1] # m[3, 1] + m[1, 1] # m[3] + m[3] # m[1, 1] + m[3, 1]
↪ # m[1] + m[3, 1, 1] # m[]
sage: m.coproduct_by_coercion(m[2,1])
m[] # m[2, 1] + m[1] # m[2] + m[2] # m[1] + m[2, 1] # m[]
sage: m.coproduct_by_coercion(m[2,1]) == m[2,1].coproduct()
True
sage: McdH = SymmetricFunctions(QQ['q','t'].fraction_field()).macdonald().H()
sage: McdH[2,1].coproduct()
McdH[] # McdH[2, 1] + ((q^2*t-1)/(q*t-1))*McdH[1] # McdH[1, 1] + ((q*t^2-1)/
↪ (q*t-1))*McdH[1] # McdH[2] + ((q^2*t-1)/(q*t-1))*McdH[1, 1] # McdH[1] +
↪ ((q*t^2-1)/(q*t-1))*McdH[2] # McdH[1] + McdH[2, 1] # McdH[]
sage: HLQp = SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood().
↪ Qp()
sage: HLQp[2,1].coproduct()
HLQp[] # HLQp[2, 1] + HLQp[1] # HLQp[1, 1] + HLQp[1] # HLQp[2] + HLQp[1, 1] #
↪ HLQp[1] + HLQp[2] # HLQp[1] + HLQp[2, 1] # HLQp[]
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: LLT = Sym.llt(3)
sage: LLT.cospin([3,2,1]).coproduct()
(t+1)*m[] # m[1, 1] + m[] # m[2] + (t+1)*m[1] # m[1] + (t+1)*m[1, 1] # m[] +
↪ m[2] # m[]
sage: f = SymmetricFunctions(ZZ).f()
sage: f[3].coproduct()
f[] # f[3] + f[3] # f[]
sage: f[3,2,1].coproduct()
f[] # f[3, 2, 1] + f[1] # f[3, 2] + f[2] # f[3, 1] + f[2, 1] # f[3] + f[3] #
↪ f[2, 1] + f[3, 1] # f[2] + f[3, 2] # f[1] + f[3, 2, 1] # f[]
```

dual_basis(*scalar=None, scalar_name='', basis_name=None, prefix=None*)

Return the dual basis of *self* with respect to the scalar product *scalar*.

INPUT:

- *scalar* – A function *zee* from partitions to the base ring which specifies the scalar product by $\langle p_\lambda, p_\lambda \rangle = \text{zee}(\lambda)$. (Independently on the function chosen, the power sum basis will always be orthogonal; the function *scalar* only determines the norms of the basis elements.) If *scalar* is *None*, then the standard (Hall) scalar product is used.
- *scalar_name* – name of the scalar function

- `prefix` – prefix used to display the basis

EXAMPLES:

The duals of the elementary symmetric functions with respect to the Hall scalar product are the forgotten symmetric functions.

```
sage: e = SymmetricFunctions(QQ).e()
sage: f = e.dual_basis(prefix='f'); f
Dual basis to Symmetric Functions over Rational Field in the elementary basis
↳with respect to the Hall scalar product
sage: f([2,1])^2
4*f[2, 2, 1, 1] + 6*f[2, 2, 2] + 2*f[3, 2, 1] + 2*f[3, 3] + 2*f[4, 1, 1] +
↳f[4, 2]
sage: f([2,1]).scalar(e([2,1]))
1
sage: f([2,1]).scalar(e([1,1,1]))
0
```

Since the power-sum symmetric functions are orthogonal, their duals with respect to the Hall scalar product are scalar multiples of themselves.

```
sage: p = SymmetricFunctions(QQ).p()
sage: q = p.dual_basis(prefix='q'); q
Dual basis to Symmetric Functions over Rational Field in the powersum basis
↳with respect to the Hall scalar product
sage: q([2,1])^2
4*q[2, 2, 1, 1]
sage: p([2,1]).scalar(q([2,1]))
1
sage: p([2,1]).scalar(q([1,1,1]))
0
```

from_polynomial (*poly*, *check=True*)

Convert polynomial to a symmetric function in the monomial basis and then to the basis `self`.

INPUT:

- `poly` – a symmetric polynomial
- `check` – (default: `True`) boolean, specifies whether the computation checks that the polynomial is indeed symmetric

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: h = Sym.homogeneous()
sage: f = (h([]) + h([2,1]) + h([3])).expand(3)
sage: h.from_polynomial(f)
h[] + h[2, 1] + h[3]
sage: s = Sym.s()
sage: g = (s([]) + s([2,1])).expand(3); g
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 + 1
sage: s.from_polynomial(g)
s[] + s[2, 1]
```

get_print_style ()

Return the value of the current print style for `self`.

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: s.get_print_style()
'lex'
sage: s.set_print_style('length')
sage: s.get_print_style()
'length'
sage: s.set_print_style('lex')

```

prefix()

Return the prefix on the elements of `self`.

EXAMPLES:

```

sage: schur = SymmetricFunctions(QQ).schur()
sage: schur([3,2,1])
s[3, 2, 1]
sage: schur.prefix()
's'

```

product_by_coercion(*left, right*)

Return the product of elements `left` and `right` by coercion to the Schur basis.

INPUT:

- `left, right` – instances of this basis

OUTPUT:

- the product of `left` and `right` expressed in the basis `self`

EXAMPLES:

```

sage: p = SymmetricFunctions(QQ).p()
sage: p.product_by_coercion(p[3,1,1], p[2,2])
p[3, 2, 2, 1, 1]
sage: m = SymmetricFunctions(QQ).m()
sage: m.product_by_coercion(m[2,1], m[1,1]) == m[2,1]*m[1,1]
True

```

set_print_style(*ps*)

Set the value of the current print style to `ps`.

INPUT:

- `ps` – a string specifying the printing style

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: s.get_print_style()
'lex'
sage: s.set_print_style('length')
sage: s.get_print_style()
'length'
sage: s.set_print_style('lex')

```

symmetric_function_ring()

Return the family of symmetric functions associated to the basis `self`.

OUTPUT:

- returns an instance of the ring of symmetric functions

EXAMPLES:

```

sage: schur = SymmetricFunctions(QQ).schur()
sage: schur.symmetric_function_ring()
Symmetric Functions over Rational Field
sage: power = SymmetricFunctions(QQ['t']).power()
sage: power.symmetric_function_ring()
Symmetric Functions over Univariate Polynomial Ring in t over Rational Field

```

transition_matrix (*basis*, *n*)

Return the transition matrix between *self* and *basis* for the homogeneous component of degree *n*.

INPUT:

- *basis* – a basis of the ring of symmetric functions
- *n* – a nonnegative integer

OUTPUT:

- a matrix of coefficients giving the expansion of the homogeneous degree-*n* elements of *self* in the degree-*n* elements of *basis*

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: m = SymmetricFunctions(QQ).m()
sage: s.transition_matrix(m, 5)
[1 1 1 1 1 1 1]
[0 1 1 2 2 3 4]
[0 0 1 1 2 3 5]
[0 0 0 1 1 3 6]
[0 0 0 0 1 2 5]
[0 0 0 0 0 1 4]
[0 0 0 0 0 0 1]
sage: s.transition_matrix(m, 1)
[1]
sage: s.transition_matrix(m, 0)
[1]

```

```

sage: p = SymmetricFunctions(QQ).p()
sage: s.transition_matrix(p, 4)
[ 1/4  1/3  1/8  1/4 1/24]
[-1/4   0 -1/8  1/4 1/8]
[  0 -1/3  1/4   0 1/12]
[ 1/4   0 -1/8 -1/4 1/8]
[-1/4  1/3  1/8 -1/4 1/24]
sage: StoP = s.transition_matrix(p, 4)
sage: a = s([3, 1]) + 5*s([1, 1, 1, 1]) - s([4])
sage: a
5*s[1, 1, 1, 1] + s[3, 1] - s[4]
sage: mon = sorted(a.support())
sage: coeffs = [a[i] for i in mon]
sage: coeffs
[5, 1, -1]
sage: mon
[[1, 1, 1, 1], [3, 1], [4]]
sage: cm = matrix([[-1, 1, 0, 0, 5]])
sage: cm * StoP
[-7/4  4/3  3/8 -5/4 7/24]

```

```
sage: p(a)
7/24*p[1, 1, 1, 1] - 5/4*p[2, 1, 1] + 3/8*p[2, 2] + 4/3*p[3, 1] - 7/4*p[4]
```

```
sage: h = SymmetricFunctions(QQ).h()
sage: e = SymmetricFunctions(QQ).e()
sage: s.transition_matrix(m, 7) == h.transition_matrix(s, 7).transpose()
True
```

```
sage: h.transition_matrix(m, 7) == h.transition_matrix(m, 7).transpose()
True
```

```
sage: h.transition_matrix(e, 7) == e.transition_matrix(h, 7)
True
```

```
sage: p.transition_matrix(s, 5)
[ 1 -1  0  1  0 -1  1]
[ 1  0 -1  0  1  0 -1]
[ 1 -1  1  0 -1  1 -1]
[ 1  1 -1  0 -1  1  1]
[ 1  0  1 -2  1  0  1]
[ 1  2  1  0 -1 -2 -1]
[ 1  4  5  6  5  4  1]
```

```
sage: e.transition_matrix(m, 7) == e.transition_matrix(m, 7).transpose()
True
```

class sage.combinat.sf.sfa.**SymmetricFunctionAlgebra_generic_Element**

Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

Class of generic elements for the symmetric function algebra.

adams_operation (*args, **opts)

arithmetic_product (x)

Return the arithmetic product of `self` and `x` in the basis of `self`.

The arithmetic product is a binary operation $\square$ on the ring of symmetric functions which is bilinear in its two arguments and satisfies

$$p_\lambda \square p_\mu = \prod_{i \geq 1, j \geq 1} p_{\text{lcm}(\lambda_i, \mu_j)}^{\text{gcd}(\lambda_i, \mu_j)}$$

for any two partitions $\lambda = (\lambda_1, \lambda_2, \lambda_3, \dots)$ and $\mu = (\mu_1, \mu_2, \mu_3, \dots)$ (where p_ν denotes the power-sum symmetric function indexed by the partition ν , and p_i denotes the i -th power-sum symmetric function). This is enough to define the arithmetic product if the base ring is torsion-free as a $\mathbf{Z}$ -module; for all other cases the arithmetic product is uniquely determined by requiring it to be functorial in the base ring. See <http://mathoverflow.net/questions/138148/> for a discussion of this arithmetic product.

If f and g are two symmetric functions which are homogeneous of degrees a and b , respectively, then $f \square g$ is homogeneous of degree ab .

The arithmetic product is commutative and associative and has unity $e_1 = p_1 = h_1$.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

Arithmetic product of `self` with `x`; this is a symmetric function over the same base ring as `self`.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([2]).arithmetic_product(s([2]))
s[1, 1, 1, 1] + 2*s[2, 2] + s[4]
sage: s([2]).arithmetic_product(s([1, 1]))
s[2, 1, 1] + s[3, 1]
```

The symmetric function `e[1]` is the unity for the arithmetic product:

```
sage: e = SymmetricFunctions(ZZ).e()
sage: all( e([1]).arithmetic_product(e(q)) == e(q) for q in Partitions(4) )
True
```

The arithmetic product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).arithmetic_product(m(q)) == m(q).arithmetic_
↪product(e(p)) # long time (26s on sage.math, 2013)
.....:         for q in Partitions(4) )
.....:         for p in Partitions(4) )
True
```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a $\mathbb{Q}$ -algebra (in which case the arithmetic product can be easily computed using the power sum basis) from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over $\mathbb{Q}$ (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

`bernstein_creation_operator(n)`

Return the image of `self` under the n -th Bernstein creation operator.

Let n be an integer. The n -th Bernstein creation operator $\mathbf{B}_n$ is defined as the endomorphism of the space Sym of symmetric functions which sends every f to

$$\sum_{i \geq 0} (-1)^i h_{n+i} e_i^\perp,$$

where usual notations are in place (h stands for the complete homogeneous symmetric functions, e for the elementary ones, and $e_i^\perp$ means skewing (`skew_by()`) by e_i).

This has been studied in [BBSSZ2012], section 2.2, where the following rule is given for computing $\mathbf{B}_n$ on a Schur function: If $(\alpha_1, \alpha_2, \dots, \alpha_n)$ is an n -tuple of integers (positive or not), then

$$\mathbf{B}_n s_{(\alpha_1, \alpha_2, \dots, \alpha_n)} = s_{(n, \alpha_1, \alpha_2, \dots, \alpha_n)}.$$

Here, $s_{(\alpha_1, \alpha_2, \dots, \alpha_n)}$ is the “Schur function” associated to the n -tuple $(\alpha_1, \alpha_2, \dots, \alpha_n)$, and defined by literally applying the Jacobi-Trudi identity, i.e., by

$$s_{(\alpha_1, \alpha_2, \dots, \alpha_n)} = \det((h_{\alpha_i - i + j})_{i,j=1,2,\dots,n}).$$

This notion of a Schur function clearly extends the classical notion of Schur function corresponding to a partition, but is easily reduced to the latter (in fact, for any n -tuple α of integers, one easily sees that s_α is

either 0 or minus-plus a Schur function corresponding to a partition; and it is easy to determine which of these is the case and find the partition by a combinatorial algorithm).

EXAMPLES:

Let us check that what this method computes agrees with the definition:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: def bernstein_creation_by_def(n, f):
....:     # `n`-th Bernstein creation operator applied to `f`
....:     # computed according to its definition.
....:     res = f.parent().zero()
....:     if not f:
....:         return res
....:     max_degree = max(sum(m) for m, c in f)
....:     for i in range(max_degree + 1):
....:         if n + i >= 0:
....:             res += (-1) ** i * h[n + i] * f.skew_by(e[i])
....:     return res
sage: all( bernstein_creation_by_def(n, s[l]) == s[l].bernstein_creation_
↪operator(n)
....:     for n in range(-2, 3) for l in Partitions(4) )
True
sage: all( bernstein_creation_by_def(n, s[l]) == s[l].bernstein_creation_
↪operator(n)
....:     for n in range(-3, 4) for l in Partitions(3) )
True
sage: all( bernstein_creation_by_def(n, e[l]) == e[l].bernstein_creation_
↪operator(n)
....:     for n in range(-3, 4) for k in range(3) for l in Partitions(k) )
True
```

Some examples:

```
sage: s[3,2].bernstein_creation_operator(3)
s[3, 3, 2]
sage: s[3,2].bernstein_creation_operator(1)
-s[2, 2, 2]
sage: h[3,2].bernstein_creation_operator(-2)
h[2, 1]
sage: h[3,2].bernstein_creation_operator(-1)
h[2, 1, 1] - h[2, 2] - h[3, 1]
sage: h[3,2].bernstein_creation_operator(0)
-h[3, 1, 1] + h[3, 2]
sage: h[3,2].bernstein_creation_operator(1)
-h[2, 2, 2] + h[3, 2, 1]
sage: h[3,2].bernstein_creation_operator(2)
-h[3, 3, 1] + h[4, 2, 1]
```

`character_to_frobenius_image(n)`

Interpret `self` as a GL_n character and then take the Frobenius image of this character of the permutation matrices S_n which naturally sit inside of GL_n .

To know the value of this character at a permutation of cycle structure ρ the symmetric function `self` is evaluated at the eigenvalues of a permutation of cycle structure ρ . The Frobenius image is then defined as $\sum_{\rho \vdash n} f[\Xi_\rho] p_\rho / z_\rho$.

See also:

`eval_at_permutation_roots()`

INPUT:

- n – a non-negative integer to interpret `self` as a character of GL_n

OUTPUT:

- a symmetric function of degree n

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([1,1]).character_to_frobenius_image(5)
s[3, 1, 1] + s[4, 1]
sage: s([2,1]).character_to_frobenius_image(5)
s[2, 2, 1] + 2*s[3, 1, 1] + 2*s[3, 2] + 3*s[4, 1] + s[5]
sage: s([2,2,2]).character_to_frobenius_image(3)
s[3]
sage: s([2,2,2]).character_to_frobenius_image(4)
s[2, 2] + 2*s[3, 1] + 2*s[4]
sage: s([2,2,2]).character_to_frobenius_image(5)
2*s[2, 2, 1] + s[3, 1, 1] + 4*s[3, 2] + 3*s[4, 1] + 2*s[5]
```

degree()

Return the degree of `self` (which is defined to be 0 for the zero element).

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1]) + 3
sage: z.degree()
4
sage: s(1).degree()
0
sage: s(0).degree()
0
```

derivative_with_respect_to_p1 ($n=1$)

Return the symmetric function obtained by taking the derivative of `self` with respect to the power-sum symmetric function p_1 when the expansion of `self` in the power-sum basis is considered as a polynomial in p_k 's (with $k \geq 1$).

This is the same as skewing `self` by the first power-sum symmetric function p_1 .

INPUT:

- n – (default: 1) nonnegative integer which determines which power of the derivative is taken

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: a = p([1,1,1])
sage: a.derivative_with_respect_to_p1()
3*p[1, 1]
sage: a.derivative_with_respect_to_p1(1)
3*p[1, 1]
sage: a.derivative_with_respect_to_p1(2)
6*p[1]
```

```
sage: a.derivative_with_respect_to_p1(3)
6*p[]
```

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([3]).derivative_with_respect_to_p1()
s[2]
sage: s([2,1]).derivative_with_respect_to_p1()
s[1, 1] + s[2]
sage: s([1,1,1]).derivative_with_respect_to_p1()
s[1, 1]
sage: s(0).derivative_with_respect_to_p1()
0
sage: s(1).derivative_with_respect_to_p1()
0
sage: s([1]).derivative_with_respect_to_p1()
s[]
```

Let us check that taking the derivative with respect to $p[1]$ is equivalent to skewing by $p[1]$:

```
sage: p1 = s([1])
sage: all( s(lam).derivative_with_respect_to_p1()
....:      == s(lam).skew_by(p1) for lam in Partitions(4) )
True
```

eval_at_permutation_roots (*rho*)

Evaluate at eigenvalues of a permutation matrix.

Evaluate a symmetric function at the eigenvalues of a permutation matrix whose cycle structure is *rho*. This computation is computed by coercing to the power sum basis where the value may be computed on the generators.

This function evaluates an element at the roots of unity

$$\Xi_{\rho_1}, \Xi_{\rho_2}, \dots, \Xi_{\rho_\ell}$$

where

$$\Xi_m = 1, \zeta_m, \zeta_m^2, \dots, \zeta_m^{m-1}$$

and ζ_m is an m root of unity. These roots of unity represent the eigenvalues of permutation matrix with cycle structure ρ .

INPUT:

- *rho* – a partition or a list of non-negative integers

OUTPUT:

- an element of the base ring

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([3,3]).eval_at_permutation_roots([6])
0
sage: s([3,3]).eval_at_permutation_roots([3])
1
sage: s([3,3]).eval_at_permutation_roots([1])
0
```

```

sage: s([3,3]).eval_at_permutation_roots([3,3])
4
sage: s([3,3]).eval_at_permutation_roots([1,1,1,1,1])
175
sage: (s[1]+s[2]+s[3]).eval_at_permutation_roots([3,2])
2

```

expand(*n*, *alphabet*='x')

Expand the symmetric function *self* as a symmetric polynomial in *n* variables.

INPUT:

- *n* – a nonnegative integer
- *alphabet* – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of *self* in the *n* variables labelled $x_0, x_1, \dots, x_{n-1}$ (or just *x* if *n* = 1), where *x* is *alphabet*.

EXAMPLES:

```

sage: J = SymmetricFunctions(QQ).jack(t=2).J()
sage: J([2,1]).expand(3)
4*x0^2*x1 + 4*x0*x1^2 + 4*x0^2*x2 + 6*x0*x1*x2 + 4*x1^2*x2 + 4*x0*x2^2 +
↪ 4*x1*x2^2
sage: (2*J([2])).expand(0)
0
sage: (3*J([])).expand(0)
3

```

frobenius(*n*)

Return the image of the symmetric function *self* under the *n*-th Frobenius operator.

The *n*-th Frobenius operator $\mathbf{f}_n$ is defined to be the map from the ring of symmetric functions to itself that sends every symmetric function $P(x_1, x_2, x_3, \dots)$ to $P(x_1^n, x_2^n, x_3^n, \dots)$. This operator $\mathbf{f}_n$ is a Hopf algebra endomorphism, and satisfies

$$\mathbf{f}_n m_{(\lambda_1, \lambda_2, \lambda_3, \dots)} = m_{(n\lambda_1, n\lambda_2, n\lambda_3, \dots)}$$

for every partition $(\lambda_1, \lambda_2, \lambda_3, \dots)$ (where *m* means the monomial basis). Moreover, $\mathbf{f}_n(p_r) = p_{nr}$ for every positive integer *r* (where p_k denotes the *k*-th powersum symmetric function).

The *n*-th Frobenius operator is also called the *n*-th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The *n*-th Frobenius operator is also the *n*-th Adams operator of the Λ -ring of symmetric functions over the integers.

The *n*-th Frobenius operator can also be described via plethysm: Every symmetric function *P* satisfies $\mathbf{f}_n(P) = p_n \circ P = P \circ p_n$, where p_n is the *n*-th powersum symmetric function, and $\circ$ denotes (outer) plethysm.

INPUT:

- *n* – a positive integer

OUTPUT:

The result of applying the *n*-th Frobenius operator (on the ring of symmetric functions) to *self*.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: s[3].frobenius(2)
-s[3, 3] + s[4, 2] - s[5, 1] + s[6]
sage: m[4, 2, 1].frobenius(3)
m[12, 6, 3]
sage: p[4, 2, 1].frobenius(3)
p[12, 6, 3]
sage: h[4].frobenius(2)
h[4, 4] - 2*h[5, 3] + 2*h[6, 2] - 2*h[7, 1] + 2*h[8]
```

The Frobenius endomorphisms are multiplicative:

```
sage: all( all( s(lam).frobenius(3) * s(mu).frobenius(3) # long time
....:         == (s(lam) * s(mu)).frobenius(3)
....:         for mu in Partitions(3) )
....:         for lam in Partitions(3) )
True
sage: all( all( m(lam).frobenius(2) * m(mu).frobenius(2)
....:         == (m(lam) * m(mu)).frobenius(2)
....:         for mu in Partitions(4) )
....:         for lam in Partitions(4) )
True
sage: all( all( p(lam).frobenius(2) * p(mu).frobenius(2)
....:         == (p(lam) * p(mu)).frobenius(2)
....:         for mu in Partitions(3) )
....:         for lam in Partitions(4) )
True
```

Being Hopf algebra endomorphisms, the Frobenius operators commute with the antipode:

```
sage: all( p(lam).frobenius(4).antipode()
....:     == p(lam).antipode().frobenius(4)
....:     for lam in Partitions(3) )
True
```

Testing the $f_n(P) = p_n \circ P = P \circ p_n$ equality (over $\mathbf{Q}$, since plethysm is currently not defined over $\mathbf{Z}$ in Sage):

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: p = Sym.p()
sage: all( s(lam).frobenius(3) == s(lam).plethysm(p[3])
....:     == s(p[3].plethysm(s(lam)))
....:     for lam in Partitions(4) )
True
```

By Exercise 7.61 in Stanley's EC2 [\[STA\]](#) (see the errata on his website), $f_n(h_m)$ is a linear combination of Schur polynomials (of straight shapes) using coefficients 0, 1 and -1 only; moreover, all partitions whose Schur polynomials occur with coefficient $\neq 0$ in this combination have empty n -cores. Let us check this on examples:

```

sage: all( all( all( (coeff == -1 or coeff == 1)
.....:         and lam.core(n) == Partition([])
.....:         for lam, coeff in s([m]).frobenius(n) )
.....:         for n in range(2, 4) )
.....:         for m in range(4) )
True

```

See also:

`plethysm()`

Todo

This method is fast on the monomial and the powersum bases, while all other bases get converted to the monomial basis. For most bases, this is probably the quickest way to do, but at least the Schur basis should have a better option. (Quoting from Stanley's EC2 [\[STA\]](#): "D. G. Duncan, J. London Math. Soc. 27 (1952), 235-236, or Y. M. Chen, A. M. Garsia, and J. B. Remmel, Contemp. Math. 34 (1984), 109-153".)

`hl_creation_operator` (*nu*, *t=None*)

This is the vertex operator that generalizes Jing's operator.

It is a linear operator that raises the degree by $|\nu|$. This creation operator is a t -analogue of multiplication by $s(\nu)$.

See also:

Proposition 5 in [\[SZ2001\]](#).

INPUT:

- *nu* – a partition
- *t* – (default: `None`, in which case t is used) a parameter

REFERENCES:

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ['t']).s()
sage: s([2]).hl_creation_operator([3,2])
s[3, 2, 2] + t*s[3, 3, 1] + t*s[4, 2, 1] + t^2*s[4, 3] + t^2*s[5, 2]

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLQp = Sym.hall_littlewood().Qp()
sage: s = Sym.s()
sage: HLQp(s([2]).hl_creation_operator([2]).hl_creation_operator([3]))
HLQp[3, 2, 2]
sage: s([2,2]).hl_creation_operator([2,1])
t*s[2, 2, 2, 1] + t^2*s[3, 2, 1, 1] + t^2*s[3, 2, 2] + t^3*s[3, 3, 1] + t^
↪ 3*s[4, 2, 1] + t^4*s[4, 3]
sage: s(1).hl_creation_operator([2,1,1])
s[2, 1, 1]
sage: s(0).hl_creation_operator([2,1,1])
0
sage: s([3,2]).hl_creation_operator([2,1,1])
(t^2-t)*s[2, 2, 2, 2, 1] + t^3*s[3, 2, 2, 1, 1] + (t^3-t^2)*s[3, 2, 2, 2] + t^
↪ 3*s[3, 3, 1, 1, 1] + t^4*s[3, 3, 2, 1] + t^3*s[4, 2, 1, 1, 1] + t^4*s[4, 2,
↪ 2, 1] + 2*t^4*s[4, 3, 1, 1] + t^5*s[4, 3, 2] + t^5*s[4, 4, 1] + t^4*s[5, 2,
↪ 1, 1] + t^5*s[5, 3, 1]

```

inner_plethysm(x)

Return the inner plethysm of `self` with `x`.

Whenever R is a $\mathbf{Q}$ -algebra, and f and g are two symmetric functions over R such that the constant term of f is zero, the inner plethysm of f with g is a symmetric function over R , and the degree of this symmetric function is the same as the degree of g . We will denote the inner plethysm of f with g by $f\{g\}$ (in contrast to the notation of outer plethysm which is generally denoted $f[g]$); in Sage syntax, it is `f.inner_plethysm(g)`.

First we describe the axiomatic definition of the operation; see below for a representation-theoretic interpretation. In the following equations, we denote the outer product (i.e., the standard product on the ring of symmetric functions, `product()`) by $\cdot$ and the Kronecker product (`itensor()`) by $*$.

$$\begin{aligned}(f + g)\{h\} &= f\{h\} + g\{h\} \\ (f \cdot g)\{h\} &= (f\{h\}) * (g\{h\}) \\ p_k\{f + g\} &= p_k\{f\} + p_k\{g\}\end{aligned}$$

where p_k is the k -th power-sum symmetric function for every $k > 0$.

Let σ be a permutation of cycle type μ and let μ^k be the cycle type of σ^k . Then,

$$p_k\{p_\mu/z_\mu\} = \sum_{\nu: \nu^k = \mu} p_\nu/z_\nu$$

Since $(p_\mu/z_\mu)_\mu$ is a basis for the symmetric functions, these four formulas define the symmetric function operation $f\{g\}$ for any symmetric functions f and g (where f has constant term 0) by expanding f in the power sum basis and g in the dual basis p_μ/z_μ .

See also:

`itensor()`, `partition_power()`, `plethysm()`

This operation admits a representation-theoretic interpretation in the case where f is a Schur function s_λ and g is a homogeneous degree n symmetric function with nonnegative integral coefficients in the Schur basis. The symmetric function $f\{g\}$ is the Frobenius image of the S_n -representation constructed as follows.

The assumptions on g imply that g is the Frobenius image of a representation ρ of the symmetric group S_n :

$$\rho : S_n \rightarrow GL_N.$$

If the degree N of this representation is greater than or equal to the number of parts of λ , then f , which denotes s_λ , corresponds to the character of some irreducible GL_N -representation, say

$$\sigma : GL_N \rightarrow GL_M.$$

The composition $\sigma \circ \rho : S_n \rightarrow GL_M$ is a representation of S_n whose Frobenius image is precisely $f\{g\}$.

If N is less than the number of parts of λ , then $f\{g\}$ is 0 by definition.

When f is a symmetric function with constant term $\neq 0$, the inner plethysm $f\{g\}$ isn't well-defined in the ring of symmetric functions. Indeed, it is not clear how to define $1\{g\}$. The most sensible way to get around this probably is defining it as the infinite sum $h_0 + h_1 + h_2 + \dots$ (where h_i means the i -th complete homogeneous symmetric function) in the completion of this ring with respect to its grading. This is how [SchaThi1994] defines $1\{g\}$. The present method, however, sets it to be the sum of h_i over all i for which the i -th homogeneous component of g is nonzero. This is rather a hack than a reasonable definition. Use with caution!

Note: If a symmetric function g is written in the form $g = g_0 + g_1 + g_2 + \cdots$ with each g_i homogeneous of degree i , then $f\{g\} = f\{g_0\} + f\{g_1\} + f\{g_2\} + \cdots$ for every f with constant term 0. But in general, inner plethysm is not linear in the second variable.

REFERENCES:

INPUT:

- x – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- an element of symmetric functions in the parent of `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: p = Sym.power()
sage: h = Sym.complete()
sage: s([2,1]).inner_plethysm(s([1,1,1]))
0
sage: s([2]).inner_plethysm(s([2,1]))
s[2, 1] + s[3]
sage: s([1,1]).inner_plethysm(s([2,1]))
s[1, 1, 1]
sage: s[2,1].inner_tensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
```

```
sage: f = s([2,1]) + 2*s([3,1])
sage: f.itensor(f)
s[1, 1, 1] + s[2, 1] + 4*s[2, 1, 1] + 4*s[2, 2] + s[3] + 4*s[3, 1] + 4*s[4]
sage: s(h([1,1]).inner_plethysm(f))

inner_tensor(x)

Return the internal (tensor) product of `self` and `x` in the basis of `self`.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda * p_\mu = \delta_{\lambda,\mu} z_\lambda p_\lambda$, where $z_\lambda = (1^{r_1} r_1!)(2^{r_2} r_2!) \cdots$ for $\lambda = (1^{r_1} 2^{r_2} \cdots)$ and where $*$ denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note: The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see [`scalar\(\)`](#)).

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the internal product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

The methods `itensor()`, `internal_product()`, `kronecker_product()`, `inner_tensor()` are all synonyms.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2, 1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3, 2, 1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
+ 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
+ 3*s[4, 2] + 2*s[5, 1] + s[6]
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function f of degree n with the n -th complete homogeneous symmetric function $h[n]$ (a.k.a. $s[n]$) is f :

```
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

The Kronecker product of a Schur function s_λ with the n -th elementary symmetric function $e[n]$, where $n = |\lambda|$, is $s_{\lambda'}$ (where λ' is the conjugate partition of λ):

```
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in
↳ Partitions(4) )
....:         for p in Partitions(4) )
True

sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p)) # long time
....:         for r in Partitions(4) )
....:         for p in Partitions(3) )
True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Non-commutative symmetric functions”, [Arxiv hep-th/9407124](https://arxiv.org/abs/hep-th/9407124), for $r = 2$:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w): # computes \mu ((u \otimes v) * \Delta(w))
↳ with
....:         # * meaning Kronecker product and \mu
↳ meaning the
....:         # usual multiplication.
....:         result = w.parent().zero()
....:         for partition_pair, coeff in w.coproduct():
....:             result += coeff * w.parent().itensor(partition_pair[0]) * w.
↳ parent().itensor(partition_pair[1])
....:         return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w]) # long time
....:                 == (e[u] * s[v]).itensor(m[w])
....:                 for w in Partitions(5) )
....:                 for v in Partitions(2) )
....:                 for u in Partitions(3) )
True
```

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.” [Arxiv 0907.4652](https://arxiv.org/abs/0907.4652):

```
sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
sage: s[3,2].itensor(s[3,2])
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] + s[4, 1] + s[5]
sage: s[4,2].itensor(s[4,2])
s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1]
↳ + s[6]
```

An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

```
sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a $\mathbf{Q}$ -algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over $\mathbf{Q}$ (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

`internal_coproduct()`

Return the inner coproduct of `self` in the basis of `self`.

The inner coproduct (also known as the Kronecker coproduct, as the internal coproduct, or as the second comultiplication on the ring of symmetric functions) is a ring homomorphism $\Delta^\times$ from the ring of symmetric functions to the tensor product (over the base ring) of this ring with itself. It is uniquely characterized by the formula

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} s_\lambda \otimes s_\lambda = \sum_{\lambda \vdash n} h_\lambda \otimes m_\lambda = \sum_{\lambda \vdash n} m_\lambda \otimes h_\lambda,$$

where $\lambda \vdash n$ means λ is a partition of n , and n is any nonnegative integer. It also satisfies

$$\Delta^\times(p_n) = p_n \otimes p_n$$

for any positive integer n . If the base ring is a $\mathbf{Q}$ -algebra, it also satisfies

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} z_\lambda^{-1} p_\lambda \otimes p_\lambda,$$

where

$$z_\lambda = \prod_{i=1}^{\infty} i^{m_i(\lambda)} m_i(\lambda)!$$

with $m_i(\lambda)$ meaning the number of appearances of i in λ (see `zee()`).

The method `kronecker_coproduct()` is a synonym of `internal_coproduct()`.

EXAMPLES:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2, 1])
sage: a.internal_coproduct()
s[1, 1, 1] # s[2, 1] + s[2, 1] # s[1, 1, 1] + s[2, 1] # s[2, 1] + s[2, 1] # s[2, 1] #
↪ s[3] + s[3] # s[2, 1]

sage: e = SymmetricFunctions(QQ).e()
sage: b = e([2])
sage: b.internal_coproduct()
e[1, 1] # e[2] + e[2] # e[1, 1] - 2*e[2] # e[2]
```

The internal coproduct is adjoint to the internal product with respect to the Hall inner product: Any three symmetric functions f, g and h satisfy $\langle f * g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle$, where we write $\Delta^\times(h)$ as $\sum_i h'_i \otimes h''_i$. Let us check this in degree 4:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_incopr(f, g, h): # computes \sum_i \left< f, h'_i \right> \left< g, h''_i \right>
↪ \left< f * g, h \right>
```

```

....:     result = h.base_ring().zero()
....:     for partition_pair, coeff in h.internal_coproduct():
....:         result += coeff * h.parent()(f).scalar(partition_pair[0]) * h.
↪parent()(g).scalar(partition_pair[1])
....:     return result
sage: all( all( all( tensor_incopr(e[u], s[v], m[w]) == (e[u].itensor(s[v])).
↪scalar(m[w]) # long time (10s on sage.math, 2013)
....:         for w in Partitions(5) )
....:         for v in Partitions(2) )
....:         for u in Partitions(3) )
True

```

Let us check the formulas for $\Delta^\times(h_n)$ and $\Delta^\times(p_n)$ given in the description of this method:

```

sage: e = SymmetricFunctions(QQ).e()
sage: p = SymmetricFunctions(QQ).p()
sage: h = SymmetricFunctions(QQ).h()
sage: s = SymmetricFunctions(QQ).s()
sage: all( s(h([n])).internal_coproduct() == sum([tensor([s(lam), s(lam)])],
↪for lam in Partitions(n)])
....:     for n in range(6) )
True
sage: all( h([n]).internal_coproduct() == sum([tensor([h(lam), h(m(lam))]),
↪for lam in Partitions(n)])
....:     for n in range(6) )
True
sage: all( factorial(n) * h([n]).internal_coproduct()
....:     == sum([lam.conjugacy_class_size() * tensor([h(p(lam)), h(p(lam))]),
....:             for lam in Partitions(n)])
....:     for n in range(6) )
True

```

internal_product(x)

Return the internal (tensor) product of `self` and `x` in the basis of `self`.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda * p_\mu = \delta_{\lambda,\mu} z_\lambda p_\lambda$, where $z_\lambda = (1^{r_1} r_1!)(2^{r_2} r_2!) \cdots$ for $\lambda = (1^{r_1} 2^{r_2} \cdots)$ and where $*$ denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note: The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see [scalar\(\)](#)).

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the internal product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

The methods `itensor()`, `internal_product()`, `kronecker_product()`, `inner_tensor()` are all synonyms.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.tensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.tensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
+ 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
+ 3*s[4, 2] + 2*s[5, 1] + s[6]
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function f of degree n with the n -th complete homogeneous symmetric function $h[n]$ (a.k.a. $s[n]$) is f :

```
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).tensor(h(p)) == h(p) for p in Partitions(5) )
True
```

The Kronecker product of a Schur function s_λ with the n -th elementary symmetric function $e[n]$, where $n = |\lambda|$, is $s_{\lambda'}$ (where λ' is the conjugate partition of λ):

```
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).tensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).tensor(m(q)) == m(q).tensor(e(p)) for q in
↪Partitions(4) )
....:      for p in Partitions(4) )
True

sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).tensor(mh(r)) == mh(r).tensor(mq(p)) # long time
....:      for r in Partitions(4) )
....:      for p in Partitions(3) )
True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Non-commutative symmetric functions”, [Arxiv hep-th/9407124](https://arxiv.org/abs/hep-th/9407124), for $r = 2$:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w): # computes \mu ((u \otimes v) * \Delta(w))
↪with
....:                          # * meaning Kronecker product and \mu
↪meaning the
```

```

....:                                     # usual multiplication.
....:     result = w.parent().zero()
....:     for partition_pair, coeff in w.coproduct():
....:         result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.
↪parent()(v).itensor(partition_pair[1])
....:     return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w])    # long time
....:                                     == (e[u] * s[v]).itensor(m[w])
....:                                     for w in Partitions(5) )
....:                                     for v in Partitions(2) )
....:                                     for u in Partitions(3) )
True

```

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.” [Arxiv 0907.4652](#):

```

sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
sage: s[3,2].itensor(s[3,2])
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] + s[4, 1] + s[5]
sage: s[4,2].itensor(s[4,2])
s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1]
↪+ s[6]

```

An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

```

sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]

```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a $\mathbb{Q}$ -algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over $\mathbb{Q}$ (using the `corresponding_basis_over` hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

`is_schur_positive()`

Return True if and only if `self` is Schur positive.

If `s` is the space of Schur functions over `self`’s base ring, then this is the same as `self._is_positive(s)`.

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1]) + s([3])
sage: a.is_schur_positive()
True
sage: a = s([2,1]) - s([3])
sage: a.is_schur_positive()
False

```

```

sage: QQx = QQ['x']
sage: s = SymmetricFunctions(QQx).s()
sage: x = QQx.gen()
sage: a = (1+x)*s([2,1])
sage: a.is_schur_positive()
True
sage: a = (1-x)*s([2,1])
sage: a.is_schur_positive()
False
sage: s(0).is_schur_positive()
True
sage: s(1+x).is_schur_positive()
True

```

itensor (*x*)

Return the internal (tensor) product of *self* and *x* in the basis of *self*.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda * p_\mu = \delta_{\lambda,\mu} z_\lambda p_\lambda$, where $z_\lambda = (1^{r_1} r_1!)(2^{r_2} r_2!) \cdots$ for $\lambda = (1^{r_1} 2^{r_2} \cdots)$ and where $*$ denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note: The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see [scalar\(\)](#)).

INPUT:

- *x* – element of the ring of symmetric functions over the same base ring as *self*

OUTPUT:

- the internal product of *self* with *x* (an element of the ring of symmetric functions in the same basis as *self*)

The methods [itensor\(\)](#), [internal_product\(\)](#), [kronecker_product\(\)](#), [inner_tensor\(\)](#) are all synonyms.

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
+ 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
+ 3*s[4, 2] + 2*s[5, 1] + s[6]

```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function f of degree n with the n -th complete homogeneous symmetric function $h[n]$ (a.k.a. $s[n]$) is f :

```
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

The Kronecker product of a Schur function s_λ with the n -th elementary symmetric function $e[n]$, where $n = |\lambda|$, is $s_{\lambda'}$ (where λ' is the conjugate partition of λ):

```
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in
↳Partitions(4) )
....:         for p in Partitions(4) )
True

sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p)) # long time
....:         for r in Partitions(4) )
....:         for p in Partitions(3) )
True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Non-commutative symmetric functions”, [Arxiv hep-th/9407124](https://arxiv.org/abs/hep-th/9407124), for $r = 2$:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w): # computes \mu ((u \otimes v) * \Delta(w))
↳with
....:                               # * meaning Kronecker product and \mu
↳meaning the
....:                               # usual multiplication.
....:     result = w.parent().zero()
....:     for partition_pair, coeff in w.coproduct():
....:         result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.
↳parent()(v).itensor(partition_pair[1])
....:     return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w]) # long time
....:                     == (e[u] * s[v]).itensor(m[w])
....:                     for w in Partitions(5) )
....:                     for v in Partitions(2) )
....:                     for u in Partitions(3) )
True
```

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.” [Arxiv 0907.4652](https://arxiv.org/abs/0907.4652):

```

sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
sage: s[3,2].itensor(s[3,2])
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] + s[4, 1] + s[5]
sage: s[4,2].itensor(s[4,2])
s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1]
↪ + s[6]

```

An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

```

sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]

```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a $\mathbf{Q}$ -algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over $\mathbf{Q}$ (using the `corresponding_basis_over` hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

`kronecker_coproduct()`

Return the inner coproduct of `self` in the basis of `self`.

The inner coproduct (also known as the Kronecker coproduct, as the internal coproduct, or as the second comultiplication on the ring of symmetric functions) is a ring homomorphism $\Delta^\times$ from the ring of symmetric functions to the tensor product (over the base ring) of this ring with itself. It is uniquely characterized by the formula

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} s_\lambda \otimes s_\lambda = \sum_{\lambda \vdash n} h_\lambda \otimes m_\lambda = \sum_{\lambda \vdash n} m_\lambda \otimes h_\lambda,$$

where $\lambda \vdash n$ means λ is a partition of n , and n is any nonnegative integer. It also satisfies

$$\Delta^\times(p_n) = p_n \otimes p_n$$

for any positive integer n . If the base ring is a $\mathbf{Q}$ -algebra, it also satisfies

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} z_\lambda^{-1} p_\lambda \otimes p_\lambda,$$

where

$$z_\lambda = \prod_{i=1}^{\infty} i^{m_i(\lambda)} m_i(\lambda)!$$

with $m_i(\lambda)$ meaning the number of appearances of i in λ (see `zee()`).

The method `kronecker_coproduct()` is a synonym of `internal_coproduct()`.

EXAMPLES:

```

sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2,1])

```

```

sage: a.internal_coproduct()
s[1, 1, 1] # s[2, 1] + s[2, 1] # s[1, 1, 1] + s[2, 1] # s[2, 1] + s[2, 1] #
↪ s[3] + s[3] # s[2, 1]

sage: e = SymmetricFunctions(QQ).e()
sage: b = e([2])
sage: b.internal_coproduct()
e[1, 1] # e[2] + e[2] # e[1, 1] - 2*e[2] # e[2]

```

The internal coproduct is adjoint to the internal product with respect to the Hall inner product: Any three symmetric functions f, g and h satisfy $\langle f * g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle$, where we write $\Delta^\times(h)$ as $\sum_i h'_i \otimes h''_i$. Let us check this in degree 4:

```

sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_incopr(f, g, h): # computes \sum_i \left< f, h'_i \right>
↪ \left< g, h''_i \right>
....:     result = h.base_ring().zero()
....:     for partition_pair, coeff in h.internal_coproduct():
....:         result += coeff * h.parent()(f).scalar(partition_pair[0]) * h.
↪ parent()(g).scalar(partition_pair[1])
....:     return result
sage: all( all( all( tensor_incopr(e[u], s[v], m[w]) == (e[u].itensor(s[v])).
↪ scalar(m[w]) # long time (10s on sage.math, 2013)
....:         for w in Partitions(5) )
....:         for v in Partitions(2) )
....:         for u in Partitions(3) )
True

```

Let us check the formulas for $\Delta^\times(h_n)$ and $\Delta^\times(p_n)$ given in the description of this method:

```

sage: e = SymmetricFunctions(QQ).e()
sage: p = SymmetricFunctions(QQ).p()
sage: h = SymmetricFunctions(QQ).h()
sage: s = SymmetricFunctions(QQ).s()
sage: all( s(h([n])).internal_coproduct() == sum([tensor([s(lam), s(lam)])
↪ for lam in Partitions(n)])
....:     for n in range(6) )
True
sage: all( h([n]).internal_coproduct() == sum([tensor([h(lam), h(m(lam))])
↪ for lam in Partitions(n)])
....:     for n in range(6) )
True
sage: all( factorial(n) * h([n]).internal_coproduct()
....:     == sum([lam.conjugacy_class_size() * tensor([h(p(lam)), h(p(lam))])
....:         for lam in Partitions(n)])
....:     for n in range(6) )
True

```

kronecker_product(x)

Return the internal (tensor) product of `self` and `x` in the basis of `self`.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda * p_\mu = \delta_{\lambda, \mu} z_\lambda p_\lambda$, where $z_\lambda = (1^{r_1} r_1!)(2^{r_2} r_2!) \cdots$ for $\lambda = (1^{r_1} 2^{r_2} \cdots)$ and where $*$ denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note: The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see `scalar()`).

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the internal product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

The methods `itensor()`, `internal_product()`, `kronecker_product()`, `inner_tensor()` are all synonyms.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2, 1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3, 2, 1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
+ 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
+ 3*s[4, 2] + 2*s[5, 1] + s[6]
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function f of degree n with the n -th complete homogeneous symmetric function $h[n]$ (a.k.a. $s[n]$) is f :

```
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

The Kronecker product of a Schur function s_λ with the n -th elementary symmetric function $e[n]$, where $n = |\lambda|$, is $s_{\lambda'}$ (where λ' is the conjugate partition of λ):

```
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in
↪Partitions(4) )
.....:         for p in Partitions(4) )
```

```

True

sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p))    # long time
.....:         for r in Partitions(4) )
.....:         for p in Partitions(3) )
True

```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Non-commutative symmetric functions”, [Arxiv hep-th/9407124](https://arxiv.org/abs/hep-th/9407124), for $r = 2$:

```

sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w): # computes \mu ((u \otimes v) * \Delta(w))
↪with
.....:         # * meaning Kronecker product and \mu
↪meaning the
.....:         # usual multiplication.
.....:         result = w.parent().zero()
.....:         for partition_pair, coeff in w.coproduct():
.....:             result += coeff * w.parent().(u).itensor(partition_pair[0]) * w.
↪parent().(v).itensor(partition_pair[1])
.....:         return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w])    # long time
.....:                 == (e[u] * s[v]).itensor(m[w])
.....:                 for w in Partitions(5) )
.....:                 for v in Partitions(2) )
.....:                 for u in Partitions(3) )
True

```

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.” [Arxiv 0907.4652](https://arxiv.org/abs/0907.4652):

```

sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
sage: s[3,2].itensor(s[3,2])
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] + s[4, 1] + s[5]
sage: s[4,2].itensor(s[4,2])
s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1]
↪+ s[6]

```

An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

```

sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]

```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a $\mathbb{Q}$ -algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the

symmetric function algebra over $\mathbb{Q}$ (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

`left_padded_kronecker_product` (*x*)

Return the left-padded Kronecker product of `self` and `x` in the basis of `self`.

The left-padded Kronecker product is a bilinear map mapping two symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let $*$ denote the Kronecker product (`itensor()`) on the space of symmetric functions. For any partitions α, β, γ , let $g_{\alpha, \beta}^{\gamma}$ denote the coefficient of the complete homogeneous symmetric function h_{γ} in the Kronecker product $h_{\alpha} * h_{\beta}$. For every partition $\lambda = (\lambda_1, \lambda_2, \lambda_3, \dots)$ and every integer $n > |\lambda| + \lambda_1$, let $\lambda[n]$ denote the n -completion of λ (this is the partition $(n - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \dots)$; see `t_completion()`). Then, for any partitions α and β and every integer $n \geq |\alpha| + |\beta| + \alpha_1 + \beta_1$, we can write the Kronecker product $h_{\alpha[n]} * h_{\beta[n]}$ in the form

$$h_{\alpha[n]} * h_{\beta[n]} = \sum_{\gamma} g_{\alpha[n], \beta[n]}^{\gamma[n]} h_{\gamma[n]}$$

with γ ranging over all partitions. The coefficients $g_{\alpha[n], \beta[n]}^{\gamma[n]}$ are independent on n . These coefficients $g_{\alpha[n], \beta[n]}^{\gamma[n]}$ are denoted by $\bar{g}_{\alpha, \beta}^{\gamma}$, and the symmetric function

$$\sum_{\gamma} \bar{g}_{\alpha, \beta}^{\gamma} h_{\gamma}$$

is said to be the *left-padded Kronecker product* of h_{α} and h_{β} . By bilinearity, this extends to a definition of a left-padded Kronecker product of any two symmetric functions.

This notion of left-padded Kronecker product can be lifted to the non-commutative symmetric functions (`left_padded_kronecker_product()`).

Warning: Don't mistake this product for the reduced Kronecker product (`reduced_kronecker_product()`), which uses the Schur functions instead of the complete homogeneous functions in its definition.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the left-padded Kronecker product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: h = Sym.h()
sage: h[2,1].left_padded_kronecker_product(h[3])
h[1, 1, 1, 1] + h[2, 1] + h[2, 1, 1] + h[2, 1, 1, 1] + h[2, 2, 1] + h[3, 2, 1]
sage: h[2,1].left_padded_kronecker_product(h[1])
h[1, 1, 1] + h[2, 1] + h[2, 1, 1]
sage: h[1].left_padded_kronecker_product(h[2,1])
h[1, 1, 1] + h[2, 1] + h[2, 1, 1]
sage: h[1,1].left_padded_kronecker_product(h[2])
h[1, 1] + 2*h[1, 1, 1] + h[2, 1, 1]
sage: h[1].left_padded_kronecker_product(h[2,1,1])
h[1, 1, 1, 1] + 2*h[2, 1, 1] + h[2, 1, 1, 1]
```

```
sage: h[2].left_padded_kronecker_product(h[3])
h[2, 1] + h[2, 1, 1] + h[3, 2]
```

Taking the left-padded Kronecker product with $1 = h$ is the identity map on the ring of symmetric functions:

```
sage: all( h[Partition([])].left_padded_kronecker_product(h[lam])
....:      == h[lam] for i in range(4)
....:      for lam in Partitions(i) )
True
```

Here is a rule for the left-padded Kronecker product of h_1 (this is the same as $h_{(1)}$) with any complete homogeneous function: Let λ be a partition. Then, the left-padded Kronecker product of h_1 and h_λ is $\sum_\mu a_\mu h_\mu$, where the sum runs over all partitions μ , and the coefficient a_μ is defined as the number of ways to obtain μ from λ by one of the following two operations:

- Insert a 1 into λ .
- Subtract 1 from one of the entries of λ (and remove the entry if it thus becomes 0), and insert a 1 into λ .

We check this for partitions of size ≤ 4 :

```
sage: def mults1(I):
....:     # Left-padded Kronecker multiplication by h[1].
....:     res = h[I[:]] + [1]
....:     for k in range(len(I)):
....:         I2 = I[:]
....:         if I2[k] == 1:
....:             I2 = I2[:k] + I2[k+1:]
....:         else:
....:             I2[k] -= 1
....:         res += h[sorted(I2 + [1], reverse=True)]
....:     return res
sage: all( mults1(I) == h[1].left_padded_kronecker_product(h[I])
....:      == h[I].left_padded_kronecker_product(h[1])
....:      for i in range(5) for I in Partitions(i) )
True
```

The left-padded Kronecker product is commutative:

```
sage: all( h[lam].left_padded_kronecker_product(h[mu])
....:      == h[mu].left_padded_kronecker_product(h[lam])
....:      for lam in Partitions(3) for mu in Partitions(3) )
True
```

nabla($q=None, t=None, power=1$)

Return the value of the nabla operator applied to `self`.

The eigenvectors of the nabla operator are the Macdonald polynomials in the H_t basis.

If the parameter `power` is an integer then it calculates nabla to that integer. The default value of `power` is 1.

INPUT:

- `q, t` – optional parameters (default: `None`, in which case `q` and `t` are used)
- `power` – (default: 1) an integer indicating how many times to apply the operator ∇ . Negative values of `power` indicate powers of ∇^{-1} .

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: p = Sym.power()
sage: p([1,1]).nabla()
(-1/2*q*t+1/2*q+1/2*t+1/2)*p[1, 1] + (1/2*q*t-1/2*q-1/2*t+1/2)*p[2]
sage: p([2,1]).nabla(q=1)
(-t-1)*p[1, 1, 1] + t*p[2, 1]
sage: p([2]).nabla(q=1)*p([1]).nabla(q=1)
(-t-1)*p[1, 1, 1] + t*p[2, 1]
sage: s = Sym.schur()
sage: s([2,1]).nabla()
(-q^3*t-q^2*t^2-q*t^3)*s[1, 1, 1] + (-q^2*t-q*t^2)*s[2, 1]
sage: s([1,1,1]).nabla()
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q*t)*s[2, 1] + s[3]
sage: s([1,1,1]).nabla(t=1)
(q^3+q^2+2*q+1)*s[1, 1, 1] + (q^2+2*q+2)*s[2, 1] + s[3]
sage: s(0).nabla()
0
sage: s(1).nabla()
s[]
sage: s([2,1]).nabla(power=-1)
((-q-t)/(q^2*t^2))*s[2, 1] + ((q^2+q*t+t^2)/(-q^3*t^3))*s[3]
sage: (s([2])+s([3])).nabla()
(-q*t)*s[1, 1] + (q^3*t^2+q^2*t^3)*s[1, 1, 1] + q^2*t^2*s[2, 1]

```

omega()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

The default implementation converts to the Schur basis, then performs the automorphism and changes back.

`omega_involution()` is a synonym for the `omega()` method.

EXAMPLES:

```

sage: J = SymmetricFunctions(QQ).jack(t=1).P()
sage: a = J([2,1]) + J([1,1,1])
sage: a.omega()
JackP[2, 1] + JackP[3]
sage: J(0).omega()
0
sage: J(1).omega()
JackP[]

```

The forgotten symmetric functions are the images of the monomial symmetric functions under omega:

```

sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.m()
sage: f = Sym.f()
sage: all( f(lam) == m(lam).omega() for lam in Partitions(3) )
True
sage: all( m(lam) == f(lam).omega() for lam in Partitions(3) )
True

```

omega_involution()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

The default implementation converts to the Schur basis, then performs the automorphism and changes back.

`omega_involution()` is a synonym for the `omega()` method.

EXAMPLES:

```

sage: J = SymmetricFunctions(QQ).jack(t=1).P()
sage: a = J([2,1]) + J([1,1,1])
sage: a.omega()
JackP[2, 1] + JackP[3]
sage: J(0).omega()
0
sage: J(1).omega()
JackP[]

```

The forgotten symmetric functions are the images of the monomial symmetric functions under omega:

```

sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.m()
sage: f = Sym.f()
sage: all( f(lam) == m(lam).omega() for lam in Partitions(3) )
True
sage: all( m(lam) == f(lam).omega() for lam in Partitions(3) )
True

```

omega_qt(q=None, t=None)

Return the image of `self` under the q, t -deformed omega automorphism which sends p_k to $(-1)^{k-1} \cdot \frac{1-q^k}{1-t^k} \cdot p_k$ for all positive integers k .

In general, this is well-defined outside of the powersum basis only if the base ring is a $\mathbb{Q}$ -algebra.

If $q = t$, then this is the omega automorphism (`omega()`).

INPUT:

• q, t – parameters (default: None, in which case ' q ' and ' t ' are used)

EXAMPLES:

```
sage: QQqt = QQ['q,t'].fraction_field()
sage: q,t = QQqt.gens()
sage: p = SymmetricFunctions(QQqt).p()
sage: p[5].omega_qt()
((-q^5+1)/(-t^5+1))*p[5]
sage: p[5].omega_qt(q,t)
((-q^5+1)/(-t^5+1))*p[5]
sage: p([2]).omega_qt(q,t)
((q^2-1)/(-t^2+1))*p[2]
sage: p([2,1]).omega_qt(q,t)
((-q^3+q^2+q-1)/(t^3-t^2-t+1))*p[2, 1]
sage: p([3,2]).omega_qt(5,q)
-(2976/(q^5-q^3-q^2+1))*p[3, 2]
sage: p(0).omega_qt()
0
sage: p(1).omega_qt()
p[]
sage: H = SymmetricFunctions(QQqt).macdonald().H()
sage: H([1,1]).omega_qt()
((2*q^2-2*q*t-2*q+2*t)/(t^3-t^2-t+1))*McdH[1, 1] + ((q-1)/(t-1))*McdH[2]
sage: H([1,1]).omega_qt(q,t)
((2*q^2-2*q*t-2*q+2*t)/(t^3-t^2-t+1))*McdH[1, 1] + ((q-1)/(t-1))*McdH[2]
sage: H([1,1]).omega_qt(t,q)
((-t^3+t^2+t-1)/(-q^3+q^2+q-1))*McdH[2]
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: S = Sym.macdonald().S()
sage: S([1,1]).omega_qt()
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdS[1, 1] + ((-q^2*t+q*t+q-1)/(-t^3+t^2+t-1))*McdS[2]
sage: s = Sym.schur()
sage: s(S([1,1]).omega_qt())
s[2]
```

plethysm(x , *include=None*, *exclude=None*)

Return the outer plethysm of *self* with x .

This is implemented only over base rings which are $\mathbf{Q}$ -algebras. (To compute outer plethysms over general binomial rings, change bases to the fraction field.)

The outer plethysm of f with g is commonly denoted by $f[g]$ or by $f \circ g$. It is an algebra map in f , but not (generally) in g .

By default, the degree one elements are taken to be the generators for the *self*'s base ring. This setting can be modified by specifying the *include* and *exclude* keywords.

INPUT:

- x – a symmetric function over the same base ring as *self*
- include* – a list of variables to be treated as degree one elements instead of the default degree one elements
- exclude* – a list of variables to be excluded from the default degree one elements

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: s ( h([3])( h([2]) ) )
s[2, 2, 2] + s[4, 2] + s[6]
sage: p = Sym.p()
sage: p([3])( s([2, 1]) )
1/3*p[3, 3, 3] - 1/3*p[9]
sage: e = Sym.e()
sage: e([3])( e([2]) )
e[3, 3] + e[4, 1, 1] - 2*e[4, 2] - e[5, 1] + e[6]

```

```

sage: R.<t> = QQ[]
sage: s = SymmetricFunctions(R).s()
sage: a = s([3])
sage: f = t*s([2])
sage: a(f)
t^3*s[2, 2, 2] + t^3*s[4, 2] + t^3*s[6]
sage: f(a)
t*s[4, 2] + t*s[6]
sage: s(0).plethysm(s[1])
0
sage: s(1).plethysm(s[1])
s[]
sage: s(1).plethysm(s(0))
s[]

```

[`frobenius\(\)`](#)

`reduced_kronecker_product(x)`

Return the reduced Kronecker product of `self` and `x` in the basis of `self`.

The reduced Kronecker product is a bilinear map mapping two symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let $*$ denote the Kronecker product ([`itensor\(\)`](#)) on the space of symmetric functions. For any partitions α, β, γ , let $g_{\alpha, \beta}^{\gamma}$ denote the coefficient of the Schur function s_{γ} in the Kronecker product $s_{\alpha} * s_{\beta}$ (this is called a Kronecker coefficient). For every partition $\lambda = (\lambda_1, \lambda_2, \lambda_3, \dots)$ and every integer $n > |\lambda| + \lambda_1$, let $\lambda[n]$ denote the n -completion of λ (this is the partition $(n - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \dots)$; see [`t\_completion\(\)`](#)). Then, Theorem 1.2 of [\[BOR09\]](#) shows that for any partitions α and β and every integer $n \geq |\alpha| + |\beta| + \alpha_1 + \beta_1$, we can write the Kronecker product $s_{\alpha[n]} * s_{\beta[n]}$ in the form

$$s_{\alpha[n]} * s_{\beta[n]} = \sum_{\gamma} g_{\alpha[n], \beta[n]}^{\gamma[n]} s_{\gamma[n]}$$

with γ ranging over all partitions. The coefficients $g_{\alpha[n], \beta[n]}^{\gamma[n]}$ are independent on n . These coefficients $g_{\alpha[n], \beta[n]}^{\gamma[n]}$ are denoted by $\bar{g}_{\alpha, \beta}^{\gamma}$, and the symmetric function

$$\sum_{\gamma} \bar{g}_{\alpha, \beta}^{\gamma} s_{\gamma}$$

is said to be the *reduced Kronecker product* of s_{α} and s_{β} . By bilinearity, this extends to a definition of a reduced Kronecker product of any two symmetric functions.

The definition of the reduced Kronecker product goes back to Murnaghan, and has recently been studied in [\[BOR09\]](#), [\[BdVO12\]](#) and other places (our notation $\bar{g}_{\alpha, \beta}^{\gamma}$ appears in these two sources).

INPUT:

- x – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the reduced Kronecker product of `self` with x (an element of the ring of symmetric functions in the same basis as `self`)

EXAMPLES:

The example from page 2 of [\[BOR09\]](#):

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: s[2].reduced_kronecker_product(s[2])
s[] + s[1] + s[1, 1] + s[1, 1, 1] + 2*s[2] + 2*s[2, 1] + s[2, 2] + s[3] + s[3,
↪ 1] + s[4]
```

Taking the reduced Kronecker product with $1 = s$ is the identity map on the ring of symmetric functions:

```
sage: all( s[Partition([])].reduced_kronecker_product(s[lam])
....:      == s[lam] for i in range(4)
....:      for lam in Partitions(i) )
True
```

While reduced Kronecker products are hard to compute in general, there is a rule for taking reduced Kronecker products with s_1 . Namely, for every partition λ , the reduced Kronecker product of s_λ with s_1 is $\sum_\mu a_\mu s_\mu$, where the sum runs over all partitions μ , and the coefficient a_μ is defined as the number of ways to obtain μ from λ by one of the following three operations:

- Add an addable cell ([addable_cells\(\)](#)) to λ .
- Remove a removable cell ([removable_cells\(\)](#)) from λ .
- First remove a removable cell from λ , then add an addable cell to the resulting Young diagram.

This is, in fact, Proposition 5.15 of [\[CO10\]](#) in an elementary wording. We check this for partitions of size ≤ 4 :

```
sage: def mults1(lam):
....:     # Reduced Kronecker multiplication by s[1], according
....:     # to [CO10]_.
....:     res = s.zero()
....:     for mu in lam.up_list():
....:         res += s(mu)
....:     for mu in lam.down_list():
....:         res += s(mu)
....:         for nu in mu.up_list():
....:             res += s(nu)
....:     return res
sage: all( mults1(lam) == s[1].reduced_kronecker_product(s[lam])
....:       for i in range(5) for lam in Partitions(i) )
True
```

Here is the example on page 3 of Christian Gutschwager’s [Arxiv 0912.4411v3](#):

```
sage: s[1,1].reduced_kronecker_product(s[2])
s[1] + 2*s[1, 1] + s[1, 1, 1] + s[2] + 2*s[2, 1] + s[2, 1, 1] + s[3] + s[3, 1]
```

Example 39 from F. D. Murnaghan, “The analysis of the Kronecker product of irreducible representations of the symmetric group”, American Journal of Mathematics, Vol. 60, No. 3, Jul. 1938:

```

sage: s[3].reduced_kronecker_product(s[2,1])
s[1] + 2*s[1, 1] + 2*s[1, 1, 1] + s[1, 1, 1, 1] + 2*s[2] + 5*s[2, 1] + 4*s[2, 1, 1]
+ s[2, 1, 1, 1] + 3*s[2, 2] + 2*s[2, 2, 1] + 2*s[3] + 5*s[3, 1] + 3*s[3, 1, 1]
+ 3*s[3, 2] + s[3, 2, 1] + 2*s[4] + 3*s[4, 1] + s[4, 1, 1] + s[4, 2] + s[5]
+ s[5, 1]

```

Todo

This implementation of the reduced Kronecker product is painfully slow.

restrict_degree (*d*, *exact=True*)

Return the degree *d* component of *self*.

INPUT:

- *d* – positive integer, degree of the terms to be returned
- *exact* – boolean, if *True*, returns the terms of degree exactly *d*, otherwise returns all terms of degree less than or equal to *d*

OUTPUT:

- the homogeneous component of *self* of degree *d*

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_degree(2)
0
sage: z.restrict_degree(1)
s[1]
sage: z.restrict_degree(3)
s[1, 1, 1] + s[2, 1]
sage: z.restrict_degree(3, exact=False)
s[1] + s[1, 1, 1] + s[2, 1]
sage: z.restrict_degree(0)
0

```

restrict_partition_lengths (*l*, *exact=True*)

Return the terms of *self* labelled by partitions of length *l*.

INPUT:

- *l* – nonnegative integer
- *exact* – boolean, defaulting to *True*

OUTPUT:

- if *True*, returns the terms labelled by partitions of length precisely *l*; otherwise returns all terms labelled by partitions of length less than or equal to *l*

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_partition_lengths(2)
s[2, 1]

```

```

sage: z.restrict_partition_lengths(0)
0
sage: z.restrict_partition_lengths(2, exact = False)
s[1] + s[2, 1] + s[4]

```

restrict_parts(*n*)

Return the terms of `self` labelled by partitions λ with $\lambda_1 \leq n$.

INPUT:

- *n* – positive integer, to restrict the parts of the partitions of the terms to be returned

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_parts(2)
s[1] + s[1, 1, 1] + s[2, 1]
sage: z.restrict_parts(1)
s[1] + s[1, 1, 1]

```

scalar(*x*, *zee=None*)

Return the standard scalar product between `self` and *x*.

INPUT:

- *x* – element of the ring of symmetric functions over the same base ring as `self`
- *zee* – an optional function on partitions giving the value for the scalar product between p_μ and p_μ (default is to use the standard `zee()` function)

This is the default implementation that converts both `self` and *x* into either Schur functions (if *zee* is not specified) or power-sum functions (if *zee* is specified) and performs the scalar product in that basis.

EXAMPLES:

```

sage: e = SymmetricFunctions(QQ).e()
sage: h = SymmetricFunctions(QQ).h()
sage: m = SymmetricFunctions(QQ).m()
sage: p4 = Partitions(4)
sage: matrix([ [e(a).scalar(h(b)) for a in p4] for b in p4])
[ 0  0  0  0  1]
[ 0  0  0  1  4]
[ 0  0  1  2  6]
[ 0  1  2  5 12]
[ 1  4  6 12 24]
sage: matrix([ [h(a).scalar(e(b)) for a in p4] for b in p4])
[ 0  0  0  0  1]
[ 0  0  0  1  4]
[ 0  0  1  2  6]
[ 0  1  2  5 12]
[ 1  4  6 12 24]
sage: matrix([ [m(a).scalar(e(b)) for a in p4] for b in p4])
[-1  2  1 -3  1]
[ 0  1  0 -2  1]
[ 0  0  1 -2  1]
[ 0  0  0 -1  1]
[ 0  0  0  0  1]
sage: matrix([ [m(a).scalar(h(b)) for a in p4] for b in p4])
[1  0  0  0  0]

```

```

[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]

sage: p = SymmetricFunctions(QQ).p()
sage: m(p[3,2]).scalar(p[3,2], zee=lambda mu: 2**mu.length())
4
sage: m(p[3,2]).scalar(p[2,2,1], lambda mu: 1)
0
sage: m[3,2].scalar(h[3,2], zee=lambda mu: 2**mu.length())
2/3

```

scalar_hl(*x*, *t=None*)

Return the *t*-deformed standard Hall-Littlewood scalar product of *self* and *x*.

INPUT:

- *x* – element of the ring of symmetric functions over the same base ring as *self*
- *t* – parameter (default: *None*, in which case *t* is used)

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: sp = a.scalar_t(a); sp
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sage: sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field

```

scalar_jack(*x*, *t=None*)

Return the Jack-scalar product between *self* and *x*.

This scalar product is defined so that the power sum elements p_μ are orthogonal and $\langle p_\mu, p_\mu \rangle = z_\mu t^{\ell(\mu)}$, where $\ell(\mu)$ denotes the length of μ .

INPUT:

- *x* – element of the ring of symmetric functions over the same base ring as *self*
- *t* – an optional parameter (default: *None* in which case *t* is used)

EXAMPLES:

```

sage: p = SymmetricFunctions(QQ['t']).power()
sage: matrix([[p(mu).scalar_jack(p(nu)) for nu in Partitions(4)] for mu in_
↪Partitions(4)])
[ 4*t      0      0      0      0]
[  0  3*t^2    0      0      0]
[  0      0  8*t^2    0      0]
[  0      0      0  4*t^3    0]
[  0      0      0      0 24*t^4]
sage: matrix([[p(mu).scalar_jack(p(nu),2) for nu in Partitions(4)] for mu in_
↪Partitions(4)])
[ 8  0  0  0  0]
[ 0 12  0  0  0]
[ 0  0 32  0  0]
[ 0  0  0 32  0]
[ 0  0  0  0 384]
sage: JQ = SymmetricFunctions(QQ['t'].fraction_field()).jack().Q()

```

```

sage: matrix([[JQ(mu).scalar_jack(JQ(nu)) for nu in Partitions(3)] for mu in
↪Partitions(3)])
[ (2*t^2 + 3*t + 1)/(6*t^3) 0
↪0]
[ 0 (t + 2)/(2*t^3 + t^2)
↪0]
[ 0 0 6/(t^3 + 3*t^2 +
↪2*t) ]

```

scalar_qt (*x*, *q*=None, *t*=None)

Returns the *q*, *t*-deformed standard Hall-Littlewood scalar product of *self* and *x*.

INPUT:

- *x* – element of the ring of symmetric functions over the same base ring as *self*
- *q*, *t* – parameters (default: None in which case *q* and *t* are used)

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: sp = a.scalar_qt(a); factor(sp)
(t - 1)^-3 * (q - 1) * (t^2 + t + 1)^-1 * (q^2*t^2 - q*t^2 + q^2 - 2*q*t + t^
↪2 - q + 1)
sage: sp.parent()
Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field
sage: a.scalar_qt(a, q=0)
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sage: a.scalar_qt(a, t=0)
-q^3 + 2*q^2 - 2*q + 1
sage: a.scalar_qt(a, 5, 7) # q=5 and t=7
490/1539
sage: (x, y) = var('x, y')
sage: a.scalar_qt(a, q=x, t=y)
1/3*(x^3 - 1)/(y^3 - 1) + 2/3*(x - 1)^3/(y - 1)^3
sage: Rn = QQ['q', 't', 'y', 'z'].fraction_field()
sage: (q, t, y, z) = Rn.gens()
sage: Mac = SymmetricFunctions(Rn).macdonald(q=y, t=z)
sage: a = Mac._sym.schur()([2,1])
sage: factor(Mac.P()(a).scalar_qt(Mac.Q()(a), q, t))
(t - 1)^-3 * (q - 1) * (t^2 + t + 1)^-1 * (q^2*t^2 - q*t^2 + q^2 - 2*q*t + t^
↪2 - q + 1)
sage: factor(Mac.P()(a).scalar_qt(Mac.Q()(a)))
(z - 1)^-3 * (y - 1) * (z^2 + z + 1)^-1 * (y^2*z^2 - y*z^2 + y^2 - 2*y*z + z^
↪2 - y + 1)

```

scalar_t (*x*, *t*=None)

Return the *t*-deformed standard Hall-Littlewood scalar product of *self* and *x*.

INPUT:

- *x* – element of the ring of symmetric functions over the same base ring as *self*
- *t* – parameter (default: None, in which case *t* is used)

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: sp = a.scalar_t(a); sp

```

```
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sage: sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

skew_by(x)

Return the result of skewing `self` by `x`. (Skewing by `x` is the endomorphism (as additive group) of the ring of symmetric functions adjoint to multiplication by `x` with respect to the Hall inner product.)

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([3,2]).skew_by(s([2]))
s[2, 1] + s[3]
sage: s([3,2]).skew_by(s([1,1,1]))
0
sage: s([3,2,1]).skew_by(s([2,1]))
s[1, 1, 1] + 2*s[2, 1] + s[3]
```

```
sage: p = SymmetricFunctions(QQ).powersum()
sage: p([4,3,3,2,2,1]).skew_by(p([2,1]))
4*p[4, 3, 3, 2]
sage: zee = sage.combinat.sf.sfa.zee
sage: zee([4,3,3,2,2,1])/zee([4,3,3,2])
4
sage: s(0).skew_by(s([1]))
0
sage: s(1).skew_by(s([1]))
0
sage: s().skew_by(s())
s[]
sage: s().skew_by(s[1])
0
```

theta(a)

Return the image of `self` under the theta endomorphism which sends p_k to $a \cdot p_k$ for every positive integer k .

In general, this is well-defined outside of the powersum basis only if the base ring is a $\mathbb{Q}$ -algebra.

INPUT:

- `a` – an element of the base ring

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([2,1]).theta(2)
2*s[1, 1, 1] + 6*s[2, 1] + 2*s[3]
sage: p = SymmetricFunctions(QQ).p()
sage: p([2]).theta(2)
2*p[2]
sage: p(0).theta(2)
0
sage: p(1).theta(2)
p[]
```

theta_qt ($q=None, t=None$)

Return the image of `self` under the q, t -deformed theta endomorphism which sends p_k to $\frac{1-q^k}{1-t^k} \cdot p_k$ for all positive integers k .

In general, this is well-defined outside of the powersum basis only if the base ring is a $\mathbb{Q}$ -algebra.

INPUT:

- q, t – parameters (default: `None`, in which case ‘ q ’ and ‘ t ’ are used)

EXAMPLES:

```
sage: QQqt = QQ['q,t'].fraction_field()
sage: q,t = QQqt.gens()
sage: p = SymmetricFunctions(QQqt).p()
sage: p([2]).theta_qt(q,t)
((-q^2+1)/(-t^2+1))*p[2]
sage: p([2,1]).theta_qt(q,t)
((q^3-q^2-q+1)/(t^3-t^2-t+1))*p[2, 1]
sage: p(0).theta_qt(q=1,t=3)
0
sage: p([2,1]).theta_qt(q=2,t=3)
3/16*p[2, 1]
sage: s = p.realization_of().schur()
sage: s([3]).theta_qt(q=0)*(1-t)*(1-t^2)*(1-t^3)
t^3*s[1, 1, 1] + (t^2+t)*s[2, 1] + s[3]
sage: p(1).theta_qt()
p[]
```

verschiebung (n)

Return the image of the symmetric function `self` under the n -th Verschiebung operator.

The n -th Verschiebung operator $\mathbf{V}_n$ is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n , and satisfies $V(h_r) = 0$ for every positive integer r not divisible by n . This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(h_r) = h_{r/n}, \quad \mathbf{V}_n(p_r) = np_{r/n}, \quad \mathbf{V}_n(e_r) = (-1)^{r-r/n} e_{r/n}$$

(where h is the complete homogeneous basis, p is the powersum basis, and e is the elementary basis). For every nonnegative integer r with $n \nmid r$, it satisfies

$$\mathbf{V}_n(h_r) = \mathbf{V}_n(p_r) = \mathbf{V}_n(e_r) = 0.$$

The n -th Verschiebung operator is also called the n -th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The n -th Verschiebung operator is adjoint to the n -th Frobenius operator (see `frobenius()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the n -th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let λ be a partition. Let n be a positive integer. If the n -core of λ is nonempty, then $\mathbf{V}_n(s_\lambda) = 0$. Otherwise, the following method computes $\mathbf{V}_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, \dots, \lambda_{ns})$ for some nonnegative integer s . (If n does not divide the length of λ , then this is achieved by adding trailing zeroes to λ .) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \dots, ns\}$. Then, $(\beta_1, \beta_2, \dots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo n . Let ξ be the sign of the permutation that is used for this

sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo n . (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $V_n(s_\lambda) = \xi^\psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \dots, \lambda^{(n-1)})$ is the n -quotient of λ .

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: s[3].verschiebung(2)
0
sage: s[3].verschiebung(3)
s[1]
sage: p[3].verschiebung(3)
3*p[1]
sage: m[3,2,1].verschiebung(3)
-18*m[1, 1] - 3*m[2]
sage: p[3,2,1].verschiebung(3)
0
sage: h[4].verschiebung(2)
h[2]
sage: p[2].verschiebung(2)
2*p[1]
sage: m[3,2,1].verschiebung(6)
12*m[1]
```

The Verschiebung endomorphisms are multiplicative:

```
sage: all( all( s(lam).verschiebung(2) * s(mu).verschiebung(2)
....:         == (s(lam) * s(mu)).verschiebung(2)
....:         for mu in Partitions(4) )
....:         for lam in Partitions(4) )
True
```

Being Hopf algebra endomorphisms, the Verschiebung operators commute with the antipode:

```
sage: all( p(lam).verschiebung(3).antipode()
....:     == p(lam).antipode().verschiebung(3)
....:     for lam in Partitions(6) )
True
```

Testing the adjointness between the Frobenius operators f_n and the Verschiebung operators V_n :

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: p = Sym.p()
sage: all( all( s(lam).verschiebung(2).scalar(p(mu))
....:         == s(lam).scalar(p(mu).frobenius(2))
....:         for mu in Partitions(3) )
```

```
.....:      for lam in Partitions(6) )
True
```

class sage.combinat.sf.sfa.**SymmetricFunctionsBases** (*parent_with_realization*)
 Bases: sage.categories.realizations.Category_realization_of_parent

The category of bases of the ring of symmetric functions.

INPUT:

- **self** – a category of bases for the symmetric functions
- **base** – ring of symmetric functions

class **ParentMethods**

Eulerian (*n, j, k=None*)

Return the Eulerian symmetric function $Q_{n,j}$ (with n either an integer or a partition) or $Q_{n,j,k}$ (if the optional argument k is specified) in terms of the basis **self**.

It is known that the Eulerian quasisymmetric functions are in fact symmetric functions [SW2010]. For more information, see [QuasiSymmetricFunctions.Fundamental.Eulerian\(\)](#), which accepts the same syntax as this method.

INPUT:

- **n** – the nonnegative integer n or a partition
- **j** – the number of excedances
- **k** – (optional) if specified, determines the number of fixed points of the permutations which are being summed over

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: m.Eulerian(3, 1)
4*m[1, 1, 1] + 3*m[2, 1] + 2*m[3]
sage: h = Sym.h()
sage: h.Eulerian(4, 2)
h[2, 2] + h[3, 1] + h[4]
sage: s = Sym.s()
sage: s.Eulerian(5, 2)
s[2, 2, 1] + s[3, 1, 1] + 5*s[3, 2] + 6*s[4, 1] + 6*s[5]
sage: s.Eulerian([2, 2, 1], 2)
s[2, 2, 1] + s[3, 2] + s[4, 1] + s[5]
sage: s.Eulerian(5, 2, 2)
s[3, 2] + s[4, 1] + s[5]
```

We check Equation (5.4) in [SW2010]:

```
sage: h.Eulerian([6], 3)
h[3, 2, 1] - h[4, 1, 1] + 2*h[4, 2] + h[5, 1]
sage: s.Eulerian([6], 3)
s[3, 2, 1] + s[3, 3] + 3*s[4, 2] + 3*s[5, 1] + 3*s[6]
```

carlitz_sharesian_wachs (*n, d, s, comparison=None*)

Return the Carlitz-Sharesian-Wachs symmetric function $X_{n,d,s}$ (if *comparison* is None), or $U_{n,d,s}$ (if *comparison* is -1), or $V_{n,d,s}$ (if *comparison* is 0), or $W_{n,d,s}$ (if *comparison* is 1) written in the basis **self**. These functions are defined below.

The Carlitz-Shareshian-Wachs symmetric functions have been introduced in [GriRei2014], Exercise 2.87, as refinements of a certain particular case of chromatic quasisymmetric functions defined by Shareshian and Wachs. Their definitions are as follows:

Let n , d and s be three nonnegative integers. Let $W(n, d, s)$ denote the set of all n -tuples $(w_1, w_2, \dots, w_n)$ of positive integers having the property that there exist precisely d elements i of $\{1, 2, \dots, n-1\}$ satisfying $w_i > w_{i+1}$, and precisely s elements i of $\{1, 2, \dots, n-1\}$ satisfying $w_i = w_{i+1}$. For every $w = (w_1, w_2, \dots, w_n) \in W(n, d, s)$, let x_w be the monomial $x_{w_1} x_{w_2} \cdots x_{w_n}$. We then define the power series $X_{n,d,s}$ by

$$X_{n,d,s} = \sum_{w \in W(n,d,s)} x_w.$$

This is a symmetric function (according to [GriRei2014], Exercise 2.87(b)), and for $s = 0$ equals the t^d -coefficient of the descent enumerator of Smirnov words of length n (an example of a chromatic quasisymmetric function which happens to be symmetric – see [ShaWach2014], Example 2.5).

Assume that $n > 0$. Then, we can define three further power series as follows:

$$U_{n,d,s} = \sum_{w_1 < w_n} x_w; \quad V_{n,d,s} = \sum_{w_1 = w_n} x_w; \quad W_{n,d,s} = \sum_{w_1 > w_n} x_w,$$

where all three sums range over $w = (w_1, w_2, \dots, w_n) \in W(n, d, s)$. These three power series $U_{n,d,s}$, $V_{n,d,s}$ and $W_{n,d,s}$ are symmetric functions as well ([GriRei2014], Exercise 2.87(c)). Their sum is $X_{n,d,s}$.

REFERENCES:

INPUT:

- n – a nonnegative integer
- d – a nonnegative integer
- s – a nonnegative integer
- `comparison` (default: `None`) – a variable which can take the forms `None`, `-1`, `0` and `1`

OUTPUT:

The Carlitz-Shareshian-Wachs symmetric function $X_{n,d,s}$ (if `comparison` is `None`), or $U_{n,d,s}$ (if `comparison` is `-1`), or $V_{n,d,s}$ (if `comparison` is `0`), or $W_{n,d,s}$ (if `comparison` is `1`) written in the basis `self`.

EXAMPLES:

The power series $X_{n,d,s}$:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.m()
sage: m.carlitz_shareshian_wachs(3, 2, 1)
0
sage: m.carlitz_shareshian_wachs(3, 1, 1)
m[2, 1]
sage: m.carlitz_shareshian_wachs(3, 2, 0)
m[1, 1, 1]
sage: m.carlitz_shareshian_wachs(3, 0, 2)
m[3]
sage: m.carlitz_shareshian_wachs(3, 1, 0)
4*m[1, 1, 1] + m[2, 1]
sage: m.carlitz_shareshian_wachs(3, 0, 1)
m[2, 1]
sage: m.carlitz_shareshian_wachs(3, 0, 0)
m[1, 1, 1]
sage: m.carlitz_shareshian_wachs(5, 2, 2)
```

```

m[2, 2, 1] + m[3, 1, 1]
sage: m.carlitz_sharesian_wachs(1, 0, 0)
m[1]
sage: m.carlitz_sharesian_wachs(0, 0, 0)
m[]

```

The power series $U_{n,d,s}$:

```

sage: m.carlitz_sharesian_wachs(3, 2, 1, comparison=-1)
0
sage: m.carlitz_sharesian_wachs(3, 1, 1, comparison=-1)
0
sage: m.carlitz_sharesian_wachs(3, 2, 0, comparison=-1)
0
sage: m.carlitz_sharesian_wachs(3, 0, 2, comparison=-1)
0
sage: m.carlitz_sharesian_wachs(3, 1, 0, comparison=-1)
2*m[1, 1, 1]
sage: m.carlitz_sharesian_wachs(3, 0, 1, comparison=-1)
m[2, 1]
sage: m.carlitz_sharesian_wachs(3, 0, 0, comparison=-1)
m[1, 1, 1]
sage: m.carlitz_sharesian_wachs(5, 2, 2, comparison=-1)
0
sage: m.carlitz_sharesian_wachs(4, 2, 0, comparison=-1)
3*m[1, 1, 1, 1]
sage: m.carlitz_sharesian_wachs(1, 0, 0, comparison=-1)
0

```

The power series $V_{n,d,s}$:

```

sage: m.carlitz_sharesian_wachs(3, 2, 1, comparison=0)
0
sage: m.carlitz_sharesian_wachs(3, 1, 1, comparison=0)
0
sage: m.carlitz_sharesian_wachs(3, 2, 0, comparison=0)
0
sage: m.carlitz_sharesian_wachs(3, 0, 2, comparison=0)
m[3]
sage: m.carlitz_sharesian_wachs(3, 1, 0, comparison=0)
m[2, 1]
sage: m.carlitz_sharesian_wachs(3, 0, 1, comparison=0)
0
sage: m.carlitz_sharesian_wachs(3, 0, 0, comparison=0)
0
sage: m.carlitz_sharesian_wachs(5, 2, 2, comparison=0)
0
sage: m.carlitz_sharesian_wachs(4, 2, 0, comparison=0)
m[2, 1, 1]
sage: m.carlitz_sharesian_wachs(1, 0, 0, comparison=0)
m[1]

```

The power series $W_{n,d,s}$:

```

sage: m.carlitz_sharesian_wachs(3, 2, 1, comparison=1)
0
sage: m.carlitz_sharesian_wachs(3, 1, 1, comparison=1)
m[2, 1]

```

```

sage: m.carlitz_sharesian_wachs(3, 2, 0, comparison=1)
m[1, 1, 1]
sage: m.carlitz_sharesian_wachs(3, 0, 2, comparison=1)
0
sage: m.carlitz_sharesian_wachs(3, 1, 0, comparison=1)
2*m[1, 1, 1]
sage: m.carlitz_sharesian_wachs(3, 0, 1, comparison=1)
0
sage: m.carlitz_sharesian_wachs(3, 0, 0, comparison=1)
0
sage: m.carlitz_sharesian_wachs(5, 2, 2, comparison=1)
m[2, 2, 1] + m[3, 1, 1]
sage: m.carlitz_sharesian_wachs(4, 2, 0, comparison=1)
8*m[1, 1, 1, 1] + 2*m[2, 1, 1] + m[2, 2]
sage: m.carlitz_sharesian_wachs(1, 0, 0, comparison=1)
0

```

corresponding_basis_over(*R*)

Return the realization of symmetric functions corresponding to *self* but over the base ring *R*. Only works when *self* is one of the classical bases, not one of the *q*, *t*-dependent ones. In the latter case, None is returned instead.

INPUT:

- *R* – a commutative ring

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: m.corresponding_basis_over(ZZ)
Symmetric Functions over Integer Ring in the monomial basis

sage: Sym = SymmetricFunctions(CyclotomicField())
sage: s = Sym.schur()
sage: s.corresponding_basis_over(Integers(13))
Symmetric Functions over Ring of integers modulo 13 in the Schur basis

sage: P = ZZ['q', 't']
sage: Sym = SymmetricFunctions(P)
sage: mj = Sym.macdonald().J()
sage: mj.corresponding_basis_over(Integers(13))

```

Todo

This function is an ugly hack using strings. It should be rewritten as soon as the bases of `SymmetricFunctions` are put on a more robust and systematic footing.

degree_on_basis(*b*)

Return the degree of the basis element indexed by *b*.

INPUT:

- *self* – a basis of the symmetric functions
- *b* – a partition

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ['q,t'].fraction_field())
sage: m = Sym.monomial()

```

```

sage: m.degree_on_basis(Partition([3,2]))
5
sage: P = Sym.macdonald().P()
sage: P.degree_on_basis(Partition([]))
0

```

gessel_reutenauer(*lam*)

Return the Gessel-Reutenauer symmetric function corresponding to the partition *lam* written in the basis *self*.

Let λ be a partition. The *Gessel-Reutenauer symmetric function* $\mathbf{GR}_\lambda$ corresponding to λ is the symmetric function denoted L_λ in [GR1993] and in Exercise 7.89 of [STA]. It can be defined in several ways:

- It is the sum of the monomials $\mathbf{x}_w$ over all words w over the alphabet $\{1, 2, 3, \dots\}$ which have CFL type λ . Here, the monomial $\mathbf{x}_w$ for a word $w = (w_1, w_2, \dots, w_k)$ is defined as $x_{w_1}x_{w_2} \cdots x_{w_k}$, and the *CFL type* of a word w is defined as the partition obtained by sorting (in decreasing order) the lengths of the factors in the Lyndon factorization (*lyndon_factorization()*) of w . The fact that this power series $\mathbf{GR}_\lambda$ is symmetric is not obvious.
- It is the sum of the fundamental quasisymmetric functions $F_{\text{Des } \sigma}$ over all permutations σ which have cycle type λ . See *sage.combinat.ncsf_qsym.qsym.QuasiSymmetricFunctions.Fundamental* for the definition of fundamental quasisymmetric functions, and *cycle_type()* for that of cycle type. For a permutation σ , we use $\text{Des } \sigma$ to denote the descent composition (*descents_composition()*) of σ . Again, this definition makes the symmetry of $\mathbf{GR}_\lambda$ far from obvious.
- For every positive integer n , we have

$$\mathbf{GR}_{(n)} = \frac{1}{n} \sum_{d|n} \mu(d) p_d^{n/d},$$

where p_d denotes the d -th power-sum symmetric function. This $\mathbf{GR}_{(n)}$ is also denoted by L_n . Now, $\mathbf{GR}_\lambda$ is defined as the product:

$$h_{m_1}[L_1] \cdot h_{m_2}[L_2] \cdot h_{m_3}[L_3] \cdots,$$

where m_i denotes the multiplicity of the part i in λ , and where the square brackets stand for plethysm (*plethysm()*). This definition makes the symmetry (but not the integrality!) of $\mathbf{GR}_\lambda$ obvious.

The equivalences of these three definitions are proven in [GR1993] Sections 2-3.

INPUT:

- *lam* – a partition or a positive integer (in the latter case, it is understood to mean the partition [*lam*])

OUTPUT:

The Gessel-Reutenauer symmetric function $\mathbf{GR}_\lambda$, where λ is *lam*, expanded in the basis *self*.

REFERENCES:

EXAMPLES:

The first few values of $\mathbf{GR}_{(n)} = L_n$:

```

sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.gessel_reutenauer(1)
h[1]
sage: h.gessel_reutenauer(2)

```

```

h[1, 1] - h[2]
sage: h.gessel_reutenauer(3)
h[2, 1] - h[3]
sage: h.gessel_reutenauer(4)
h[2, 1, 1] - h[2, 2]
sage: h.gessel_reutenauer(5)
h[2, 1, 1, 1] - h[2, 2, 1] - h[3, 1, 1] + h[3, 2] + h[4, 1] - h[5]
sage: h.gessel_reutenauer(6)
h[2, 1, 1, 1, 1] - h[2, 2, 1, 1] - h[2, 2, 2]
- 2*h[3, 1, 1, 1] + 5*h[3, 2, 1] - 2*h[3, 3] + h[4, 1, 1]
- h[4, 2] - h[5, 1] + h[6]

```

Gessel-Reutenauer functions indexed by partitions:

```

sage: h.gessel_reutenauer([2, 1])
h[1, 1, 1] - h[2, 1]
sage: h.gessel_reutenauer([2, 2])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 2*h[2, 2] + h[3, 1] - h[4]

```

The Gessel-Reutenauer functions are Schur-positive:

```

sage: s = Sym.s()
sage: s.gessel_reutenauer([2, 1])
s[1, 1, 1] + s[2, 1]
sage: s.gessel_reutenauer([2, 2, 1])
s[1, 1, 1, 1, 1] + s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 2]

```

They do not form a basis, as the following example (from [GR1993] p. 201) shows:

```

sage: s.gessel_reutenauer([4]) == s.gessel_reutenauer([2, 1, 1])
True

```

Of the above three equivalent definitions of $\mathbf{GR}_\lambda$, we use the third one for computations. Let us check that the second one gives the same results:

```

sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F() # fundamental basis
sage: def GR_def2(lam): # '\mathbf{GR}_\lambda'
....:     n = lam.size()
....:     r = F.sum_of_monomials([sigma.descents_composition()
....:                             for sigma in Permutations(n)
....:                             if sigma.cycle_type() == lam])
....:     return r.to_symmetric_function()
sage: all( GR_def2(lam) == h.gessel_reutenauer(lam)
....:       for n in range(5) for lam in Partitions(n) )
True

```

And the first one, too (assuming symmetry):

```

sage: m = Sym.m()
sage: def GR_def1(lam): # '\mathbf{GR}_\lambda'
....:     n = lam.size()
....:     Permuset = sage.combinat.permutation.Permutations_mset
....:     def coeff_of_m_mu_in_result(mu):
....:         words_to_check = Permuset([i for (i, l) in enumerate(mu)
....:                                     for _ in range(l)])
....:         return sum((1 for w in words_to_check if
....:                     Partition(list(reversed(sorted([len(v) for v in
....: Word(w).lyndon_factorization())))))

```

```

.....:                                     == lam))
.....:         r = m.sum_of_terms([(mu, coeff_of_m_mu_in_result(mu))
.....:                               for mu in Partitions(n)],
.....:                               distinct=True)
.....:         return r
sage: all( GR_def1(lam) == h.gessel_reutenauer(lam)
.....:       for n in range(5) for lam in Partitions(n) )
True

```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a $\mathbf{Q}$ -algebra from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over $\mathbf{Q}$ (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

is_commutative()

Returns whether this symmetric function algebra is commutative.

INPUT:

- `self` – a basis of the symmetric functions

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: s.is_commutative()
True

```

is_field(*proof=True*)

Return whether `self` is a field. (It is not.)

INPUT:

- `self` – a basis of the symmetric functions
- `proof` – an optional argument (default value: `True`)

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: s.is_field()
False

```

is_integral_domain(*proof=True*)

Return whether `self` is an integral domain. (It is if and only if the base ring is an integral domain.)

INPUT:

- `self` – a basis of the symmetric functions
- `proof` – an optional argument (default value: `True`)

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: s.is_integral_domain()
True

```

The following doctest is disabled pending [trac ticket #15475](#):

```

sage: s = SymmetricFunctions(Zmod(14)).s() # not tested
sage: s.is_integral_domain() # not tested
False

```

one_basis()

Returns the empty partition, as per `AlgebrasWithBasis.ParentMethods.one_basis`

INPUT:

•self – a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: s = Sym.s()
sage: s.one_basis()
[]
sage: Q = Sym.hall_littlewood().Q()
sage: Q.one_basis()
[]
```

Todo

generalize to `Modules.Graded.Connected.ParentMethods`

skew_schur(x)

Return the skew Schur function indexed by `x` in `self`.

INPUT:

•x – a skew partition

EXAMPLES:

```
sage: sp = SkewPartition([[5,3,3,1], [3,2,1]])
sage: s = SymmetricFunctions(QQ).s()
sage: s.skew_schur(sp)
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 3*s[3, 2, 1]
+ s[3, 3] + 2*s[4, 1, 1] + 2*s[4, 2] + s[5, 1]

sage: e = SymmetricFunctions(QQ).e()
sage: ess = e.skew_schur(sp); ess
e[2, 1, 1, 1, 1] - e[2, 2, 1, 1] - e[3, 1, 1, 1] + e[3, 2, 1]
sage: ess == e(s.skew_schur(sp))
True
```

SymmetricFunctionsBases.super_categories()

The super categories of `self`.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import SymmetricFunctionsBases
sage: Sym = SymmetricFunctions(QQ)
sage: bases = SymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of realizations of Symmetric Functions over Rational Field,
Category of commutative hopf algebras with basis over Rational Field,
Join of Category of realizations of hopf algebras over Rational Field
and Category of graded algebras over Rational Field]
```

sage.combinat.sf.sfa.is_SymmetricFunction(x)

Checks whether `x` is a symmetric function.

EXAMPLES:

```

sage: from sage.combinat.sf.sfa import is_SymmetricFunction
sage: s = SymmetricFunctions(QQ).s()
sage: is_SymmetricFunction(2)
False
sage: is_SymmetricFunction(s(2))
True
sage: is_SymmetricFunction(s([2,1]))
True

```

`sage.combinat.sf.sfa.is_SymmetricFunctionAlgebra(x)`
 Checks whether x is a symmetric function algebra.

EXAMPLES:

```

sage: from sage.combinat.sf.sfa import is_SymmetricFunctionAlgebra
sage: is_SymmetricFunctionAlgebra(5)
False
sage: is_SymmetricFunctionAlgebra(ZZ)
False
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(ZZ).schur())
True
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(QQ).e())
True
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(QQ).macdonald(q=1,t=1).P())
True
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(FractionField(QQ['q','t'])).
↪macdonald().P())
True

```

`sage.combinat.sf.sfa.zee(part)`
 Return the size of the centralizer of any permutation of cycle type $part$.

Note that the size of the centralizer is the inner product between $p(part)$ and itself, where p is the power-sum symmetric functions.

INPUT:

- $part$ – an integer partition (for example, $[2, 1, 1]$)

OUTPUT:

- the integer $\prod_i i^{m_i(part)} m_i(part)!$ where $m_i(part)$ is the number of parts in the partition $part$ equal to i

EXAMPLES:

```

sage: from sage.combinat.sf.sfa import zee
sage: zee([2,1,1])
4

```

5.1.281 Witt symmetric functions

```

class sage.combinat.sf.witt.SymmetricFunctionAlgebra_witt(Sym,
                                                            coerce_h=True,
                                                            coerce_e=False,
                                                            coerce_p=False)

```

Bases: `sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative`

The Witt symmetric function basis (or Witt basis, to be short).

The Witt basis of the ring of symmetric functions is denoted by (x_λ) in [HazWitt1], section 9.63, and by (q_λ) in [DoranIV1996]. We will denote this basis by (w_λ) (which is precisely how it is denoted in [GriRei2014], Exercise 2.79(d)). It is a multiplicative basis (meaning that $w_\emptyset = 1$ and that every partition λ satisfies $w_\lambda = w_{\lambda_1} w_{\lambda_2} w_{\lambda_3} \cdots$, where w_i means $w_{(i)}$ for every nonnegative integer i).

This basis can be defined in various ways. Probably the most well-known one is using the equation

$$\prod_{d=1}^{\infty} (1 - w_d t^d)^{-1} = \sum_{n=0}^{\infty} h_n t^n$$

where t is a formal variable and h_n are the complete homogeneous symmetric functions, extended to 0 by $h_0 = 1$. This equation allows one to uniquely determine the functions $w_1, w_2, w_3, \dots$ by recursion; one consequently extends the definition to all w_λ by requiring multiplicativity.

A way to rewrite the above equation without power series is:

$$h_n = \sum_{\lambda \vdash n} w_\lambda$$

for all nonnegative integers n , where $\lambda \vdash n$ means that λ is a partition of n .

A similar equation (which is easily seen to be equivalent to the former) is

$$e_n = \sum_{\lambda} (-1)^{n-\ell(\lambda)} w_\lambda,$$

with the sum running only over *strict* partitions λ of n this time. This equation can also be used to recursively define the w_n . Furthermore, every positive integer n satisfies

$$p_n = \sum_{d|n} d w_d^{n/d},$$

and this can be used to define the w_n recursively over any ring which is torsion-free as a $\mathbf{Z}$ -module. While these equations all yield easy formulas for classical bases of the ring of symmetric functions in terms of the Witt symmetric functions, it seems difficult to obtain explicit formulas in the other direction.

The Witt symmetric functions owe their name to the fact that the ring of symmetric functions can be viewed as the coordinate ring of the group scheme of Witt vectors, and the Witt symmetric functions are the functions that send a Witt vector to its components (whereas the powersum symmetric functions send a Witt vector to its ghost components). Details can be found in [HazWitt1] or section 3.2 of [BorWi2004].

INPUT:

- `Sym` – an instance of the ring of the symmetric functions.
- `coerce_h` – (default: `True`) a boolean that determines whether the transition maps between the Witt basis and the complete homogeneous basis will be cached and registered as coercions.
- `coerce_e` – (default: `False`) a boolean that determines whether the transition maps between the Witt basis and the elementary symmetric basis will be cached and registered as coercions.
- `coerce_p` – (default: `False`) a boolean that determines whether the transition maps between the Witt basis and the powersum basis will be cached and registered as coercions (or conversions, if the base ring is not a $\mathbf{Q}$ -algebra).

REFERENCES:

EXAMPLES:

Here are the first few Witt symmetric functions, in various bases:

```

sage: Sym = SymmetricFunctions(QQ)
sage: w = Sym.w()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: p(w([1]))
p[1]
sage: m(w([1]))
m[1]
sage: e(w([1]))
e[1]
sage: h(w([1]))
h[1]
sage: s(w([1]))
s[1]

sage: p(w([2]))
-1/2*p[1, 1] + 1/2*p[2]
sage: m(w([2]))
-m[1, 1]
sage: e(w([2]))
-e[2]
sage: h(w([2]))
-h[1, 1] + h[2]
sage: s(w([2]))
-s[1, 1]

sage: p(w([3]))
-1/3*p[1, 1, 1] + 1/3*p[3]
sage: m(w([3]))
-2*m[1, 1, 1] - m[2, 1]
sage: e(w([3]))
-e[2, 1] + e[3]
sage: h(w([3]))
-h[2, 1] + h[3]
sage: s(w([3]))
-s[2, 1]

sage: Sym = SymmetricFunctions(ZZ)
sage: w = Sym.w()
sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: p = Sym.p()
sage: m(w([4]))
-9*m[1, 1, 1, 1] - 4*m[2, 1, 1] - 2*m[2, 2] - m[3, 1]
sage: e(w([4]))
-e[2, 1, 1] + e[3, 1] - e[4]
sage: h(w([4]))
-h[1, 1, 1, 1] + 2*h[2, 1, 1] - h[2, 2] - h[3, 1] + h[4]
sage: s(w([4]))
-s[1, 1, 1, 1] - s[2, 1, 1] - s[2, 2] - s[3, 1]

```

Some examples of conversions the other way:

```

sage: w(h[3])
w[1, 1, 1] + w[2, 1] + w[3]
sage: w(e[3])
-w[2, 1] + w[3]
sage: w(m[2,1])
2*w[2, 1] - 3*w[3]
sage: w(p[3])
w[1, 1, 1] + 3*w[3]

```

Antipodes:

```

sage: w([1]).antipode()
-w[1]
sage: w([2]).antipode()
-w[1, 1] - w[2]

```

The following holds for all odd i and is easily proven by induction:

```

sage: all( w([i]).antipode() == -w([i]) for i in range(1, 10, 2) )
True

```

The Witt basis does not allow for simple expressions for comultiplication and antipode in general (this is related to the fact that the sum of two Witt vectors isn't easily described in terms of the components). Therefore, most computations with Witt symmetric functions, as well as conversions and coercions, pass through the complete homogeneous symmetric functions by default. However, one can also use the elementary symmetric functions instead, or (if the base ring is a $\mathbb{Q}$ -algebra) the powersum symmetric functions. This is what the optional keyword variables `coerce_e`, `coerce_h` and `coerce_p` are for. These variables do not affect the results of the (non-underscored) methods of `self`, but they affect the speed of the computations (the more of these variables are set to `True`, the faster these are) and the size of the cache (the more of these variables are set to `True`, the bigger the cache). Let us check that the results are the same no matter what the variables are set:

```

sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: wh = Sym.w()
sage: we = Sym.w(coerce_h=False, coerce_e=True)
sage: wp = Sym.w(coerce_h=False, coerce_p=True)
sage: all( p(wh(lam)) == p(we(lam)) == p(wp(lam)) for lam in Partitions(4) )
True
sage: all ( wh(p(lam)).monomial_coefficients()
.....:      == we(p(lam)).monomial_coefficients()
.....:      == wp(p(lam)).monomial_coefficients() for lam in Partitions(4) )
True

```

coproduct (*elt*)

Return the coproduct of the element `elt`.

INPUT:

- `elt` – a symmetric function written in this basis

OUTPUT:

- The coproduct acting on `elt`; the result is an element of the tensor squared of the basis `self`

EXAMPLES:

```

sage: w = SymmetricFunctions(QQ).w()
sage: w[2].coproduct()
w[] # w[2] - w[1] # w[1] + w[2] # w[]

```

```

sage: w.coproduct(w[2])
w[] # w[2] - w[1] # w[1] + w[2] # w[]
sage: w[2,1].coproduct()
w[] # w[2, 1] - w[1] # w[1, 1] + w[1] # w[2] - w[1, 1] # w[1] + w[2] # w[1] +
↪w[2, 1] # w[]
sage: w.coproduct(w[2,1])
w[] # w[2, 1] - w[1] # w[1, 1] + w[1] # w[2] - w[1, 1] # w[1] + w[2] # w[1] +
↪w[2, 1] # w[]

```

from_other_uncached(u)

Return an element u of another basis of the ring of symmetric functions, expanded in the Witt basis `self`. The result is the same as `self(u)`, but the `from_other_uncached` method does not precompute a cache with transition matrices. Thus, `from_other_uncached` is faster when u is sparse.

INPUT:

- u – an element of `self.realization_of()`

OUTPUT:

- the expansion of u in the Witt basis `self`

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: w = Sym.w()
sage: a = p([3,2]) - p([4,1]) + 27 * p([3])
sage: w.from_other_uncached(a) == w(a)
True

```

Here's a verification of an obvious fact that would take long with regular coercion:

```

sage: foc = w.from_other_uncached
sage: foc(p([15]))
w[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1] + 3*w[3, 3, 3, 3, 3] + 5*w[5,
↪5, 5] + 15*w[15]
sage: foc(p([15])) * foc(p([14])) == foc(p([15, 14]))
True

```

Other bases:

```

sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: all( foc(e(lam)) == w(e(lam)) for lam in Partitions(5) )
True
sage: all( foc(h(lam)) == w(h(lam)) for lam in Partitions(5) )
True
sage: all( foc(p(lam)) == w(p(lam)) for lam in Partitions(5) )
True
sage: all( foc(s(lam)) == w(s(lam)) for lam in Partitions(5) )
True

```

verschiebung(n)

Return the image of the symmetric function `self` under the n -th Verschiebung operator.

The n -th Verschiebung operator V_n is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n , and satisfies

$V(h_r) = 0$ for every positive integer r not divisible by n . This operator V_n is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$V_n(h_r) = h_{r/n}, \quad V_n(p_r) = np_{r/n}, \quad V_n(e_r) = (-1)^{r-r/n} e_{r/n}, \quad V_n(w_r) = w_{r/n},$$

(where h is the complete homogeneous basis, p is the powersum basis, e is the elementary basis, and w is the Witt basis). For every nonnegative integer r with $n \nmid r$, it satisfies

$$V_n(h_r) = V_n(p_r) = V_n(e_r) = V_n(w_r) = 0.$$

The n -th Verschiebung operator is also called the n -th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The n -th Verschiebung operator is adjoint to the n -th Frobenius operator (see `frobenius()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the n -th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let λ be a partition. Let n be a positive integer. If the n -core of λ is nonempty, then $V_n(s_\lambda) = 0$. Otherwise, the following method computes $V_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, \dots, \lambda_{ns})$ for some nonnegative integer s . (If n does not divide the length of λ , then this is achieved by adding trailing zeroes to λ .) Set $\beta_i = \lambda_i + ns - i$ for every $i \in \{1, 2, \dots, ns\}$. Then, $(\beta_1, \beta_2, \dots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo n . Let ξ be the sign of the permutation that is used for this sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo n . (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $V_n(s_\lambda) = \xi\psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \dots, \lambda^{(n-1)})$ is the n -quotient of λ .

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: w = Sym.w()
sage: w[3].verschiebung(2)
0
sage: w[4].verschiebung(4)
w[1]
```

5.1.282 Shard intersection order

This file builds a combinatorial version of the shard intersection order of type A (in the classification of finite Coxeter groups). This is a lattice on the set of permutations, closely related to noncrossing partitions and the weak order.

For technical reasons, the elements of the posets are not permutations, but can be easily converted from and to permutations:

```
sage: from sage.combinat.shard_order import ShardPosetElement
sage: p0 = Permutation([1, 3, 4, 2])
sage: e0 = ShardPosetElement(p0); e0
```

```
(1, 3, 4, 2)
sage: Permutation(list(e0)) == p0
True
```

See also:

A general implementation for all finite Coxeter groups is available as `shard_poset()`

REFERENCES:

class `sage.combinat.shard_order.ShardPosetElement` (*p*)
 Bases: `tuple`

An element of the shard poset.

This is basically a permutation with extra stored arguments:

- *p* – the permutation itself as a tuple
- *runs* – the decreasing runs as a tuple of tuples
- *run_indices* – a list integer $\rightarrow$ index of the run
- *dpg* – the transitive closure of the shard preorder graph
- *spg* – the transitive reduction of the shard preorder graph

These elements can easily be converted from and to permutations:

```
sage: from sage.combinat.shard_order import ShardPosetElement
sage: p0 = Permutation([1, 3, 4, 2])
sage: e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
sage: Permutation(list(e0)) == p0
True
```

`sage.combinat.shard_order.shard_poset` (*n*)

Return the shard intersection order on permutations of size *n*.

This is defined on the set of permutations. To every permutation, one can attach a pre-order, using the descending runs and their relative positions.

The shard intersection order is given by the implication (or refinement) order on the set of pre-orders defined from all permutations.

This can also be seen in a geometrical way. Every pre-order defines a cone in a vector space of dimension *n*. The shard poset is given by the inclusion of these cones.

See also:

`shard_preorder_graph()`

EXAMPLES:

```
sage: P = posets.ShardPoset(4); P # indirect doctest
Finite poset containing 24 elements
sage: P.chain_polynomial()
34*q^4 + 90*q^3 + 79*q^2 + 24*q + 1
sage: P.characteristic_polynomial()
q^3 - 11*q^2 + 23*q - 13
sage: P.zeta_polynomial()
17/3*q^3 - 6*q^2 + 4/3*q
sage: P.is_selfdual()
False
```

```
sage.combinat.shard_order.shard_preorder_graph(runs)
```

Return the preorder attached to a tuple of decreasing runs.

This is a directed graph, whose vertices correspond to the runs.

There is an edge from a run R to a run S if R is before S in the list of runs and the two intervals defined by the initial and final indices of R and S overlap.

This only depends on the initial and final indices of the runs. For this reason, this input can also be given in that shorten way.

INPUT:

- a tuple of tuples, the runs of a permutation, or
- a tuple of pairs (i, j) , each one standing for a run from i to j .

OUTPUT:

a directed graph, with vertices labelled by integers

EXAMPLES:

```
sage: from sage.combinat.shard_order import shard_preorder_graph
sage: s = Permutation([2,8,3,9,6,4,5,1,7])
sage: def cut(lr):
....:     return tuple((r[0], r[-1]) for r in lr)
sage: shard_preorder_graph(cut(s.decreasing_runs()))
Digraph on 5 vertices
sage: s = Permutation([9,4,3,2,8,6,5,1,7])
sage: P = shard_preorder_graph(s.decreasing_runs())
sage: P.is_isomorphic(digraphs.TransitiveTournament(3))
True
```

5.1.283 Shuffle product of iterables

The shuffle product of two sequences of lengths m and n is a sum over the $\binom{m+n}{n}$ ways of interleaving the two sequences.

That could be defined inductively by:

$$(a_n)_{n \geq 0} \mathbin{\mathbb{U}} (b_m)_{m \geq 0} = a_0 \cdot ((a_n)_{n \geq 1} \mathbin{\mathbb{U}} (b_m)_{m \geq 0}) + b_0 \cdot ((a_n)_{n \geq 0} \mathbin{\mathbb{U}} (b_m)_{m \geq 1})$$

with (a_n) and (b_m) two non-empty sequences and if one of them is empty then the product is equals to the other.

The shuffle product has been introduced by S. Eilenberg and S. Mac Lane in 1953 [*EilLan53*].

EXAMPLES:

```
sage: from sage.combinat.shuffle import ShuffleProduct
sage: list(ShuffleProduct([1,2], ["a", "b", "c"]))
[[1, 2, 'a', 'b', 'c'],
 ['a', 1, 2, 'b', 'c'],
 [1, 'a', 2, 'b', 'c'],
 ['a', 'b', 1, 2, 'c'],
 ['a', 1, 'b', 2, 'c'],
 [1, 'a', 'b', 2, 'c'],
 ['a', 'b', 'c', 1, 2],
 ['a', 'b', 1, 'c', 2],
```

```
['a', 1, 'b', 'c', 2],
[1, 'a', 'b', 'c', 2]]
```

References:

Author:

- Jean-Baptiste Prieze

class sage.combinat.shuffle.**SetShuffleProduct** (*l1, l2, element_constructor=None*)
 Bases: sage.structure.sage_object.SageObject

The union of all possible shuffle products of two sets of iterables.

EXAMPLES:

```
sage: from sage.combinat.shuffle import SetShuffleProduct
sage: sorted(SetShuffleProduct({(1,)}, {(4,5)}, {(6,)}))
[[1, 4, 5],
 [1, 6],
 [2, 3, 4, 5],
 [2, 3, 6],
 [2, 4, 3, 5],
 [2, 4, 5, 3],
 [2, 6, 3],
 [4, 1, 5],
 [4, 2, 3, 5],
 [4, 2, 5, 3],
 [4, 5, 1],
 [4, 5, 2, 3],
 [6, 1],
 [6, 2, 3]]
```

cardinality ()

The cardinality is defined by the sum of the cardinality of all shuffles. That means by a sum of binomials.

class sage.combinat.shuffle.**ShuffleProduct** (*l1, l2, element_constructor=None*)
 Bases: sage.structure.sage_object.SageObject

Shuffle product of two iterable.

EXAMPLES:

```
sage: from sage.combinat.shuffle import ShuffleProduct
sage: list(ShuffleProduct("abc", "de", element_constructor="".join))
['abcde',
 'adbce',
 'dabce',
 'abdce',
 'adebc',
 'daebc',
 'deabc',
 'adbec',
 'dabec',
 'abdec']
sage: list(ShuffleProduct("", "de", element_constructor="".join))
['de']
```

cardinality ()

Return the number of shuffles of l_1 and l_2 , respectively of lengths m and n , which is $\binom{m+n}{n}$.

5.1.284 Sidon sets and their generalizations, Sidon g -sets

AUTHORS:

- Martin Raum (07-25-2011)

`sage.combinat.sidon_sets.sidon_sets(N, g=1)`

Return the set of all Sidon- g sets that have elements less than or equal to N .

A Sidon- g set is a set of positive integers $A \subset [1, N]$ such that any integer M can be obtain at most g times as sums of unordered pairs of elements of A (the two elements are not necessary distinct):

$$\#\{(a_i, a_j) | a_i, a_j \in A, a_i + a_j = M, a_i \leq a_j\} \leq g$$

INPUT:

- N – A positive integer.
- g – A positive integer (default: 1).

OUTPUT:

- A Sage set with categories whose element are also set of integers.

EXAMPLES:

```
sage: S = sidon_sets(3, 2)
sage: S
{{2}, {3}, {1, 2}, {}, {2, 3}, {1}, {1, 3}, {1, 2, 3}}
sage: S.cardinality()
8
sage: S.category()
Category of finite sets
sage: sid = S.an_element()
sage: sid
{2}
sage: sid.category()
Category of finite sets
```

`sage.combinat.sidon_sets.sidon_sets_rec(N, g=1)`

Return the set of all Sidon- g sets that have elements less than or equal to N without checking the arguments. This internal function should not be call directly by user.

5.1.285 Similarity class types of matrices with entries in a finite field

The notion of a matrix conjugacy class type was introduced by J. A. Green in [Green55], in the context of computing the irreducible charcaters of finite general linear groups. The class types are equivalence classes of similarity classes of square matrices with entries in a finite field which, roughly speaking, have the same qualitative properties.

For example, all similarity classes of the same class type have centralizers of the same cardinality and the same degrees of elementary divisors. Qualitative properties of similarity classes such as semisimplicity and regularity descend to class types.

The most important feature of similarity class types is that, for any n , the number of similarity class types of $n \times n$ matrices is independent of q . This makes it possible to perform many combinatorial calculations treating q as a formal variable.

In order to define similarity class types, recall that similarity classes of $n \times n$ matrices with entries in $\mathbf{F}_q$ correspond to functions

$$c : \text{Irr}\mathbf{F}_{q[t]} \rightarrow \Lambda$$

such that

$$\sum_{f \in \text{Irr}\mathbf{F}_{q[t]}} |c(f)| \deg f = n,$$

where we denote the set of irreducible monic polynomials in $\mathbf{F}_{q[t]}$ by $\text{Irr}\mathbf{F}_{q[t]}$, the set of all partitions by Λ , and the size of $\lambda \in \Lambda$ by $|\lambda|$.

Similarity classes indexed by functions c_1 and c_2 as above are said to be of the same type if there exists a degree-preserving self-bijection σ of $\text{Irr}\mathbf{F}_{q[t]}$ such that $c_2 = c_1 \circ \sigma$. Thus, the type of c remembers only the degrees of the polynomials (and not the polynomials themselves) for which c takes a certain value λ . Replacing each irreducible polynomial of degree d for which c takes a non-trivial value λ by the pair (d, λ) , we obtain a multiset of such pairs. Clearly, c_1 and c_2 have the same type if and only if these multisets are equal. Thus a similarity class type may be viewed as a multiset of pairs of the form (d, λ) .

For 2×2 matrices there are four types:

```
sage: for tau in SimilarityClassTypes(2):
....:     print(tau)
[[1, [1]], [1, [1]]]
[[1, [2]]]
[[1, [1, 1]]]
[[2, [1]]]
```

These four types correspond to the regular split semisimple matrices, the non-semisimple matrices, the central matrices and the irreducible matrices respectively.

For any matrix A in a given similarity class type, it is possible to calculate the number elements in the similarity class of A , the dimension of the algebra of matrices in $M_n(A)$ that commute with A , and the cardinality of the subgroup of $GL_n(\mathbf{F}_q)$ that commute with A . For each similarity class type, it is also possible to compute the number of classes of that type (and hence, the total number of matrices of that type). All these calculations treat the cardinality q of the finite field as a formal variable:

```
sage: M = SimilarityClassType([[1, [1]], [1, [1]]])
sage: M.class_card()
q^2 + q
sage: M.centralizer_algebra_dim()
2
sage: M.centralizer_group_card()
q^2 - 2*q + 1
sage: M.number_of_classes()
1/2*q^2 - 1/2*q
sage: M.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

We now describe two applications of similarity class types.

We say that an $n \times n$ matrix has rational canonical form type λ for some partition λ of n if the diagonal blocks in the rational canonical form have sizes given by the parts of λ . Thus the matrices with rational canonical type (n) are the regular ones, while the matrices with rational canonical type (1^n) are the central ones.

Using similarity class types, it becomes easy to get a formula for the number of matrices with a given rational canonical type:

```
sage: def matrices_with_rcf(la):
....:     return sum([tau.number_of_matrices() for tau in filter(lambda tau:tau.
→rcf()==la, SimilarityClassTypes(la.size()))])
sage: matrices_with_rcf(Partition([2,1]))
q^6 + q^5 + q^4 - q^3 - q^2 - q
```

Similarity class types can also be used to calculate the number of simultaneous similarity classes of k -tuples of $n \times n$ matrices with entries in $\mathbf{F}_q$ by using Burnside's lemma:

```
sage: from sage.combinat.similarity_class_type import order_of_general_linear_group, \
↳centralizer_algebra_dim
sage: q = ZZ['q'].gen()
sage: def simultaneous_similarity_classes(n,k):
.....:     return SimilarityClassTypes(n).sum(lambda la: q**(k*centralizer_algebra_
↳dim(la)), invertible = True)/order_of_general_linear_group(n)
sage: simultaneous_similarity_classes(3, 2)
q^10 + q^8 + 2*q^7 + 2*q^6 + 2*q^5 + q^4
```

Similarity class types can be used to calculate the coefficients of generating functions coming from the cycle index type techniques of Kung and Stong (see Morrison [\[Morrison06\]](#)).

Along with the results of [\[PSS13\]](#), similarity class types can be used to calculate the number of similarity classes of matrices of order n with entries in a principal ideal local ring of length two with residue field of cardinality q with centralizer of any given cardinality up to $n = 4$. Among these, the classes which are selftranspose can also be counted:

```
sage: from sage.combinat.similarity_class_type import matrix_centralizer_
↳cardinalities_length_two
sage: list(matrix_centralizer_cardinalities_length_two(3))
[(q^6 - 3*q^5 + 3*q^4 - q^3, 1/6*q^6 - 1/2*q^5 + 1/3*q^4),
 (q^6 - 2*q^5 + q^4, q^5 - q^4),
 (q^8 - 3*q^7 + 3*q^6 - q^5, 1/2*q^5 - q^4 + 1/2*q^3),
 (q^8 - 2*q^7 + q^6, q^4 - q^3),
 (q^10 - 2*q^9 + 2*q^7 - q^6, q^4 - q^3),
 (q^8 - q^7 - q^6 + q^5, 1/2*q^5 - q^4 + 1/2*q^3),
 (q^6 - q^5 - q^4 + q^3, 1/2*q^6 - 1/2*q^5),
 (q^6 - q^5, q^4),
 (q^10 - 2*q^9 + q^8, q^3),
 (q^8 - 2*q^7 + q^6, q^4 - q^3),
 (q^8 - q^7, q^3 + q^2),
 (q^12 - 3*q^11 + 3*q^10 - q^9, 1/6*q^4 - 1/2*q^3 + 1/3*q^2),
 (q^12 - 2*q^11 + q^10, q^3 - q^2),
 (q^14 - 2*q^13 + 2*q^11 - q^10, q^3 - q^2),
 (q^12 - q^11 - q^10 + q^9, 1/2*q^4 - 1/2*q^3),
 (q^12 - q^11, q^2),
 (q^14 - 2*q^13 + q^12, q^2),
 (q^18 - q^17 - q^16 + q^14 + q^13 - q^12, q^2),
 (q^12 - q^9, 1/3*q^4 - 1/3*q^2),
 (q^6 - q^3, 1/3*q^6 - 1/3*q^4)]
```

class sage.combinat.similarity_class_type.**PrimarySimilarityClassType** (*parent*,
deg, par)

Bases: sage.structure.element.Element

A primary similarity class type is a pair consisting of a partition and a positive integer.

For a partition λ and a positive integer d , the primary similarity class type (d, λ) represents similarity classes of

square matrices of order $|\lambda| \cdot d$ with entries in a finite field of order q which correspond to the $\mathbb{F}_{q[t]}$ -module

$$\frac{\mathbf{F}_{q[t]}}{p(t)^{\lambda_1}} \oplus \frac{\mathbf{F}_{q[t]}}{p(t)^{\lambda_2}} \oplus \cdots$$

for some irreducible polynomial $p(t)$ of degree d .

centralizer_algebra_dim()

Return the dimension of the algebra of matrices which commute with a matrix of type `self`.

For a partition (d, λ) this dimension is given by $d(\lambda_1 + 3\lambda_2 + 5\lambda_3 + \cdots)$.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.centralizer_algebra_dim()
28
```

centralizer_group_card($q=None$)

Return the cardinality of the centralizer group of a matrix of type `self` in a field of order q .

INPUT:

- q – an integer or an indeterminate

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(1, [])
sage: PT.centralizer_group_card()
1
sage: PT = PrimarySimilarityClassType(2, [1, 1])
sage: PT.centralizer_group_card()
q^8 - q^6 - q^4 + q^2
```

degree()

Return degree of `self`.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.degree()
2
```

partition()

Return partition corresponding to `self`.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.partition()
[3, 2, 1]
```

size()

Return the size of `self`.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.size()
12
```

statistic (*func*, *q=None*)

Return $n_\lambda(q^d)$ where n_λ is the value returned by *func* upon input λ , if *self* is (d, λ) .

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 1])
sage: q = ZZ['q'].gen()
sage: PT.statistic(lambda la:q**la.size(), q = q)
q^8
```

class sage.combinat.similarity_class_type.**PrimarySimilarityClassTypes** (*n*, *min*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

All primary similarity class types of size *n* whose degree is greater than that of *min* or whose degree is that of *min* and whose partition is less than of *min* in lexicographic order.

A primary similarity class type of size *n* is a pair (λ, d) consisting of a partition λ and a positive integer *d* such that $|\lambda|d = n$.

INPUT:

- *n* – a positive integer
- *min* – a primary matrix type of size *n*

EXAMPLES:

If *min* is not specified, then the class of all primary similarity class types of size *n* is created:

```
sage: PTC = PrimarySimilarityClassTypes(2)
sage: for PT in PTC:
....:     print(PT)
[1, [2]]
[1, [1, 1]]
[2, [1]]
```

If *min* is specified, then the class consists of only those primary similarity class types whose degree is greater than that of *min* or whose degree is that of *min* and whose partition is less than of *min* in lexicographic order:

```
sage: PTC = PrimarySimilarityClassTypes(2, min = PrimarySimilarityClassType(1, [1,
↪ 1]))
sage: for PT in PTC:
....:     print(PT)
[1, [1, 1]]
[2, [1]]
```

Element

alias of *PrimarySimilarityClassType*

size ()

Return size of elements of *self*.

The size of a primary similarity class type (d, λ) is $d|\lambda|$.

EXAMPLES:

```
sage: PTC = PrimarySimilarityClassTypes(2)
sage: PTC.size()
2
```

class `sage.combinat.similarity_class_type.SimilarityClassType` (*parent, tau*)
 Bases: `sage.combinat.combinat.CombinatorialElement`

A similarity class type.

A matrix type is a multiset of primary similarity class types.

INPUT:

- *tau* – A list of primary similarity class types

EXAMPLES:

```
sage: tau1 = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]]); tau1
[[2, [2, 1]], [3, [3, 2, 1]]]
```

as_partition_dictionary()

Return a dictionary whose keys are the partitions of types occurring in `self` and the value at the key λ is the partition formed by sorting the degrees of primary types with partition λ .

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.as_partition_dictionary()
{[1]: [1, 1]}
```

centralizer_algebra_dim()

Return the dimension of the algebra of matrices which commute with a matrix of type `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.centralizer_algebra_dim()
2
```

centralizer_group_card (*q=None*)

Return the cardinality of the group of matrices in $GL_n(\mathbf{F}_q)$ which commute with a matrix of type `self`.

INPUT:

- *q* – an integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.centralizer_group_card()
q^2 - 2*q + 1
```

class_card (*q=None*)

Return the number of matrices in each similarity class of type `self`.

INPUT:

- *q* – an integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1, 1, 1, 1]]])
sage: tau.class_card()
1
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.class_card()
q^2 + q
```

is_regular()

Return True if every primary type in `self` has partition with one part.

EXAMPLES:

```
sage: tau = SimilarityClassType([[2, [1]], [1, [3]]])
sage: tau.is_regular()
True
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [3]]])
sage: tau.is_regular()
False
```

is_semisimple()

Return True if every primary similarity class type in `self` has all parts equal to 1.

EXAMPLES:

```
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [1]]])
sage: tau.is_semisimple()
True
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [2]]])
sage: tau.is_semisimple()
False
```

number_of_classes (*invertible=False, q=None*)

Return the number of similarity classes of matrices of type `self`.

INPUT:

- `invertible` – Boolean; return number of invertible classes if set to True
- `q` – An integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.number_of_classes()
1/2*q^2 - 1/2*q
```

number_of_matrices (*invertible=False, q=None*)

Return the number of matrices of type `self`.

INPUT:

- `invertible` – A boolean; return the number of invertible matrices if set

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]]])
sage: tau.number_of_matrices()
q
sage: tau.number_of_matrices(invertible = True)
q - 1
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

rcf()

Return the partition corresponding to the rational canonical form of a matrix of type `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[2, [1, 1, 1]], [1, [3, 2]]])
sage: tau.rcf()
[5, 4, 2]
```

size()

Return the sum of the sizes of the primary parts of `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]])
sage: tau.size()
24
```

statistic (*func*, *q=None*)

Return

$$\prod_{(d,\lambda) \in \tau} n_{\lambda}(q^d)$$

where $n_{\lambda}(q)$ is the value returned by `func` on the input λ .

INPUT:

- `func` – a function that takes a partition to a polynomial in q
- q – an integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [2, 1]], [2, [1, 1]]])
sage: from sage.combinat.similarity_class_type import fq
sage: tau.statistic(lambda la: prod([fq(m) for m in la.to_exp()]))
(q^9 - 3*q^8 + 2*q^7 + 2*q^6 - 4*q^5 + 4*q^4 - 2*q^3 - 2*q^2 + 3*q - 1)/q^9
sage: q = ZZ['q'].gen()
sage: tau.statistic(lambda la: q**la.size(), q = q)
q^8
```

class `sage.combinat.similarity_class_type.SimilarityClassTypes` (*n*, *min*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Class of all similarity class types of size n with all primary matrix types greater than or equal to the primary matrix type `min`.

A similarity class type is a multiset of primary matrix types.

INPUT:

- n – a non-negative integer
- `min` – a primary similarity class type

EXAMPLES:

If `min` is not specified, then the class of all matrix types of size n is constructed:

```
sage: M = SimilarityClassTypes(2)
sage: for tau in M:
....:     print(tau)
[[1, [1]], [1, [1]]]
[[1, [2]]]
```

```
[[1, [1, 1]]]
[[2, [1]]]
```

If `min` is specified, then the class consists of only those similarity class types which are multisets of primary matrix types which either have size greater than that of `min`, or if they have size equal to that of `min`, then they occur after `min` in the iterator for `PrimarySimilarityClassTypes(n)`, where `n` is the size of `min`:

```
sage: M = SimilarityClassTypes(2, min = [1, [1, 1]])
sage: for tau in M:
....:     print(tau)
[[1, [1, 1]]]
[[2, [1]]]
```

Element

alias of *SimilarityClassType*

size()

Return size of `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]])
sage: tau.parent().size()
24
```

sum(stat, sumover='matrices', invertible=False, q=None)

Return the sum of a local statistic over all types.

Given a set of functions $n_\lambda(q)$ (these could be polynomials or rational functions in q , for each similarity class type τ define

$$n_\tau(q) = \prod_{(d,\lambda) \in \tau} n_\lambda(q^d).$$

This function returns

$$\sum n_{\tau(g)}(q)$$

where $\tau(g)$ denotes the type of a matrix g , and the sum is over all $n \times n$ matrices if `sumover` is set to "matrices", is over all $n \times n$ similarity classes if `sumover` is set to "classes", and over all $n \times n$ types if `sumover` is set to "types". If `invertible` is set to `True`, then the sum is only over invertible matrices or classes.

INPUT:

- `stat` – a function which takes partitions and returns a function of q
- `sumover` – can be one of the following:
 - "matrices"
 - "classes"
 - "types"
- `q` – an integer or an indeterminate

OUTPUT:

A function of q .

EXAMPLES:

```

sage: M = SimilarityClassTypes(2)
sage: M.sum(lambda la:1)
q^4
sage: M.sum(lambda la:1, invertible = True)
q^4 - q^3 - q^2 + q
sage: M.sum(lambda la:1, sumover = "classes")
q^2 + q
sage: M.sum(lambda la:1, sumover = "classes", invertible = True)
q^2 - 1

```

Burside's lemma can be used to calculate the number of similarity classes of matrices:

```

sage: from sage.combinat.similarity_class_type import centralizer_algebra_dim,
↪ order_of_general_linear_group
sage: q = ZZ['q'].gen()
sage: M.sum(lambda la:q**centralizer_algebra_dim(la), invertible = True)/
↪ order_of_general_linear_group(2)
q^2 + q

```

`sage.combinat.similarity_class_type.centralizer_algebra_dim(la)`

Return the dimension of the centralizer algebra in $M_n(\mathbb{F}_q)$ of a nilpotent matrix whose Jordan blocks are given by la .

EXAMPLES:

```

sage: from sage.combinat.similarity_class_type import centralizer_algebra_dim
sage: centralizer_algebra_dim(Partition([2, 1]))
5

```

Note: If it is a list, la is expected to be sorted in decreasing order.

`sage.combinat.similarity_class_type.centralizer_group_cardinality(la,  $q=None$ )`

Return the cardinality of the centralizer group in $GL_n(\mathbb{F}_q)$ of a nilpotent matrix whose Jordan blocks are given by la .

INPUT:

- la – a partition
- q – an integer or an indeterminate

OUTPUT:

A polynomial function of q .

EXAMPLES:

```

sage: from sage.combinat.similarity_class_type import centralizer_group_
↪ cardinality
sage: q = ZZ['q'].gen()
sage: centralizer_group_cardinality(Partition([2, 1]))
q^5 - 2*q^4 + q^3

```

`sage.combinat.similarity_class_type.dictionary_from_generator(gen)`

Given a generator for a list of pairs (c, f) , construct a dictionary whose keys are the distinct values for c and whose value at c is the sum of f over all pairs of the form (c', f) such that $c = c'$.

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import dictionary_from_generator
sage: dictionary_from_generator([(floor(x/2), x) for x in range(10)])
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

It also works with lists:

```
sage: dictionary_from_generator([(floor(x/2), x) for x in range(10)])
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

Note: Since the generator is first converted to a list, memory usage could be high.

`sage.combinat.similarity_class_type.ext_orbit_centralizers` (*input_data*, *q=None*, *selftranspose=False*)

Generate pairs consisting of centralizer cardinalities of orbits in $\text{Ext}^1(M, M)$ for the action of $\text{Aut}(M, M)$, where M is the $\mathbf{F}_{q[t]}$ -module constructed from *input* and their frequencies.

INPUT:

- *input_data* – input for `input_parsing()`
- *q* – (default: *q*) an integer or an indeterminate
- *selftranspose* – (default: `False`) boolean stating if we only want selftranspose type

`sage.combinat.similarity_class_type.ext_orbits` (*input_data*, *q=None*, *selftranspose=False*)

Return the number of orbits in $\text{Ext}^1(M, M)$ for the action of $\text{Aut}(M, M)$, where M is the $\mathbf{F}_{q[t]}$ -module constructed from *input_data*.

INPUT:

- *input_data* – input for `input_parsing()`
- *q* – (default: *q*) an integer or an indeterminate
- *selftranspose* – (default: `False`) boolean stating if we only want selftranspose type

`sage.combinat.similarity_class_type.fq` (*n*, *q=None*)

Return $(1 - q^{-1})(1 - q^{-2}) \cdots (1 - q^{-n})$.

INPUT:

- *n* – A non-negative integer
- *q* – an integer or an indeterminate

OUTPUT:

A rational function in *q*.

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import fq
sage: fq(0)
1
sage: fq(3)
(q^6 - q^5 - q^4 + q^2 + q - 1)/q^6
```

`sage.combinat.similarity_class_type.input_parsing` (*data*)

Recognize and return the intended type of input.

```
sage.combinat.similarity_class_type.matrix_centralizer_cardinalities(n,
                                                                    q=None,
                                                                    invert-
                                                                    ible=False)
```

Generate pairs consisting of centralizer cardinalities of matrices over a finite field and their frequencies.

```
sage.combinat.similarity_class_type.matrix_centralizer_cardinalities_length_two(n,
                                                                                q=None,
                                                                                self-
                                                                                trans-
                                                                                pose=False,
                                                                                in-
                                                                                vert-
                                                                                ible=False)
```

Generate pairs consisting of centralizer cardinalities of matrices over a principal ideal local ring of length two with residue field of order q and their frequencies.

INPUT:

- n – the order
- q – (default: q) an integer or an indeterminate
- `selftranspose` – (default: `False`) boolean stating if we only want selftranspose type
- `invertible` – (default: `False`) boolean stating if we only want invertible type

```
sage.combinat.similarity_class_type.matrix_similarity_classes(n, q=None, in-
                                                             vertible=False)
```

Return the number of matrix similarity classes over a finite field of order q .

```
sage.combinat.similarity_class_type.matrix_similarity_classes_length_two(n,
                                                                            q=None,
                                                                            self-
                                                                            trans-
                                                                            pose=False,
                                                                            in-
                                                                            vert-
                                                                            ible=False)
```

Return the number of similarity classes of matrices of order n with entries in a principal ideal local ring of length two.

INPUT:

- n – the order
- q – (default: q) an integer or an indeterminate
- `selftranspose` – (default: `False`) boolean stating if we only want selftranspose type
- `invertible` – (default: `False`) boolean stating if we only want invertible type

EXAMPLES:

We can generate Table 6 of [PSS13]:

```
sage: from sage.combinat.similarity_class_type import matrix_similarity_classes_
      ↪ length_two
sage: matrix_similarity_classes_length_two(2)
q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(2, invertible = True)
q^4 - q
sage: matrix_similarity_classes_length_two(3)
```

```

q^6 + q^5 + 2*q^4 + q^3 + 2*q^2
sage: matrix_similarity_classes_length_two(3, invertible = true)
q^6 - q^3 + 2*q^2 - 2*q
sage: matrix_similarity_classes_length_two(4)
q^8 + q^7 + 3*q^6 + 3*q^5 + 5*q^4 + 3*q^3 + 3*q^2
sage: matrix_similarity_classes_length_two(4, invertible = True)
q^8 + q^6 - q^5 + 2*q^4 - 2*q^3 + 2*q^2 - 3*q

```

And also Table 7:

```

sage: matrix_similarity_classes_length_two(2, selftranspose = True)
q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(2, selftranspose = True, invertible =
↳ True)
q^4 - q
sage: matrix_similarity_classes_length_two(3, selftranspose = True)
q^6 + q^5 + 2*q^4 + q^3
sage: matrix_similarity_classes_length_two(3, selftranspose = True, invertible =
↳ True)
q^6 - q^3
sage: matrix_similarity_classes_length_two(4, selftranspose = True)
q^8 + q^7 + 3*q^6 + 3*q^5 + 3*q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(4, selftranspose = True, invertible =
↳ True)
q^8 + q^6 - q^5 - q

```

`sage.combinat.similarity_class_type.order_of_general_linear_group(n, q=None)`
Return the cardinality of the group of $n \times n$ invertible matrices with entries in a field of order q .

INPUT:

- n – a non-negative integer
- q – an integer or an indeterminate

EXAMPLES:

```

sage: from sage.combinat.similarity_class_type import order_of_general_linear_
↳ group
sage: order_of_general_linear_group(0)
1
sage: order_of_general_linear_group(2)
q^4 - q^3 - q^2 + q

```

`sage.combinat.similarity_class_type.primitives(n, invertible=False, q=None)`
Return the number of similarity classes of simple matrices of order n with entries in a finite field of order q . This is the same as the number of irreducible polynomials of degree d .

If `invertible` is `True`, then only the number of similarity classes of invertible matrices is returned.

Note: All primitive classes are invertible unless n is 1.

INPUT:

- n – a positive integer
- `invertible` – boolean; if set, only number of non-zero classes is returned
- q – an integer or an indeterminate

OUTPUT:

- a rational function of the variable q

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import primitives
sage: primitives(1)
q
sage: primitives(1, invertible = True)
q - 1
sage: primitives(4)
1/4*q^4 - 1/4*q^2
sage: primitives(4, invertible = True)
1/4*q^4 - 1/4*q^2
```

5.1.286 sine-Gordon Y-system plotter

This class builds the triangulations associated to sine-Gordon and reduced sine-Gordon Y-systems as constructed in [NS].

AUTHORS:

- Salvatore Stella (2014-07-18): initial version

EXAMPLES:

A reduced sine-Gordon example with 3 generations:

```
sage: Y = SineGordonYsystem('A', (6,4,3)); Y
A sine-Gordon Y-system of type A with defining integer tuple (6, 4, 3)
sage: Y.plot()      #not tested
```

The same integer tuple but for the non-reduced case:

```
sage: Y = SineGordonYsystem('D', (6,4,3)); Y
A sine-Gordon Y-system of type D with defining integer tuple (6, 4, 3)
sage: Y.plot()      #not tested
```

Todo

The code for plotting is extremely slow.

REFERENCES:

class `sage.combinat.sine_gordon.SineGordonYsystem` (X, na)

Bases: `sage.structure.sage_object.SageObject`

A class to model a (reduced) sine-Gordon Y-system

Note that the generations, together with all integer tuples, in this implementation are numbered from 0 while in [NS] they are numbered from 1

INPUT:

- X – the type of the Y-system to construct (either ‘A’ or ‘D’)
- na – the tuple of positive integers defining the Y-system with $na[0] > 2$

See [\[NS\]](#)

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6,4,3)); Y
A sine-Gordon Y-system of type A with defining integer tuple (6, 4, 3)
sage: Y.intervals()
((0, 0, 'R'),),
 (0, 17, 'L'),
 (17, 34, 'L'),
 ...
 (104, 105, 'R'),
 (105, 0, 'R'))
sage: Y.triangulation()
((17, 89),
 (17, 72),
 (34, 72),
 ...
 (102, 105),
 (103, 105))
sage: Y.plot()      #not tested
```

F()

Return the number of generations in self.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6,4,3));
sage: Y.F()
3
```

intervals()

Return, divided by generation, the list of intervals used to construct the initial triangulation.

Each such interval is a triple (p, q, X) where p and q are the two extremal vertices of the interval and X is the type of the interval (one of 'L', 'R', 'NL', 'NR').

ALGORITHM:

The algorithm used here is the one described in section 5.1 of [\[NS\]](#). The only difference is that we get rid of the special case of the first generation by treating the whole disk as a type 'R' interval.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6,4,3));
sage: Y.intervals()
((0, 0, 'R'),),
 (0, 17, 'L'),
 (17, 34, 'L'),
 ...
 (104, 105, 'R'),
 (105, 0, 'R'))
```

na()

Return the sequence of the integers n_a defining self.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6,4,3));
sage: Y.na()
(6, 4, 3)
```

pa()

Return the sequence of integers p_a , i.e. the total number of intervals of types ‘NL’ and ‘NR’ in the $(a+1)$ -th generation.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6, 4, 3));
sage: Y.pa()
(1, 6, 25)
```

plot(kws)**

Plot the initial triangulation associated to `self`.

INPUT:

- `radius` - the radius of the disk; by default the length of the circle is the number of vertices
- `points_color` - the color of the vertices; default ‘black’
- `points_size` - the size of the vertices; default 7
- `triangulation_color` - the color of the arcs; default ‘black’
- `triangulation_thickness` - the thickness of the arcs; default 0.5
- `shading_color` - the color of the shading used on neuter intervals; default ‘lightgray’
- `reflections_color` - the color of the reflection axes; default ‘blue’
- `reflections_thickness` - the thickness of the reflection axes; default 1

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6, 4, 3));
sage: Y.plot()      # not tested
```

qa()

Return the sequence of integers q_a , i.e. the total number of intervals of types ‘L’ and ‘R’ in the $(a+1)$ -th generation.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6, 4, 3));
sage: Y.qa()
(6, 25, 81)
```

r()

Return the number of vertices in the polygon realizing `self`.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6, 4, 3));
sage: Y.r()
106
```

rk()

Return the sequence of integers $r^{\{k\}}$, i.e. the width of an interval of type ‘L’ or ‘R’ in the k -th generation.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6, 4, 3));
sage: Y.rk()
(106, 17, 4)
```

triangulation()

Return the initial triangulation of the polygon realizing `self` as a tuple of pairs of vertices.

Warning: In type 'D' the returned triangulation does NOT contain the two radii.

ALGORITHM:

We implement the four cases described by Figure 14 in [NS].

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6, 4, 3));
sage: Y.triangulation()
((17, 89),
 (17, 72),
 ...
 (102, 105),
 (103, 105))
```

type()

Return the type of `self`.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6, 4, 3));
sage: Y.type()
'A'
```

vertices()

Return the vertices of the polygon realizing `self` as the ring of integers modulo `self.r()`.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6, 4, 3));
sage: Y.vertices()
Ring of integers modulo 106
```

5.1.287 Six Vertex Model

class sage.combinat.six_vertex_model.**SixVertexConfiguration**

Bases: sage.structure.list_clone.ClonableArray

A configuration in the six vertex model.

check()

Check if `self` is a valid 6 vertex configuration.

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: M[0].check()
```

energy (*epsilon*)

Return the energy of the configuration.

The energy of a configuration ν is defined as

$$E(\nu) = n_0\epsilon_0 + n_1\epsilon_1 + \cdots + n_5\epsilon_5$$

where n_i is the number of vertices of type i and ϵ_i is the i -th energy constant.

Note: We number our configurations as:

0.LR

1.LU

2.LD

3.UD

4.UR

5.RD

which differs from [Wikipedia article Ice-type_model](#).

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: nu = M[2]; nu
      ^      ^      ^
      |      |      |
--> # -> # <- # <--
      ^      |      ^
      |      V      |
--> # <- # -> # <--
      |      ^      |
      V      |      V
--> # -> # <- # <--
      |      |      |
      V      V      V
sage: nu.energy([1, 2, 1, 2, 1, 2])
15
```

A KDP energy:

```
sage: nu.energy([1, 1, 0, 1, 0, 1])
7
```

A Rys F energy:

```
sage: nu.energy([0, 1, 1, 0, 1, 1])
4
```

The zero field assumption:

```
sage: nu.energy([1, 2, 3, 1, 3, 2])
15
```

plot (*color='sign'*)

Return a plot of self.

INPUT:

•color – can be any of the following:

- 4 - use 4 colors: black, red, blue, and green with each corresponding to up, right, down, and left respectively
- 2 - use 2 colors: red for horizontal, blue for vertical arrows
- 'sign' - use red for right and down arrows, blue for left and up arrows
- a list of 4 colors for each direction
- a function which takes a direction and a boolean corresponding to the sign

EXAMPLES:

```
sage: M = SixVertexModel(2, boundary_conditions='ice')
sage: print(M[0].plot().description())
Arrow from (-1.0,0.0) to (0.0,0.0)
Arrow from (-1.0,1.0) to (0.0,1.0)
Arrow from (0.0,0.0) to (0.0,-1.0)
Arrow from (0.0,0.0) to (1.0,0.0)
Arrow from (0.0,1.0) to (0.0,0.0)
Arrow from (0.0,1.0) to (0.0,2.0)
Arrow from (1.0,0.0) to (1.0,-1.0)
Arrow from (1.0,0.0) to (1.0,1.0)
Arrow from (1.0,1.0) to (0.0,1.0)
Arrow from (1.0,1.0) to (1.0,2.0)
Arrow from (2.0,0.0) to (1.0,0.0)
Arrow from (2.0,1.0) to (1.0,1.0)
```

to_signed_matrix()

Return the signed matrix of self.

The signed matrix corresponding to a six vertex configuration is given by 0 if there is a cross flow, a 1 if the outward arrows are vertical and –1 if the outward arrows are horizontal.

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: [x.to_signed_matrix() for x in M]
[
[1 0 0] [1 0 0] [0 1 0] [0 1 0] [0 1 0] [0 0 1] [0 0 1]
[0 1 0] [0 0 1] [1 -1 1] [1 0 0] [0 0 1] [1 0 0] [0 1 0]
[0 0 1], [0 1 0], [0 1 0], [0 0 1], [1 0 0], [0 1 0], [1 0 0]
]
```

class sage.combinat.six_vertex_model.**SixVertexModel**(*n, m, boundary_conditions*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The six vertex model.

We model a configuration by indicating which configuration by the following six configurations which are determined by the two outgoing arrows in the Up, Right, Down, Left directions:

1.LR:

```

  |
  V
<-- # -->
```

```

      ^
      |

```

2.LU:

```

      ^
      |
<-- # <--
      |
      ^
      |

```

3.LD:

```

      |
      V
<-- # <--
      |
      V

```

4.UD:

```

      ^
      |
--> # <--
      |
      V

```

5.UR:

```

      ^
      |
--> # -->
      |
      ^
      |

```

6.RD:

```

      |
      V
--> # -->
      |
      V

```

INPUT:

- `n` – the number of rows
- `m` – (optional) the number of columns, if not specified, then the number of columns is the number of rows
- `boundary_conditions` – (optional) a quadruple of tuples whose entries are either:
 - True for an inward arrow,
 - False for an outward arrow, or
 - None for no boundary condition.

There are also the following predefined boundary conditions:

- 'ice' - The top and bottom boundary conditions are outward and the left and right boundary conditions are inward; this gives the square ice model. Also called domain wall boundary conditions.

- 'domain wall' - Same as 'ice'.
- 'alternating' - The boundary conditions alternate between inward and outward.
- 'free' - There are no boundary conditions.

EXAMPLES:

Here are the six types of vertices that can be created:

```
sage: M = SixVertexModel(1)
sage: list(M)
[
  |      ^      |      ^      ^      |
  V      |      V      |      |      V
<-- # --> <-- # <-- <-- # <-- --> # <-- --> # --> --> # -->
  ^      ^      |      |      ^      |
  |      |      V      V      |      V
]
```

When using the square ice model, it is known that the number of configurations is equal to the number of alternating sign matrices:

```
sage: M = SixVertexModel(1, boundary_conditions='ice')
sage: len(M)
1
sage: M = SixVertexModel(4, boundary_conditions='ice')
sage: len(M)
42
sage: all(len(SixVertexModel(n, boundary_conditions='ice'))
....:      == AlternatingSignMatrices(n).cardinality() for n in range(1, 7))
True
```

An example with a specified non-standard boundary condition and non-rectangular shape:

```
sage: M = SixVertexModel(2, 1, [[None], [True, True], [None], [None, None]])
sage: list(M)
[
  ^      ^      |      ^
  |      |      V      |
<-- # <-- <-- # <-- <-- # <-- --> # <--
  ^      ^      |      |
  |      |      V      V
<-- # <-- --> # <-- <-- # <-- <-- # <--
  ^      |      |      |
  |      V      V      V
]
```

REFERENCES:

- [Wikipedia article Vertex_model](#)
- [Wikipedia article Ice-type_model](#)

Element

alias of *SixVertexConfiguration*

boundary_conditions()

Return the boundary conditions of self.

EXAMPLES:

```
sage: M = SixVertexModel(2, boundary_conditions='ice')
sage: M.boundary_conditions()
((False, False), (True, True), (False, False), (True, True))
```

partition_function (*beta*, *epsilon*)

Return the partition function of self.

The partition function of a 6 vertex model is defined by:

$$Z = \sum_{\nu} e^{-\beta E(\nu)}$$

where we sum over all configurations and E is the energy function. The constant β is known as the *inverse temperature* and is equal to $1/k_B T$ where k_B is Boltzmann's constant and T is the system's temperature.

INPUT:

- *beta* – the inverse temperature constant β
- *epsilon* – the energy constants, see [energy\(\)](#)

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: M.partition_function(2, [1,2,1,2,1,2])
e^(-24) + 2*e^(-28) + e^(-30) + 2*e^(-32) + e^(-36)
```

REFERENCES:

[Wikipedia article Partition_function_\(statistical_mechanics\)](#)

class `sage.combinat.six_vertex_model.SquareIceModel` (*n*)

Bases: `sage.combinat.six_vertex_model.SixVertexModel`

The square ice model.

The square ice model is a 6 vertex model on an $n \times n$ grid with the boundary conditions that the top and bottom boundaries are pointing outward and the left and right boundaries are pointing inward. These boundary conditions are also called domain wall boundary conditions.

Configurations of the 6 vertex model with domain wall boundary conditions are in bijection with alternating sign matrices.

class `Element`

Bases: `sage.combinat.six_vertex_model.SixVertexConfiguration`

An element in the square ice model.

to_alternating_sign_matrix()

Return an alternating sign matrix of self.

See also:

`to_signed_matrix()`

EXAMPLES:

```
sage: M = SixVertexModel(4, boundary_conditions='ice')
sage: M[6].to_alternating_sign_matrix()
[1 0 0 0]
[0 0 0 1]
[0 0 1 0]
[0 1 0 0]
```

```
sage: M[7].to_alternating_sign_matrix()
[ 0  1  0  0]
[ 1 -1  1  0]
[ 0  1 -1  1]
[ 0  0  1  0]
```

`SquareIceModel.from_alternating_sign_matrix(asm)`

Return a configuration from the alternating sign matrix `asm`.

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: asm = AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]])
sage: M.from_alternating_sign_matrix(asm)
      ^      ^      ^
      |      |      |
--> # -> # <- # <--
      ^      |      ^
      |      V      |
--> # <- # -> # <--
      |      ^      |
      V      |      V
--> # -> # <- # <--
      |      |      |
      V      V      V
```

5.1.288 Skew Partitions

A skew partition `skp` of size n is a pair of partitions $[p_1, p_2]$ where p_1 is a partition of the integer n_1 , p_2 is a partition of the integer n_2 , p_2 is an inner partition of p_1 , and $n = n_1 - n_2$. We say that p_1 and p_2 are respectively the *inner* and *outer* partitions of `skp`.

A skew partition can be depicted by a diagram made of rows of cells, in the same way as a partition. Only the cells of the outer partition p_1 which are not in the inner partition p_2 appear in the picture. For example, this is the diagram of the skew partition $[[5,4,3,1],[3,3,1]]$.

```
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).diagram())
  **
 *
 **
 *
```

A skew partition can be *connected*, which can easily be described in graphic terms: for each pair of consecutive rows, there are at least two cells (one in each row) which have a common edge. This is the diagram of the connected skew partition $[[5,4,3,1],[3,1]]$:

```
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
  **
 ***
 ***
 *
sage: SkewPartition([[5,4,3,1],[3,1]]).is_connected()
True
```

The first example of a skew partition is not a connected one.

Applying a reflection with respect to the main diagonal yields the diagram of the *conjugate skew partition*, here $[[4, 3, 3, 2, 1], [3, 3, 2]]$:

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).conjugate()
[4, 3, 3, 2, 1] / [3, 2, 2]
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).conjugate().diagram())
*
*
*
**
*
```

The *outer corners* of a skew partition are the corners of its outer partition. The *inner corners* are the internal corners of the outer partition when the inner partition is taken off. Shown below are the coordinates of the inner and outer corners.

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).outer_corners()
[(0, 4), (1, 3), (2, 2), (3, 0)]
sage: SkewPartition([[5,4,3,1],[3,3,1]]).inner_corners()
[(0, 3), (2, 1), (3, 0)]
```

EXAMPLES:

There are 9 skew partitions of size 3, with no empty row nor empty column:

```
sage: SkewPartitions(3).cardinality()
9
sage: SkewPartitions(3).list()
[[3] / [],
 [2, 1] / [],
 [3, 1] / [1],
 [2, 2] / [1],
 [3, 2] / [2],
 [1, 1, 1] / [],
 [2, 2, 1] / [1, 1],
 [2, 1, 1] / [1],
 [3, 2, 1] / [2, 1]]
```

There are 4 connected skew partitions of size 3:

```
sage: SkewPartitions(3, overlap=1).cardinality()
4
sage: SkewPartitions(3, overlap=1).list()
[[3] / [], [2, 1] / [], [2, 2] / [1], [1, 1, 1] / []]
```

This is the conjugate of the skew partition $[[4, 3, 1], [2]]$

```
sage: SkewPartition([[4,3,1],[2]]).conjugate()
[3, 2, 2, 1] / [1, 1]
```

Geometrically, we just applied a reflection with respect to the main diagonal on the diagram of the partition. Of course, this operation is an involution:

```
sage: SkewPartition([[4,3,1],[2]]).conjugate().conjugate()
[4, 3, 1] / [2]
```

The `jacobi_trudi()` method computes the Jacobi-Trudi matrix. See [\[Mac95\]](#) for a definition and discussion.

```
sage: SkewPartition([[4,3,1],[2]]).jacobi_trudi()
[h[2] h[] 0]
[h[5] h[3] h[]]
[h[6] h[4] h[1]]
```

This example shows how to compute the corners of a skew partition.

```
sage: SkewPartition([[4,3,1],[2]]).inner_corners()
[(0, 2), (1, 0)]
sage: SkewPartition([[4,3,1],[2]]).outer_corners()
[(0, 3), (1, 2), (2, 0)]
```

- Travis Scrimshaw (2013-02-11): Factored out `CombinatorialClass`

class sage.combinat.skew_partition.**SkewPartition**(parent, skip)
 Bases: *sage.combinat.combinat.CombinatorialElement*

A skew partition.

A skew partition of shape λ/μ is the Young diagram from the partition λ and removing the partition μ from the upper-left corner in English convention.

cell_poset (orientation='SE')

Return the Young diagram of `self` as a poset. The optional keyword variable `orientation` determines the order relation of the poset.

The poset always uses the set of cells of the Young diagram of `self` as its ground set. The order relation of the poset depends on the `orientation` variable (which defaults to "SE"). Concretely, `orientation` has to be specified to one of the strings "NW", "NE", "SW", and "SE", standing for “northwest”, “northeast”, “southwest” and “southeast”, respectively. If `orientation` is "SE", then the order relation of the poset is such that a cell u is greater or equal to a cell v in the poset if and only if u lies weakly southeast of v (this means that u can be reached from v by a sequence of south and east steps; the sequence is allowed to consist of south steps only, or of east steps only, or even be empty). Similarly the order relation is defined for the other three orientations. The Young diagram is supposed to be drawn in English notation.

The elements of the poset are the cells of the Young diagram of `self`, written as tuples of zero-based coordinates (so that (3, 7) stands for the 8-th cell of the 4-th row, etc.).

EXAMPLES:

```
sage: p = SkewPartition([[3,3,1],[2,1]])
sage: Q = p.cell_poset(); Q
Finite poset containing 4 elements
sage: sorted(Q)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: sorted(Q.maximal_elements())
[(1, 2), (2, 0)]
sage: sorted(Q.minimal_elements())
[(0, 2), (1, 1), (2, 0)]
sage: sorted(Q.upper_covers((1, 1)))
[(1, 2)]
sage: sorted(Q.upper_covers((0, 2)))
[(1, 2)]
```

```

sage: P = p.cell_poset(orientation="NW"); P
Finite poset containing 4 elements
sage: sorted(P)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: sorted(P.minimal_elements())
[(1, 2), (2, 0)]
sage: sorted(P.maximal_elements())
[(0, 2), (1, 1), (2, 0)]
sage: sorted(P.upper_covers((1, 2)))
[(0, 2), (1, 1)]

sage: R = p.cell_poset(orientation="NE"); R
Finite poset containing 4 elements
sage: sorted(R)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: R.maximal_elements()
[(0, 2)]
sage: R.minimal_elements()
[(2, 0)]
sage: R.upper_covers((2, 0))
[(1, 1)]
sage: sorted([len(R.upper_covers(v)) for v in R])
[0, 1, 1, 1]

```

cells()

Return the coordinates of the cells of self. Coordinates are given as (row-index, column-index) and are 0 based.

EXAMPLES:

```

sage: SkewPartition([[4, 3, 1], [2]]).cells()
[(0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: SkewPartition([[4, 3, 1], []]).cells()
[(0, 0), (0, 1), (0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: SkewPartition([[2], []]).cells()
[(0, 0), (0, 1)]

```

column_lengths()

Return the column lengths of self.

EXAMPLES:

```

sage: SkewPartition([[3, 2, 1], [1, 1]]).column_lengths()
[1, 2, 1]
sage: SkewPartition([[5, 2, 2, 2], [2, 1]]).column_lengths()
[2, 3, 1, 1, 1]

```

columns_intersection_set()

Return the set of cells in the columns of the outer shape of self which columns intersect the skew diagram of self.

EXAMPLES:

```

sage: skp = SkewPartition([[3, 2, 1], [2, 1]])
sage: cells = Set([(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (2, 0)])
sage: skp.columns_intersection_set() == cells
True

```

conjugate()

Return the conjugate of the skew partition `skp`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2]]).conjugate()
[3, 2, 1] / [1, 1]
```

diagram()

Return the Ferrers diagram of `self`.

EXAMPLES:

```
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).ferrers_diagram())
  **
  *
 **
*
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
  **
 ***
 ***
*
sage: SkewPartitions.options(diagram_str='#', convention="French")
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
#
###
###
##
sage: SkewPartitions.options._reset()
```

ferrers_diagram()

Return the Ferrers diagram of `self`.

EXAMPLES:

```
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).ferrers_diagram())
  **
  *
 **
*
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
  **
 ***
 ***
*
sage: SkewPartitions.options(diagram_str='#', convention="French")
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
#
###
###
##
sage: SkewPartitions.options._reset()
```

frobenius_rank()

Return the Frobenius rank of the skew partition `self`.

The Frobenius rank of a skew partition λ/μ can be defined in various ways. The quickest one is probably the following: Writing λ as $(\lambda_1, \lambda_2, \dots, \lambda_N)$, and writing μ as $(\mu_1, \mu_2, \dots, \mu_N)$, we define the Frobenius

rank of λ/μ to be the number of all $1 \leq i \leq N$ such that

$$\lambda_i - i \notin \{\mu_1 - 1, \mu_2 - 2, \dots, \mu_N - N\}.$$

In other words, the Frobenius rank of λ/μ is the number of rows in the Jacobi-Trudi matrix of λ/μ which don't contain h_0 . Further definitions have been considered in [\[Stan2002\]](#) (where Frobenius rank is just being called rank).

If μ is the empty shape, then the Frobenius rank of λ/μ is just the usual Frobenius rank of the partition λ (see `frobenius_rank()`).

REFERENCES:

EXAMPLES:

```
sage: SkewPartition([[8,8,7,4], [4,1,1]]).frobenius_rank()
4
sage: SkewPartition([[2,1], [1]]).frobenius_rank()
2
sage: SkewPartition([[2,1,1], [1]]).frobenius_rank()
2
sage: SkewPartition([[2,1,1], [1,1]]).frobenius_rank()
2
sage: SkewPartition([[5,4,3,2], [2,1,1]]).frobenius_rank()
3
sage: SkewPartition([[4,2,1], [3,1,1]]).frobenius_rank()
2
sage: SkewPartition([[4,2,1], [3,2,1]]).frobenius_rank()
1
```

If the inner shape is empty, then the Frobenius rank of the skew partition is just the standard Frobenius rank of the partition:

```
sage: all( SkewPartition([lam, Partition([])]).frobenius_rank()
....:      == lam.frobenius_rank() for i in range(6)
....:      for lam in Partitions(i) )
True
```

If the inner and outer shapes are equal, then the Frobenius rank is zero:

```
sage: all( SkewPartition([lam, lam]).frobenius_rank() == 0
....:      for i in range(6) for lam in Partitions(i) )
True
```

inner()

Return the inner partition of self.

EXAMPLES:

```
sage: SkewPartition([[3,2,1], [1,1]]).inner()
[1, 1]
```

inner_corners()

Return a list of the inner corners of self.

EXAMPLES:

```
sage: SkewPartition([[4, 3, 1], [2]]).inner_corners()
[(0, 2), (1, 0)]
```

```
sage: SkewPartition([[4, 3, 1], []]).inner_corners()
[(0, 0)]
```

is_connected()

Return True if `self` is a connected skew partition.

A skew partition is said to be *connected* if for each pair of consecutive rows, there are at least two cells (one in each row) which have a common edge.

EXAMPLES:

```
sage: SkewPartition([[5, 4, 3, 1], [3, 3, 1]]).is_connected()
False
sage: SkewPartition([[5, 4, 3, 1], [3, 1]]).is_connected()
True
```

is_overlap(n)

Return True if the overlap of `self` is at most `n`.

See also:

`overlap()`

EXAMPLES:

```
sage: SkewPartition([[5, 4, 3, 1], [3, 1]]).is_overlap(1)
True
```

is_ribbon()

Return True if and only if `self` is a ribbon, that is, if it has exactly one cell in each of q consecutive diagonals for some nonnegative integer q .

EXAMPLES:

```
sage: P=SkewPartition([[4, 4, 3, 3], [3, 2, 2]])
sage: P.pp()
  *
  **
  *
***
sage: P.is_ribbon()
True

sage: P=SkewPartition([[4, 3, 3], [1, 1]])
sage: P.pp()
  ***
  **
  ***
sage: P.is_ribbon()
False

sage: P=SkewPartition([[4, 4, 3, 2], [3, 2, 2]])
sage: P.pp()
  *
  **
  *
  **
sage: P.is_ribbon()
False
```

```

sage: P=SkewPartition([[4,4,3,3],[4,2,2,1]])
sage: P.pp()

**
*
**
sage: P.is_ribbon()
True

sage: P=SkewPartition([[4,4,3,3],[4,2,2]])
sage: P.pp()

**
*
***
sage: P.is_ribbon()
True

sage: SkewPartition([[2,2,1],[2,2,1]]).is_ribbon()
True

```

jacobi_trudi()

Return the Jacobi-Trudi matrix of `self`.

EXAMPLES:

```

sage: SkewPartition([[3,2,1],[2,1]]).jacobi_trudi()
[h[1]  0  0]
[h[3] h[1]  0]
[h[5] h[3] h[1]]
sage: SkewPartition([[4,3,2],[2,1]]).jacobi_trudi()
[h[2]  h[]  0]
[h[4] h[2]  h[]]
[h[6] h[4] h[2]]

```

k_conjugate(k)

Return the k -conjugate of the skew partition.

EXAMPLES:

```

sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(3)
[2, 1, 1, 1, 1] / [2, 1]
sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(4)
[2, 2, 1, 1] / [2, 1]
sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(5)
[3, 2, 1] / [2, 1]

```

outer()

Return the outer partition of `self`.

EXAMPLES:

```

sage: SkewPartition([[3,2,1],[1,1]]).outer()
[3, 2, 1]

```

outer_corners()

Return a list of the outer corners of `self`.

EXAMPLES:

```
sage: SkewPartition([[4, 3, 1], [2]]).outer_corners()
[(0, 3), (1, 2), (2, 0)]
```

overlap()

Return the overlap of self.

The overlap of two consecutive rows in a skew partition is the number of pairs of cells (one in each row) that share a common edge. This number can be positive, zero, or negative.

The overlap of a skew partition is the minimum of the overlap of the consecutive rows, or infinity in the case of at most one row. If the overlap is positive, then the skew partition is called *connected*.

EXAMPLES:

```
sage: SkewPartition([], []).overlap()
+Infinity
sage: SkewPartition([[1], []]).overlap()
+Infinity
sage: SkewPartition([[10], []]).overlap()
+Infinity
sage: SkewPartition([[10], [2]]).overlap()
+Infinity
sage: SkewPartition([[10, 1], [2]]).overlap()
-1
sage: SkewPartition([[10, 10], [1]]).overlap()
9
```

pieri_macdonald_coeffs()

Computation of the coefficients which appear in the Pieri formula for Macdonald polynomials given in his book (Chapter 6.6 formula 6.24(ii))

EXAMPLES:

```
sage: SkewPartition([[3, 2, 1], [2, 1]]).pier_i_macdonald_coeffs()
1
sage: SkewPartition([[3, 2, 1], [2, 2]]).pier_i_macdonald_coeffs()
(q^2*t^3 - q^2*t - t^2 + 1)/(q^2*t^3 - q*t^2 - q*t + 1)
sage: SkewPartition([[3, 2, 1], [2, 2, 1]]).pier_i_macdonald_coeffs()
(q^6*t^8 - q^6*t^6 - q^4*t^7 - q^5*t^5 + q^4*t^5 - q^3*t^6 + q^5*t^3 + 2*q^
↪ 3*t^4 + q*t^5 - q^3*t^2 + q^2*t^3 - q*t^3 - q^2*t - t^2 + 1)/(q^6*t^8 - q^
↪ 5*t^7 - q^5*t^6 - q^4*t^6 + q^3*t^5 + 2*q^3*t^4 + q^3*t^3 - q^2*t^2 - q*t^2 -
↪ q*t + 1)
sage: SkewPartition([[3, 3, 2, 2], [3, 2, 2, 1]]).pier_i_macdonald_coeffs()
(q^5*t^6 - q^5*t^5 + q^4*t^6 - q^4*t^5 - q^4*t^3 + q^4*t^2 - q^3*t^3 - q^2*t^
↪ 4 + q^3*t^2 + q^2*t^3 - q*t^4 + q*t^3 + q*t - q + t - 1)/(q^5*t^6 - q^4*t^5 -
↪ q^3*t^4 - q^3*t^3 + q^2*t^3 + q^2*t^2 + q*t - 1)
```

pp()

Pretty-print self.

EXAMPLES:

```
sage: SkewPartition([[5, 4, 3, 1], [3, 3, 1]]).pp()
**
*
**
*
```

quotient (*k*)

The quotient map extended to skew partitions.

EXAMPLES:

```
sage: SkewPartition([[3, 3, 2, 1], [2, 1]]).quotient(2)
[[3] / [], [] / []]
```

row_lengths ()Return the row lengths of *self*.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).row_lengths()
[2, 1, 1]
```

rows_intersection_set ()Return the set of cells in the rows of the outer shape of *self* which rows intersect the skew diagram of *self*.

EXAMPLES:

```
sage: skp = SkewPartition([[3,2,1],[2,1]])
sage: cells = Set([(0,0), (0, 1), (0,2), (1, 0), (1, 1), (2, 0)])
sage: skp.rows_intersection_set() == cells
True
```

size ()Return the size of *self*.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).size()
4
```

to_dag (*format='string'*)Return a directed acyclic graph corresponding to the skew partition *self*.The directed acyclic graph corresponding to a skew partition *p* is the digraph whose vertices are the cells of *p*, and whose edges go from each cell to its lower and right neighbors (in English notation).

INPUT:

- *format* – either 'string' or 'tuple' (default: 'string'); determines whether the vertices of the resulting dag will be strings or 2-tuples of coordinates

EXAMPLES:

```
sage: dag = SkewPartition([[3, 3, 1], [1, 1]]).to_dag()
sage: dag.edges()
[('0,1', '0,2', None),
 ('0,1', '1,1', None),
 ('0,2', '1,2', None),
 ('1,1', '1,2', None)]
sage: dag.vertices()
['0,1', '0,2', '1,1', '1,2', '2,0']
sage: dag = SkewPartition([[3, 2, 1], [1, 1]]).to_dag(format="tuple")
sage: dag.edges()
[((0, 1), (0, 2), None), ((0, 1), (1, 1), None)]
sage: dag.vertices()
[(0, 1), (0, 2), (1, 1), (2, 0)]
```

to_list()

Return self as a list of lists.

EXAMPLES:

```
sage: s = SkewPartition([[4,3,1],[2]])
sage: s.to_list()
[[4, 3, 1], [2]]
sage: type(s.to_list())
<... 'list'>
```

class sage.combinat.skew_partition.**SkewPartitions** (*is_infinite=False*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Skew partitions.

Warning: The iterator of this class only yields skew partitions which are reduced, in the sense that there are no empty rows before the last nonempty row, and there are no empty columns before the last nonempty column.

EXAMPLES:

```
sage: SkewPartitions(4)
Skew partitions of 4
sage: SkewPartitions(4).cardinality()
28
sage: SkewPartitions(row_lengths=[2,1,2])
Skew partitions with row lengths [2, 1, 2]
sage: SkewPartitions(4, overlap=2)
Skew partitions of 4 with a minimum overlap of 2
sage: SkewPartitions(4, overlap=2).list()
[[4] / [], [2, 2] / []]
```

Element

alias of *SkewPartition*

from_row_and_column_length (*rowL, colL*)

Construct a partition from its row lengths and column lengths.

INPUT:

- *rowL* – A composition or a list of positive integers
- *colL* – A composition or a list of positive integers

OUTPUT:

- If it exists the unique skew-partitions with row lengths *rowL* and column lengths *colL*.
- Raise a `ValueError` if *rowL* and *colL* are not compatible.

EXAMPLES:

```
sage: S = SkewPartitions()
sage: print(S.from_row_and_column_length([3,1,2,2],[2,3,1,1,1]).diagram())
***
*
**
**
```

```

sage: S.from_row_and_column_length([], [])
[] / []
sage: S.from_row_and_column_length([1], [1])
[1] / []
sage: S.from_row_and_column_length([2, 1], [2, 1])
[2, 1] / []
sage: S.from_row_and_column_length([1, 2], [1, 2])
[2, 2] / [1]
sage: S.from_row_and_column_length([1, 2], [1, 3])
Traceback (most recent call last):
...
ValueError: Sum mismatch : [1, 2] and [1, 3]
sage: S.from_row_and_column_length([3, 2, 1, 2], [2, 3, 1, 1, 1])
Traceback (most recent call last):
...
ValueError: Incompatible row and column length : [3, 2, 1, 2] and [2, 3, 1, 1,
↪ 1]

```

Warning: If some rows and columns have length zero, there is no way to retrieve unambiguously the skew partition. We therefore raise a `ValueError`. For examples here are two skew partitions with the same row and column lengths:

```

sage: skp1 = SkewPartition([[2, 2], [2, 2]])
sage: skp2 = SkewPartition([[2, 1], [2, 1]])
sage: skp1.row_lengths(), skp1.column_lengths()
([0, 0], [0, 0])
sage: skp2.row_lengths(), skp2.column_lengths()
([0, 0], [0, 0])
sage: SkewPartitions().from_row_and_column_length([0, 0], [0, 0])
Traceback (most recent call last):
...
ValueError: row and column length must be positive

```

global_options (*args, **kws)

Deprecated: Use `options()` instead. See [trac ticket #18555](#) for details.

options (*get_value, **set_value)

Sets and displays the options for elements of the skew partition classes. If no parameters are set, then the function returns a copy of the options dictionary.

The options to skew partitions can be accessed as the method `SkewPartitions.options` of `SkewPartitions` and related parent classes.

OPTIONS:

- `convention` – (default: English) Sets the convention used for displaying tableaux and partitions
 - English – use the English convention
 - French – use the French convention
- `diagram_str` – (default: *) The character used for the cells when printing Ferrers diagrams
- `display` – (default: quotient) Specifies how skew partitions should be printed
 - array – alias for diagram
 - diagram – as a skew Ferrers diagram

- ferrers_diagram – alias for diagram
- lists – displayed as a pair of lists
- pair – alias for lists
- quotient – displayed as a quotient of partitions
- young_diagram – alias for diagram
- latex** – (default: young_diagram) Specifies how skew partitions should be latexed
 - array – alias for diagram
 - diagram – latex as a skew Ferrers diagram
 - ferrers_diagram – alias for diagram
 - marked – latex as a partition where the skew shape is marked
 - young_diagram – latex as a skew Young diagram
- latex_diagram_str** – (default: \ast) The character used for the cells when latexing Ferrers diagrams
- latex_marking_str** – (default: X) The character used to marked the deleted cells when latexing marked partitions
- notation** – alternative name for convention

EXAMPLES:

```
sage: SP = SkewPartition([[4,2,2,1], [3, 1, 1]])
sage: SP
[4, 2, 2, 1] / [3, 1, 1]
sage: SkewPartitions.options.display="lists"
sage: SP
[[4, 2, 2, 1], [3, 1, 1]]
```

Changing the convention for skew partitions also changes the convention option for partitions and tableaux and vice versa:

```
sage: SkewPartitions.options(display="diagram", convention='French')
sage: SP
*
*
*
*
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
4 5
1 2 3
sage: P = Partition([4, 2, 2, 1])
sage: P.pp()
*
**
**
****
sage: Tableaux.options.convention="english"
sage: SP
*
*
*
```

```
*
sage: T.pp()
  1  2  3
  4  5
sage: SkewPartitions.options._reset()
```

See `GlobalOptions` for more features of these options.

class `sage.combinat.skew_partition.SkewPartitions_all`
Bases: `sage.combinat.skew_partition.SkewPartitions`

Class of all skew partitions.

class `sage.combinat.skew_partition.SkewPartitions_n(n, overlap)`
Bases: `sage.combinat.skew_partition.SkewPartitions`

The set of skew partitions of n with overlap at least `overlap` and no empty row.

INPUT:

- `n` – a non-negative integer
- `overlap` – an integer (default: 0)

Caveat: this set is stable under conjugation only for `overlap` equal to 0 or 1. What exactly happens for negative overlaps is not yet well specified and subject to change (we may want to introduce vertical overlap constraints as well).

Todo

As is, this set is essentially the composition of `Compositions(n)` (which give the row lengths) and `SkewPartition(n, row_lengths=...)`, and one would want to “inherit” list and cardinality from this composition.

`cardinality()`

Return the number of skew partitions of the integer n (with given `overlap`, if specified; and with no empty rows before the last row).

EXAMPLES:

```
sage: SkewPartitions(0).cardinality()
1
sage: SkewPartitions(4).cardinality()
28
sage: SkewPartitions(5).cardinality()
87
sage: SkewPartitions(4, overlap=1).cardinality()
9
sage: SkewPartitions(5, overlap=1).cardinality()
20
sage: s = SkewPartitions(5, overlap=-1)
sage: s.cardinality() == len(s.list())
True
```

class `sage.combinat.skew_partition.SkewPartitions_rowlengths(co, overlap)`
Bases: `sage.combinat.skew_partition.SkewPartitions`

All skew partitions with given row lengths.

`sage.combinat.skew_partition.row_lengths_aux(skp)`

EXAMPLES:

```
sage: from sage.combinat.skew_partition import row_lengths_aux
sage: row_lengths_aux([[5,4,3,1],[3,3,1]])
[2, 1, 2]
sage: row_lengths_aux([[5,4,3,1],[3,1]])
[2, 3]
```

5.1.289 Skew Tableaux

AUTHORS:

- Mike Hansen: Initial version
- Travis Scrimshaw, Arthur Lubovsky (2013-02-11): Factored out `CombinatorialClass`

class `sage.combinat.skew_tableau.SemistandardSkewTableaux` (*category=None*)

Bases: `sage.combinat.skew_tableau.SkewTableaux`

Semistandard skew tableaux.

This class can be initialized with several optional variables: the size of the skew tableaux (as a nameless integer variable), their shape (as a nameless skew partition variable), their weight (`weight()`), as a nameless second variable after either the size or the shape) and their maximum entry (as an optional keyword variable called `max_entry`, unless the weight has been specified). If neither the weight nor the maximum entry is specified, the maximum entry defaults to the size of the tableau.

Note that “maximum entry” does not literally mean the highest entry; instead it is just an upper bound that no entry is allowed to surpass.

EXAMPLES:

The (infinite) class of all semistandard skew tableaux:

```
sage: SemistandardSkewTableaux()
Semistandard skew tableaux
```

The (still infinite) class of all semistandard skew tableaux with maximum entry 2:

```
sage: SemistandardSkewTableaux(max_entry=2)
Semistandard skew tableaux with maximum entry 2
```

The class of all semistandard skew tableaux of given size 3 and maximum entry 3:

```
sage: SemistandardSkewTableaux(3)
Semistandard skew tableaux of size 3 and maximum entry 3
```

To set a different maximum entry:

```
sage: SemistandardSkewTableaux(3, max_entry = 7)
Semistandard skew tableaux of size 3 and maximum entry 7
```

Specifying a shape:

```
sage: SemistandardSkewTableaux([[2,1],[ ]])
Semistandard skew tableaux of shape [2, 1] / [ ] and maximum entry 3
```

Specifying both a shape and a maximum entry:

```

sage: S = SemistandardSkewTableaux([[2,1],[1]], max_entry = 3); S
Semistandard skew tableaux of shape [2, 1] / [1] and maximum entry 3
sage: S.list()
[[[None, 1], [1]],
 [[None, 2], [1]],
 [[None, 1], [2]],
 [[None, 3], [1]],
 [[None, 1], [3]],
 [[None, 2], [2]],
 [[None, 3], [2]],
 [[None, 2], [3]],
 [[None, 3], [3]]]

sage: for n in range(5):
....:     print("{} {}".format(n, len(SemistandardSkewTableaux([[2,2,1],[1]], max_
→entry = n))))
0 0
1 0
2 1
3 9
4 35

```

Specifying a shape and a weight:

```

sage: SemistandardSkewTableaux([[2,1],[1]], [2,1])
Semistandard skew tableaux of shape [2, 1] / [1] and weight [2, 1]

```

(the maximum entry is redundant in this case and thus is ignored).

Specifying a size and a weight:

```

sage: SemistandardSkewTableaux(3, [2,1])
Semistandard skew tableaux of size 3 and weight [2, 1]

```

Warning: If the shape is not specified, the iterator of this class yields only skew tableaux whose shape is reduced, in the sense that there are no empty rows before the last nonempty row, and there are no empty columns before the last nonempty column. (Otherwise it would go on indefinitely.)

Warning: This class acts as a factory. The resulting classes are mainly useful for iteration. Do not rely on their containment tests, as they are not correct, e. g.:

```

sage: SkewTableau([[None]]) in SemistandardSkewTableaux(2)
True

```

class sage.combinat.skew_tableau.**SemistandardSkewTableaux_all**(max_entry)

Bases: [sage.combinat.skew_tableau.SemistandardSkewTableaux](#)

Class of all semistandard skew tableaux, possibly with a given maximum entry.

class sage.combinat.skew_tableau.**SemistandardSkewTableaux_shape**(p, max_entry)

Bases: [sage.combinat.skew_tableau.SemistandardSkewTableaux](#)

Class of semistandard skew tableaux of a fixed skew shape λ/μ with a given max entry.

A semistandard skew tableau with max entry i is required to have all its entries less or equal to i . It is not required to actually contain an entry i .

INPUT:

- p – A skew partition
- `max_entry` – The max entry; defaults to the size of p .

Warning: Input is not checked; please use `SemistandardSkewTableaux` to ensure the options are properly parsed.

cardinality()

EXAMPLES:

```
sage: SemistandardSkewTableaux([[2,1],[1]]).cardinality()
8
sage: SemistandardSkewTableaux([[2,1],[1]], max_entry=2).cardinality()
2
```

class `sage.combinat.skew_tableau.SemistandardSkewTableaux_shape_weight` (p, μ)

Bases: `sage.combinat.skew_tableau.SemistandardSkewTableaux`

Class of semistandard skew tableaux of a fixed skew shape λ/ν and weight μ .

class `sage.combinat.skew_tableau.SemistandardSkewTableaux_size` ($n, \text{max\_entry}$)

Bases: `sage.combinat.skew_tableau.SemistandardSkewTableaux`

Class of all semistandard skew tableaux of a fixed size n , possibly with a given maximum entry.

cardinality()

EXAMPLES:

```
sage: SemistandardSkewTableaux(2).cardinality()
8
```

class `sage.combinat.skew_tableau.SemistandardSkewTableaux_size_weight` (n, μ)

Bases: `sage.combinat.skew_tableau.SemistandardSkewTableaux`

Class of semistandard tableaux of a fixed size n and weight μ .

cardinality()

EXAMPLES:

```
sage: SemistandardSkewTableaux(2, [1,1]).cardinality()
4
```

class `sage.combinat.skew_tableau.SkewTableau` (parent, st)

Bases: `sage.structure.list_clone.ClonableList`

A skew tableau.

Note that Sage by default uses the English convention for partitions and tableaux. To change this, see `Tableaux.options()`.

EXAMPLES:

```
sage: st = SkewTableau([None, 1], [2,3]); st
[None, 1], [2, 3]
sage: st.inner_shape()
```

```
[1]
sage: st.outer_shape()
[2, 2]
```

The `expr` form of a skew tableau consists of the inner partition followed by a list of the entries in each row from bottom to top:

```
sage: SkewTableau(expr=[[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

The `chain` form of a skew tableau consists of a list of partitions $\lambda_1, \lambda_2, \dots$, such that all cells in λ_{i+1} that are not in λ_i have entry i :

```
sage: SkewTableau(chain=[[2], [2, 1], [3, 1], [4, 3, 2, 1]])
[[None, None, 2, 3], [1, 3, 3], [3, 3], [3]]
```

bender_knuth_involution (k , $rows=None$, $check=True$)

Return the image of `self` under the k -th Bender–Knuth involution, assuming `self` is a skew semistandard tableau.

Let T be a tableau, then a *lower free* ' k ' in ' T ' means a cell of T which is filled with the integer k and whose direct lower neighbor is not filled with the integer $k + 1$ (in particular, this lower neighbor might not exist at all). Let an *upper free* ' $k + 1$ ' in ' T ' mean a cell of T which is filled with the integer $k + 1$ and whose direct upper neighbor is not filled with the integer k (in particular, this neighbor might not exist at all). It is clear that for any row r of T , the lower free k 's and the upper free $k + 1$'s in r together form a contiguous interval or r .

The ' k -th Bender–Knuth switch at row ' i ' changes the entries of the cells in this interval in such a way that if it used to have a entries of k and b entries of $k + 1$, it will now have b entries of k and a entries of $k + 1$. For fixed k , the k -th Bender–Knuth switches for different i commute. The composition of the k -th Bender–Knuth switches for all rows is called the ' k -th Bender–Knuth involution'. This is used to show that the Schur functions defined by semistandard (skew) tableaux are symmetric functions.

INPUT:

- k – an integer
- `rows` – (Default `None`) When set to `None`, the method computes the k -th Bender–Knuth involution as defined above. When an iterable, this computes the composition of the k -th Bender–Knuth switches at row i over all i in `rows`. When set to an integer i , the method computes the k -th Bender–Knuth switch at row i . Note the indexing of the rows starts with 1.
- `check` – (Default: `True`) Check to make sure `self` is semistandard. Set to `False` to avoid this check.

OUTPUT:

The image of `self` under either the k -th Bender–Knuth involution, the k -th Bender–Knuth switch at a certain row, or the composition of such switches, as detailed in the INPUT section.

EXAMPLES:

```
sage: t = SkewTableau([[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7], [None, 4,
↪ 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]])
sage: t
[[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7], [None, 4, 5, 8, ↪
↪ 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
sage: t.bender_knuth_involution(1)
[[None, None, None, 4, 4, 5, 6, 7], [None, 1, 4, 6, 7, 7, 7], [None, 4, 5, 8, ↪
↪ 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
```

```

sage: t.bender_knuth_involution(4)
[[None, None, None, 4, 5, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7], [None, 5, 5, 8, ↵
↵8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [5]]
sage: t.bender_knuth_involution(5)
[[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 5, 7, 7, 7], [None, 4, 6, 8, ↵
↵8, 9], [None, 5, 7, 10], [None, 8, 8, 11], [None], [4]]
sage: t.bender_knuth_involution(6)
[[None, None, None, 4, 4, 5, 6, 6], [None, 2, 4, 6, 6, 7, 7], [None, 4, 5, 8, ↵
↵8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
sage: t.bender_knuth_involution(666) == t
True
sage: t.bender_knuth_involution(4, 2) == t
True
sage: t.bender_knuth_involution(4, 3)
[[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7], [None, 5, 5, 8, ↵
↵8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]

```

The Bender–Knuth involution is an involution:

```

sage: t = SkewTableau([[None, 3, 4, 4], [None, 6, 10], [7, 7, 11], [18]])
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(k) == t for k ↵
↵in range(1, 4))
True

```

The same for the single switches:

```

sage: all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j) == t ↵
↵for k in range(1, 5) for j in range(1, 5))
True

```

Locality of the Bender–Knuth involutions:

```

sage: all(t.bender_knuth_involution(k).bender_knuth_involution(l) == t.bender_ ↵
↵knuth_involution(l).bender_knuth_involution(k) for k in range(1, 5) for l in ↵
↵range(1, 5) if abs(k - l) > 1)
True

```

AUTHORS:

- Darij Grinberg (2013-05-14)

cells()

Return the cells in `self`.

EXAMPLES:

```

sage: s = SkewTableau([[None, 1, 2], [3], [6]])
sage: s.cells()
[(0, 1), (0, 2), (1, 0), (2, 0)]

```

cells_by_content(c)

Return the coordinates of the cells in `self` with content `c`.

EXAMPLES:

```

sage: s = SkewTableau([[None, 1, 2], [3, 4, 5], [6]])
sage: s.cells_by_content(0)
[(1, 1)]
sage: s.cells_by_content(1)

```

```

[(0, 1), (1, 2)]
sage: s.cells_by_content(2)
[(0, 2)]
sage: s.cells_by_content(-1)
[(1, 0)]
sage: s.cells_by_content(-2)
[(2, 0)]

```

cells_containing(*i*)

Return the list of cells in which the letter *i* appears in the tableau `self`. The list is ordered with cells appearing from left to right.

Cells are given as pairs of coordinates (a, b) , where both rows and columns are counted from 0 (so $a = 0$ means the cell lies in the leftmost column of the tableau, etc.).

EXAMPLES:

```

sage: t = SkewTableau([[None, None, 3], [None, 3, 5], [4, 5]])
sage: t.cells_containing(5)
[(2, 1), (1, 2)]
sage: t.cells_containing(4)
[(2, 0)]
sage: t.cells_containing(2)
[]

sage: t = SkewTableau([[None, None, None, None], [None, 4, 5], [None, 5, 6], [None, 9],
↪ [None]])
sage: t.cells_containing(2)
[]
sage: t.cells_containing(4)
[(1, 1)]
sage: t.cells_containing(5)
[(2, 1), (1, 2)]

sage: SkewTableau([]).cells_containing(3)
[]

sage: SkewTableau([[None, None], [None]]).cells_containing(3)
[]

```

check()

Check that `self` is a valid skew tableau. This is currently far too liberal, and only checks some trivial things.

EXAMPLES:

```

sage: t = SkewTableau([[None, 1, 1], [2]])
sage: t.check()

sage: t = SkewTableau([[None, None, 1], [2, 4], [], [3, 4, 5]])
Traceback (most recent call last):
...
TypeError: a skew tableau cannot have an empty list for a row

```

conjugate()

Return the conjugate of `self`.

EXAMPLES:

```
sage: SkewTableau([[None, 1], [2, 3]]).conjugate()
[[None, 2], [1, 3]]
```

entries_by_content(*c*)

Return the entries in *self* with content *c*.

EXAMPLES:

```
sage: s = SkewTableau([[None, 1, 2], [3, 4, 5], [6]])
sage: s.entries_by_content(0)
[4]
sage: s.entries_by_content(1)
[1, 5]
sage: s.entries_by_content(2)
[2]
sage: s.entries_by_content(-1)
[3]
sage: s.entries_by_content(-2)
[6]
```

evaluation()

Return the weight (aka evaluation) of the tableau *self*. Trailing zeroes are omitted when returning the weight.

The weight of a skew tableau *T* is the sequence $(a_1, a_2, a_3, \dots)$, where a_k is the number of entries of *T* equal to k . This sequence contains only finitely many nonzero entries.

The weight of a skew tableau *T* is the same as the weight of the reading word of *T*, for any reading order.

evaluation() is a synonym for this method.

EXAMPLES:

```
sage: SkewTableau([[1, 2], [3, 4]]).weight()
[1, 1, 1, 1]

sage: SkewTableau([[None, 2], [None, 4], [None, 5], [None]]).weight()
[0, 1, 0, 1, 1]

sage: SkewTableau([]).weight()
[]

sage: SkewTableau([[None, None, None], [None]]).weight()
[]

sage: SkewTableau([[None, 3, 4], [None, 6, 7], [4, 8], [5, 13], [6], [7]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]
```

filling()

Return a list of the non-empty entries in *self*.

EXAMPLES:

```
sage: t = SkewTableau([[None, 1], [2, 3]])
sage: t.filling()
[[1], [2, 3]]
```

inner_shape()

Return the inner shape of *self*.

EXAMPLES:

```
sage: SkewTableau([[None, 1, 2], [None, 3], [4]]).inner_shape()
[1, 1]
sage: SkewTableau([[1, 2], [3, 4], [7]]).inner_shape()
[]
sage: SkewTableau([[None, None, None, 2, 3], [None, 1], [None], [2]]).inner_shape()
[3, 1, 1]
```

inner_size()

Return the size of the inner shape of `self`.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).inner_size()
2
sage: SkewTableau([[None, 2], [1, 3]]).inner_size()
1
```

is_k_tableau(*k*)

Checks whether `self` is a valid skew weak k -tableau.

EXAMPLES:

```
sage: t = SkewTableau([[None, 2, 3], [2, 3], [3]])
sage: t.is_k_tableau(3)
True
sage: t = SkewTableau([[None, 1, 3], [2, 2], [3]])
sage: t.is_k_tableau(3)
False
```

is_ribbon()

Return True if and only if the shape of `self` is a ribbon, that is, if it has exactly one cell in each of q consecutive diagonals for some nonnegative integer q .

EXAMPLES:

```
sage: S=SkewTableau([[None, None, 1, 2], [None, None, 3], [1, 3, 4]])
sage: S.pp()
. . 1 2
. . 3
1 3 4
sage: S.is_ribbon()
True

sage: S=SkewTableau([[None, 1, 1, 2], [None, 2, 3], [1, 3, 4]])
sage: S.pp()
. 1 1 2
. 2 3
1 3 4
sage: S.is_ribbon()
False

sage: S=SkewTableau([[None, None, 1, 2], [None, None, 3], [1]])
sage: S.pp()
. . 1 2
. . 3
1
sage: S.is_ribbon()
```

```

False

sage: S=SkewTableau([[None, None, None, None],[None, None, 3],[1, 2, 4]])
sage: S.pp()
. . . .
. . 3
1 2 4
sage: S.is_ribbon()
True

sage: S=SkewTableau([[None, None, None, None],[None, None, 3],[None, 2, 4]])
sage: S.pp()
. . . .
. . 3
. 2 4
sage: S.is_ribbon()
True

sage: S=SkewTableau([[None, None],[None]])
sage: S.pp()
. .
.
sage: S.is_ribbon()
True

```

is_semistandard()

Return True if self is a semistandard skew tableau and False otherwise.

EXAMPLES:

```

sage: SkewTableau([[None, 2, 2], [1, 3]]).is_semistandard()
True
sage: SkewTableau([[None, 2], [2, 4]]).is_semistandard()
True
sage: SkewTableau([[None, 3], [2, 4]]).is_semistandard()
True
sage: SkewTableau([[None, 2], [1, 2]]).is_semistandard()
False
sage: SkewTableau([[None, 2, 3]]).is_semistandard()
True
sage: SkewTableau([[None, 3, 2]]).is_semistandard()
False
sage: SkewTableau([[None, 2, 3], [1, 4]]).is_semistandard()
True
sage: SkewTableau([[None, 2, 3], [1, 2]]).is_semistandard()
False
sage: SkewTableau([[None, 2, 3], [None, None, 4]]).is_semistandard()
False

```

is_standard()

Return True if self is a standard skew tableau and False otherwise.

EXAMPLES:

```

sage: SkewTableau([[None, 2], [1, 3]]).is_standard()
True
sage: SkewTableau([[None, 2], [2, 4]]).is_standard()
False

```

```
sage: SkewTableau([[None, 3], [2, 4]]).is_standard()
False
sage: SkewTableau([[None, 2], [2, 4]]).is_standard()
False
```

outer_shape()

Return the outer shape of self.

EXAMPLES:

```
sage: SkewTableau([[None, 1, 2], [None, 3], [4]]).outer_shape()
[3, 2, 1]
```

outer_size()

Return the size of the outer shape of self.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).outer_size()
6
sage: SkewTableau([[None, 2], [1, 3]]).outer_size()
4
```

pp()

Return a pretty print string of the tableau.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 3], [None, 4], [5]]).pp()
.  2  3
.  4
5
```

rectify (*algorithm=None*)

Return a *StandardTableau*, *SemistandardTableau*, or just *Tableau* formed by applying the jeu de taquin process to self.

See page 15 of [\[Fulton97\]](#).

INPUT:

- *algorithm* – optional: if set to 'jdt', rectifies by jeu de taquin; if set to 'schensted', rectifies by Schensted insertion of the reading word; otherwise, guesses which will be faster.

EXAMPLES:

```
sage: S = SkewTableau([[None, 1], [2, 3]])
sage: S.rectify()
[[1, 3], [2]]
sage: T = SkewTableau([[None, None, None, 4], [None, None, 1, 6], [None, None, 5], [2,
↪ 3]])
sage: T.rectify()
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='jdt')
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='schensted')
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='spaghetti')
Traceback (most recent call last):
```

```
...
ValueError: algorithm must be 'jdt', 'schensted', or None
```

REFERENCES:

restrict (*n*)

Return the restriction of the (semi)standard skew tableau to all the numbers less than or equal to *n*.

Note: If only the outer shape of the restriction, rather than the whole restriction, is needed, then the faster method `restriction_outer_shape()` is preferred. Similarly if only the skew shape is needed, use `restriction_shape()`.

EXAMPLES:

```
sage: SkewTableau([[None,1],[2],[3]]).restrict(2)
[[None, 1], [2]]
sage: SkewTableau([[None,1],[2],[3]]).restrict(1)
[[None, 1]]
sage: SkewTableau([[None,1],[1],[2]]).restrict(1)
[[None, 1], [1]]
```

restriction_outer_shape (*n*)

Return the outer shape of the restriction of the semistandard skew tableau `self` to *n*.

If *T* is a semistandard skew tableau and *n* is a nonnegative integer, then the restriction of *T* to *n* is defined as the (semistandard) skew tableau obtained by removing all cells filled with entries greater than *n* from *T*.

This method computes merely the outer shape of the restriction. For the restriction itself, use `restrict()`.

EXAMPLES:

```
sage: SkewTableau([[None,None],[2,3],[3,4]]).restriction_outer_shape(3)
[2, 2, 1]
sage: SkewTableau([[None,2],[None],[4],[5]]).restriction_outer_shape(2)
[2, 1]
sage: T = SkewTableau([[None,None,3,5],[None,4,4],[17]])
sage: T.restriction_outer_shape(0)
[2, 1]
sage: T.restriction_outer_shape(2)
[2, 1]
sage: T.restriction_outer_shape(3)
[3, 1]
sage: T.restriction_outer_shape(4)
[3, 3]
sage: T.restriction_outer_shape(19)
[4, 3, 1]
```

restriction_shape (*n*)

Return the skew shape of the restriction of the semistandard skew tableau `self` to *n*.

If *T* is a semistandard skew tableau and *n* is a nonnegative integer, then the restriction of *T* to *n* is defined as the (semistandard) skew tableau obtained by removing all cells filled with entries greater than *n* from *T*.

This method computes merely the skew shape of the restriction. For the restriction itself, use `restrict()`.

EXAMPLES:

```
sage: SkewTableau([[None, None], [2, 3], [3, 4]]).restriction_shape(3)
[2, 2, 1] / [2]
sage: SkewTableau([[None, 2], [None], [4], [5]]).restriction_shape(2)
[2, 1] / [1, 1]
sage: T = SkewTableau([[None, None, 3, 5], [None, 4, 4], [17]])
sage: T.restriction_shape(0)
[2, 1] / [2, 1]
sage: T.restriction_shape(2)
[2, 1] / [2, 1]
sage: T.restriction_shape(3)
[3, 1] / [2, 1]
sage: T.restriction_shape(4)
[3, 3] / [2, 1]
```

shape()

Return the shape of `self`.

EXAMPLES:

```
sage: SkewTableau([[None, 1, 2], [None, 3], [4]]).shape()
[3, 2, 1] / [1, 1]
```

shuffle(t2)

Shuffle the standard tableaux `self` and `t2`.

Let `t1 = self`. The shape of `t2` must extend the shape of `t1`, that is, `self.outer_shape() == t2.inner_shape()`. Then this function computes the pair of tableaux (`t2_new`, `t1_new`) obtained by using jeu de taquin slides to move the boxes of `t2` behind the boxes of `self`.

The entries of `t2_new` are obtained by performing successive inwards jeu de taquin slides on `t2` in the order indicated by the entries of `t1`, from largest to smallest. The entries of `t1` then slide outwards one by one and land in the squares vacated successively by `t2`, forming `t1_new`.

Note: Equivalently, the entries of `t1_new` are obtained by performing outer jeu de taquin slides on `t1` in the order indicated by the entries of `t2`, from smallest to largest. In this case the entries of `t2` slide backwards and fill the squares successively vacated by `t1` and so form `t2_new`. (This is not how the algorithm is implemented.)

INPUT:

- `self`, `t2` – a pair of standard *SkewTableaux* with `self.outer_shape() == t2.inner_shape()`

OUTPUT:

- `t2_new`, `t1_new` – a pair of standard *SkewTableaux* with `t2_new.outer_shape() == t1_new.inner_shape()`

EXAMPLES:

```
sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: (t2_new, t1_new) = t1.shuffle(t2)
sage: t1_new
[[None, None, None, 2], [None, None, 1], [None, 3, 4]]
sage: t2_new
[[None, 2, 3], [1, 4], [5]]
```

```
sage: t1_new.outer_shape() == t2.outer_shape()
True
sage: t2_new.inner_shape() == t1.inner_shape()
True
```

Shuffling is an involution:

```
sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: sh = lambda x,y : x.shuffle(y)
sage: (t1, t2) == sh(*sh(t1, t2))
True
```

Both tableaux must be standard:

```
sage: t1 = SkewTableau([[None, 1, 2], [2, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the tableaux must be standard
sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 6]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the tableaux must be standard
```

The shapes (not just the nonempty cells) must be adjacent:

```
sage: t1 = SkewTableau([[None, None, None], [1]])
sage: t2 = SkewTableau([[None], [None], [1]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the shapes must be adjacent
```

size()

Return the number of cells in *self*.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).size()
4
sage: SkewTableau([[None, 2], [1, 3]]).size()
3
```

slide (*corner=None, return_vacated=False*)

Apply a jeu-de-taquin slide to *self* on the specified inner corner and return the resulting tableau.

If no corner is given, the topmost inner corner is chosen.

The optional parameter *return_vacated=True* causes the output to be the pair (*t*, (*i*, *j*)) where *t* is the new tableau and (*i*, *j*) are the coordinates of the vacated square.

See [Fulton97] p12-13.

EXAMPLES:

```

sage: st = SkewTableau([[None, None, None, None, 2], [None, None, None, None, 6], [None, 2, 4, 4], [2, 3, 6], [5, 5]])
sage: st.slide((2, 0))
[[None, None, None, None, 2], [None, None, None, None, 6], [2, 2, 4, 4], [3, 5, 6], [5]]
sage: st2 = SkewTableau([[None, None, 3], [None, 2, 4], [1, 5]])
sage: st2.slide((1, 0), True)
[[None, None, 3], [1, 2, 4], [5]], (2, 1))

```

standardization (*check=True*)

Return the standardization of *self*, assuming *self* is a semistandard skew tableau.

The standardization of a semistandard skew tableau T is the standard skew tableau $st(T)$ of the same shape as T whose reversed reading word is the standardization of the reversed reading word of T .

The standardization of a word w can be formed by replacing all 1's in w by $1, 2, \dots, k_1$ from left to right, all 2's in w by $k_1 + 1, k_1 + 2, \dots, k_2$, and repeating for all letters that appear in w . See also `Word.standard_permutation()`.

INPUT:

- *check* – (Default: `True`) Check to make sure *self* is semistandard. Set to `False` to avoid this check.

EXAMPLES:

```

sage: t = SkewTableau([[None, None, 3, 4, 7, 19], [None, 4, 4, 8], [None, 5, 16, 17], [None], [2], [3]])
sage: t.standardization()
[[None, None, 3, 6, 8, 12], [None, 4, 5, 9], [None, 7, 10, 11], [None], [1], [2]]

```

Standard skew tableaux are fixed under standardization:

```

sage: p = Partition([4, 3, 3, 2])
sage: q = Partitions(3).random_element()
sage: all((t == t.standardization() for t in StandardSkewTableaux([p, q])))
True

```

The reading word of the standardization is the standardization of the reading word:

```

sage: t = SkewTableau([[None, 3, 4, 4], [None, 6, 10], [7, 7, 11], [18]])
sage: t.to_word().standard_permutation() == t.standardization().to_word().permutation()
True

```

to_chain (*max_entry=None*)

Return the chain of partitions corresponding to the (semi)standard skew tableau *self*.

The optional keyword parameter *max_entry* can be used to customize the length of the chain. Specifically, if this parameter is set to a nonnegative integer n , then the chain is constructed from the positions of the letters $1, 2, \dots, n$ in the tableau.

EXAMPLES:

```

sage: SkewTableau([[None, 1], [2], [3]]).to_chain()
[[1], [2], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None, 1], [1], [2]]).to_chain()
[[1], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None, 1], [1], [2]]).to_chain(max_entry=2)

```

```

[[1], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None, 1], [1], [2]]).to_chain(max_entry=3)
[[1], [2, 1], [2, 1, 1], [2, 1, 1]]
sage: SkewTableau([[None, 1], [1], [2]]).to_chain(max_entry=1)
[[1], [2, 1]]
sage: SkewTableau([[None, None, 2], [None, 3], [None, 5]]).to_chain(max_entry=6)
[[2, 1, 1], [2, 1, 1], [3, 1, 1], [3, 2, 1], [3, 2, 1], [3, 2, 2], [3, 2, 2]]
sage: SkewTableau([]).to_chain()
[[]]
sage: SkewTableau([]).to_chain(max_entry=1)
[[], []]

```

to_expr()

The first list in a result corresponds to the inner partition of the skew shape. The second list is a list of the rows in the skew tableau read from the bottom up.

Provided for compatibility with MuPAD-Combinat. In MuPAD-Combinat, if `t` is a skew tableau, then `to_expr` gives the same result as `expr(t)` would give in MuPAD-Combinat.

EXAMPLES:

```

sage: SkewTableau([[None, 1, 1, 3], [None, 2, 2], [1]]).to_expr()
[[1, 1], [[1], [2, 2], [1, 1, 3]]]
sage: SkewTableau([]).to_expr()
[[], []]

```

to_list()

Return a (mutable) list representation of `self`.

EXAMPLES:

```

sage: stlist = [[None, None, 3], [None, 1, 3], [2, 2]]
sage: st = SkewTableau(stlist)
sage: st.to_list()
[[None, None, 3], [None, 1, 3], [2, 2]]
sage: st.to_list() == stlist
True

```

to_permutation()

Return a permutation with the entries of `self` obtained by reading `self` row by row, from the bottommost to the topmost row, with each row being read from left to right, in English convention. See [to_word_by_row\(\)](#).

EXAMPLES:

```

sage: SkewTableau([[None, 2], [3, 4], [None], [1]]).to_permutation()
[1, 3, 4, 2]
sage: SkewTableau([[None, 2], [None, 4], [1], [3]]).to_permutation()
[3, 1, 4, 2]
sage: SkewTableau([[None]]).to_permutation()
[]

```

to_ribbon(*check_input=True*)

Return `self` as a ribbon-shaped tableau (*RibbonShapedTableau*), provided that the shape of `self` is a ribbon.

INPUT:

- `check_input` – (default: `True`) whether or not to check that `self` indeed has ribbon shape

EXAMPLES:

```
sage: SkewTableau([[None, 1], [2, 3]]).to_ribbon()  
[[None, 1], [2, 3]]
```

to_tableau()

Returns a tableau with the same filling. This only works if the inner shape of the skew tableau has size zero.

EXAMPLES:

```
sage: SkewTableau([[1, 2], [3, 4]]).to_tableau()  
[[1, 2], [3, 4]]
```

to_word()

Return a word obtained from a row reading of `self`.

This is the word obtained by concatenating the rows from the bottommost one (in English notation) to the topmost one.

EXAMPLES:

```
sage: s = SkewTableau([[None, 1], [2, 3]])  
sage: s.pp()  
. 1  
2 3  
sage: s.to_word_by_row()  
word: 231  
sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])  
sage: s.pp()  
. 2 4  
. 3  
1  
sage: s.to_word_by_row()  
word: 1324
```

to_word_by_column()

Return the word obtained from a column reading of the skew tableau.

This is the word obtained by concatenating the columns from the rightmost one (in English notation) to the leftmost one.

EXAMPLES:

```
sage: s = SkewTableau([[None, 1], [2, 3]])  
sage: s.pp()  
. 1  
2 3  
sage: s.to_word_by_column()  
word: 132
```

```
sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])  
sage: s.pp()  
. 2 4  
. 3  
1  
sage: s.to_word_by_column()  
word: 4231
```

to_word_by_row()

Return a word obtained from a row reading of `self`.

This is the word obtained by concatenating the rows from the bottommost one (in English notation) to the topmost one.

EXAMPLES:

```
sage: s = SkewTableau([[None, 1], [2, 3]])
sage: s.pp()
.  1
2  3
sage: s.to_word_by_row()
word: 231
sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])
sage: s.pp()
.  2  4
.  3
1
sage: s.to_word_by_row()
word: 1324
```

weight()

Return the weight (aka evaluation) of the tableau `self`. Trailing zeroes are omitted when returning the weight.

The weight of a skew tableau T is the sequence $(a_1, a_2, a_3, \dots)$, where a_k is the number of entries of T equal to k . This sequence contains only finitely many nonzero entries.

The weight of a skew tableau T is the same as the weight of the reading word of T , for any reading order.

`evaluation()` is a synonym for this method.

EXAMPLES:

```
sage: SkewTableau([[1, 2], [3, 4]]).weight()
[1, 1, 1, 1]

sage: SkewTableau([[None, 2], [None, 4], [None, 5], [None]]).weight()
[0, 1, 0, 1, 1]

sage: SkewTableau([]).weight()
[]

sage: SkewTableau([[None, None, None], [None]]).weight()
[]

sage: SkewTableau([[None, 3, 4], [None, 6, 7], [4, 8], [5, 13], [6], [7]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]
```

class `sage.combinat.skew_tableau.SkewTableau_class` (*parent*, *st*)

Bases: `sage.combinat.skew_tableau.SkewTableau`

This exists solely for unpickling `SkewTableau_class` objects.

class `sage.combinat.skew_tableau.SkewTableaux` (*category=None*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Class of all skew tableaux.

Elementalias of *SkewTableau***from_chain**(*chain*)

Return the tableau corresponding to the chain of partitions.

EXAMPLES:

```
sage: SkewTableaux().from_chain([[1,1], [2,1], [3,1], [3,2], [3,3], [3,3,1]])
[[None, 1, 2], [None, 3, 4], [5]]
```

from_expr(*expr*)Return a *SkewTableau* from a MuPAD-Combinat *expr* for a skew tableau. The first list in *expr* is the inner shape of the skew tableau. The second list are the entries in the rows of the skew tableau from bottom to top.

Provided primarily for compatibility with MuPAD-Combinat.

EXAMPLES:

```
sage: SkewTableaux().from_expr([[1,1], [[5], [3,4], [1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

from_shape_and_word(*shape*, *word*)Return the skew tableau corresponding to the skew partition *shape* and the word *word* obtained from the row reading.

EXAMPLES:

```
sage: t = SkewTableau([[None, 1, 3], [None, 2], [4]])
sage: shape = t.shape()
sage: word = t.to_word()
sage: SkewTableaux().from_shape_and_word(shape, word)
[[None, 1, 3], [None, 2], [4]]
```

global_options(**args*, ***kws*)Deprecated: Use *options()* instead. See [trac ticket #18555](#) for details.**options**(**get_value*, ***set_value*)

Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- *ascii_art* – (default: *repr*) Controls the ascii art output for tableaux
 - compact* – minimal length ascii art
 - repr* – display using the diagram string representation
 - table* – display as a table
- *convention* – (default: *English*) Sets the convention used for displaying tableaux and partitions
 - English* – use the English convention
 - French* – use the French convention
- *display* – (default: *list*) Controls the way in which tableaux are printed
 - array* – alias for *diagram*
 - compact* – minimal length string representation

- `diagram` – display as Young diagram (similar to `pp()`)
- `ferrers_diagram` – alias for `diagram`
- `list` – print tableaux as lists
- `young_diagram` – alias for `diagram`
- `latex` – (default: `diagram`) Controls the way in which tableaux are latexed
 - `array` – alias for `diagram`
 - `diagram` – as a Young diagram
 - `ferrers_diagram` – alias for `diagram`
 - `list` – as a list
 - `young_diagram` – alias for `diagram`
- `notation` – alternative name for `convention`

Note: Changing the `convention` for tableaux also changes the `convention` for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.options.display="array"
sage: T
  1  2  3
  4  5
sage: Tableaux.options.convention="french"
sage: T
  4  5
  1  2  3
```

Changing the `convention` for tableaux also changes the `convention` for partitions and vice versa:

```
sage: P = Partition([3,3,1])
sage: print(P.ferrers_diagram())
*
***
***
sage: Partitions.options.convention="english"
sage: print(P.ferrers_diagram())
***
***
*
sage: T
  1  2  3
  4  5
```

The ASCII art can also be changed:

```
sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
  1  2  3
```

```

4 5
sage: Tableaux.options.ascii_art="table"
sage: ascii_art(t)
+---+---+
| 4 | 5 |
+---+---+
| 1 | 2 | 3 |
+---+---+
sage: Tableaux.options.ascii_art="compact"
sage: ascii_art(t)
|4|5|
|1|2|3|
sage: Tableaux.options._reset()

```

See `GlobalOptions` for more features of these options.

class `sage.combinat.skew_tableau.StandardSkewTableaux` (*category=None*)
 Bases: `sage.combinat.skew_tableau.SkewTableaux`

Standard skew tableaux.

EXAMPLES:

```

sage: S = StandardSkewTableaux(); S
Standard skew tableaux
sage: S.cardinality()
+Infinity

```

```

sage: S = StandardSkewTableaux(2); S
Standard skew tableaux of size 2
sage: S.cardinality()
4

```

```

sage: StandardSkewTableaux([[3, 2, 1], [1, 1]]).list()
[[[None, 1, 2], [None, 3], [4]],
 [[None, 1, 2], [None, 4], [3]],
 [[None, 1, 3], [None, 2], [4]],
 [[None, 1, 4], [None, 2], [3]],
 [[None, 1, 3], [None, 4], [2]],
 [[None, 1, 4], [None, 3], [2]],
 [[None, 2, 3], [None, 4], [1]],
 [[None, 2, 4], [None, 3], [1]]]

```

class `sage.combinat.skew_tableau.StandardSkewTableaux_all`
 Bases: `sage.combinat.skew_tableau.StandardSkewTableaux`

Class of all standard skew tableaux.

class `sage.combinat.skew_tableau.StandardSkewTableaux_shape` (*skp*)
 Bases: `sage.combinat.skew_tableau.StandardSkewTableaux`

Standard skew tableaux of a fixed skew shape λ/μ .

cardinality ()

Return the number of standard skew tableaux with shape of the skew partition `skp`. This uses a formula due to Aitken (see Cor. 7.16.3 of [\[Sta-EC2\]](#)).

EXAMPLES:

```
sage: StandardSkewTableaux([[3, 2, 1], [1, 1]]).cardinality()
8
```

class sage.combinat.skew_tableau.**StandardSkewTableaux_size**(*n*)

Bases: *sage.combinat.skew_tableau.StandardSkewTableaux*

Standard skew tableaux of a fixed size *n*.

cardinality()

EXAMPLES:

```
sage: StandardSkewTableaux(1).cardinality()
1
sage: StandardSkewTableaux(2).cardinality()
4
sage: StandardSkewTableaux(3).cardinality()
24
sage: StandardSkewTableaux(4).cardinality()
194
```

5.1.290 Functions that compute some of the sequences in Sloane's tables

EXAMPLES:

Type `sloane.[tab]` to see a list of the sequences that are defined.

```
sage: a = sloane.A000005; a
The integer sequence tau(n), which is the number of divisors of n.
sage: a(1)
1
sage: a(6)
4
sage: a(100)
9
```

Type `d._eval??` to see how the function that computes an individual term of the sequence is implemented.

The input must be a positive integer:

```
sage: a(0)
Traceback (most recent call last):
...
ValueError: input n (=0) must be a positive integer
sage: a(1/3)
Traceback (most recent call last):
...
TypeError: input must be an int or Integer
```

You can also change how a sequence prints:

```
sage: a = sloane.A000005; a
The integer sequence tau(n), which is the number of divisors of n.
sage: a.rename('(..., tau(n), ...)')
sage: a
(..., tau(n), ...)
sage: a.reset_name()
sage: a
The integer sequence tau(n), which is the number of divisors of n.
```

See also:

- If you want to get more informations relative to a sequence (references, links, examples, programs, ...), you can use the On-Line Encyclopedia of Integer Sequences provided by the OEIS module.
- If you plan to do a lot of automatic searches for subsequences, you should consider installing `SloaneEncyclopedia`, a local partial copy of the OEIS.

```

AUTHORS:

•Jaap Spies (2007-01-18)

class `sage.combinat.sloane_functions.A000027`
 Bases: `sage.combinat.sloane_functions.SloaneSequence`

The natural numbers. Also called the whole numbers, the counting numbers or the positive integers.

The following examples are tests of `SloaneSequence` more than A000027.

EXAMPLES:

```

sage: s = sloane.A000027; s
The natural numbers.
sage: s(10)
10

```

Index n is interpreted as `_eval(n)`:

```
sage: s[10]
10
```

Slices are interpreted with absolute offsets, so the following returns the terms of the sequence up to but not including the third term:

```
sage: s[:3]
[1, 2]
sage: s[3:6]
[3, 4, 5]
sage: s.list(5)
[1, 2, 3, 4, 5]
```

class `sage.combinat.sloane_functions.A000030`
 Bases: `sage.combinat.sloane_functions.SloaneSequence`

Initial digit of n .

INPUT:

- n - non negative integer

OUTPUT:

- integer - function value

EXAMPLES:

```
sage: a = sloane.A000030; a
Initial digit of n
sage: a(0)
0
sage: a(1)
1
sage: a(8)
8
sage: a(454)
4
sage: a(-4)

Permanent of (0,1)-matrix of size $n \times (n + d)$ with $d = 6$ and $n - 1$ zeros not on a line.

$$a(n) = (n + 1) * a(n - 1) + (n - 2) * a(n - 2) [a(1) = 7, a(2) = 49]$$

$$A090016a(n) = A090010(n - 1) + A090010(n), a(1) = 7$$

This is a special case of Theorem 2.3 of Seok-Zun Song et al. Extremes of permanents of (0,1)-matrices, p. 201-202.

REFERENCES:

- Seok-Zun Song et al., Extremes of permanents of (0,1)-matrices, Lin. Algebra and its Applic. 373 (2003), p. 197-210.

INPUT:

- n - positive integer

OUTPUT:

- integer - function value

EXAMPLES:

```

sage: a = sloane.A090016;a
Permanent of (0,1)-matrix of size n X (n+d) with d=6 and n-1 zeros not on a line.
sage: a(0)
Traceback (most recent call last):

AUTHORS:

- Jaap Spies (2007-01-23)

class sage.combinat.sloane_functions.**A109814**

Bases: *sage.combinat.sloane_functions.SloaneSequence*

The n th term of the sequence $a(n)$ is the largest k such that n can be written as sum of k consecutive integers.

By definition, n is the sum of at most $a(n)$ consecutive positive integers. Suppose n is to be written as sum of k consecutive integers starting with m , then $2n = k(2m + k - 1)$. Only one of the factors is odd. For each odd divisor d of n there is a unique corresponding $k = \min(d, 2n/d)$. $a(n)$ can be alternatively defined as the largest among those k .

`is_number_of_the_third_kind( $n$ )`

This function returns True if and only if n is a number of the third kind.

A number is of the third kind if it can be written as a sum of at least three consecutive positive integers. Odd primes can only be written as a sum of two consecutive integers. Powers of 2 do not have a representation as a sum of k consecutive integers (other than the trivial $n = n$ for $k = 1$).

See: <http://www.jaapspies.nl/mathfiles/problem2005-2C.pdf>

INPUT:

- n - positive integer

OUTPUT:

- True - if n is not prime and not a power of 2 False -

EXAMPLES:

```
sage: a = sloane.A111774
sage: a.is_number_of_the_third_kind(6)
True
sage: a.is_number_of_the_third_kind(100)
True
sage: a.is_number_of_the_third_kind(16)
False
sage: a.is_number_of_the_third_kind(97)
False
```

```
sage: sloane.A111774.list(12)
[6, 9, 10, 12, 14, 15, 18, 20, 21, 22, 24, 25]
```

class `sage.combinat.sloane_functions.A111775`

Bases: `sage.combinat.sloane_functions.SloaneSequence`

Number of ways n can be written as a sum of at least three consecutive integers.

Powers of 2 and (odd) primes can not be written as a sum of at least three consecutive integers. $a(n)$ strongly depends on the number of odd divisors of n (A001227): Suppose n is to be written as sum of k consecutive integers starting with m , then $2n = k(2m + k - 1)$. Only one of the factors is odd. For each odd divisor of n there is a unique corresponding k , $k = 1$ and $k = 2$ must be excluded.

See: <http://www.jaapspies.nl/mathfiles/problem2005-2C.pdf>

INPUT:

• n - non negative integer

OUTPUT:

•integer - function value

EXAMPLES:

class `sage.combinat.sloane_functions.A111787`

Bases: `sage.combinat.sloane_functions.SloaneSequence`

This function returns the n -th number of Sloane's sequence A111787

$a(n) = 0$ if n is an odd prime or a power of 2. For numbers of the third kind (see A111774) we proceed as follows: suppose n is to be written as sum of k consecutive integers starting with m , then $2n = k(2m + k - 1)$. Let p be the smallest odd prime divisor of n then $a(n) = \min(p, 2n/p)$.

See: <http://www.jaapspies.nl/mathfiles/problem2005-2C.pdf>

INPUT:

- n - positive integer

OUTPUT:

- integer - function value

EXAMPLES:

```
sage: a = sloane.A111787; a
a(n) is the least k >= 3 such that n can be written as sum of k consecutive
↳ integers. a(n)=0 if such a k does not exist.

```

AUTHORS:

- Jaap Spies (2007-01-14)

class `sage.combinat.sloane_functions.ExponentialNumbers(a)`

Bases: `sage.combinat.sloane_functions.SloaneSequence`

A sequence of Exponential numbers.

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import ExponentialNumbers
sage: ExponentialNumbers(0)
Sequence of Exponential numbers around 0
```

class `sage.combinat.sloane_functions.ExtremesOfPermanentsSequence(offset=1)`

Bases: `sage.combinat.sloane_functions.SloaneSequence`

A sequence starting at offset (=1 by default).

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import SloaneSequence
sage: SloaneSequence().offset
1
sage: SloaneSequence(4).offset
4
```

gen (*a0*, *a1*, *d*)

EXAMPLES:

```
sage: it = sloane.A000153.gen(0,1,2)
sage: [next(it) for i in range(5)]
[0, 1, 2, 7, 32]
```

list (*n*)

EXAMPLES:

```
sage: sloane.A000153.list(8)
[0, 1, 2, 7, 32, 181, 1214, 9403]
```

class `sage.combinat.sloane_functions.ExtremesOfPermanentsSequence2` (*offset=1*)

Bases: `sage.combinat.sloane_functions.ExtremesOfPermanentsSequence`

A sequence starting at offset (=1 by default).

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import SloaneSequence
sage: SloaneSequence().offset
1
sage: SloaneSequence(4).offset
4
```

gen (*a0*, *a1*, *d*)

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import ExtremesOfPermanentsSequence2
sage: e = ExtremesOfPermanentsSequence2()
sage: it = e.gen(6,43,6)
sage: [next(it) for i in range(5)]
[6, 43, 307, 2542, 23799]
```

class `sage.combinat.sloane_functions.RecurrenceSequence` (*offset=1*)

Bases: `sage.combinat.sloane_functions.SloaneSequence`

A sequence starting at offset (=1 by default).

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import SloaneSequence
sage: SloaneSequence().offset
1
sage: SloaneSequence(4).offset
4
```

list (*n*)

EXAMPLES:

```
sage: sloane.A001110.list(8)
[0, 1, 36, 1225, 41616, 1413721, 48024900, 1631432881]
```

class `sage.combinat.sloane_functions.RecurrenceSequence2` (*offset=1*)

Bases: `sage.combinat.sloane_functions.SloaneSequence`

A sequence starting at offset (=1 by default).

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import SloaneSequence
sage: SloaneSequence().offset
1
sage: SloaneSequence(4).offset
4
```

list (*n*)

EXAMPLES:

```
sage: sloane.A001906.list(10)
[0, 1, 3, 8, 21, 55, 144, 377, 987, 2584]
```

class `sage.combinat.sloane_functions.Sloane`

Bases: `sage.structure.sage_object.SageObject`

A collection of Sloane generating functions.

This class inspects `sage.combinat.sloane_functions`, accumulating all the `SloaneSequence` classes starting with 'A'. These are listed for tab completion, but not instantiated until requested.

EXAMPLES: Ensure we have lots of entries:

```
sage: len(sloane.trait_names()) > 100
True
```

And ensure none are being incorrectly returned:

```
sage: [ None for n in sloane.trait_names() if not n.startswith('A') ]
[]
```

Ensure we can access dynamic constructions and cache correctly:

```
sage: s = sloane.A000587
sage: s is sloane.A000587
True
```

And that we can access other functions in parent classes:

```
sage: sloane.__class__
<class 'sage.combinat.sloane_functions.Sloane'>
```

AUTHORS:

- Nick Alexander

trait_names ()

List Sloane generating functions for tab-completion. The member classes are inspected from module `sage.combinat.sloane_functions`.

They must be sub classes of `SloaneSequence` and must start with 'A'. These restrictions are only to prevent typos, incorrect inspecting, etc.

EXAMPLES:

```
sage: type(sloane.trait_names())
<... 'list'>
```

class `sage.combinat.sloane_functions.SloaneSequence` (*offset=1*)

Bases: `sage.structure.sage_object.SageObject`

Base class for a Sloane integer sequence.

EXAMPLES:

We create a dummy sequence:

list (*n*)

Return *n* terms of the sequence: `sequence[offset]`, `sequence[offset+1]`, ... , `sequence[offset+n-1]`. EXAMPLES:

```
sage: sloane.A000012.list(4)
[1, 1, 1, 1]
```

`sage.combinat.sloane_functions.perm_mh` (*m*, *h*)

This functions calculates $f(g, h)$ from Sloane's sequences A079908-A079928

INPUT:

- *m* - positive integer
- *h* - non negative integer

OUTPUT: permanent of the *m* x (*m*+*h*) matrix, etc.

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import perm_mh
sage: perm_mh(3,3)
36
sage: perm_mh(3,4)
76
```

AUTHORS:

- Jaap Spies (2006)

`sage.combinat.sloane_functions.recur_gen2` (*a0*, *a1*, *a2*, *a3*)

homogeneous general second-order linear recurrence generator with fixed coefficients

$a(0) = a_0$, $a(1) = a_1$, $a(n) = a_2 * a(n-1) + a_3 * a(n-2)$

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import recur_gen2
sage: it = recur_gen2(1,1,1,1)
sage: [next(it) for i in range(10)]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]
```

`sage.combinat.sloane_functions.recur_gen2b` (*a0*, *a1*, *a2*, *a3*, *b*)

inhomogenous second-order linear recurrence generator with fixed coefficients and $b = f(n)$

$a(0) = a_0$, $a(1) = a_1$, $a(n) = a_2 * a(n-1) + a_3 * a(n-2) + f(n)$.

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import recur_gen2b
sage: it = recur_gen2b(1,1,1,1, lambda n: 0)
sage: [next(it) for i in range(10)]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]
```

`sage.combinat.sloane_functions.recur_gen3(a0, a1, a2, a3, a4, a5)`
homogeneous general third-order linear recurrence generator with fixed coefficients
 $a(0) = a_0, a(1) = a_1, a(2) = a_2, a(n) = a_3 \cdot a(n-1) + a_4 \cdot a(n-2) + a_5 \cdot a(n-3)$

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import recur_gen3
sage: it = recur_gen3(1,1,1,1,1,1)
sage: [next(it) for i in range(10)]
[1, 1, 1, 3, 5, 9, 17, 31, 57, 105]
```

5.1.292 Combinatorial species features that are imported by default in the interpreter namespace

5.1.293 Characteristic Species

class `sage.combinat.species.characteristic_species.CharacteristicSpecies` (*n*,
min=None,
max=None,
weight=None)
sage.

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`,
`structure.unique_representation.UniqueRepresentation`

Return the characteristic species of order n .

This species has exactly one structure on a set of size n and no structures on sets of any other size.

EXAMPLES:

```
sage: X = species.CharacteristicSpecies(1)
sage: X.structures([1]).list()
[1]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series().coefficients(4)
[0, 1, 0, 0]
sage: X.isotype_generating_series().coefficients(4)
```

```

[0, 1, 0, 0]
sage: X.cycle_index_series().coefficients(4)
[0, p[1], 0, 0]

sage: F = species.CharacteristicSpecies(3)
sage: c = F.generating_series().coefficients(4)
sage: F._check()
True
sage: F == loads(dumps(F))
True

```

class `sage.combinat.species.characteristic_species.CharacteristicSpeciesStructure` (*parent, labels, list*)

Bases: `sage.combinat.species.structure.GenericSpeciesStructure`

This is a base class from which the classes for the structures inherit.

EXAMPLES:

```

sage: from sage.combinat.species.structure import GenericSpeciesStructure
sage: a = GenericSpeciesStructure(None, [2,3,4], [1,2,3])
sage: a
[2, 3, 4]
sage: a.parent() is None
True
sage: a == loads(dumps(a))
True

```

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed. For the characteristic species, there is only one structure, so every permutation is in its automorphism group.

EXAMPLES:

```

sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.automorphism_group()
Symmetric group of order 3! as a permutation group

```

canonical_label()

EXAMPLES:

```

sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.canonical_label()
{'a', 'b', 'c'}

```

transport (*perm*)

Returns the transport of this structure along the permutation perm.

EXAMPLES:

```

sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}

```

```
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
{'a', 'b', 'c'}
```

sage.combinat.species.characteristic_species.**CharacteristicSpecies_class**
alias of *CharacteristicSpecies*

class sage.combinat.species.characteristic_species.**EmptySetSpecies** (*min=None*,
max=None,
weight=None)
Bases: *sage.combinat.species.characteristic_species.CharacteristicSpecies*

Returns the empty set species.

This species has exactly one structure on the empty set. It is the same (and is implemented) as *CharacteristicSpecies(0)*.

EXAMPLES:

```
sage: X = species.EmptySetSpecies()
sage: X.structures([]).list()
[{}]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series().coefficients(4)
[1, 0, 0, 0]
sage: X.isotype_generating_series().coefficients(4)
[1, 0, 0, 0]
sage: X.cycle_index_series().coefficients(4)
[p[], 0, 0, 0]
```

sage.combinat.species.characteristic_species.**EmptySetSpecies_class**
alias of *EmptySetSpecies*

class sage.combinat.species.characteristic_species.**SingletonSpecies** (*min=None*,
max=None,
weight=None)
Bases: *sage.combinat.species.characteristic_species.CharacteristicSpecies*

Returns the species of singletons.

This species has exactly one structure on a set of size 1. It is the same (and is implemented) as *CharacteristicSpecies(1)*.

EXAMPLES:

```
sage: X = species.SingletonSpecies()
sage: X.structures([1]).list()
[1]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series().coefficients(4)
[0, 1, 0, 0]
sage: X.isotype_generating_series().coefficients(4)
[0, 1, 0, 0]
sage: X.cycle_index_series().coefficients(4)
[0, p[1], 0, 0]
```

sage.combinat.species.characteristic_species.**SingletonSpecies_class**
alias of *SingletonSpecies*

5.1.294 Combinatorial Logarithm

This file provides the cycle index series for the virtual species Ω , the ‘combinatorial logarithm’, defined to be the compositional inverse of the species E^+ of nonempty sets:

$$\Omega \circ E^+ = E^+ \circ \Omega = X.$$

Warning: This module is now deprecated. Please use `sage.combinat.species.generating_series.CycleIndexSeriesRing.exponential()` instead of `CombinatorialLogarithmSeries()`.

AUTHORS:

- Andrew Gainer-Dewar (2013): initial version

`sage.combinat.species.combinatorial_logarithm.CombinatorialLogarithmSeries` ($R=\text{Rational Field}$)

Return the cycle index series of the virtual species Ω , the compositional inverse of the species E^+ of nonempty sets.

The notion of virtual species is treated thoroughly in [BLL]. The specific algorithm used here to compute the cycle index of Ω is found in [Labelle].

EXAMPLES:

The virtual species Ω is ‘properly virtual’, in the sense that its cycle index has negative coefficients:

```
sage: from sage.combinat.species.combinatorial_logarithm import _
      ↪ CombinatorialLogarithmSeries
sage: CombinatorialLogarithmSeries().coefficients(4)
doctest:...: DeprecationWarning: CombinatorialLogarithmSeries is deprecated, use
      ↪ CycleIndexSeriesRing(R).logarithm_series() or CycleIndexSeries().logarithm()
      ↪ instead
See http://trac.sagemath.org/14846 for details.
[0, p[1], -1/2*p[1, 1] - 1/2*p[2], 1/3*p[1, 1, 1] - 1/3*p[3]]
```

Its defining property is that $\Omega \circ E^+ = E^+ \circ \Omega = X$ (that is, that composition with E^+ in both directions yields the multiplicative identity X):

```
sage: Eplus = sage.combinat.species.set_species.SetSpecies(min=1).cycle_index_
      ↪ series()
sage: CombinatorialLogarithmSeries().compose(Eplus).coefficients(4)
[0, p[1], 0, 0]
```

5.1.295 Composition species

`class sage.combinat.species.composition_species.CompositionSpecies` (F , G ,
 min=None ,
 max=None ,
 weight=None)

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

Returns the composition of two species.

EXAMPLES:

```

sage: E = species.SetSpecies()
sage: C = species.CycleSpecies()
sage: S = E(C)
sage: S.generating_series().coefficients(5)
[1, 1, 1, 1, 1]
sage: E(C) is S
True

```

weight_ring()

Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.

EXAMPLES:

```

sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: L.weight_ring()
Rational Field

```

class sage.combinat.species.composition_species.**CompositionSpeciesStructure** (*parent, labels, pi, f, gs*)

Bases: *sage.combinat.species.structure.GenericSpeciesStructure*

change_labels (*labels*)

Return a relabelled structure.

INPUT:

- *labels*, a list of labels.

OUTPUT:

A structure with the *i*-th label of self replaced with the *i*-th label of the list.

EXAMPLES:

```

sage: p = PermutationGroupElement((2,3))
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: S = L.structures(['a', 'b', 'c']).list()
sage: a = S[2]; a
F-structure: {{'a', 'c'}, {'b'}}; G-structures: (('a', 'c'), ('b'))
sage: a.change_labels([1,2,3])
F-structure: {{1, 3}, {2}}; G-structures: [(1, 3), (2)]

```

transport (*perm*)

EXAMPLES:

```

sage: p = PermutationGroupElement((2,3))
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: S = L.structures(['a', 'b', 'c']).list()
sage: a = S[2]; a
F-structure: {{'a', 'c'}, {'b'}}; G-structures: (('a', 'c'), ('b'))
sage: a.transport(p)
F-structure: {{'a', 'b'}, {'c'}}; G-structures: (('a', 'c'), ('b'))

```

`sage.combinat.species.composition_species.CompositionSpecies_class`
 alias of *CompositionSpecies*

5.1.296 Cycle Species

class `sage.combinat.species.cycle_species.CycleSpecies` (*min=None, max=None, weight=None*)
 Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

Returns the species of cycles.

EXAMPLES:

```
sage: C = species.CycleSpecies(); C
Cyclic permutation species
sage: C.structures([1,2,3,4]).list()
[(1, 2, 3, 4),
 (1, 2, 4, 3),
 (1, 3, 2, 4),
 (1, 3, 4, 2),
 (1, 4, 2, 3),
 (1, 4, 3, 2)]
```

```
sage: species.CycleSpecies() is species.CycleSpecies()
True
sage: P = species.CycleSpecies()
sage: c = P.generating_series().coefficients(3)
sage: P._check()
True
sage: P == loads(dumps(P))
True
```

class `sage.combinat.species.cycle_species.CycleSpeciesStructure` (*parent, labels, list*)
 Bases: `sage.combinat.species.structure.GenericSpeciesStructure`

This is a base class from which the classes for the structures inherit.

EXAMPLES:

```
sage: from sage.combinat.species.structure import GenericSpeciesStructure
sage: a = GenericSpeciesStructure(None, [2,3,4], [1,2,3])
sage: a
[2, 3, 4]
sage: a.parent() is None
True
sage: a == loads(dumps(a))
True
```

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed.

EXAMPLES:

```
sage: P = species.CycleSpecies()
sage: a = P.structures([1, 2, 3, 4]).random_element(); a
(1, 2, 3, 4)
```

```
sage: a.automorphism_group()
Permutation Group with generators [(1,2,3,4)]
```

```
sage: [a.transport(perm) for perm in a.automorphism_group()]
[(1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4)]
```

canonical_label()

EXAMPLES:

```
sage: P = species.CycleSpecies()
sage: P.structures(["a", "b", "c"]).random_element().canonical_label()
('a', 'b', 'c')
```

permutation_group_element()

Returns this cycle as a permutation group element.

EXAMPLES:

```
sage: F = species.CycleSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
('a', 'b', 'c')
sage: a.permutation_group_element()
(1,2,3)
```

transport (perm)

Returns the transport of this structure along the permutation perm.

EXAMPLES:

```
sage: F = species.CycleSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
('a', 'b', 'c')
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
('a', 'c', 'b')
```

`sage.combinat.species.cycle_species.CycleSpecies_class`

alias of *CycleSpecies*

5.1.297 Empty Species

class `sage.combinat.species.empty_species.EmptySpecies` (*min=None*, *max=None*, *weight=None*)

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

Returns the empty species. This species has no structure at all. It is the zero of the semi-ring of species.

EXAMPLES:

```
sage: X = species.EmptySpecies(); X
Empty species
sage: X.structures([]).list()
[]
sage: X.structures([1]).list()
[]
sage: X.structures([1,2]).list()
[]
```

```

[]
sage: X.generating_series().coefficients(4)
[0, 0, 0, 0]
sage: X.isotype_generating_series().coefficients(4)
[0, 0, 0, 0]
sage: X.cycle_index_series().coefficients(4)
[0, 0, 0, 0]

```

The empty species is the zero of the semi-ring of species. The following tests that it is neutral with respect to addition:

```

sage: Empt = species.EmptySpecies()
sage: S = species.CharacteristicSpecies(2)
sage: X = S + Empt
sage: X == S      # TODO: Not Implemented
True
sage: (X.generating_series().coefficients(4) ==
....:  S.generating_series().coefficients(4))
True
sage: (X.isotype_generating_series().coefficients(4) ==
....:  S.isotype_generating_series().coefficients(4))
True
sage: (X.cycle_index_series().coefficients(4) ==
....:  S.cycle_index_series().coefficients(4))
True

```

The following tests that it is the zero element with respect to multiplication:

```

sage: Y = Empt*S
sage: Y == Empt   # TODO: Not Implemented
True
sage: Y.generating_series().coefficients(4)
[0, 0, 0, 0]
sage: Y.isotype_generating_series().coefficients(4)
[0, 0, 0, 0]
sage: Y.cycle_index_series().coefficients(4)
[0, 0, 0, 0]

```

sage.combinat.species.empty_species.**EmptySpecies_class**
alias of *EmptySpecies*

5.1.298 Functorial composition species

class sage.combinat.species.functorial_composition_species.**FunctorialCompositionSpecies**(*F*,
G,
min=N,
max=N,
weight)

Bases: *sage.combinat.species.species.GenericCombinatorialSpecies*

Returns the functorial composition of two species.

EXAMPLES:

```

sage: E = species.SetSpecies()
sage: E2 = species.SetSpecies(size=2)
sage: WP = species.SubsetSpecies()

```

```

sage: P2 = E2*E
sage: G = WP.functorial_composition(P2)
sage: G.isotype_generating_series().coefficients(5)
[1, 1, 2, 4, 11]

sage: G = species.SimpleGraphSpecies()
sage: c = G.generating_series().coefficients(2)
sage: type(G)
<class 'sage.combinat.species.functorial_composition_species.
↳FunctorialCompositionSpecies'>
sage: G == loads(dumps(G))
True
sage: G._check() #False due to isomorphism types not being implemented
False

```

weight_ring()

Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.

EXAMPLES:

```

sage: G = species.SimpleGraphSpecies()
sage: G.weight_ring()
Rational Field

```

`sage.combinat.species.functorial_composition_species.FunctorialCompositionSpecies_class`
alias of *FunctorialCompositionSpecies*

class `sage.combinat.species.functorial_composition_species.FunctorialCompositionStructure` (parameters: *parent, labels, list*)

Bases: *sage.combinat.species.structure.GenericSpeciesStructure*

This is a base class from which the classes for the structures inherit.

EXAMPLES:

```

sage: from sage.combinat.species.structure import GenericSpeciesStructure
sage: a = GenericSpeciesStructure(None, [2,3,4], [1,2,3])
sage: a
[2, 3, 4]
sage: a.parent() is None
True
sage: a == loads(dumps(a))
True

```

5.1.299 Generating Series

This file makes a number of extensions to lazy power series by endowing them with some semantic content for how they're to be interpreted.

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html>. In particular, the relevant section for this file can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse10.html>. One notable difference is that we use power-sum symmetric functions as the coefficients of our cycle index series.

```

sage: geo1 = CIS((p([1])^i for i in _integers_from(0)))
sage: geo2 = CIS((p([2])^i for i in _integers_from(0)))
sage: s = geo1 * geo2
sage: s[0]
p[]
sage: s[1]
p[1] + p[2]
sage: s[2]
p[1, 1] + p[2, 1] + p[2, 2]
sage: s[3]
p[1, 1, 1] + p[2, 1, 1] + p[2, 2, 1] + p[2, 2, 2]

```

Whereas the coefficients of the above test are homogeneous with respect to total degree, the following test groups with respect to weighted degree where each variable x_i has weight i .

```

sage: def g():
....:     for i in _integers_from(0):
....:         yield p([2])^i
....:         yield p(0)
sage: geo1 = CIS((p([1])^i for i in _integers_from(0)))
sage: geo2 = CIS(g())
sage: s = geo1 * geo2
sage: s[0]
p[]
sage: s[1]
p[1]
sage: s[2]
p[1, 1] + p[2]
sage: s[3]
p[1, 1, 1] + p[2, 1]
sage: s[4]
p[1, 1, 1, 1] + p[2, 1, 1] + p[2, 2]

```

REFERENCES:

class `sage.combinat.species.generating_series.CycleIndexSeries` (*A*, *stream=None*,
order=None,
aorder=None,
aorder_changed=True,
is_initialized=False,
name=None)

Bases: `sage.combinat.species.series.LazyPowerSeries`

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: f = L()
sage: loads(dumps(f))
Uninitialized lazy power series

```

arithmetic_product (*g*, *check_input=True*)

Return the arithmetic product of *self* with *g*.

For species M and N such that $M[\emptyset] = N[\emptyset] = \emptyset$, their arithmetic product is the species $M \boxtimes N$ of “ M -assemblies of cloned N -structures”. This operation is defined and several examples are given in [\[MM\]](#).

The cycle index series for $M \boxtimes N$ can be computed in terms of the component series Z_M and Z_N , as implemented in this method.

INPUT:

- `g` – a cycle index series having the same parent as `self`.
- `check_input` – (default: `True`) a Boolean which, when set to `False`, will cause input checks to be skipped.

OUTPUT:

The arithmetic product of `self` with `g`. This is a cycle index series defined in terms of `self` and `g` such that if `self` and `g` are the cycle index series of two species M and N , their arithmetic product is the cycle index series of the species $M \boxtimes N$.

EXAMPLES:

For C the species of (oriented) cycles and L_+ the species of nonempty linear orders, $C \boxtimes L_+$ corresponds to the species of “regular octopuses”; a $(C \boxtimes L_+)$ -structure is a cycle of some length, each of whose elements is an ordered list of a length which is consistent for all the lists in the structure.

```
sage: C = species.CycleSpecies().cycle_index_series()
sage: Lplus = species.LinearOrderSpecies(min=1).cycle_index_series()
sage: RegularOctopuses = C.arithmetic_product(Lplus)
sage: RegOctSpeciesSeq = RegularOctopuses.generating_series().counts(8)
sage: RegOctSpeciesSeq
[0, 1, 3, 8, 42, 144, 1440, 5760]
```

It is shown in [MM] that the exponential generating function for regular octopuses satisfies $(C \boxtimes L_+)(x) = \sum_{n \geq 1} \sigma(n)(n-1)! \frac{x^n}{n!}$ (where $\sigma(n)$ is the sum of the divisors of n).

```
sage: RegOctDirectSeq = [0] + [sum(divisors(i))*factorial(i-1) for i in_
↪ range(1,8)]
sage: RegOctDirectSeq == RegOctSpeciesSeq
True
```

AUTHORS:

- Andrew Gainer-Dewar (2013)

REFERENCES:

coefficient_cycle_type(*t*)

Returns the coefficient of a cycle type t in `self`.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SymmetricFunctions(QQ).power()
sage: CIS = CycleIndexSeriesRing(QQ)
sage: f = CIS([0, p([1]), 2*p([1,1]), 3*p([2,1])])
sage: f.coefficient_cycle_type([1])
1
sage: f.coefficient_cycle_type([1,1])
2
sage: f.coefficient_cycle_type([2,1])
3
```

compositional_inverse()

Return the compositional inverse of `self` if possible.

(Specifically, if `self` is of the form $0 + p_1 + \dots$)

The compositional inverse is the inverse with respect to plethystic substitution. This is the operation on cycle index series which corresponds to substitution, a.k.a. partitional composition, on the level of species. See Section 2.2 of [BLL] for a definition of this operation.

EXAMPLES:

```
sage: Eplus = species.SetSpecies(min=1).cycle_index_series()
sage: Eplus(Eplus.compositional_inverse()).coefficients(8)
[0, p[1], 0, 0, 0, 0, 0, 0]
```

ALGORITHM:

Let F be a species satisfying $F = 0 + X + F_2 + F_3 + \dots$ for X the species of singletons. (Equivalently, $|F[\emptyset]| = 0$ and $|F[\{1\}]| = 1$.) Then there exists a (virtual) species G satisfying $F \circ G = G \circ F = X$.

It follows that $(F - X) \circ G = F \circ G - X \circ G = X - G$. Rearranging, we obtain the recursive equation $G = X - (F - X) \circ G$, which can be solved using iterative methods.

Warning: This algorithm is functional but can be very slow. Use with caution!

See also:

The compositional inverse Ω of the species E_+ of nonempty sets can be handled much more efficiently using specialized methods. These are implemented in [CombinatorialLogarithmSeries](#).

AUTHORS:

- Andrew Gainer-Dewar

count (t)

Return the number of structures corresponding to a certain cycle type t .

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SymmetricFunctions(QQ).power()
sage: CIS = CycleIndexSeriesRing(QQ)
sage: f = CIS([0, p([1]), 2*p([1,1]), 3*p([2,1])])
sage: f.count([1])
1
sage: f.count([1,1])
4
sage: f.count([2,1])
6
```

derivative ($order=1$)

Return the species-theoretic n th derivative of `self`, where n is `order`.

For a cycle index series $F(p_1, p_2, p_3, \dots)$, its derivative is the cycle index series $F' = D_{p_1} F$ (that is, the formal derivative of F with respect to the variable p_1).

If F is the cycle index series of a species S then F' is the cycle index series of an associated species S' of S -structures with a “hole”.

EXAMPLES:

The species E of sets satisfies the relationship $E' = E$:

```
sage: E = species.SetSpecies().cycle_index_series()
sage: E.coefficients(8) == E.derivative().coefficients(8)
True
```

The species C of cyclic orderings and the species L of linear orderings satisfy the relationship $C' = L$:

```
sage: C = species.CycleSpecies().cycle_index_series()
sage: L = species.LinearOrderSpecies().cycle_index_series()
sage: L.coefficients(8) == C.derivative().coefficients(8)
True
```

expand_as_sf(n , $alphabet='x'$)

Returns the expansion of a cycle index series as a symmetric function in n variables.

Specifically, this returns a *LazyPowerSeries* whose i th term is obtained by calling *expand()* on the i th term of *self*.

This relies on the (standard) interpretation of a cycle index series as a symmetric function in the power sum basis.

INPUT:

- *self* – a cycle index series
- n – a positive integer
- *alphabet* – a variable for the expansion (default: x)

EXAMPLES:

```
sage: from sage.combinat.species.set_species import SetSpecies
sage: SetSpecies().cycle_index_series().expand_as_sf(2).coefficients(4)
[1, x0 + x1, x0^2 + x0*x1 + x1^2, x0^3 + x0^2*x1 + x0*x1^2 + x1^3]
```

exponential()

Return the species-theoretic exponential of *self*.

For a cycle index Z_F of a species F , its exponential is the cycle index series Z_E *circ* Z_F , where Z_E is the *ExponentialCycleIndexSeries*().

The exponential $Z_E \circ Z_F$ is then the cycle index series of the species E *circ* F of “sets of F -structures”.

EXAMPLES:

Let BT be the species of binary trees, BF the species of binary forests, and E the species of sets. Then we have $BF = E \circ BT$:

```
sage: BT = species.BinaryTreeSpecies().cycle_index_series()
sage: BF = species.BinaryForestSpecies().cycle_index_series()
sage: BT.exponential().isotype_generating_series().coefficients(8) == BF.
isotype_generating_series().coefficients(8)
True
```

functorial_composition(g)

Returns the functorial composition of *self* and g .

If F and G are species, their functorial composition is the species $F \square G$ obtained by setting $(F \square G)[A] = F[G[A]]$. In other words, an $(F \square G)$ -structure on a set A of labels is an F -structure whose labels are the set of all G -structures on A .

It can be shown (as in section 2.2 of [BLL]) that there is a corresponding operation on cycle indices:

$$Z_F \square Z_G = \sum_{n \geq 0} \frac{1}{n!} \sum_{\sigma \in \mathfrak{S}_n} \text{fix } F[(G[\sigma])_1, (G[\sigma])_2, \dots] p_1^{\sigma_1} p_2^{\sigma_2} \dots$$

This method implements that operation on cycle index series.

EXAMPLES:

The species G of simple graphs can be expressed in terms of a functorial composition: $G = p \square p_2$, where p is the *SubsetSpecies*. This is how it is implemented in *SimpleGraphSpecies*():

```
sage: S = species.SimpleGraphSpecies()
sage: S.cycle_index_series().coefficients(5)
[p[],
 p[1],
 p[1, 1] + p[2],
 4/3*p[1, 1, 1] + 2*p[2, 1] + 2/3*p[3],
 8/3*p[1, 1, 1, 1] + 4*p[2, 1, 1] + 2*p[2, 2] + 4/3*p[3, 1] + p[4]]
```

generating_series()

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: cis = P.cycle_index_series()
sage: f = cis.generating_series()
sage: f.coefficients(5)
[1, 1, 1, 5/6, 5/8]
```

integral(*args)

Given a cycle index G , it is not in general possible to recover a single cycle index F such that $F' = G$ (even up to addition of a constant term).

More broadly, it may be the case that there are many non-isomorphic species S such that $S' = T$ for a given species T . For example, the species $3C_3$ of 3-cycles from three distinct classes and the species X^3 of 3-sets are not isomorphic, but $(3C_3)' = (X^3)' = 3X^2$.

EXAMPLES:

```
sage: C3 = species.CycleSpecies(size=3).cycle_index_series()
sage: X = species.SingletonSpecies().cycle_index_series()
sage: (3*C3).derivative().coefficients(8) == (3*X^2).coefficients(8)
True
sage: (X^3).derivative().coefficients(8) == (3*X^2).coefficients(8)
True
```

Warning: This method has no implementation and exists only to prevent you from doing something strange. Calling it raises a `NotImplementedError`!

isotype_generating_series()

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: cis = P.cycle_index_series()
sage: f = cis.isotype_generating_series()
sage: f.coefficients(10)
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]
```

logarithm()

Return the combinatorial logarithm of `self`.

For a cycle index Z_F of a species F , its logarithm is the cycle index series $Z_\Omega \circ Z_F$, where Z_Ω is the `LogarithmCycleIndexSeries()`.

The logarithm $Z_\Omega \circ Z_F$ is then the cycle index series of the (virtual) species $\Omega \circ F$ of “connected F -structures”. In particular, if $F = E^+ \circ G$ for E^+ the species of nonempty sets and G some other species, then $\Omega \circ F = G$.

EXAMPLES:

Let G be the species of nonempty graphs and CG be the species of nonempty connected graphs. Then $G = E^+ \circ CG$, so $CG = \Omega \circ G$:

```
sage: G = species.SimpleGraphSpecies().cycle_index_series() - 1
sage: from sage.combinat.species.generating_series import _
      ↪ LogarithmCycleIndexSeries
sage: CG = LogarithmCycleIndexSeries().compose(G)
sage: CG.isotype_generating_series().coefficients(8)
[0, 1, 1, 2, 6, 21, 112, 853]
```

pointing()

Return the species-theoretic pointing of `self`.

For a cycle index F , its pointing is the cycle index series $F^\bullet = p_1 \cdot F'$.

If F is the cycle index series of a species S then $F^\bullet$ is the cycle index series of an associated species $S^\bullet$ of S -structures with a marked “root”.

EXAMPLES:

The species $E^\bullet$ of “pointed sets” satisfies $E^\bullet = X \cdot E$:

```
sage: E = species.SetSpecies().cycle_index_series()
sage: X = species.SingletonSpecies().cycle_index_series()
sage: E.pointing().coefficients(8) == (X*E).coefficients(8)
True
```

stretch(k)

Return the stretch of the cycle index series `self` by a positive integer k .

If

$$f = \sum_{n=0}^{\infty} f_n(p_1, p_2, p_3, \dots),$$

then the stretch g of f by k is

$$g = \sum_{n=0}^{\infty} f_n(p_k, p_{2k}, p_{3k}, \dots).$$

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SymmetricFunctions(QQ).power()
sage: CIS = CycleIndexSeriesRing(QQ)
sage: f = CIS([p[], p[1]], p[2], p[3], p.zero())
sage: f.stretch(3).coefficients(10)
[p[], 0, 0, p[3], 0, 0, p[6], 0, 0, 0]
```

weighted_composition (*y_species*)

Returns the composition of this cycle index series with the cycle index series of *y_species* where *y_species* is a weighted species.

Note that this is basically the same algorithm as `composition` except we can not use the optimization that the powering of cycle index series commutes with ‘stretching’.

EXAMPLES:

```
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: E_cis = E.cycle_index_series()
sage: E_cis.weighted_composition(C).coefficients(4)
[p[], p[1], p[1, 1] + p[2], p[1, 1, 1] + p[2, 1] + p[3]]
sage: E(C).cycle_index_series().coefficients(4)
[p[], p[1], p[1, 1] + p[2], p[1, 1, 1] + p[2, 1] + p[3]]
```

`sage.combinat.species.generating_series.CycleIndexSeriesRing` (*R*)

Return the ring of cycle index series over *R*.

This is the ring of formal power series $\Lambda[x]$, where Λ is the ring of symmetric functions over *R* in the *p*-basis. Its purpose is to house the cycle index series of species (in a somewhat nonstandard notation tailored to Sage): If *F* is a species, then the *cycle index series* of *F* is defined to be the formal power series

$$\sum_{n \geq 0} \frac{1}{n!} \left(\sum_{\sigma \in S_n} \text{fix } F[\sigma] \prod_{z \text{ is a cycle of } \sigma} p_{\text{length of } z} \right) x^n \in \Lambda_{\mathbf{Q}}[x],$$

where $\text{fix } F[\sigma]$ denotes the number of fixed points of the permutation $F[\sigma]$ of $F[n]$. We notice that this power series is “equigraded” (meaning that its x^n -coefficient is homogeneous of degree *n*). A more standard convention in combinatorics would be to use x_i instead of p_i , and drop the x (that is, evaluate the above power series at $x = 1$); but this would be more difficult to implement in Sage, as it would be an element of a power series ring in infinitely many variables.

Note that it is just a *LazyPowerSeriesRing* (whose base ring is Λ) whose elements have some extra methods.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: R = CycleIndexSeriesRing(QQ); R
Cycle Index Series Ring over Symmetric Functions over Rational Field in the_
↪powersum basis
sage: R([1]).coefficients(4) # This is not combinatorially
....:                        # meaningful.
[1, 1, 1, 1]
```

```
sage: R is CycleIndexSeriesRing(QQ)
True
```

class `sage.combinat.species.generating_series.CycleIndexSeriesRing_class` (*R*)

Bases: `sage.combinat.species.series.LazyPowerSeriesRing`

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: R = CycleIndexSeriesRing(QQ); R
Cycle Index Series Ring over Symmetric Functions over Rational Field in the_
↪powersum basis
sage: R == loads(dumps(R))
True
```

`sage.combinat.species.generating_series.ExponentialCycleIndexSeries` ($R=\text{Rational Field}$)

Return the cycle index series of the species E of sets.

This cycle index satisfies

$$Z_E = \sum_{n \geq 0} \sum_{\lambda \vdash n} \frac{p_\lambda}{z_\lambda}.$$

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import _
      ↪ ExponentialCycleIndexSeries
sage: ExponentialCycleIndexSeries().coefficients(5)
[p[], p[1], 1/2*p[1, 1] + 1/2*p[2], 1/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3], 1/
      ↪ 24*p[1, 1, 1, 1] + 1/4*p[2, 1, 1] + 1/8*p[2, 2] + 1/3*p[3, 1] + 1/4*p[4]]
```

class `sage.combinat.species.generating_series.ExponentialGeneratingSeries` (A ,
 $stream=None$,
 $or-$
 $der=None$,
 $aorder=None$,
 $aorder\_changed=True$,
 $is\_initialized=False$,
 $name=None$)

Bases: `sage.combinat.species.series.LazyPowerSeries`

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L()
sage: loads(dumps(f))
Uninitialized lazy power series
```

count (n)

Return the number of structures of size n .

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import _
      ↪ ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ)
sage: f = R([1])
sage: [f.count(i) for i in range(7)]
[1, 1, 2, 6, 24, 120, 720]
```

counts (n)

Return the number of structures on a set for size i for each i in range (n).

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import _
      ↪ ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.counts(5)
[0, 1, 4, 18, 96]
```

functorial_composition (y)

Return the exponential generating series which is the functorial composition of `self` with y .

If $f = \sum_{n=0}^{\infty} f_n \frac{x^n}{n!}$ and $g = \sum_{n=0}^{\infty} g_n \frac{x^n}{n!}$, then functorial composition $f \square g$ is defined as

$$f \square g = \sum_{n=0}^{\infty} f_{g_n} \frac{x^n}{n!}$$

REFERENCES:

- Section 2.2 of [BLL].

EXAMPLES:

```
sage: G = species.SimpleGraphSpecies()
sage: g = G.generating_series()
sage: g.coefficients(10)
[1, 1, 1, 4/3, 8/3, 128/15, 2048/45, 131072/315, 2097152/315, 536870912/2835]
```

`sage.combinat.species.generating_series.ExponentialGeneratingSeriesRing(R)`

Return the ring of exponential generating series over R.

Note that it is just a *LazyPowerSeriesRing* whose elements have some extra methods.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import _
      ↪ ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ); R
Lazy Power Series Ring over Rational Field
sage: R([1]).coefficients(4)
[1, 1, 1, 1]
sage: R([1]).counts(4)
[1, 1, 2, 6]
```

```
sage: R is ExponentialGeneratingSeriesRing(QQ)
True
```

class `sage.combinat.species.generating_series.ExponentialGeneratingSeriesRing_class(R)`

Bases: `sage.combinat.species.series.LazyPowerSeriesRing`

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import _
      ↪ ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ)
sage: R == loads(dumps(R))
True
```

`sage.combinat.species.generating_series.LogarithmCycleIndexSeries(R=Rational Field)`

Return the cycle index series of the virtual species Ω , the compositional inverse of the species E^+ of nonempty sets.

The notion of virtual species is treated thoroughly in [BLL]. The specific algorithm used here to compute the cycle index of Ω is found in [Labelle].

EXAMPLES:

The virtual species Ω is ‘properly virtual’, in the sense that its cycle index has negative coefficients:

```
sage: from sage.combinat.species.generating_series import _
↪LogarithmCycleIndexSeries
sage: LogarithmCycleIndexSeries().coefficients(4)
[0, p[1], -1/2*p[1, 1] - 1/2*p[2], 1/3*p[1, 1, 1] - 1/3*p[3]]
```

Its defining property is that $\Omega \circ E^+ = E^+ \circ \Omega = X$ (that is, that composition with E^+ in both directions yields the multiplicative identity X):

```
sage: Eplus = sage.combinat.species.set_species.SetSpecies(min=1).cycle_index_
↪series()
sage: LogarithmCycleIndexSeries().compose(Eplus).coefficients(4)
[0, p[1], 0, 0]
```

REFERENCES:

```
class sage.combinat.species.generating_series.OrdinaryGeneratingSeries(A,
                                                                    stream=None,
                                                                    or-
                                                                    der=None,
                                                                    aorder=None,
                                                                    aorder_changed=True,
                                                                    is_initialized=False,
                                                                    name=None)
```

Bases: *sage.combinat.species.series.LazyPowerSeries*

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L()
sage: loads(dumps(f))
Uninitialized lazy power series
```

count (n)

Return the number of structures on a set of size n.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import _
↪OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.count(10)
10
```

counts (n)

Return the number of structures on a set for size i for each i in range(n).

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import _
↪OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.counts(10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

```
sage.combinat.species.generating_series.OrdinaryGeneratingSeriesRing(R)
Return the ring of ordinary generating series over R.
```

Note that it is just a *LazyPowerSeriesRing* whose elements have some extra methods.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import _
      ↪ OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ); R
Lazy Power Series Ring over Rational Field
sage: R([1]).coefficients(4)
[1, 1, 1, 1]
sage: R([1]).counts(4)
[1, 1, 1, 1]
```

```
sage: R is OrdinaryGeneratingSeriesRing(QQ)
True
```

class `sage.combinat.species.generating_series.OrdinaryGeneratingSeriesRing_class(R)`
 Bases: `sage.combinat.species.series.LazyPowerSeriesRing`

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import _
      ↪ OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: R == loads(dumps(R))
True
```

`sage.combinat.species.generating_series.factorial_gen()`

A generator for the factorials starting at 0.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import factorial_gen
sage: g = factorial_gen()
sage: [next(g) for i in range(5)]
[1, 1, 2, 6, 24]
```

5.1.300 Examples of Combinatorial Species

`sage.combinat.species.library.BinaryForestSpecies()`

Returns the species of binary forests. Binary forests are defined as sets of binary trees.

EXAMPLES:

```
sage: F = species.BinaryForestSpecies()
sage: F.generating_series().counts(10)
[1, 1, 3, 19, 193, 2721, 49171, 1084483, 28245729, 848456353]
sage: F.isotype_generating_series().counts(10)
[1, 1, 2, 4, 10, 26, 77, 235, 758, 2504]
sage: F.cycle_index_series().coefficients(7)
[p[],
 p[1],
 3/2*p[1, 1] + 1/2*p[2],
 19/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3],
 193/24*p[1, 1, 1, 1] + 3/4*p[2, 1, 1] + 5/8*p[2, 2] + 1/3*p[3, 1] + 1/4*p[4],
 907/40*p[1, 1, 1, 1, 1] + 19/12*p[2, 1, 1, 1] + 5/8*p[2, 2, 1] + 1/2*p[3, 1, 1]
 ↪ + 1/6*p[3, 2] + 1/4*p[4, 1] + 1/5*p[5],
 49171/720*p[1, 1, 1, 1, 1, 1] + 193/48*p[2, 1, 1, 1, 1] + 15/16*p[2, 2, 1, 1]
 ↪ + 61/48*p[2, 2, 2] + 19/18*p[3, 1, 1, 1] + 1/6*p[3, 2, 1] + 7/18*p[3, 3] + 3/
 ↪ + 8*p[4, 1, 1] + 1/8*p[4, 2] + 1/5*p[5, 1] + 1/6*p[6]]
```

```
sage.combinat.species.library.BinaryTreeSpecies()
```

Returns the species of binary trees on n leaves. The species of binary trees B is defined by $B = X + B*B$ where X is the singleton species.

EXAMPLES:

```
sage: B = species.BinaryTreeSpecies()
sage: B.generating_series().counts(10)
[0, 1, 2, 12, 120, 1680, 30240, 665280, 17297280, 518918400]
sage: B.isotype_generating_series().counts(10)
[0, 1, 1, 2, 5, 14, 42, 132, 429, 1430]
sage: B._check()
True
```

```
sage: B = species.BinaryTreeSpecies()
sage: a = B.structures([1,2,3,4,5]).random_element(); a
2*((5*3)*(4*1))
sage: a.automorphism_group()
Permutation Group with generators [()]
```

```
sage.combinat.species.library.SimpleGraphSpecies()
```

Returns the species of simple graphs.

EXAMPLES:

```
sage: S = species.SimpleGraphSpecies()
sage: S.generating_series().counts(10)
[1, 1, 2, 8, 64, 1024, 32768, 2097152, 268435456, 68719476736]
sage: S.cycle_index_series().coefficients(5)
[p[],
 p[1],
 p[1, 1] + p[2],
 4/3*p[1, 1, 1] + 2*p[2, 1] + 2/3*p[3],
 8/3*p[1, 1, 1, 1] + 4*p[2, 1, 1] + 2*p[2, 2] + 4/3*p[3, 1] + p[4]]
sage: S.isotype_generating_series().coefficients(6)
[1, 1, 2, 4, 11, 34]
```

```
sage: seq = S.generating_series().counts(10)[1:]
sage: oeis(seq)[0] # optional -- internet
A006125: a(n) = 2^(n(n-1)/2).
```

5.1.301 Linear-order Species

class sage.combinat.species.linear_order_species.LinearOrderSpecies (*min=None*,
max=None,
weight=None)

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

Returns the species of linear orders.

EXAMPLES:

```
sage: L = species.LinearOrderSpecies()
sage: L.generating_series().coefficients(5)
```

```
[1, 1, 1, 1, 1]

sage: L = species.LinearOrderSpecies()
sage: L._check()
True
sage: L == loads(dumps(L))
True
```

class `sage.combinat.species.linear_order_species.LinearOrderSpeciesStructure` (*parent, labels, list*)

Bases: `sage.combinat.species.structure.GenericSpeciesStructure`

This is a base class from which the classes for the structures inherit.

EXAMPLES:

```
sage: from sage.combinat.species.structure import GenericSpeciesStructure
sage: a = GenericSpeciesStructure(None, [2,3,4], [1,2,3])
sage: a
[2, 3, 4]
sage: a.parent() is None
True
sage: a == loads(dumps(a))
True
```

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed. For the species of linear orders, there is no non-trivial automorphism.

EXAMPLES:

```
sage: F = species.LinearOrderSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
['a', 'b', 'c']
sage: a.automorphism_group()
Symmetric group of order 1! as a permutation group
```

canonical_label()

EXAMPLES:

```
sage: P = species.LinearOrderSpecies()
sage: s = P.structures(["a", "b", "c"]).random_element()
sage: s.canonical_label()
['a', 'b', 'c']
```

transport (*perm*)

Returns the transport of this structure along the permutation perm.

EXAMPLES:

```
sage: F = species.LinearOrderSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
['a', 'b', 'c']
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
['b', 'a', 'c']
```

`sage.combinat.species.linear_order_species.LinearOrderSpecies_class`
 alias of `LinearOrderSpecies`

5.1.302 Miscellaneous Functions

`sage.combinat.species.misc.accept_size(f)`

The purpose of this decorator is to change calls like `species.SetSpecies(size=1)` to `species.SetSpecies(min=1, max=2)`. This is to make caching species easier and to restrict the number of parameters that the lower level code needs to know about.

EXAMPLES:

```
sage: from sage.combinat.species.misc import accept_size
sage: def f(*args, **kwargs):
....:     print("{} {}".format(args, list(sorted(kwargs.items()))))
sage: f = accept_size(f)
sage: f(min=1)
() [('min', 1)]
sage: f(size=2)
() [('max', 3), ('min', 2)]
```

`sage.combinat.species.misc.change_support(perm, support, change_perm=None)`

Changes the support of a permutation defined on $[1, \dots, n]$ to support.

EXAMPLES:

```
sage: from sage.combinat.species.misc import change_support
sage: p = PermutationGroupElement((1,2,3)); p
(1,2,3)
sage: change_support(p, [3,4,5])
(3,4,5)
```

5.1.303 Partition Species

class `sage.combinat.species.partition_species.PartitionSpecies` (*min=None*,
max=None,
weight=None)

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`

Returns the species of partitions.

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: P.generating_series().coefficients(5)
[1, 1, 1, 5/6, 5/8]
sage: P.isotype_generating_series().coefficients(5)
[1, 1, 2, 3, 5]

sage: P = species.PartitionSpecies()
sage: P._check()
True
sage: P == loads(dumps(P))
True
```

class sage.combinat.species.partition_species.**PartitionSpeciesStructure** (*parent,*
la-
bels,
list)

Bases: *sage.combinat.species.structure.GenericSpeciesStructure*

EXAMPLES:

```
sage: from sage.combinat.species.partition_species import _
↪PartitionSpeciesStructure
sage: P = species.PartitionSpecies()
sage: s = PartitionSpeciesStructure(P, ['a', 'b', 'c'], [[1,2],[3]]); s
{{'a', 'b'}, {'c'}}
sage: s == loads(dumps(s))
True
```

automorphism_group()

Returns the group of permutations whose action on this set partition leave it fixed.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import _
↪PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.automorphism_group()
Permutation Group with generators [(1,2)]
```

canonical_label()

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[{{'a', 'b', 'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a'}, {'b'}, {'c'}}]
```

change_labels(labels)

Return a relabelled structure.

INPUT:

- labels, a list of labels.

OUTPUT:

A structure with the i-th label of self replaced with the i-th label of the list.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import _
↪PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.change_labels([1,2,3])
{{1, 2}, {3}}
```

transport (*perm*)

Returns the transport of this set partition along the permutation perm. For set partitions, this is the direct product of the automorphism groups for each of the blocks.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import _
      ↪ PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.transport(p)
{{2, 4}, {3}}
```

sage.combinat.species.partition_species.**PartitionSpecies_class**
alias of *PartitionSpecies*

5.1.304 Permutation species

class sage.combinat.species.permutation_species.**PermutationSpecies** (*min=None*,
max=None,
weight=None)

Bases: *sage.combinat.species.species.GenericCombinatorialSpecies*, sage.
structure.unique_representation.UniqueRepresentation

Returns the species of permutations.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: P.generating_series().coefficients(5)
[1, 1, 1, 1, 1]
sage: P.isotype_generating_series().coefficients(5)
[1, 1, 2, 3, 5]

sage: P = species.PermutationSpecies()
sage: c = P.generating_series().coefficients(3)
sage: P._check()
True
sage: P == loads(dumps(P))
True
```

class sage.combinat.species.permutation_species.**PermutationSpeciesStructure** (*parent*,
labels,
list)

Bases: *sage.combinat.species.structure.GenericSpeciesStructure*

This is a base class from which the classes for the structures inherit.

EXAMPLES:

```
sage: from sage.combinat.species.structure import GenericSpeciesStructure
sage: a = GenericSpeciesStructure(None, [2,3,4], [1,2,3])
sage: a
[2, 3, 4]
sage: a.parent() is None
True
```

```
sage: a == loads(dumps(a))
True
```

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"]).random_element(); a
['a', 'c', 'b', 'd']
sage: a.automorphism_group()
Permutation Group with generators [(2,3), (1,4)]
```

```
sage: [a.transport(perm) for perm in a.automorphism_group()]
[['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd']]
```

canonical_label()

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[['a', 'b', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'c', 'a'],
 ['b', 'c', 'a'],
 ['b', 'a', 'c']]
```

permutation_group_element()

Returns self as a permutation group element.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"]).random_element(); a
['a', 'c', 'b', 'd']
sage: a.permutation_group_element()
(2,3)
```

transport(perm)

Returns the transport of this structure along the permutation perm.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"]).random_element(); a
['a', 'c', 'b', 'd']
sage: a.transport(p)
['a', 'd', 'c', 'b']
```

`sage.combinat.species.permutation_species.PermutationSpecies_class`
 alias of *PermutationSpecies*

5.1.305 Sum species

class `sage.combinat.species.product_species.ProductSpecies` (*F*, *G*, *min=None*,
max=None,
weight=None)

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

EXAMPLES:

```
sage: X = species.SingletonSpecies()
sage: A = X*X
sage: A.generating_series().coefficients(4)
[0, 0, 1, 0]

sage: P = species.PermutationSpecies()
sage: F = P * P; F
Product of (Permutation species) and (Permutation species)
sage: F == loads(dumps(F))
True
sage: F._check()
True
```

left_factor()

Returns the left factor of this product.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: X = species.SingletonSpecies()
sage: F = P*X
sage: F.left_factor()
Permutation species
```

right_factor()

Returns the right factor of this product.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: X = species.SingletonSpecies()
sage: F = P*X
sage: F.right_factor()
Singleton species
```

weight_ring()

Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: C = S*S
sage: C.weight_ring()
Rational Field
```

```
sage: S = species.SetSpecies(weight=QQ['t'].gen())
sage: C = S*S
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

```
sage: S = species.SetSpecies()
sage: C = (S*S).weighted(QQ['t'].gen())
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

class sage.combinat.species.product_species.**ProductSpeciesStructure** (*parent, labels, subset, left, right*)

Bases: *sage.combinat.species.structure.GenericSpeciesStructure*

automorphism_group()

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures([1,2,3,4]).random_element(); a
{1}*{2, 3, 4}
sage: a.automorphism_group()
Permutation Group with generators [(2,3), (2,3,4)]
```

```
sage: [a.transport(g) for g in a.automorphism_group()]
[{1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4}]
```

```
sage: a = F.structures([1,2,3,4]).random_element(); a
{2, 3}*{1, 4}
sage: [a.transport(g) for g in a.automorphism_group()]
[{2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}]
```

canonical_label()

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: F = S * S
sage: S = F.structures(['a','b','c']).list(); S
[{}*{'a', 'b', 'c'},
 {'a'}*{'b', 'c'},
 {'b'}*{'a', 'c'},
 {'c'}*{'a', 'b'},
 {'a', 'b'}*{'c'},
 {'a', 'c'}*{'b'},
 {'b', 'c'}*{'a'},
 {'a', 'b', 'c'}*{}]
```

```
sage: F.isotypes(['a','b','c']).cardinality()
4
```

```
sage: [s.canonical_label() for s in S]
[{}*{'a', 'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a', 'b'}*{'c'},
 {'a', 'b'}*{'c'},
 {'a', 'b'}*{'c'},
 {'a', 'b', 'c'}*{}]
```

change_labels (*labels*)

Return a relabelled structure.

INPUT:

- *labels*, a list of labels.

OUTPUT:

A structure with the *i*-th label of self replaced with the *i*-th label of the list.

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures(['a', 'b', 'c']).random_element(); a
{}*{'a', 'b', 'c'}
sage: a.change_labels([1, 2, 3])
{}*{1, 2, 3}
```

transport (*perm*)

EXAMPLES:

```
sage: p = PermutationGroupElement((2, 3))
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures(['a', 'b', 'c'])[4]; a
{'a', 'b'}*{'c'}
sage: a.transport(p)
{'a', 'c'}*{'b'}
```

`sage.combinat.species.product_species.ProductSpecies_class`

alias of *ProductSpecies*

5.1.306 Recursive Species

class `sage.combinat.species.recursive_species.CombinatorialSpecies`

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`

EXAMPLES:

```
sage: F = CombinatorialSpecies()
sage: loads(dumps(F))
Combinatorial species
```

```
sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
```

```

sage: L.define(E+X*L)
sage: L.generating_series().coefficients(4)
[1, 1, 1, 1]
sage: LL = loads(dumps(L))
sage: LL.generating_series().coefficients(4)
[1, 1, 1, 1]

```

define(x)

Define self to be equal to the combinatorial species x.

This is used to define combinatorial species recursively. All of the real work is done by calling the .set() method for each of the series associated to self.

EXAMPLES: The species of linear orders L can be recursively defined by $L = 1 + X * L$ where 1 represents the empty set species and X represents the singleton species.

```

sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
sage: L.define(E+X*L)
sage: L.generating_series().coefficients(4)
[1, 1, 1, 1]
sage: L.structures([1,2,3]).cardinality()
6
sage: L.structures([1,2,3]).list()
[1*(2*(3*{})),
 1*(3*(2*{})),
 2*(1*(3*{})),
 2*(3*(1*{})),
 3*(1*(2*{})),
 3*(2*(1*{}))]

```

```

sage: L = species.LinearOrderSpecies()
sage: L.generating_series().coefficients(4)
[1, 1, 1, 1]
sage: L.structures([1,2,3]).cardinality()
6
sage: L.structures([1,2,3]).list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

```

```

sage: A = CombinatorialSpecies()
sage: A.define(X+A*A)
sage: A.generating_series().coefficients(6)
[0, 1, 1, 2, 5, 14]
sage: A.generating_series().counts(6)
[0, 1, 2, 12, 120, 1680]
sage: len(A.structures([1,2,3]).list())
12
sage: A.isotype_generating_series().coefficients(6)
[0, 1, 1, 2, 5, 14]
sage: len(A.isotypes([1,2,3,4]).list())
5

```

```

sage: X2 = X*X
sage: X5 = X2*X2*X
sage: A = CombinatorialSpecies()
sage: B = CombinatorialSpecies()

```

```

sage: C = CombinatorialSpecies()
sage: A.define(X5+B*B)
sage: B.define(X5+C*C)
sage: C.define(X2+C*C+A*A)
sage: A.generating_series().coefficients(Integer(10))
[0, 0, 0, 0, 0, 1, 0, 0, 1, 2]
sage: A.generating_series().coefficients(15)
[0, 0, 0, 0, 0, 1, 0, 0, 1, 2, 5, 4, 14, 10, 48]
sage: B.generating_series().coefficients(15)
[0, 0, 0, 0, 1, 1, 2, 0, 5, 0, 14, 0, 44, 0, 138]
sage: C.generating_series().coefficients(15)
[0, 0, 1, 0, 1, 0, 2, 0, 5, 0, 15, 0, 44, 2, 142]

```

```

sage: F = CombinatorialSpecies()
sage: F.define(E+X+(X*F+X*X*F))
sage: F.generating_series().counts(10)
[1, 2, 6, 30, 192, 1560, 15120, 171360, 2217600, 32296320]
sage: F.generating_series().coefficients(10)
[1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
sage: F.isotype_generating_series().coefficients(10)
[1, 2, 3, 5, 8, 13, 21, 34, 55, 89]

```

weight_ring()

EXAMPLES:

```

sage: F = species.CombinatorialSpecies()
sage: F.weight_ring()
Rational Field

```

```

sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
sage: L.define(E+X*L)
sage: L.weight_ring()
Rational Field

```

class `sage.combinat.species.recursive_species.CombinatorialSpeciesStructure` (*parent*, *s*, ***options*)

Bases: `sage.combinat.species.structure.SpeciesStructureWrapper`

This is a class for the structures of species such as the sum species that do not provide “additional” structure. For example, if you have the sum C of species A and B , then a structure of C will either be either something from A or B . Instead of just returning one of these directly, a “wrapper” is put around them so that they have their parent is C rather than A or B :

```

sage: X = species.SingletonSpecies()
sage: X2 = X+X
sage: s = X2.structures([1]).random_element(); s
1
sage: s.parent()
Sum of (Singleton species) and (Singleton species)
sage: from sage.combinat.species.structure import SpeciesStructureWrapper
sage: isinstance(s, SpeciesStructureWrapper)
True

```

EXAMPLES:

```

sage: E = species.SetSpecies(); B = E+E
sage: s = B.structures([1,2,3]).random_element()
sage: s.parent()
Sum of (Set species) and (Set species)
sage: s == loads(dumps(s))
True

```

5.1.307 Lazy Power Series

This file provides an implementation of lazy univariate power series, which uses the stream class for its internal data structure. The lazy power series keep track of their approximate order as much as possible without forcing the computation of any additional coefficients. This is required for recursively defined power series.

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html>. In particular, the relevant section for this file can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse9.html>.

```

class sage.combinat.species.series.LazyPowerSeries(A,          stream=None,          or-
                                                    der=None,          aorder=None,
                                                    aorder_changed=True,
                                                    is_initialized=False, name=None)

```

Bases: sage.structure.element.AlgebraElement

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: f = L()
sage: loads(dumps(f))
Uninitialized lazy power series

```

add(y)

EXAMPLES: Test Plus 1

```

sage: from sage.combinat.species.series import *
sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: gs0 = L([0])
sage: gs1 = L([1])
sage: sum1 = gs0 + gs1
sage: sum2 = gs1 + gs1
sage: sum3 = gs1 + gs0
sage: [gs0.coefficient(i) for i in range(11)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
sage: [gs1.coefficient(i) for i in range(11)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: [sum1.coefficient(i) for i in range(11)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: [sum2.coefficient(i) for i in range(11)]
[2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2]
sage: [sum3.coefficient(i) for i in range(11)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]

```

Test Plus 2

```

sage: gs1 = L([1,2,4,8,0])
sage: gs2 = L([-1, 0,-1,-9,22,0])
sage: sum = gs1 + gs2
sage: sum2 = gs2 + gs1
sage: [ sum.coefficient(i) for i in range(5) ]
[0, 2, 3, -1, 22]
sage: [ sum.coefficient(i) for i in range(5, 11) ]
[0, 0, 0, 0, 0, 0]
sage: [ sum2.coefficient(i) for i in range(5) ]
[0, 2, 3, -1, 22]
sage: [ sum2.coefficient(i) for i in range(5, 11) ]
[0, 0, 0, 0, 0, 0]

```

coefficient (*n*)

Returns the coefficient of x^n in self.

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: f = L(ZZ)
sage: [f.coefficient(i) for i in range(5)]
[0, 1, -1, 2, -2]

```

coefficients (*n*)

Returns the first *n* coefficients of self.

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: f = L([1,2,3,0])
sage: f.coefficients(5)
[1, 2, 3, 0, 0]

```

compose (*y*)

Returns the composition of this power series and the power series *y*.

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: s = L([1])
sage: t = L([0,0,1])
sage: u = s(t)
sage: u.coefficients(11)
[1, 0, 1, 1, 2, 3, 5, 8, 13, 21, 34]

```

Test Compose 2

```

sage: s = L([1])
sage: t = L([0,0,1,0])
sage: u = s(t)
sage: u.aorder
0
sage: u.order
Unknown series order
sage: u.coefficients(10)
[1, 0, 1, 0, 1, 0, 1, 0, 1, 0]
sage: u.aorder
0

```

```
sage: u.order
0
```

Test Compose 3 $s = 1/(1-x)$, $t = x/(1-x)$ $s(t) = (1-x)/(1-2x)$

```
sage: s = L([1])
sage: t = L([0,1])
sage: u = s(t)
sage: u.coefficients(14)
[1, 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096]
```

composition(y)

Returns the composition of this power series and the power series y.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: s = L([1])
sage: t = L([0,0,1])
sage: u = s(t)
sage: u.coefficients(11)
[1, 0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

Test Compose 2

```
sage: s = L([1])
sage: t = L([0,0,1,0])
sage: u = s(t)
sage: u.aorder
0
sage: u.order
Unknown series order
sage: u.coefficients(10)
[1, 0, 1, 0, 1, 0, 1, 0, 1, 0]
sage: u.aorder
0
sage: u.order
0
```

Test Compose 3 $s = 1/(1-x)$, $t = x/(1-x)$ $s(t) = (1-x)/(1-2x)$

```
sage: s = L([1])
sage: t = L([0,1])
sage: u = s(t)
sage: u.coefficients(14)
[1, 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096]
```

compute_aorder(**args*, ***kwargs*)

The default compute_aorder does nothing.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L(1)
sage: a.compute_aorder() is None
True
```

compute_coefficients(i)

Computes all the coefficients of self up to i.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([1,2,3])
sage: a.compute_coefficients(5)
sage: a
1 + 2*x + 3*x^2 + 3*x^3 + 3*x^4 + 3*x^5 + ...
```

define (*x*)

EXAMPLES: Test Recursive 0

```
sage: L = LazyPowerSeriesRing(QQ)
sage: one = L(1)
sage: monom = L.gen()
sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s)
sage: s.aorder
0
sage: s.order
Unknown series order
sage: [s.coefficient(i) for i in range(6)]
[1, 1, 1, 1, 1, 1]
```

Test Recursive 1

```
sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s*s)
sage: s.aorder
0
sage: s.order
Unknown series order
sage: [s.coefficient(i) for i in range(6)]
[1, 1, 2, 5, 14, 42]
```

Test Recursive 1b

```
sage: s = L()
sage: s._name = 's'
sage: s.define(monom + s*s)
sage: s.aorder
1
sage: s.order
Unknown series order
sage: [s.coefficient(i) for i in range(7)]
[0, 1, 1, 2, 5, 14, 42]
```

Test Recursive 2

```
sage: s = L()
sage: s._name = 's'
sage: t = L()
sage: t._name = 't'
sage: s.define(one+monom*t*t*t)
sage: t.define(one+monom*s*s)
sage: [s.coefficient(i) for i in range(9)]
[1, 1, 3, 9, 34, 132, 546, 2327, 10191]
```

```
sage: [t.coefficient(i) for i in range(9)]
[1, 1, 2, 7, 24, 95, 386, 1641, 7150]
```

Test Recursive 2b

```
sage: s = L()
sage: s._name = 's'
sage: t = L()
sage: t._name = 't'
sage: s.define(monom + t*t*t)
sage: t.define(monom + s*s)
sage: [s.coefficient(i) for i in range(9)]
[0, 1, 0, 1, 3, 3, 7, 30, 63]
sage: [t.coefficient(i) for i in range(9)]
[0, 1, 1, 0, 2, 6, 7, 20, 75]
```

Test Recursive 3

```
sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s*s*s)
sage: [s.coefficient(i) for i in range(10)]
[1, 1, 3, 12, 55, 273, 1428, 7752, 43263, 246675]
```

derivative()

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: one = L(1)
sage: monom = L.gen()
sage: s = L([1])
sage: u = s.derivative()
sage: u.coefficients(10)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

```
sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s*s)
sage: u = s.derivative()
sage: u.coefficients(5) #[1*1, 2*2, 3*5, 4*14, 5*42]
[1, 4, 15, 56, 210]
```

```
sage: s = L([1])
sage: t = L([0,1])
sage: u = s(t).derivative()
sage: v = (s.derivative().compose(t))*t.derivative()
sage: u.coefficients(11)
[1, 4, 12, 32, 80, 192, 448, 1024, 2304, 5120, 11264]
sage: v.coefficients(11)
[1, 4, 12, 32, 80, 192, 448, 1024, 2304, 5120, 11264]
```

```
sage: s = L(); s._name='s'
sage: t = L(); t._name='t'
sage: s.define(monom+t*t*t)
sage: t.define(monom+s*s)
sage: u = (s*t).derivative()
```

```

sage: v = s.derivative()*t + s*t.derivative()
sage: u.coefficients(10)
[0, 2, 3, 4, 30, 72, 133, 552, 1791, 4260]
sage: v.coefficients(10)
[0, 2, 3, 4, 30, 72, 133, 552, 1791, 4260]
sage: u.coefficients(10) == v.coefficients(10)
True

```

```

sage: f = L._new_initial(2, Stream([0,0,4,5,6,0]))
sage: d = f.derivative()
sage: d.get_aorder()
1
sage: d.coefficients(5)
[0, 8, 15, 24, 0]

```

exponential()

get_aorder()

Returns the approximate order of self.

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: a = L.gen()
sage: a.get_aorder()
1

```

get_order()

Returns the order of self.

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: a = L.gen()
sage: a.get_order()
1

```

get_stream()

Returns self's underlying Stream object.

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: a = L.gen()
sage: s = a.get_stream()
sage: [s[i] for i in range(5)]
[0, 1, 0, 0, 0]

```

initialize_coefficient_stream(*compute_coefficients*)

Initializes the coefficient stream.

INPUT: *compute_coefficients*

```

sage: f = L()
sage: compute_coefficients = lambda ao: iter(ZZ)
sage: f.order = 1
sage: f.aorder = 1
sage: f.initialize_coefficient_stream(compute_coefficients)

```

```
sage: f.coefficients(5)
[0, 1, -1, 2, -2]
```

integral (*integration_constant=0*)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: zero = L(0)
sage: s = zero
sage: t = s.integral()
sage: t.is_zero()
True
```

```
sage: s = zero
sage: t = s.integral(1)
sage: t.coefficients(6)
[1, 0, 0, 0, 0, 0]
sage: t._stream.is_constant()
True
```

```
sage: s = L.term(1, 0)
sage: t = s.integral()
sage: t.coefficients(6)
[0, 1, 0, 0, 0, 0]
sage: t._stream.is_constant()
True
```

```
sage: s = L.term(1,0)
sage: t = s.integral(1)
sage: t.coefficients(6)
[1, 1, 0, 0, 0, 0]
sage: t._stream.is_constant()
True
```

```
sage: s = L.term(1, 4)
sage: t = s.integral()
sage: t.coefficients(10)
[0, 0, 0, 0, 0, 0, 1/5, 0, 0, 0, 0]
```

```
sage: s = L.term(1,4)
sage: t = s.integral(1)
sage: t.coefficients(10)
[1, 0, 0, 0, 0, 0, 1/5, 0, 0, 0, 0]
```

is_finite (*n=None*)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([0,0,1,0,0]); a
O(1)
sage: a.is_finite()
False
sage: c = a[4]
sage: a.is_finite()
False
sage: a.is_finite(4)
```

```
False
sage: c = a[5]
sage: a.is_finite()
True
sage: a.is_finite(4)
True
```

is_zero()

Returns True if and only if self is zero.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: s = L([0, 2, 3, 0])
sage: s.is_zero()
False
```

```
sage: s = L(0)
sage: s.is_zero()
True
```

```
sage: s = L([0])
sage: s.is_zero()
False
sage: s.coefficient(0)
0
sage: s.coefficient(1)
0
sage: s.is_zero()
True
```

iterator (*n=0, initial=None*)

Returns an iterator for the coefficients of self starting at n.

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L(range(10))
sage: g = f.iterator(2)
sage: [next(g) for i in range(5)]
[2, 3, 4, 5, 6]
sage: g = f.iterator(2, initial=[0, 0])
sage: [next(g) for i in range(5)]
[0, 0, 2, 3, 4]
```

refine_aorder()

Refines the approximate order of self as much as possible without computing any coefficients.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([0, 0, 0, 0, 1])
sage: a.aorder
0
sage: a.coefficient(2)
0
sage: a.aorder
```

```
0
sage: a.refine_aorder()
sage: a.aorder
3
```

```
sage: a = L([0,0])
sage: a.aorder
0
sage: a.coefficient(5)
0
sage: a.refine_aorder()
sage: a.aorder
Infinite series order
```

```
sage: a = L([0,0,1,0,0,0])
sage: a[4]
0
sage: a.refine_aorder()
sage: a.aorder
2
```

restricted (*min=None, max=None*)

Returns the power series restricted to the coefficients starting at *min* and going up to, but not including *max*. If *min* is not specified, then it is assumed to be zero. If *max* is not specified, then it is assumed to be infinity.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([1])
sage: a.restricted().coefficients(10)
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: a.restricted(min=2).coefficients(10)
[0, 0, 1, 1, 1, 1, 1, 1, 1, 1]
sage: a.restricted(max=5).coefficients(10)
[1, 1, 1, 1, 1, 0, 0, 0, 0, 0]
sage: a.restricted(min=2, max=6).coefficients(10)
[0, 0, 1, 1, 1, 1, 0, 0, 0, 0]
```

set_approximate_order (*new_order*)

Sets the approximate order of self and returns True if the approximate order has changed otherwise it will return False.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L([0,0,0,3,2,1,0])
sage: f.get_aorder()
0
sage: f.set_approximate_order(3)
True
sage: f.set_approximate_order(3)
False
```

tail ()

Returns the power series whose coefficients obtained by subtracting the constant term from this series and then dividing by *x*.

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L(range(20))
sage: g = f.tail()
sage: g.coefficients(10)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

times(y)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: gs0 = L(0)
sage: gs1 = L([1])
```

```
sage: prod0 = gs0 * gs1
sage: [prod0.coefficient(i) for i in range(11)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
```

```
sage: prod1 = gs1 * gs0
sage: [prod1.coefficient(i) for i in range(11)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
```

```
sage: prod2 = gs1 * gs1
sage: [prod2.coefficient(i) for i in range(11)]
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]
```

```
sage: gs1 = L([1, 2, 4, 8, 0])
sage: gs2 = L([-1, 0, -1, -9, 22, 0])
```

```
sage: prod1 = gs1 * gs2
sage: [prod1.coefficient(i) for i in range(11)]
[-1, -2, -5, -19, 0, 0, 16, 176, 0, 0, 0]
```

```
sage: prod2 = gs2 * gs1
sage: [prod2.coefficient(i) for i in range(11)]
[-1, -2, -5, -19, 0, 0, 16, 176, 0, 0, 0]
```

class sage.combinat.species.series.**LazyPowerSeriesRing**(*R*, *element_class=None*,
names=None)

Bases: sage.rings.ring.Algebra

gen(*i=0*)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: L.gen().coefficients(5)
[0, 1, 0, 0, 0]
```

identity_element()

Returns the one power series.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: L.identity_element()
1
```

ngens()

EXAMPLES:

```
sage: LazyPowerSeriesRing(QQ).ngens()
1
```

product_generator(g)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: s1 = L([1, 1, 0])
sage: s2 = L([1, 0, 1, 0])
sage: s3 = L([1, 0, 0, 1, 0])
sage: s4 = L([1, 0, 0, 0, 1, 0])
sage: s5 = L([1, 0, 0, 0, 0, 1, 0])
sage: s6 = L([1, 0, 0, 0, 0, 0, 1, 0])
sage: s = [s1, s2, s3, s4, s5, s6]
sage: def g():
....:     for a in s:
....:         yield a
sage: p = L.product_generator(g())
sage: p.coefficients(26)
[1, 1, 1, 2, 2, 3, 4, 4, 4, 5, 5, 5, 5, 4, 4, 4, 3, 2, 2, 1, 1, 1, 0, 0, 0, 0]
```

```
sage: def m(n):
....:     yield 1
....:     while True:
....:         for i in range(n-1):
....:             yield 0
....:             yield 1
sage: def s(n):
....:     q = 1/n
....:     yield 0
....:     while True:
....:         for i in range(n-1):
....:             yield 0
....:             yield q
```

```
sage: def lhs_gen():
....:     n = 1
....:     while True:
....:         yield L(m(n))
....:         n += 1
```

```
sage: def rhs_gen():
....:     n = 1
....:     while True:
....:         yield L(s(n))
....:         n += 1
sage: lhs = L.product_generator(lhs_gen())
sage: rhs = L.sum_generator(rhs_gen()).exponential()
sage: lhs.coefficients(10)
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]
```

```
sage: rhs.coefficients(10)
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]
```

sum(a)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: l = [L(ZZ)]*3
sage: L.sum(l).coefficients(10)
[0, 3, -3, 6, -6, 9, -9, 12, -12, 15]
```

sum_generator(g)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: g = [L([1])]*6 + [L(0)]
sage: t = L.sum_generator(g)
sage: t.coefficients(10)
[1, 2, 3, 4, 5, 6, 6, 6, 6, 6]
```

```
sage: s = L([1])
sage: def g():
....:     while True:
....:         yield s
sage: t = L.sum_generator(g())
sage: t.coefficients(9)
[1, 2, 3, 4, 5, 6, 7, 8, 9]
```

term(r, n)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: L.term(0,0)
0
sage: L.term(3,2).coefficients(5)
[0, 0, 3, 0, 0]
```

zero()

Returns the zero power series.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: L.zero()
0
```

zero_element(*args, **kws)

Deprecated: Use `zero()` instead. See [trac ticket #17694](#) for details.

`sage.combinat.species.series.uninitialized()`

EXAMPLES:

```
sage: from sage.combinat.species.series import uninitialized
sage: uninitialized()
Traceback (most recent call last):
...
RuntimeError: we should never be here
```

5.1.308 Series Order

This file provides some utility classes which are useful when working with unknown, known, and infinite series orders for univariate power series.

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html>. In particular, the relevant section for this file can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinats30.html>.

```
class sage.combinat.species.series_order.InfiniteSeriesOrder
    Bases: sage.combinat.species.series_order.SeriesOrderElement
```

```
class sage.combinat.species.series_order.SeriesOrderElement
```

```
class sage.combinat.species.series_order.UnknownSeriesOrder
    Bases: sage.combinat.species.series_order.SeriesOrderElement
```

```
sage.combinat.species.series_order.bounded_decrement (x)
```

EXAMPLES:

```
sage: from sage.combinat.species.series_order import *
sage: u = UnknownSeriesOrder()
sage: bounded_decrement(u)
Unknown series order
sage: bounded_decrement(4)
3
sage: bounded_decrement(0)
0
```

```
sage.combinat.species.series_order.increment (x)
```

EXAMPLES:

```
sage: from sage.combinat.species.series_order import *
sage: u = UnknownSeriesOrder()
sage: increment(u)
Unknown series order
sage: increment(2)
3
```

5.1.309 Set Species

```
class sage.combinat.species.set_species.SetSpecies (min=None, max=None,
                                                    weight=None)
    Bases: sage.combinat.species.species.GenericCombinatorialSpecies, sage.
           structure.unique_representation.UniqueRepresentation
```

Returns the species of sets.

EXAMPLES:

```
sage: E = species.SetSpecies()
sage: E.structures([1,2,3]).list()
[{1, 2, 3}]
sage: E.isotype_generating_series().coefficients(4)
[1, 1, 1, 1]

sage: S = species.SetSpecies()
sage: c = S.generating_series().coefficients(3)
```

```
sage: S._check()
True
sage: S == loads(dumps(S))
True
```

class `sage.combinat.species.set_species.SetSpeciesStructure` (*parent, labels, list*)
 Bases: `sage.combinat.species.structure.GenericSpeciesStructure`

This is a base class from which the classes for the structures inherit.

EXAMPLES:

```
sage: from sage.combinat.species.structure import GenericSpeciesStructure
sage: a = GenericSpeciesStructure(None, [2,3,4], [1,2,3])
sage: a
[2, 3, 4]
sage: a.parent() is None
True
sage: a == loads(dumps(a))
True
```

automorphism_group()

Returns the group of permutations whose action on this set leave it fixed. For the species of sets, there is only one isomorphism class, so every permutation is in its automorphism group.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.automorphism_group()
Symmetric group of order 3! as a permutation group
```

canonical_label()

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: a = S.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.canonical_label()
{'a', 'b', 'c'}
```

transport (*perm*)

Returns the transport of this set along the permutation perm.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
{'a', 'b', 'c'}
```

`sage.combinat.species.set_species.SetSpecies_class`
 alias of `SetSpecies`

5.1.310 Combinatorial Species

This file defines the main classes for working with combinatorial species, operations on them, as well as some implementations of basic species required for other constructions.

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html>. In particular, the relevant section for this file can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse8.html>.

Weighted Species:

As a first application of weighted species, we count unlabeled ordered trees by total number of nodes and number of internal nodes. To achieve this, we assign a weight of 1 to the leaves and of q to internal nodes:

```
sage: q = QQ['q'].gen()
sage: leaf = species.SingletonSpecies()
sage: internal_node = species.SingletonSpecies(weight=q)
sage: L = species.LinearOrderSpecies(min=1)
sage: T = species.CombinatorialSpecies()
sage: T.define(leaf + internal_node*L(T))
sage: T.isotype_generating_series().coefficients(6)
[0, 1, q, q^2 + q, q^3 + 3*q^2 + q, q^4 + 6*q^3 + 6*q^2 + q]
```

Consider the following:

```
sage: T.isotype_generating_series().coefficient(4)
q^3 + 3*q^2 + q
```

This means that, among the trees on 4 nodes, one has a single internal node, three have two internal nodes, and one has three internal nodes.

```
class sage.combinat.species.species.GenericCombinatorialSpecies (min=None,
                                                                    max=None,
                                                                    weight=None)
```

Bases: sage.structure.sage_object.SageObject

algebraic_equation_system()

Returns a system of algebraic equations satisfied by this species. The nodes are numbered in the order that they appear as vertices of the associated digraph.

EXAMPLES:

```
sage: B = species.BinaryTreeSpecies()
sage: B.algebraic_equation_system()
[-node3^2 + node1, -node1 + node3 - z]
```

```
sage: B.digraph().vertices()
[Combinatorial species,
 Product of (Combinatorial species) and (Combinatorial species),
 Singleton species,
 Sum of (Singleton species) and (Product of (Combinatorial species) and_
 ↪ (Combinatorial species))]
```

```
sage: B.algebraic_equation_system()[0].parent()
Multivariate Polynomial Ring in node0, node1, node2, node3 over Fraction_
↪ Field of Univariate Polynomial Ring in z over Rational Field
```

composition(g)

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: S(S)
Composition of (Set species) and (Set species)
```

cycle_index_series (*base_ring=None*)

Returns the cycle index series for this species.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: g = P.cycle_index_series()
sage: g.coefficients(4)
[p[], p[1], p[1, 1] + p[2], p[1, 1, 1] + p[2, 1] + p[3]]
```

digraph ()

Returns a directed graph where the vertices are the individual species that make up this one.

EXAMPLES:

```
sage: X = species.SingletonSpecies()
sage: B = species.CombinatorialSpecies()
sage: B.define(X+B*B)
sage: g = B.digraph(); g
Multi-digraph on 4 vertices
```

```
sage: g_c, labels = g.canonical_label(certificate=True)
sage: g.relabel()
sage: g_r = g.canonical_label()
sage: g_c == g_r
True
sage: list(sorted(labels))
[Combinatorial species,
 Product of (Combinatorial species) and (Combinatorial species),
 Singleton species,
 Sum of (Singleton species) and (Product of (Combinatorial species) and
 ↪ (Combinatorial species))]
sage: list(sorted(labels.values()))
[0, 1, 2, 3]
```

functorial_composition (*g*)

Returns the functorial composition of self with *g*.

EXAMPLES:

```
sage: E = species.SetSpecies()
sage: E2 = E.restricted(min=2, max=3)
sage: WP = species.SubsetSpecies()
sage: P2 = E2*E
sage: G = WP.functorial_composition(P2)
sage: G.isotype_generating_series().coefficients(5)
[1, 1, 2, 4, 11]
```

generating_series (*base_ring=None*)

Returns the generating series for this species. This is an exponential generating series so the *n*th coefficient of the series corresponds to the number of labeled structures with *n* labels divided by *n*!.

EXAMPLES:

```

sage: P = species.PermutationSpecies()
sage: g = P.generating_series()
sage: g.coefficients(4)
[1, 1, 1, 1]
sage: g.counts(4)
[1, 1, 2, 6]
sage: P.structures([1,2,3]).list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
sage: len(_)
6

```

is_weighted()

Returns True if this species has a nontrivial weighting associated with it.

EXAMPLES:

```

sage: C = species.CycleSpecies()
sage: C.is_weighted()
False

```

isotype_generating_series (*base_ring=None*)

Returns the isotype generating series for this species. The *n*th coefficient of this series corresponds to the number of isomorphism types for the structures on *n* labels.

EXAMPLES:

```

sage: P = species.PermutationSpecies()
sage: g = P.isotype_generating_series()
sage: g.coefficients(4)
[1, 1, 2, 3]
sage: g.counts(4)
[1, 1, 2, 3]
sage: P.isotypes([1,2,3]).list()
[[2, 3, 1], [2, 1, 3], [1, 2, 3]]
sage: len(_)
3

```

isotypes (*labels, structure_class=None*)

EXAMPLES:

```

sage: F = CombinatorialSpecies()
sage: F.isotypes([1,2,3]).list()
Traceback (most recent call last):
...
NotImplementedError

```

product (*g*)

Returns the product of self and *g*.

EXAMPLES:

```

sage: P = species.PermutationSpecies()
sage: F = P * P; F
Product of (Permutation species) and (Permutation species)

```

restricted (**args, **kws*)

EXAMPLES:

```

sage: S = species.SetSpecies().restricted(min=3); S
Set species with min=3
sage: S.structures([1,2]).list()
[]
sage: S.generating_series().coefficients(5)
[0, 0, 0, 1/6, 1/24]

```

structures (*labels*, *structure_class=None*)

EXAMPLES:

```

sage: F = CombinatorialSpecies()
sage: F.structures([1,2,3]).list()
Traceback (most recent call last):
...
NotImplementedError

```

sum (*g*)

Returns the sum of self and *g*.

EXAMPLES:

```

sage: P = species.PermutationSpecies()
sage: F = P + P; F
Sum of (Permutation species) and (Permutation species)
sage: F.structures([1,2]).list()
[[1, 2], [2, 1], [1, 2], [2, 1]]

```

weight_ring ()

Returns the ring in which the weights of this species occur.

By default, this is just the field of rational numbers.

EXAMPLES:

```

sage: species.SetSpecies().weight_ring()
Rational Field

```

weighted (*weight*)

Returns a version of this species with the specified weight.

EXAMPLES:

```

sage: t = ZZ['t'].gen()
sage: C = species.CycleSpecies(); C
Cyclic permutation species
sage: C.weighted(t)
Cyclic permutation species with weight=t

```

5.1.311 Streams or Infinite Arrays

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html>. In particular, the relevant section for this file can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse12.html>.

`sage.combinat.species.stream.Stream` (*x=None*, *const=None*)

Returns a stream.

EXAMPLES: We can create a constant stream by just passing a

```
sage: from sage.combinat.species.stream import Stream
sage: s = Stream(const=0)
sage: [s[i] for i in range(10)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
```

class sage.combinat.species.stream.**Stream_class** (*gen=None, const=None, func=None*)

Bases: sage.structure.sage_object.SageObject

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream
sage: from builtins import zip
sage: s = Stream(const=0)
sage: len(s)
1
sage: [x for (x,i) in zip(s, range(4))]
[0, 0, 0, 0]
sage: len(s)
1
```

```
sage: s = Stream(const=4)
sage: g = iter(s)
sage: l1 = [x for (x,i) in zip(g, range(10))]
sage: l = [4 for k in range(10)]
sage: l == l1
True
```

```
sage: h = lambda l: 1 if len(l) < 2 else l[-1] + l[-2]
sage: fib = Stream(h)
sage: [x for (x,i) in zip(fib, range(11))]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
```

```
sage: r = [4, 3, 5, 2, 6, 1, 1, 1, 1, 1]
sage: l = [4, 3, 5, 2, 6, 1]
sage: s = Stream(l)
sage: s[3] = -1
sage: [x for (x,i) in zip(s, r)]
[4, 3, 5, -1, 6, 1, 1, 1, 1, 1]
sage: s[5] = -2
sage: [x for (x,i) in zip(s, r)]
[4, 3, 5, -1, 6, -2, 1, 1, 1, 1]
sage: s[6] = -3
sage: [x for (x,i) in zip(s, r)]
[4, 3, 5, -1, 6, -2, -3, 1, 1, 1]
sage: s[8] = -4
sage: [x for (x,i) in zip(s, r)]
[4, 3, 5, -1, 6, -2, -3, 1, -4, 1]
sage: a = Stream(const=0)
sage: a[2] = 3
sage: [x for (x,i) in zip(a, range(4))]
[0, 0, 3, 0]
```

data()

Returns a list of all the coefficients computed so far.

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream, _integers_from
sage: s = Stream(_integers_from(3))
sage: s.data()
[]
sage: s[5]
8
sage: s.data()
[3, 4, 5, 6, 7, 8]

```

is_constant()

Returns True if and only if

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream
sage: s = Stream([1,2,3])
sage: s.is_constant()
False
sage: s[3]
3
sage: s.data()
[1, 2, 3]
sage: s.is_constant()
True

```

```

sage: s = Stream(const='I am constant.')
sage: s.is_constant()
True

```

map(f)

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream
sage: s = Stream(ZZ)
sage: square = lambda x: x^2
sage: ss = s.map(square)
sage: [ss[i] for i in range(10)]
[0, 1, 1, 4, 4, 9, 9, 16, 16, 25]

```

```

sage: double = lambda z: 2*z
sage: o = Stream([0,1,2,3])
sage: [x for (x,i) in zip(o, range(6))]
[0, 1, 2, 3, 3, 3]
sage: t = o.map(double)
sage: [x for (x,i) in zip(t, range(6))]
[0, 2, 4, 6, 6, 6]

```

number_computed()

Returns the number of coefficients computed so far.

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream
sage: l = [4,3,5,7,4,1,9,7]
sage: s = Stream(l)
sage: s[3]
7
sage: len(s)

```

```

4
sage: s[3]
7
sage: len(s)
4
sage: s[1]
3
sage: len(s)
4
sage: s[4]
4
sage: len(s)
5

```

set_gen(gen)

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream
sage: from builtins import zip
sage: fib = Stream()
sage: def g():
....:     yield 1
....:     yield 1
....:     n = 0
....:     while True:
....:         yield fib[n] + fib[n+1]
....:         n += 1

```

```

sage: fib.set_gen(g())
sage: [x for (x,i) in zip(fib, range(11))]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]

```

```

sage: l = [4,3,5,2,6,1]
sage: s = Stream(l)
sage: s[3]
2
sage: len(s)
4
sage: g = iter(l)
sage: s.set_gen(g)
sage: s[5]
3
sage: len(s)
6

```

stretch(k)

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream
sage: s = Stream(range(1, 10))
sage: s2 = s.stretch(2)
sage: [s2[i] for i in range(10)]
[1, 0, 2, 0, 3, 0, 4, 0, 5, 0]

```

5.1.312 Species structures

We will illustrate the use of the structure classes using the “balls and bars” model for integer compositions. An integer composition of 6 such as [2, 1, 3] can be represented in this model as ‘ooooo’ where the 6 o’s correspond to the balls and the 2 ‘s correspond to the bars. If BB is our species for this model, then it satisfies the following recursive definition:

$$BB = o + o*BB + o*|*BB$$

Here we define this species using the default structures:

```
sage: ball = species.SingletonSpecies(); o = var('o')
sage: bar = species.EmptySetSpecies()
sage: BB = CombinatorialSpecies()
sage: BB.define(ball + ball*BB + ball*bar*BB)
sage: BB.isotypes([o]*3).list()
[o*(o*o), o*((o*{ })*o), (o*{ })*(o*o), (o*{ })*((o*{ })*o)]
```

If we ignore the parentheses, we can read off that the integer compositions are [3], [2, 1], [1, 2], and [1, 1, 1].

class `sage.combinat.species.structure.GenericSpeciesStructure` (*parent, labels, list*)
 Bases: `sage.combinat.combinat.CombinatorialObject`

This is a base class from which the classes for the structures inherit.

EXAMPLES:

```
sage: from sage.combinat.species.structure import GenericSpeciesStructure
sage: a = GenericSpeciesStructure(None, [2, 3, 4], [1, 2, 3])
sage: a
[2, 3, 4]
sage: a.parent() is None
True
sage: a == loads(dumps(a))
True
```

change_labels (*labels*)

Return a relabelled structure.

INPUT:

- *labels*, a list of labels.

OUTPUT:

A structure with the *i*-th label of self replaced with the *i*-th label of the list.

EXAMPLES:

```
sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.change_labels([1, 2, 3]) for s in S]
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

is_isomorphic (*x*)

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: a = S.structures([1, 2, 3]).random_element(); a
{1, 2, 3}
sage: b = S.structures(['a', 'b', 'c']).random_element(); b
```

```
{'a', 'b', 'c'}
sage: a.is_isomorphic(b)
True
```

labels()

Returns the labels used for this structure.

Note: This includes labels which may not “appear” in this particular structure.

EXAMPLES:

```
sage: P = species.SubsetSpecies()
sage: s = P.structures(["a", "b", "c"]).random_element()
sage: s.labels()
['a', 'b', 'c']
```

parent()

Returns the species that this structure is associated with.

EXAMPLES:

```
sage: L = species.LinearOrderSpecies()
sage: a,b = L.structures([1,2])
sage: a.parent()
Linear order species
```

class `sage.combinat.species.structure.IsotypesWrapper` (*species, labels, structure_class*)
 Bases: `sage.combinat.species.structure.SpeciesWrapper`

A base class for the set of isotypes of a species with given set of labels. An object of this type is returned when you call the `isotypes()` method of a species.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: S = F.isotypes([1,2,3])
sage: S == loads(dumps(S))
True
```

class `sage.combinat.species.structure.SimpleIsotypesWrapper` (*species, labels, structure_class*)
 Bases: `sage.combinat.species.structure.SpeciesWrapper`

Warning: This is deprecated and currently not used for anything.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True
```

class `sage.combinat.species.structure.SimpleStructuresWrapper` (*species, labels, structure_class*)
 Bases: `sage.combinat.species.structure.SpeciesWrapper`

Warning: This is deprecated and currently not used for anything.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True
```

`sage.combinat.species.structure.SpeciesStructure`
alias of *GenericSpeciesStructure*

class `sage.combinat.species.structure.SpeciesStructureWrapper`(*parent, s, **options*)
Bases: *sage.combinat.species.structure.GenericSpeciesStructure*

This is a class for the structures of species such as the sum species that do not provide “additional” structure. For example, if you have the sum C of species A and B , then a structure of C will either be either something from A or B . Instead of just returning one of these directly, a “wrapper” is put around them so that they have their parent is C rather than A or B :

```
sage: X = species.SingletonSpecies()
sage: X2 = X+X
sage: s = X2.structures([1]).random_element(); s
1
sage: s.parent()
Sum of (Singleton species) and (Singleton species)
sage: from sage.combinat.species.structure import SpeciesStructureWrapper
sage: issubclass(type(s), SpeciesStructureWrapper)
True
```

EXAMPLES:

```
sage: E = species.SetSpecies(); B = E+E
sage: s = B.structures([1,2,3]).random_element()
sage: s.parent()
Sum of (Set species) and (Set species)
sage: s == loads(dumps(s))
True
```

canonical_label()

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: s = (P+P).structures([1,2,3]).random_element(); s
{{1, 3}, {2}}
sage: s.canonical_label()
{{1, 2}, {3}}
```

change_labels(*labels*)

Return a relabelled structure.

INPUT:

- *labels*, a list of labels.

OUTPUT:

A structure with the i -th label of self replaced with the i -th label of the list.

EXAMPLES:

```
sage: X = species.SingletonSpecies()
sage: X2 = X+X
sage: s = X2.structures([1]).random_element(); s
1
sage: s.change_labels(['a'])
'a'
```

transport (*perm*)

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: s = (P+P).structures([1,2,3]).random_element(); s
{{1, 3}, {2}}
sage: s.transport(PermutationGroupElement((2,3)))
{{1, 2}, {3}}
```

class `sage.combinat.species.structure.SpeciesWrapper` (*species, labels, iterator, generating_series, name, structure_class*)
 Bases: `sage.combinat.combinat.CombinatorialClass`

This is a abstract base class for the set of structures of a species as well as the set of isotypes of the species.

Note: One typically does not use *SpeciesWrapper* directly, but instead instantiates one of its subclasses: *StructuresWrapper* or *IsotypesWrapper*.

EXAMPLES:

```
sage: from sage.combinat.species.structure import SpeciesWrapper
sage: F = species.SetSpecies()
sage: S = SpeciesWrapper(F, [1,2,3], "_structures", "generating_series",
↪ 'Structures', None)
sage: S
Structures for Set species with labels [1, 2, 3]
sage: S.list()
[[1, 2, 3]]
sage: S.cardinality()
1
```

cardinality ()

Returns the number of structures in this set.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: F.structures([1,2,3]).cardinality()
1
```

labels ()

Returns the labels used on these structures. If X is the species, then *labels* () returns the preimage of these structures under the functor X .

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: F.structures([1,2,3]).labels()
[1, 2, 3]
```

class `sage.combinat.species.structure.StructuresWrapper` (*species*, *labels*, *structure_class*)

Bases: `sage.combinat.species.structure.SpeciesWrapper`

A base class for the set of structures of a species with given set of labels. An object of this type is returned when you call the `structures()` method of a species.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True
```

5.1.313 Subset Species

class `sage.combinat.species.subset_species.SubsetSpecies` (*min=None*, *max=None*, *weight=None*)

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

Returns the species of subsets.

EXAMPLES:

```
sage: S = species.SubsetSpecies()
sage: S.generating_series().coefficients(5)
[1, 2, 2, 4/3, 2/3]
sage: S.isotype_generating_series().coefficients(5)
[1, 2, 3, 4, 5]

sage: S = species.SubsetSpecies()
sage: c = S.generating_series().coefficients(3)
sage: S._check()
True
sage: S == loads(dumps(S))
True
```

class `sage.combinat.species.subset_species.SubsetSpeciesStructure` (*parent*, *labels*, *list*)

Bases: `sage.combinat.species.structure.GenericSpeciesStructure`

This is a base class from which the classes for the structures inherit.

EXAMPLES:

```
sage: from sage.combinat.species.structure import GenericSpeciesStructure
sage: a = GenericSpeciesStructure(None, [2,3,4], [1,2,3])
sage: a
[2, 3, 4]
sage: a.parent() is None
True
sage: a == loads(dumps(a))
True
```

automorphism_group()

Returns the group of permutations whose action on this subset leave it fixed.

EXAMPLES:

```

sage: F = species.SubsetSpecies()
sage: a = F.structures([1,2,3,4])[6]; a
{1, 3}
sage: a.automorphism_group()
Permutation Group with generators [(2,4), (1,3)]

```

```

sage: [a.transport(g) for g in a.automorphism_group()]
[{1, 3}, {1, 3}, {1, 3}, {1, 3}]

```

canonical_label()

EXAMPLES:

```

sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[{}, {'a'}, {'a'}, {'a'}, {'a', 'b'}, {'a', 'b'}, {'a', 'b'}, {'a', 'b', 'c'}]

```

complement()

EXAMPLES:

```

sage: F = species.SubsetSpecies()
sage: a = F.structures(["a", "b", "c"])[5]; a
{'a', 'c'}
sage: a.complement()
{'b'}

```

label_subset()

Returns a subset of the labels that “appear” in this structure.

EXAMPLES:

```

sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.label_subset() for s in S]
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]

```

transport(*perm*)

Returns the transport of this subset along the permutation perm.

EXAMPLES:

```

sage: F = species.SubsetSpecies()
sage: a = F.structures(["a", "b", "c"])[5]; a
{'a', 'c'}
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
{'b', 'c'}
sage: p = PermutationGroupElement((1,3))
sage: a.transport(p)
{'a', 'c'}

```

sage.combinat.species.subset_species.**SubsetSpecies_class**
 alias of *SubsetSpecies*

5.1.314 Sum species

class `sage.combinat.species.sum_species.SumSpecies` (*F*, *G*, *min=None*, *max=None*,
weight=None)
 Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

Returns the sum of two species.

EXAMPLES:

```
sage: S = species.PermutationSpecies()
sage: A = S+S
sage: A.generating_series().coefficients(5)
[2, 2, 2, 2, 2]

sage: P = species.PermutationSpecies()
sage: F = P + P
sage: F._check()
True
sage: F == loads(dumps(F))
True
```

left_summand()

Returns the left summand of this species.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: F = P + P*P
sage: F.left_summand()
Permutation species
```

right_summand()

Returns the right summand of this species.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: F = P + P*P
sage: F.right_summand()
Product of (Permutation species) and (Permutation species)
```

weight_ring()

Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you add elements of the weight rings for each of the operands.

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: C = S+S
sage: C.weight_ring()
Rational Field
```

```
sage: S = species.SetSpecies(weight=QQ['t'].gen())
sage: C = S + S
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

class `sage.combinat.species.sum_species.SumSpeciesStructure` (*parent, s, **options*)
 Bases: `sage.combinat.species.structure.SpeciesStructureWrapper`

This is a class for the structures of species such as the sum species that do not provide “additional” structure. For example, if you have the sum C of species A and B , then a structure of C will either be either something from A or B . Instead of just returning one of these directly, a “wrapper” is put around them so that they have their parent is C rather than A or B :

```
sage: X = species.SingletonSpecies()
sage: X2 = X+X
sage: s = X2.structures([1]).random_element(); s
1
sage: s.parent()
Sum of (Singleton species) and (Singleton species)
sage: from sage.combinat.species.structure import SpeciesStructureWrapper
sage: issubclass(type(s), SpeciesStructureWrapper)
True
```

EXAMPLES:

```
sage: E = species.SetSpecies(); B = E+E
sage: s = B.structures([1,2,3]).random_element()
sage: s.parent()
Sum of (Set species) and (Set species)
sage: s == loads(dumps(s))
True
```

`sage.combinat.species.sum_species.SumSpecies_class`
 alias of `SumSpecies`

5.1.315 Subsets

The set of subsets of a finite set. The set can be given as a list or a Set or else as an integer n which encodes the set $\{1, 2, \dots, n\}$. See [Subsets](#) for more information and examples.

AUTHORS:

- Mike Hansen: initial version
- Florent Hivert (2009/02/06): doc improvements + new methods

class `sage.combinat.subset.SubMultiset_s` (*s*)
 Bases: `sage.structure.parent.Parent`

The combinatorial class of the sub multisets of s .

EXAMPLES:

```
sage: S = Subsets([1,2,2,3], submultiset=True)
sage: S.cardinality()
12
sage: S.list()
[[],
 [1],
 [2],
 [3],
 [1, 2],
 [1, 3],
 [2, 2],
```

```

[2, 3],
[1, 2, 2],
[1, 2, 3],
[2, 2, 3],
[1, 2, 2, 3]]
sage: S.first()
[]
sage: S.last()
[1, 2, 2, 3]

```

cardinality()

Return the cardinality of self

EXAMPLES:

```

sage: S = Subsets([1,1,2,3],submultiset=True)
sage: S.cardinality()
12
sage: len(S.list())
12

sage: S = Subsets([1,1,2,2,3],submultiset=True)
sage: S.cardinality()
18
sage: len(S.list())
18

sage: S = Subsets([1,1,1,2,2,3],submultiset=True)
sage: S.cardinality()
24
sage: len(S.list())
24

```

generating_serie (*variable='x'*)

Return the serie (here a polynom) associated to the counting of the element of self weighted by the number of element they contain.

EXAMPLES:

```

sage: Subsets([1,1],submultiset=True).generating_serie()
x^2 + x + 1
sage: Subsets([1,1,2,3],submultiset=True).generating_serie()
x^4 + 3*x^3 + 4*x^2 + 3*x + 1
sage: Subsets([1,1,1,2,2,3,3,4],submultiset=True).generating_serie()
x^8 + 4*x^7 + 9*x^6 + 14*x^5 + 16*x^4 + 14*x^3 + 9*x^2 + 4*x + 1

sage: S = Subsets([1,1,1,2,2,3,3,4],submultiset=True)
sage: S.cardinality()
72
sage: sum(S.generating_serie())
72

```

random_element()

Return a random element of self with uniform law

EXAMPLES:

```
sage: S = Subsets([1,1,2,3], submultiset=True)
sage: S.random_element()
[2]
```

class `sage.combinat.subset.SubMultiset_sk(s, k)`

Bases: `sage.combinat.subset.SubMultiset_s`

The combinatorial class of the subsets of size `k` of a multiset `s`. Note that each subset is represented by a list of the elements rather than a set since we can have multiplicities (no multiset data structure yet in sage).

EXAMPLES:

```
sage: S = Subsets([1,2,3,3],2,submultiset=True)
sage: S._k
2
sage: S.cardinality()
4
sage: S.first()
[1, 2]
sage: S.last()
[3, 3]
sage: [sub for sub in S]
[[1, 2], [1, 3], [2, 3], [3, 3]]
```

cardinality()

Return the cardinality of self

EXAMPLES:

```
sage: S = Subsets([1,2,2,3,3,3],4,submultiset=True)
sage: S.cardinality()
5
sage: len(list(S))
5

sage: S = Subsets([1,2,2,3,3,3],3,submultiset=True)
sage: S.cardinality()
6
sage: len(list(S))
6
```

generating_serie (*variable='x'*)

Return the serie (this case a polynom) associated to the counting of the element of self weighted by the number of element they contains

EXAMPLES:

```
sage: x = ZZ['x'].gen()
sage: l = [1,1,1,1,2,2,3]
sage: for k in range(len(l)):
....:     S = Subsets(l,k,submultiset=True)
....:     print(S.generating_serie(x) == S.cardinality()*x**k)
True
True
True
True
True
True
True
```

random_element()

Return a random submultiset of given length

EXAMPLES:

```
sage: Subsets(7,3).random_element()
{1, 4, 7}
sage: Subsets(7,5).random_element()
{1, 3, 4, 5, 7}
```

`sage.combinat.subset.Subsets(s, k=None, submultiset=False)`

Return the combinatorial class of the subsets of the finite set s . The set can be given as a list, Set or any iterable convertible to a set. Alternatively, a non-negative integer n can be provided in place of s ; in this case, the result is the combinatorial class of the subsets of the set $\{1, 2, \dots, n\}$ (i.e. of the Sage `range(1, n+1)`).

A second optional parameter k can be given. In this case, `Subsets` returns the combinatorial class of subsets of s of size k .

Warning: The subsets are returned as Sets. Do not assume that these Sets are ordered; they often are not! (E.g., `Subsets(10).list()[619]` returns `{10, 4, 5, 6, 7}` on my system.) See [SubsetsSorted](#) for a similar class which returns the subsets as sorted tuples.

Finally the option `submultiset` allows one to deal with sets with repeated elements, usually called multisets. The method then returns the class of all multisets in which every element is contained at most as often as it is contained in s . These multisets are encoded as lists.

EXAMPLES:

```
sage: S = Subsets([1, 2, 3]); S
Subsets of {1, 2, 3}
sage: S.cardinality()
8
sage: S.first()
{}
sage: S.last()
{1, 2, 3}
sage: S.random_element() # random
{2}
sage: S.list()
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

Here is the same example where the set is given as an integer:

```
sage: S = Subsets(3)
sage: S.list()
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

We demonstrate various the effect of the various options:

```
sage: S = Subsets(3, 2); S
Subsets of {1, 2, 3} of size 2
sage: S.list()
[{1, 2}, {1, 3}, {2, 3}]

sage: S = Subsets([1, 2, 2], submultiset=True); S
SubMultiset of [1, 2, 2]
sage: S.list()
```

```

[[], [1], [2], [1, 2], [2, 2], [1, 2, 2]]

sage: S = Subsets([1, 2, 2, 3], 3, submultiset=True); S
SubMultiset of [1, 2, 2, 3] of size 3
sage: S.list()
[[1, 2, 2], [1, 2, 3], [2, 2, 3]]

sage: S = Subsets(['a', 'b', 'a', 'b'], 2, submultiset=True); S.list()
[['a', 'a'], ['a', 'b'], ['b', 'b']]

```

And it is possible to play with subsets of subsets:

```

sage: S = Subsets(3)
sage: S2 = Subsets(S); S2
Subsets of Subsets of {1, 2, 3}
sage: S2.cardinality()
256
sage: it = iter(S2)
sage: [next(it) for _ in range(8)]
[{}, {{}}, {{1}}, {{2}}, {{3}}, {{1, 2}}, {{1, 3}}, {{2, 3}}]
sage: S2.random_element() # random
{{2}, {1, 2, 3}, {}}
sage: [S2.unrank(k) for k in range(256)] == S2.list()
True

sage: S3 = Subsets(S2)
sage: S3.cardinality()
115792089237316195423570985008687907853269984665640564039457584007913129639936
sage: S3.unrank(14123091480)
{{{1, 3}, {1, 2, 3}, {2}, {1}},
 {{2}, {1, 2, 3}, {}, {1, 2}},
 {},
 {{2}, {1, 2, 3}, {}, {3}, {1, 2}},
 {{1, 2, 3}, {}, {1}}, {{2}, {2, 3}, {}, {1, 2}}}

sage: T = Subsets(S2, 10)
sage: T.cardinality()
278826214642518400
sage: T.unrank(1441231049)
{{{3}, {1, 2}, {}, {2, 3}, {1}, {1, 3}, ..., {{2, 3}, {}}, {}}}

```

class `sage.combinat.subset.SubsetsSorted(s)`

Bases: `sage.combinat.subset.Subsets_s`

Lightweight class of all subsets of some set S , with each subset being encoded as a sorted tuple.

Used to model indices of algebras given by subsets (so we don't have to explicitly build all 2^n subsets in memory). For example, `CliffordAlgebra`.

first()

Return the first element of `self`.

EXAMPLES:

```

sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: S.first()
()

```

last()

Return the last element of self.

EXAMPLES:

```
sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: S.last()
(0, 1, 2)
```

random_element()

Return a random element of self.

EXAMPLES:

```
sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: isinstance(S.random_element(), tuple)
True
```

unrank(r)

Return the subset which has rank r.

EXAMPLES:

```
sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: S.unrank(4)
(0, 1)
```

class sage.combinat.subset.**Subsets_s**(s)

Bases: sage.structure.parent.Parent

Subsets of a given set.

EXAMPLES:

```
sage: S = Subsets(4); S
Subsets of {1, 2, 3, 4}
sage: S.cardinality()
16
sage: S.list()
[{}, {1}, {2}, {3}, {4},
 {1, 2}, {1, 3}, {1, 4}, {2, 3}, {2, 4}, {3, 4},
 {1, 2, 3}, {1, 2, 4}, {1, 3, 4}, {2, 3, 4},
 {1, 2, 3, 4}]

sage: S = Subsets(Subsets(Subsets(GF(3)))); S
Subsets of Subsets of Subsets of Finite Field of size 3
sage: S.cardinality()
115792089237316195423570985008687907853269984665640564039457584007913129639936
sage: S.unrank(3149254230)
[{{1, 2}, {0, 1, 2}, {0, 2}, {0, 1}},
 {{1, 2}, {}, {0, 2}, {1}, {0, 1, 2}, {2}},
 {{1, 2}, {0}}, {{1, 2}, {0, 1}, {0, 1, 2}, {1}},
 {{0, 2}, {1}}]
```

an_element()

Returns an example of subset.

EXAMPLES:

```
sage: Subsets(0).an_element()
{}
sage: Subsets(3).an_element()
{1, 2}
sage: Subsets([2, 4, 5]).an_element()
{2, 4}
```

cardinality()

Return the number of subsets of the set s .

This is given by $2^{|s|}$.

EXAMPLES:

```
sage: Subsets(Set([1, 2, 3])).cardinality()
8
sage: Subsets([1, 2, 3, 3]).cardinality()
8
sage: Subsets(3).cardinality()
8
```

element_class

alias of `Set_object_enumerated`

first()

Returns the first subset of s . Since we aren't restricted to subsets of a certain size, this is always the empty set.

EXAMPLES:

```
sage: Subsets([1, 2, 3]).first()
{}
sage: Subsets(3).first()
{}
```

last()

Return the last subset of s . Since we aren't restricted to subsets of a certain size, this is always the set s itself.

EXAMPLES:

```
sage: Subsets([1, 2, 3]).last()
{1, 2, 3}
sage: Subsets(3).last()
{1, 2, 3}
```

random_element()

Return a random element of the class of subsets of s (in other words, a random subset of s).

EXAMPLES:

```
sage: Subsets(3).random_element()           # random
{2}
sage: Subsets([4, 5, 6]).random_element()   # random
{5}

sage: S = Subsets(Subsets(Subsets([0, 1, 2])))
sage: S.cardinality()
```

```

115792089237316195423570985008687907853269984665640564039457584007913129639936
sage: s = S.random_element()
sage: s          # random
{{{1, 2}, {2}, {0}, {1}}, {{1, 2}, {0, 1, 2}, {0, 2}, {0}, {0, 1}}, ..., {{1, 2}, {2}, {1}}, {{2}, {0, 2}, {}, {1}}}
sage: s in S
True

```

rank(sub)

Return the rank of sub as a subset of s.

EXAMPLES:

```

sage: Subsets(3).rank([])
0
sage: Subsets(3).rank([1,2])
4
sage: Subsets(3).rank([1,2,3])
7
sage: Subsets(3).rank([2,3,4])
Traceback (most recent call last):
...
ValueError: {2, 3, 4} is not a subset of {1, 2, 3}

```

underlying_set()

Return the set of elements.

EXAMPLES:

```

sage: Subsets(GF(13)).underlying_set()
{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12}

```

unrank(r)

Return the subset of s that has rank k.

EXAMPLES:

```

sage: Subsets(3).unrank(0)
{}
sage: Subsets([2,4,5]).unrank(1)

```

class sage.combinat.subset.**Subsets_sk**(s,k)

Bases: *sage.combinat.subset.Subsets_s*

Subsets of fixed size of a set.

EXAMPLES:

```

sage: S = Subsets([0,1,2,5,7], 3); S
Subsets of {0, 1, 2, 5, 7} of size 3
sage: S.cardinality()
10
sage: S.first(), S.last()
({0, 1, 2}, {2, 5, 7})

```

```

sage: S.random_element() # random
{0, 5, 7}
sage: S([0,2,7])
{0, 2, 7}
sage: S([0,3,5])
Traceback (most recent call last):
...
ValueError: {0, 3, 5} not in Subsets of {0, 1, 2, 5, 7} of size 3
sage: S([0])
Traceback (most recent call last):
...
ValueError: {0} not in Subsets of {0, 1, 2, 5, 7} of size 3

```

an_element()

Returns an example of subset.

EXAMPLES:

```

sage: Subsets(0,0).an_element()
{}
sage: Subsets(3,2).an_element()
{1, 3}
sage: Subsets([2,4,5],2).an_element()
{2, 5}

```

cardinality()

EXAMPLES:

```

sage: Subsets(Set([1,2,3]), 2).cardinality()
3
sage: Subsets([1,2,3,3], 2).cardinality()
3
sage: Subsets([1,2,3], 1).cardinality()
3
sage: Subsets([1,2,3], 3).cardinality()
1
sage: Subsets([1,2,3], 0).cardinality()
1
sage: Subsets([1,2,3], 4).cardinality()
0
sage: Subsets(3,2).cardinality()
3
sage: Subsets(3,4).cardinality()
0

```

first()

Returns the first subset of s of size k.

EXAMPLES:

```

sage: Subsets(Set([1,2,3]), 2).first()
{1, 2}
sage: Subsets([1,2,3,3], 2).first()
{1, 2}
sage: Subsets(3,2).first()
{1, 2}
sage: Subsets(3,4).first()
Traceback (most recent call last):

```

```
...
EmptySetError
```

last ()

Returns the last subset of s of size k .

EXAMPLES:

```
sage: Subsets(Set([1,2,3]), 2).last()
{2, 3}
sage: Subsets([1,2,3,3], 2).last()
{2, 3}
sage: Subsets(3,2).last()
{2, 3}
sage: Subsets(3,4).last()
Traceback (most recent call last):
...
EmptySetError
```

random_element ()

Return a random element of the class of subsets of s of size k (in other words, a random subset of s of size k).

EXAMPLES:

```
sage: Subsets(3, 2).random_element()
{1, 2}
sage: Subsets(3,4).random_element()
Traceback (most recent call last):
...
EmptySetError
```

rank (sub)

Return the rank of sub as a subset of s of size k .

EXAMPLES:

```
sage: Subsets(3,2).rank([1,2])
0
sage: Subsets([2,3,4],2).rank([3,4])
2
sage: Subsets([2,3,4],2).rank([2])
Traceback (most recent call last):
...
ValueError: {2} is not a subset of length 2 of {2, 3, 4}
sage: Subsets([2,3,4],4).rank([2,3,4,5])
Traceback (most recent call last):
...
ValueError: {2, 3, 4, 5} is not a subset of length 4 of {2, 3, 4}
```

unrank (r)

Return the subset of s of size k that has rank r .

EXAMPLES:

```
sage: Subsets(3,2).unrank(0)
{1, 2}
sage: Subsets([2,4,5],2).unrank(0)
{2, 4}
```

```
sage: Subsets([1,2,8],3).unrank(42)
Traceback (most recent call last):
...
IndexError: index out of range
```

`sage.combinat.subset.dict_to_list(d)`

Return a list whose elements are the elements of d repeated with multiplicity $d[i]$.

EXAMPLES:

```
sage: from sage.combinat.subset import dict_to_list
sage: dict_to_list({'a':1, 'b':3})
['a', 'b', 'b', 'b']
```

`sage.combinat.subset.list_to_dict(l)`

Return a dictionary whose keys are the elements of l and values are the multiplicity they appear in l .

EXAMPLES:

```
sage: from sage.combinat.subset import list_to_dict
sage: list_to_dict(['a', 'b', 'b', 'b'])
{'a': 1, 'b': 3}
```

5.1.316 Subsets satisfying a hereditary property

`sage.combinat.subsets_hereditary.subsets_with_hereditary_property(f, X, max_obstruction_size=None, ncpus=1)`

Return all subsets S of X such that $f(S)$ is true.

The boolean function f must be decreasing, i.e. $f(S) \Rightarrow f(S')$ if $S' \subseteq S$.

This function is implemented to call f as few times as possible. More precisely, f will be called on all sets S such that $f(S)$ is true, as well as on all inclusionwise minimal sets S such that $f(S)$ is false.

The problem that this function answers is also known as the learning problem on monotone boolean functions, or as computing the set of winning coalitions in a simple game.

INPUT:

- f – a boolean function which takes as input a list of elements from X .
- X – a list/iterable.
- `max_obstruction_size` (integer) – if you know that there is a k such that $f(S)$ is true if and only if $f(S')$ is true for all $S' \subseteq S$ with $|S'| \leq k$, set `max_obstruction_size=k`. It may dramatically decrease the number of calls to f . Set to `None` by default, meaning $k = |X|$.
- `ncpus` – number of cpus to use for this computation. Note that changing the value from 1 (default) to anything different *enables* parallel computations which can have a cost by itself, so it is not necessarily a good move. In some cases, however, it is a *great* move. Set to `None` to automatically detect and use the maximum number of cpus available.

Note: Parallel computations are performed through the `parallel()` decorator. See its documentation for more information, in particular with respect to the memory context.

EXAMPLES:

Sets whose elements all have the same remainder mod 2:

```
sage: from sage.combinat.subsets_hereditary import subsets_with_hereditary_
      ↪property
sage: f = lambda x: (not x) or all(xx%2 == x[0]%2 for xx in x)
sage: list(subsets_with_hereditary_property(f, range(4)))
[[], [0], [1], [2], [3], [0, 2], [1, 3]]
```

Same, on two threads:

```
sage: sorted(list(subsets_with_hereditary_property(f, range(4), ncpus=2)))
[[], [0], [0, 2], [1], [1, 3], [2], [3]]
```

One can use this function to compute the independent sets of a graph. We know, however, that in this case the maximum obstructions are the edges, and have size 2. We can thus set `max_obstruction_size=2`, which reduces the number of calls to f from 91 to 56:

```
sage: num_calls=0
sage: g = graphs.PetersenGraph()
sage: def is_independent_set(S):
....:     global num_calls
....:     num_calls+=1
....:     return g.subgraph(S).size()==0
sage: l1=list(subsets_with_hereditary_property(is_independent_set, g.vertices()))
sage: num_calls
91
sage: num_calls=0
sage: l2=list(subsets_with_hereditary_property(is_independent_set, g.vertices(),
      ↪max_obstruction_size=2))
sage: num_calls
56
sage: l1==l2
True
```

5.1.317 Subsets whose elements satisfy a predicate pairwise

```
class sage.combinat.subsets_pairwise.PairwiseCompatibleSubsets(ambient, predicate, maximal=False, element_class=<class 'sage.sets.set.Set_object_enumerated'>)
```

Bases: `sage.combinat.backtrack.SearchForest`

The set of all subsets of `ambient` whose elements satisfy `predicate` pairwise

INPUT:

- `ambient` – a set (or iterable)
- `predicate` – a binary predicate

Assumptions: `predicate` is symmetric (`predicate(x, y) == predicate(y, x)`) and reflexive (`predicate(x, x) == True`).

Note: in fact, `predicate(x, x)` is never called.

Warning: The current name is suboptimal and is subject to change. Suggestions for a good name, and a good user entry point are welcome. Maybe `Subsets(..., independant = predicate)`.

EXAMPLES:

We construct the set of all subsets of $\{4, 5, 6, 8, 9\}$ whose elements are pairwise relatively prime:

```
sage: from sage.combinat.subsets_pairwise import PairwiseCompatibleSubsets
sage: def predicate(x,y): return gcd(x,y) == 1
sage: P = PairwiseCompatibleSubsets([4,5,6,8,9], predicate); P
An enumerated set with a forest structure
sage: P.list()
[{}, {4}, {4, 5}, {9, 4, 5}, {9, 4}, {5}, {5, 6}, {8, 5}, {8, 9, 5}, {9, 5}, {6},
↪ {8}, {8, 9}, {9}]
sage: P.cardinality()
14
sage: P.category()
Category of finite enumerated sets
```

Here we consider only those subsets which are maximal for inclusion (not yet implemented):

```
sage: P = PairwiseCompatibleSubsets([4,5,6,8,9], predicate, maximal = True); P
An enumerated set with a forest structure
sage: P.list() # todo: not implemented
[{}]
```

Algorithm

In the following, we order the elements of the ambient set by order of apparition. The elements of `self` are generated by organizing them in a search tree. Each node of this tree is of the form `(subset, rest)`, where:

- `subset` represents an element of `self`, represented by an increasing tuple
- `rest` is the set of all y 's such that y appears after x in the ambient set and `predicate(x, y)` holds, represented by a decreasing tuple

The root of this tree is `((), ambient)`. All the other elements are generated by recursive depth first search, which gives lexicographic order.

children (*subset_rest*)

Returns the children of a node in the tree.

post_process (*subset_rest*)

5.1.318 Subwords

A subword of a word w is a word obtained by deleting the letters at some (non necessarily adjacent) positions in w . It is not to be confused with the notion of factor where one keeps adjacent positions in w . Sometimes it is useful to allow repeated uses of the same letter of w in a “generalized” subword. We call this a subword with repetitions.

For example:

- “bnjr” is a subword of the word “bonjour” but not a factor;
- “njo” is both a factor and a subword of the word “bonjour”;
- “nr” is a subword of “bonjour”;
- “rn” is not a subword of “bonjour”;
- “nnu” is not a subword of “bonjour”;
- “nnu” is a subword with repetitions of “bonjour”;

A word can be given either as a string, as a list or as a tuple.

As repetition can occur in the initial word, the subwords of a given words is not a set in general but an enumerated multiset!

Todo

- implement subwords with repetitions
 - implement the category of EnumeratedMultiset and inheritate from when needed (i.e. the initial word has repeated letters)
-

AUTHORS:

- Mike Hansen: initial version
- Florent Hivert (2009/02/06): doc improvements + new methods + bug fixes

`sage.combinat.subword.Subwords` (*w*, *k=None*, *element_constructor=None*)

Return the set of subwords of *w*.

INPUT:

- *w* – a word (can be a list, a string, a tuple or a word)
- *k* – an optional integer to specify the length of subwords
- *element_constructor* – an optional function that will be used to build the subwords

EXAMPLES:

```
sage: S = Subwords(['a', 'b', 'c']); S
Subwords of ['a', 'b', 'c']
sage: S.first()
[]
sage: S.last()
['a', 'b', 'c']
sage: S.list()
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

The same example using string, tuple or a word:

```
sage: S = Subwords('abc'); S
Subwords of 'abc'
sage: S.list()
['', 'a', 'b', 'c', 'ab', 'ac', 'bc', 'abc']

sage: S = Subwords((1, 2, 3)); S
Subwords of (1, 2, 3)
sage: S.list()
[(), (1,), (2,), (3,), (1, 2), (1, 3), (2, 3), (1, 2, 3)]
```

```

sage: w = Word([1,2,3])
sage: S = Subwords(w); S
Subwords of word: 123
sage: S.list()
[word: , word: 1, word: 2, word: 3, word: 12, word: 13, word: 23, word: 123]

```

Using word with specified length:

```

sage: S = Subwords(['a','b','c'], 2); S
Subwords of ['a', 'b', 'c'] of length 2
sage: S.list()
[['a', 'b'], ['a', 'c'], ['b', 'c']]

```

An example that uses the `element_constructor` argument:

```

sage: p = Permutation([3,2,1])
sage: Subwords(p, element_constructor=tuple).list()
[(), (3,), (2,), (1,), (3, 2), (3, 1), (2, 1), (3, 2, 1)]
sage: Subwords(p, 2, element_constructor=tuple).list()
[(3, 2), (3, 1), (2, 1)]

```

class `sage.combinat.subword.Subwords_w(w, element_constructor)`
 Bases: `sage.structure.parent.Parent`

Subwords of a given word.

cardinality()
 EXAMPLES:

```

sage: Subwords([1,2,3]).cardinality()
8

```

first()
 EXAMPLES:

```

sage: Subwords([1,2,3]).first()
[]
sage: Subwords((1,2,3)).first()
()
sage: Subwords('123').first()
''

```

last()
 EXAMPLES:

```

sage: Subwords([1,2,3]).last()
[1, 2, 3]
sage: Subwords((1,2,3)).last()
(1, 2, 3)
sage: Subwords('123').last()
'123'

```

random_element()
 Return a random subword with uniform law.
 EXAMPLES:

```

sage: S1 = Subwords([1,2,3,2,1,3])
sage: S2 = Subwords([4,6,6,6,7,4,5,5])
sage: for i in range(100):
....:     w = S1.random_element()
....:     if w in S2:
....:         assert(w == [])
sage: for i in range(100):
....:     w = S2.random_element()
....:     if w in S1:
....:         assert(w == [])

```

class sage.combinat.subword.**Subwords_wk**(*w, k, element_constructor*)

Bases: *sage.combinat.subword.Subwords_w*

Subwords with fixed length of a given word.

cardinality()

Returns the number of subwords of *w* of length *k*.

EXAMPLES:

```

sage: Subwords([1,2,3], 2).cardinality()
3

```

first()

EXAMPLES:

```

sage: Subwords([1,2,3], 2).first()
[1, 2]
sage: Subwords([1,2,3], 0).first()
[]
sage: Subwords((1,2,3), 2).first()
(1, 2)
sage: Subwords((1,2,3), 0).first()
()
sage: Subwords('123', 2).first()
'12'
sage: Subwords('123', 0).first()
''

```

last()

EXAMPLES:

```

sage: Subwords([1,2,3], 2).last()
[2, 3]
sage: Subwords([1,2,3], 0).last()
[]
sage: Subwords((1,2,3), 2).last()
(2, 3)
sage: Subwords((1,2,3), 0).last()
()
sage: Subwords('123', 2).last()
'23'
sage: Subwords('123', 0).last()
''

```

random_element()

Return a random subword of given length with uniform law.

EXAMPLES:

```
sage: S1 = Subwords([1,2,3,2,1],3)
sage: S2 = Subwords([4,4,5,5,4,5,4,4],3)
sage: for i in range(100):
....:   w = S1.random_element()
....:   if w in S2:
....:       assert(w == [])
sage: for i in range(100):
....:   w = S2.random_element()
....:   if w in S1:
....:       assert(w == [])
```

`sage.combinat.subword.smallest_positions(word, subword, pos=0)`

Return the smallest positions for which `subword` appears as a subword of `word`. If `pos` is specified, then it returns the positions of the first appearance of `subword` starting at `pos`.

If `subword` is not found in `word`, then return `False`.

EXAMPLES:

```
sage: sage.combinat.subword.smallest_positions([1,2,3,4], [2,4])
[1, 3]
sage: sage.combinat.subword.smallest_positions([1,2,3,4,4], [2,4])
[1, 3]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4])
[2, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4],2)
[2, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4],3)
[3, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,4], [2,3])
[1, 2]
sage: sage.combinat.subword.smallest_positions([1,2,3,4], [5,5])
False
sage: sage.combinat.subword.smallest_positions([1,3,3,4,5], [3,5])
[1, 4]
sage: sage.combinat.subword.smallest_positions([1,3,3,5,4,5,3,5], [3,5,3])
[1, 3, 6]
sage: sage.combinat.subword.smallest_positions([1,3,3,5,4,5,3,5], [3,5,3],2)
[2, 3, 6]
sage: sage.combinat.subword.smallest_positions([1,2,3,4,3,4,4], [2,3,3,1])
False
sage: sage.combinat.subword.smallest_positions([1,3,3,5,4,5,3,5], [3,5,3],3)
False
```

5.1.319 Subword complex

Fix a Coxeter system (W, S) . The subword complex $\mathcal{SC}(Q, w)$ associated to a word $Q \in S^*$ and an element $w \in W$ is the simplicial complex whose ground set is the set of positions in Q and whose facets are complements of sets of positions defining a reduced expression for w .

A subword complex is a shellable sphere if and only if the Demazure product of Q equals w , otherwise it is a shellable ball.

The code is optimized to be used with `ReflectionGroup`, it works as well with `CoxeterGroup`, but many methods fail for `WeylGroup`.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 3]); I = list(W.index_set())           # optional - gap3
sage: Q = I + W.w0.coxeter_sorting_word(I); Q                         # optional - gap3
[1, 2, 3, 1, 2, 3, 1, 2, 1]

sage: S = SubwordComplex(Q, W.w0)                                     # optional - gap3
sage: for F in S: print("{} {}".format(F, F.root_configuration()))   #
↪ optional - gap3
(0, 1, 2) [(1, 0, 0), (0, 1, 0), (0, 0, 1)]
(0, 1, 8) [(1, 0, 0), (0, 1, 0), (0, 0, -1)]
(0, 2, 6) [(1, 0, 0), (0, 1, 1), (0, -1, 0)]
(0, 6, 7) [(1, 0, 0), (0, 0, 1), (0, -1, -1)]
(0, 7, 8) [(1, 0, 0), (0, -1, 0), (0, 0, -1)]
(1, 2, 3) [(1, 1, 0), (0, 0, 1), (-1, 0, 0)]
(1, 3, 8) [(1, 1, 0), (-1, 0, 0), (0, 0, -1)]
(2, 3, 4) [(1, 1, 1), (0, 1, 0), (-1, -1, 0)]
(2, 4, 6) [(1, 1, 1), (-1, 0, 0), (0, -1, 0)]
(3, 4, 5) [(0, 1, 0), (0, 0, 1), (-1, -1, -1)]
(3, 5, 8) [(0, 1, 0), (-1, -1, 0), (0, 0, -1)]
(4, 5, 6) [(0, 1, 1), (-1, -1, -1), (0, -1, 0)]
(5, 6, 7) [(-1, 0, 0), (0, 0, 1), (0, -1, -1)]
(5, 7, 8) [(-1, 0, 0), (0, -1, 0), (0, 0, -1)]

```

Testing that the implementation also works with CoxeterGroup:

```

sage: W = CoxeterGroup(['A', 3]); I = list(W.index_set())
sage: Q = I + W.w0.coxeter_sorting_word(I); Q
[1, 2, 3, 1, 2, 3, 1, 2, 1]
sage: S = SubwordComplex(Q, W.w0); S
Subword complex of type ['A', 3] for Q = (1, 2, 3, 1, 2, 3, 1, 2, 1) and pi = [1, 2, ↪
↪ 3, 1, 2, 1]
sage: P = S.increasing_flip_poset(); P; len(P.cover_relations())
Finite poset containing 14 elements
21

```

The root configuration works:

```

sage: for F in S: print("{} {}".format(F, F.root_configuration()))
(0, 1, 2) [(1, 0, 0), (0, 1, 0), (0, 0, 1)]
(0, 1, 8) [(1, 0, 0), (0, 1, 0), (0, 0, -1)]
(0, 2, 6) [(1, 0, 0), (0, 1, 1), (0, -1, 0)]
(0, 6, 7) [(1, 0, 0), (0, 0, 1), (0, -1, -1)]
(0, 7, 8) [(1, 0, 0), (0, -1, 0), (0, 0, -1)]
(1, 2, 3) [(1, 1, 0), (0, 0, 1), (-1, 0, 0)]
(1, 3, 8) [(1, 1, 0), (-1, 0, 0), (0, 0, -1)]
(2, 3, 4) [(1, 1, 1), (0, 1, 0), (-1, -1, 0)]
(2, 4, 6) [(1, 1, 1), (-1, 0, 0), (0, -1, 0)]
(3, 4, 5) [(0, 1, 0), (0, 0, 1), (-1, -1, -1)]
(3, 5, 8) [(0, 1, 0), (-1, -1, 0), (0, 0, -1)]
(4, 5, 6) [(0, 1, 1), (-1, -1, -1), (0, -1, 0)]
(5, 6, 7) [(-1, 0, 0), (0, 0, 1), (0, -1, -1)]
(5, 7, 8) [(-1, 0, 0), (0, -1, 0), (0, 0, -1)]

```

And the weight configuration also works:

```

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)

```

```

sage: F = SC([1,2])
sage: F.extended_weight_configuration()
[(4/3, 2/3), (2/3, 4/3), (-2/3, 2/3), (2/3, 4/3), (-2/3, 2/3)]
sage: F.extended_weight_configuration(coefficients=(1,2))
[(4/3, 2/3), (4/3, 8/3), (-2/3, 2/3), (4/3, 8/3), (-2/3, 2/3)]

```

One finally can compute the brick polytope, using all functionality on weight configurations, though it does not realize to live in real space:

```

sage: W = CoxeterGroup(['A',3]); I = list(W.index_set())
sage: Q = I + W.w0.coxeter_sorting_word(I)
sage: S = SubwordComplex(Q,W.w0)
sage: S.brick_polytope()
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 14 vertices

sage: W = CoxeterGroup(['H',3]); I = list(W.index_set())
sage: Q = I + W.w0.coxeter_sorting_word(I)
sage: S = SubwordComplex(Q,W.w0)
sage: S.brick_polytope()
doctest:...: RuntimeWarning: the polytope is build with rational vertices
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 32 vertices

```

          homology.simplicial_complex.SimplicialComplex

```

Fix a Coxeter system (W, S) . The subword complex $SC(Q, w)$ associated to a word $Q \in S^*$ and an element $w \in W$ is the simplicial complex whose ground set is the set of positions in Q and whose facets are complements of sets of positions defining a reduced expression for w .

A subword complex is a shellable sphere if and only if the Demazure product of Q equals w , otherwise it is a shellable ball.

Warning: This implementation only works for groups build using `CoxeterGroup`, and does not work with groups build using `WeylGroup`.

EXAMPLES:

As an example, dual associahedra are subword complexes in type A_{n-1} given by the word $[1, \dots, n, 1, \dots, n, 1, \dots, n-1, \dots, 1, 2, 1]$ and the permutation w_0 .

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w); SC # optional - gap3
Subword complex of type ['A', 2] for Q = (1, 2, 1, 2, 1) and pi = [1, 2, 1]
sage: SC.facets() # optional - gap3
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])

```

```

sage: SC = SubwordComplex([1,2,1,2,1], w); SC
Subword complex of type ['A', 2] for Q = (1, 2, 1, 2, 1) and pi = [1, 2, 1]
sage: SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

```

REFERENCES: [\[KnuMil\]](#), [\[PilStu\]](#)

Element

alias of *SubwordComplexFacet*

barycenter()

Return the barycenter of the brick polytope of *self*.

See also:

brick_polytope()

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2])                                     # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)                         # optional - gap3
sage: SC.barycenter()                                                # optional - gap3
(2/3, 4/3)

sage: W = CoxeterGroup(['A', 2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.barycenter()
(4/3, 8/3)

```

brick_fan()

Return the brick fan of *self*.

It is the normal fan of the brick polytope of *self*. It is formed by the cones generated by the weight configurations of the facets of *self*.

See also:

weight_cone

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2])                                     # optional - gap3
sage: w = W.from_reduced_word([1,2,1])                               # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w)                            # optional - gap3
sage: SC.brick_fan()                                                # optional - gap3
Rational polyhedral fan in 2-d lattice N

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.brick_fan()
Rational polyhedral fan in 2-d lattice N

```

brick_polytope(coefficients=None)

Return the brick polytope of *self*.

This polytope is the convex hull of the brick vectors of *self*.

INPUT:

- *coefficients* – (optional) a list of coefficients used to scale the fundamental weights

See also:

`brick_vectors()`

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0) # optional - gap3
sage: X = SC.brick_polytope(); X # optional - gap3
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

sage: Y = SC.brick_polytope(coefficients=[1,2]); Y # optional - gap3
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

sage: X == Y # optional - gap3
False

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: X = SC.brick_polytope(); X
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

sage: W = ReflectionGroup(['H',3]) # optional - gap3
sage: c = W.index_set(); Q = c + tuple(W.w0.coxeter_sorting_word(c)) #
↪ optional - gap3
sage: SC = SubwordComplex(Q,W.w0) # optional - gap3
sage: SC.brick_polytope() # optional - gap3
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 32 vertices
```

brick_vectors (*coefficients=None*)

Return the list of all brick vectors of facets of self.

INPUT:

- *coefficients* – (optional) a list of coefficients used to scale the fundamental weights

See also:

`brick_vector`

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0) # optional - gap3
sage: SC.brick_vectors() # optional - gap3
[(5/3, 7/3), (5/3, 1/3), (2/3, 7/3), (-1/3, 4/3), (-1/3, 1/3)]
sage: SC.brick_vectors(coefficients=(1,2)) # optional - gap3
[(7/3, 11/3), (7/3, 2/3), (4/3, 11/3), (-2/3, 5/3), (-2/3, 2/3)]

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.brick_vectors()
[(10/3, 14/3), (10/3, 2/3), (4/3, 14/3), (-2/3, 8/3), (-2/3, 2/3)]
sage: SC.brick_vectors(coefficients=(1,2))
[(14/3, 22/3), (14/3, 4/3), (8/3, 22/3), (-4/3, 10/3), (-4/3, 4/3)]
```

cartan_type ()

Return the Cartan type of self.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: SC.cartan_type() # optional - gap3
['A', 2]

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: SC.cartan_type()
['A', 2]

```

cover_relations (*label=False*)

Return the set of cover relations in the associated poset.

INPUT:

- *label* – boolean (default `False`) whether or not to label the cover relations by the position of flip

OUTPUT:

a list of pairs of facets

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0) # optional - gap3
sage: SC.cover_relations() # optional - gap3
[(0, 1), (1, 2)],
[(0, 1), (0, 4)],
[(1, 2), (2, 3)],
[(0, 4), (3, 4)],
[(2, 3), (3, 4)]

sage: W = CoxeterGroup(['A', 2])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0)
sage: SC.cover_relations()
[(0, 1), (1, 2)],
[(0, 1), (0, 4)],
[(1, 2), (2, 3)],
[(0, 4), (3, 4)],
[(2, 3), (3, 4)]

```

dimension ()

Return the dimension of self.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0) # optional - gap3
sage: SC.dimension() # optional - gap3
1

sage: W = CoxeterGroup(['A', 2])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0)
sage: SC.dimension()
1

```

facets ()

Return all facets of self.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w) # optional - gap3
sage: SC.facets() # optional - gap3
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
```

greedy_facet (*side='positive'*)

Return the negative (or positive) greedy facet of self.

This is the lexicographically last (or first) facet of self.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w) # optional - gap3
sage: SC.greedy_facet(side="positive") # optional - gap3
(0, 1)
sage: SC.greedy_facet(side="negative") # optional - gap3
(3, 4)

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.greedy_facet(side="positive")
(0, 1)
sage: SC.greedy_facet(side="negative")
(3, 4)
```

group ()

Return the group associated to self.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w) # optional - gap3
sage: SC.group() # optional - gap3
Irreducible real reflection group of rank 2 and type A2

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.group()
Finite Coxeter group over Integer Ring with Coxeter matrix:
[1 3]
[3 1]
```

increasing_flip_graph (*label=True*)

Return the increasing flip graph of the subword complex.

OUTPUT:

a directed graph

EXAMPLES:

```
sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0) # optional - gap3
sage: SC.increasing_flip_graph() # optional - gap3
Digraph on 5 vertices

sage: W = CoxeterGroup(['A', 2])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0)
sage: SC.increasing_flip_graph()
Digraph on 5 vertices
```

increasing_flip_poset()

Return the increasing flip poset of the subword complex.

OUTPUT:

a poset

EXAMPLES:

```
sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0) # optional - gap3
sage: SC.increasing_flip_poset() # optional - gap3
Finite poset containing 5 elements

sage: W = CoxeterGroup(['A', 2])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0)
sage: SC.increasing_flip_poset()
Finite poset containing 5 elements
```

interval(I, J)

Return the interval [I, J] in the increasing flip graph subword complex.

INPUT:

• I, J – two facets

OUTPUT:

a set of facets

EXAMPLES:

```
sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0) # optional - gap3
sage: F = SC([1, 2]) # optional - gap3
sage: SC.interval(F, F) # optional - gap3
{(1, 2)}

sage: W = CoxeterGroup(['A', 2])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0)
sage: F = SC([1, 2])
sage: SC.interval(F, F)
{(1, 2)}
```

is_ball()

Return True if the subword complex `self` is a ball.

This is the case if and only if it is not a sphere.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 3])           # optional - gap3
sage: w = W.from_reduced_word([2, 3, 2])     # optional - gap3
sage: SC = SubwordComplex([3, 2, 3, 2, 3], w) # optional - gap3
sage: SC.is_ball()                           # optional - gap3
False

sage: SC = SubwordComplex([3, 2, 1, 3, 2, 3], w) # optional - gap3
sage: SC.is_ball()                           # optional - gap3
True

sage: W = CoxeterGroup(['A', 3])
sage: w = W.from_reduced_word([2, 3, 2])
sage: SC = SubwordComplex([3, 2, 3, 2, 3], w)
sage: SC.is_ball()
False

```

is_double_root_free()

Return True if self is double-root-free.

This means that the root configurations of all facets do not contain a root twice.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2])           # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1])     # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: SC.is_double_root_free()               # optional - gap3
True

sage: SC = SubwordComplex([1, 1, 2, 2, 1, 1], w) # optional - gap3
sage: SC.is_double_root_free()               # optional - gap3
True

sage: SC = SubwordComplex([1, 2, 1, 2, 1, 2], w) # optional - gap3
sage: SC.is_double_root_free()               # optional - gap3
False

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: SC.is_double_root_free()
True

```

is_pure()

Return True since all subword complexes are pure.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 3])           # optional - gap3
sage: w = W.from_reduced_word([2, 3, 2])     # optional - gap3
sage: SC = SubwordComplex([3, 2, 3, 2, 3], w) # optional - gap3
sage: SC.is_pure()                           # optional - gap3
True

sage: W = CoxeterGroup(['A', 3])
sage: w = W.from_reduced_word([2, 3, 2])
sage: SC = SubwordComplex([3, 2, 3, 2, 3], w)

```

```
sage: SC.is_pure()
True
```

is_root_independent()

Return True if self is root-independent.

This means that the root configuration of any (or equivalently all) facets is linearly independent.

EXAMPLES:

```
sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0) # optional - gap3
sage: SC.is_root_independent() # optional - gap3
True

sage: SC = SubwordComplex([1, 2, 1, 2, 1, 2], W.w0) # optional - gap3
sage: SC.is_root_independent() # optional - gap3
False

sage: W = CoxeterGroup(['A', 2])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0)
sage: SC.is_root_independent()
True
```

is_sphere()

Return True if the subword complex self is a sphere.

EXAMPLES:

```
sage: W = ReflectionGroup(['A', 3]) # optional - gap3
sage: w = W.from_reduced_word([2, 3, 2]) # optional - gap3
sage: SC = SubwordComplex([3, 2, 3, 2, 3], w) # optional - gap3
sage: SC.is_sphere() # optional - gap3
True

sage: SC = SubwordComplex([3, 2, 1, 3, 2, 3], w) # optional - gap3
sage: SC.is_sphere() # optional - gap3
False

sage: W = CoxeterGroup(['A', 3])
sage: w = W.from_reduced_word([2, 3, 2])
sage: SC = SubwordComplex([3, 2, 3, 2, 3], w)
sage: SC.is_sphere()
True
```

kappa_preimages()

Return a dictionary containing facets of self as keys, and list of elements of self.group() as values.

See also:

[*kappa_preimage*](#)

EXAMPLES:

```
sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: kappa = SC.kappa_preimages() # optional - gap3
sage: for F in SC: print("{} {}".format(F, [w.reduced_word() for w in_
↳ kappa[F]])) # optional - gap3
```

```

(0, 1) [[]]
(0, 4) [[2], [2, 1]]
(1, 2) [[1]]
(2, 3) [[1, 2]]
(3, 4) [[1, 2, 1]]

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: kappa = SC.kappa_preimages()
sage: for F in SC: print("{} {}".format(F, [w.reduced_word() for w in_
↪kappa[F]]))
(0, 1) [[]]
(0, 4) [[2], [2, 1]]
(1, 2) [[1]]
(2, 3) [[1, 2]]
(3, 4) [[1, 2, 1]]

```

minkowski_summand(*i*)

Return the *i* th Minkowski summand of self.

INPUT:

i – an integer defining a position in the word *Q*

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0) # optional - gap3
sage: SC.minkowski_summand(1) # optional - gap3
A 0-dimensional polyhedron in QQ^2 defined as the convex hull of 1 vertex

sage: W = CoxeterGroup(['A', 2])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0)
sage: SC.minkowski_summand(1)
A 0-dimensional polyhedron in QQ^2 defined as the convex hull of 1 vertex

```

pi()

Return the element in the Coxeter group associated to self.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: SC.pi().reduced_word() # optional - gap3
[1, 2, 1]

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: SC.pi().reduced_word()
[1, 2, 1]

```

word()

Return the word in the simple generators associated to self.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: SC.word() # optional - gap3
(1, 2, 1, 2, 1)

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: SC.word()
(1, 2, 1, 2, 1)

```

class sage.combinat.subword_complex.**SubwordComplexFacet** (*parent*, *positions*, *facet_test=True*)

Bases: sage.homology.simplicial_complex.Simplex, sage.structure.element.Element

A facet of a subword complex.

Facets of the subword complex $SC(Q, w)$ are complements of sets of positions in Q defining a reduced expression for w .

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: F = SC[0]; F # optional - gap3
(0, 1)

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: F = SC[0]; F
(0, 1)

```

brick_vector (*coefficients=None*)

Return the brick vector of self.

This is the sum of the weight vectors in the extended weight configuration.

INPUT:

- *coefficients* – (optional) a list of coefficients used to scale the fundamental weights

See also:

[`extended\_weight\_configuration\(\)`](#)

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: F = SC([1, 2]); F # optional - gap3
(1, 2)
sage: F.extended_weight_configuration() # optional - gap3
[(2/3, 1/3), (1/3, 2/3), (-1/3, 1/3), (1/3, 2/3), (-1/3, 1/3)]
sage: F.brick_vector() # optional - gap3
(2/3, 7/3)
sage: F.brick_vector(coefficients=[1, 2]) # optional - gap3

```

```
(4/3, 11/3)

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: F = SC([1, 2])
sage: F.brick_vector()
(4/3, 14/3)
sage: F.brick_vector(coefficients=[1, 2])
(8/3, 22/3)
```

extended_root_configuration()

Return the extended root configuration of `self`.

Let $Q = q_1 \dots q_m \in S^*$ and $w \in W$. The extended root configuration of a facet I of $\mathcal{SC}(Q, w)$ is the sequence $r(I, 1), \dots, r(I, m)$ of roots defined by $r(I, k) = \Pi Q_{[k-1] \setminus I}(\alpha_{q_k})$, where $\Pi Q_{[k-1] \setminus I}$ is the product of the simple reflections q_i for $i \in [k-1] \setminus I$ in this order.

The extended root configuration is used to perform flips efficiently.

See also:

`flip()`

EXAMPLES:

```
sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: F = SC([1, 2]); F # optional - gap3
(1, 2)
sage: F.extended_root_configuration() # optional - gap3
[(1, 0), (1, 1), (-1, 0), (1, 1), (0, 1)]

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: F = SC([1, 2]); F
(1, 2)
sage: F.extended_root_configuration()
[(1, 0), (1, 1), (-1, 0), (1, 1), (0, 1)]
```

extended_weight_configuration(coefficients=None)

Return the extended weight configuration of `self`.

Let $Q = q_1 \dots q_m \in S^*$ and $w \in W$. The extended weight configuration of a facet I of $\mathcal{SC}(Q, w)$ is the sequence $w(I, 1), \dots, w(I, m)$ of weights defined by $w(I, k) = \Pi Q_{[k-1] \setminus I}(\omega_{q_k})$, where $\Pi Q_{[k-1] \setminus I}$ is the product of the simple reflections q_i for $i \in [k-1] \setminus I$ in this order.

The extended weight configuration is used to compute the brick vector.

INPUT:

- `coefficients` – (optional) a list of coefficients used to scale the fundamental weights

See also:

`brick_vector()`

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: F = SC([1, 2]) # optional - gap3
sage: F.extended_weight_configuration() # optional - gap3
[(2/3, 1/3), (1/3, 2/3), (-1/3, 1/3), (1/3, 2/3), (-1/3, 1/3)]
sage: F.extended_weight_configuration(coefficients=(1, 2)) # optional - gap3
[(2/3, 1/3), (2/3, 4/3), (-1/3, 1/3), (2/3, 4/3), (-1/3, 1/3)]

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: F = SC([1, 2])
sage: F.extended_weight_configuration()
[(4/3, 2/3), (2/3, 4/3), (-2/3, 2/3), (2/3, 4/3), (-2/3, 2/3)]
sage: F.extended_weight_configuration(coefficients=(1, 2))
[(4/3, 2/3), (4/3, 8/3), (-2/3, 2/3), (4/3, 8/3), (-2/3, 2/3)]

```

flip (*i*, *return_position=False*)

Return the facet obtained after flipping position *i* in self.

INPUT:

- *i* – position in the word Q (integer).
- *return_position* – boolean (default: False) tells whether the new position should be returned as well.

OUTPUT:

- The new subword complex facet.
- The new position if *return_position* is True.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: F = SC([1, 2]); F # optional - gap3
(1, 2)
sage: F.flip(1) # optional - gap3
(2, 3)
sage: F.flip(1, return_position=True) # optional - gap3
((2, 3), 3)

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: F = SC([1, 2]); F
(1, 2)
sage: F.flip(1)
(2, 3)
sage: F.flip(1, return_position=True)
((2, 3), 3)

```

is_vertex ()

Return True if self is a vertex of the brick polytope of self.parent.

A facet is a vertex of the brick polytope if its root cone is pointed. Note that this property is always satisfied for root-independent subword complexes.

See also:

`root_cone()`

EXAMPLES:

```
sage: W = ReflectionGroup(['A',1]) # optional - gap3
sage: w = W.from_reduced_word([1]) # optional - gap3
sage: SC = SubwordComplex([1,1,1],w) # optional - gap3
sage: F = SC([0,1]); F.is_vertex() # optional - gap3
True
sage: F = SC([0,2]); F.is_vertex() # optional - gap3
False

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1,2,1],w) # optional - gap3
sage: F = SC([0,1,2,3]); F.is_vertex() # optional - gap3
True
sage: F = SC([0,1,2,6]); F.is_vertex() # optional - gap3
False

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1,2,1],w)
sage: F = SC([0,1,2,3]); F.is_vertex()
True
sage: F = SC([0,1,2,6]); F.is_vertex()
False
```

`kappa_preimage()`

Return the fiber of `self` under the κ map.

The κ map sends an element $w \in W$ to the unique facet of $I \in \mathcal{SC}(Q, w)$ such that the root configuration of I is contained in $w(\Phi^+)$. In other words, w is in the preimage of `self` under κ if and only if w^{-1} sends every root in the root configuration to a positive root.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w) # optional - gap3

sage: F = SC([1,2]); F # optional - gap3
(1, 2)
sage: F.kappa_preimage() # optional - gap3
[(1, 4) (2, 3) (5, 6)]

sage: F = SC([0,4]); F # optional - gap3
(0, 4)
sage: F.kappa_preimage() # optional - gap3
[(1, 3) (2, 5) (4, 6), (1, 2, 6) (3, 4, 5)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)

sage: F = SC([1,2]); F
(1, 2)
sage: F.kappa_preimage()
```

```

[
[-1  1]
[ 0  1]
]

sage: F = SC([0,4]); F
(0, 4)
sage: F.kappa_preimage()
[
[ 1  0]  [-1  1]
[ 1 -1], [-1  0]
]

```

plot (*list_colors*=[], *labels*=[], *thickness*=3, *fontsize*=14, *shift*=(0, 0), *compact*=False, *roots*=True, ***args*)

In type *A* or *B*, plot a pseudoline arrangement representing the facet *self*.

Pseudoline arrangements are graphical representations of facets of types *A* or *B* subword complexes.

INPUT:

- *list_colors* – list (default: []) to change the colors of the pseudolines.
- *labels* – list (default: []) to change the labels of the pseudolines.
- *thickness* – integer (default: 3) for the thickness of the pseudolines.
- *fontsize* – integer (default: 14) for the size of the font used for labels.
- *shift* – couple of coordinates (default: (0, 0)) to change the origin.
- *compact* – boolean (default: False) to require a more compact representation.
- *roots* – boolean (default: True) to print the extended root configuration.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w) # optional - gap3
sage: F = SC([1,2]); F.plot() # optional - gap3
Graphics object consisting of 26 graphics primitives

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F.plot()
Graphics object consisting of 26 graphics primitives

sage: W = ReflectionGroup(['B',3]) # optional - gap3
sage: c = W.from_reduced_word([1,2,3]) # optional - gap3
sage: Q = c.reduced_word()*2 + W.w0.coxeter_sorting_word(c) # optional - gap3
sage: SC = SubwordComplex(Q, W.w0) # optional - gap3
sage: F = SC[15]; F.plot() # optional - gap3
Graphics object consisting of 52 graphics primitives

```

REFERENCES: [\[PilStu\]](#)

root_cone ()

Return the polyhedral cone generated by the root configuration of *self*.

See also:

```
root_configuration()
```

EXAMPLES:

```
sage: W = ReflectionGroup(['A', 1]) # optional - gap3
sage: w = W.from_reduced_word([1]) # optional - gap3
sage: SC = SubwordComplex([1, 1, 1], w) # optional - gap3
sage: F = SC([0, 2]); F.root_cone() # optional - gap3
1-d cone in 1-d lattice N

sage: W = CoxeterGroup(['A', 1])
sage: w = W.from_reduced_word([1])
sage: SC = SubwordComplex([1, 1, 1], w)
sage: F = SC([0, 2]); F.root_cone()
1-d cone in 1-d lattice N
```

root_configuration()

Return the root configuration of self.

Let $Q = q_1 \dots q_m \in S^*$ and $w \in W$. The root configuration of a facet $I = [i_1, \dots, i_n]$ of $SC(Q, w)$ is the sequence $r(I, i_1), \dots, r(I, i_n)$ of roots defined by $r(I, k) = \Pi_{Q_{[k-1] \setminus I}}(\alpha_{q_k})$, where $\Pi_{Q_{[k-1] \setminus I}}$ is the product of the simple reflections q_i for $i \in [k-1] \setminus I$ in this order.

EXAMPLES:

```
sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: F = SC([1, 2]); F # optional - gap3
(1, 2)
sage: F.root_configuration() # optional - gap3
[(1, 1), (-1, 0)]

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: F = SC([1, 2]); F
(1, 2)
sage: F.root_configuration() # optional - gap3
[(1, 1), (-1, 0)]
```

show(*kws, **args)

Show the facet self.

See also:

```
plot()
```

EXAMPLES:

```
sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: F = SC([1, 2]); F.show() # optional - gap3
```

upper_root_configuration()

Return the positive roots of the root configuration of self.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: F = SC([1, 2]); F # optional - gap3
(1, 2)
sage: F.root_configuration() # optional - gap3
[(1, 1), (-1, 0)]
sage: F.upper_root_configuration() # optional - gap3
[(1, 0)]

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: F = SC([1, 2]); F
(1, 2)
sage: F.upper_root_configuration()
[(1, 0)]

```

weight_cone()

Return the polyhedral cone generated by the weight configuration of self.

See also:

[`weight\_configuration\(\)`](#)

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: F = SC([1, 2]); F # optional - gap3
(1, 2)
sage: WC = F.weight_cone(); WC # optional - gap3
2-d cone in 2-d lattice N
sage: WC.rays() # optional - gap3
N( 1, 2),
N(-1, 1)
in 2-d lattice N

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: F = SC([1, 2]); F
(1, 2)
sage: WC = F.weight_cone(); WC
2-d cone in 2-d lattice N

```

weight_configuration()

Return the weight configuration of self.

Let $Q = q_1 \dots q_m \in S^*$ and $w \in W$. The weight configuration of a facet $I = [i_1, \dots, i_n]$ of $SC(Q, w)$ is the sequence $w(I, i_1), \dots, w(I, i_n)$ of weights defined by $w(I, k) = \Pi Q_{[k-1] \setminus I}(\omega_{q_k})$, where $\Pi Q_{[k-1] \setminus I}$ is the product of the simple reflections q_i for $i \in [k-1] \setminus I$ in this order.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3

```

```

sage: F = SC([1,2]); F                                     # optional - gap3
(1, 2)
sage: F.weight_configuration()                             # optional - gap3
[(1/3, 2/3), (-1/3, 1/3)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.weight_configuration()
[(2/3, 4/3), (-2/3, 2/3)]

```

5.1.320 Symmetric Group Algebra

`sage.combinat.symmetric_group_algebra.HeckeAlgebraSymmetricGroupT`(R , n , $q=None$)

Return the Hecke algebra of the symmetric group S_n on the T-basis with quantum parameter q over the ring R .

If R is a commutative ring and q is an invertible element of R , and if n is a nonnegative integer, then the Hecke algebra of the symmetric group S_n over R with quantum parameter q is defined as the algebra generated by the generators $T_1, T_2, \dots, T_{n-1}$ with relations

$$T_i T_{i+1} T_i = T_{i+1} T_i T_{i+1}$$

for all $i < n - 1$ (“braid relations”),

$$T_i T_j = T_j T_i$$

for all i and j such that $|i - j| > 1$ (“locality relations”), and

$$T_i^2 = q + (q - 1)T_i$$

for all i (the “quadratic relations”, also known in the form $(T_i + 1)(T_i - q) = 0$). (This is only one of several existing definitions in literature, not all of which are fully equivalent. We are following the conventions of [GS93].) For any permutation $w \in S_n$, we can define an element T_w of this Hecke algebra by setting $T_w = T_{i_1} T_{i_2} \cdots T_{i_k}$, where $w = s_{i_1} s_{i_2} \cdots s_{i_k}$ is a reduced word for w (with s_i meaning the transposition $(i, i + 1)$, and the product of permutations being evaluated by first applying s_{i_k} , then $s_{i_{k-1}}$, etc.). This element is independent of the choice of the reduced decomposition, and can be computed in Sage by calling `H[w]` where `H` is the Hecke algebra and `w` is the permutation.

The Hecke algebra of the symmetric group S_n with quantum parameter q over R can be seen as a deformation of the group algebra RS_n ; indeed, it becomes RS_n when $q = 1$.

Warning: The multiplication on the Hecke algebra of the symmetric group does *not* follow the global option `mult` of the `Permutations` class (see `options()`). It is always as defined above. It does not match the default option (`mult=l2r`) of the symmetric group algebra!

REFERENCES:

EXAMPLES:

```

sage: HeckeAlgebraSymmetricGroupT(QQ, 3)
Hecke algebra of the symmetric group of order 3 on the T basis over Univariate_
↪Polynomial Ring in q over Rational Field

```

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3, 2)
Hecke algebra of the symmetric group of order 3 with q=2 on the T basis over
↪Rational Field
```

The multiplication on the Hecke algebra follows a different convention than the one on the symmetric group algebra does by default:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3([1, 3, 2]) * H3([2, 1, 3])
T[3, 1, 2]
sage: S3 = SymmetricGroupAlgebra(QQ, 3)
sage: S3([1, 3, 2]) * S3([2, 1, 3])
[2, 3, 1]

sage: TestSuite(H3).run()
```

class sage.combinat.symmetric_group_algebra.**HeckeAlgebraSymmetricGroup_generic** (*R*, *n*, *q=None*)
 Bases: *sage.combinat.combinatorial_algebra.CombinatorialAlgebra*

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3, q=1)
Hecke algebra of the symmetric group of order 3 with q=1 on the T basis over
↪Rational Field
```

q()

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3).q()
q
sage: HeckeAlgebraSymmetricGroupT(QQ, 3, 2).q()
2
```

class sage.combinat.symmetric_group_algebra.**HeckeAlgebraSymmetricGroup_t** (*R*, *n*, *q=None*)
 Bases: *sage.combinat.symmetric_group_algebra.HeckeAlgebraSymmetricGroup_generic*

algebra_generators()

Return the generators of the algebra.

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3).algebra_generators()
[T[2, 1, 3], T[1, 3, 2]]
```

jucys_murphy(k)

Return the Jucys-Murphy element J_k of the Hecke algebra.

These Jucys-Murphy elements are defined by

$$J_k = (T_{k-1}T_{k-2} \cdots T_1)(T_1T_2 \cdots T_{k-1}).$$

More explicitly,

$$J_k = q^{k-1} + \sum_{l=1}^{k-1} (q^l - q^{l-1})T_{(l,k)}.$$

For generic q , the J_k generate a maximal commutative sub-algebra of the Hecke algebra.

Warning: The specialization $q = 1$ does *not* map these elements J_k to the Young-Jucys-Murphy elements of the group algebra RS_n . (Instead, it maps the “reduced” Jucys-Murphy elements $(J_k - q^{k-1})/(q-1)$ to the Young-Jucys-Murphy elements of RS_n .)

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: j2 = H3.jucys_murphy(2); j2
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
sage: j3 = H3.jucys_murphy(3); j3
q^2*T[1, 2, 3] + (q^2-q)*T[1, 3, 2] + (q-1)*T[3, 2, 1]
sage: j2*j3 == j3*j2
True
sage: j0 = H3.jucys_murphy(1); j0 == H3.one()
True
sage: H3.jucys_murphy(0)
Traceback (most recent call last):
...
ValueError: k (= 0) must be between 1 and n (= 3)
```

t(i)

Return the element T_i of the Hecke algebra self.

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3.t(1)
T[2, 1, 3]
sage: H3.t(2)
T[1, 3, 2]
sage: H3.t(0)
Traceback (most recent call last):
...
ValueError: i (= 0) must be between 1 and n-1 (= 2)
```

t_action(a, i)

Return the product $T_i \cdot a$.

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: a = H3([2, 1, 3]) + 2*H3([1, 2, 3])
sage: H3.t_action(a, 1)
q*T[1, 2, 3] + (q+1)*T[2, 1, 3]
sage: H3.t(1)*a
q*T[1, 2, 3] + (q+1)*T[2, 1, 3]
```

t_action_on_basis($perm, i$)

Return the product $T_i \cdot T_{perm}$, where $perm$ is a permutation in the symmetric group S_n .

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3.t_action_on_basis(Permutation([2, 1, 3]), 1)
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
```

```

sage: H3.t_action_on_basis(Permutation([1,2,3]), 1)
T[2, 1, 3]
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3, 1)
sage: H3.t_action_on_basis(Permutation([2,1,3]), 1)
T[1, 2, 3]
sage: H3.t_action_on_basis(Permutation([1,3,2]), 2)
T[1, 2, 3]

```

`sage.combinat.symmetric_group_algebra.SymmetricGroupAlgebra(R, W, category=None)`

Return the symmetric group algebra of order W over the ring R .

INPUT:

- W – a symmetric group; alternatively an integer n can be provided, as shorthand for `Permutations(n)`.
- R – a base ring
- `category` – a category (default: the category of W)

This supports several implementations of the symmetric group. At this point this has been tested with $W = \text{Permutations}(n)$ and $W = \text{SymmetricGroup}(n)$.

Warning: Some features are failing in the latter case, in particular if the domain of the symmetric group is not $1, \dots, n$.

Note: The brave can also try setting $W = \text{WeylGroup}(['A', n-1])$, but little support for this currently exists.

EXAMPLES:

```

sage: QS3 = SymmetricGroupAlgebra(QQ, 3); QS3
Symmetric group algebra of order 3 over Rational Field
sage: QS3(1)
[1, 2, 3]
sage: QS3(2)
2*[1, 2, 3]
sage: basis = [QS3(p) for p in Permutations(3)]
sage: a = sum(basis); a
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: a^2
6*[1, 2, 3] + 6*[1, 3, 2] + 6*[2, 1, 3] + 6*[2, 3, 1] + 6*[3, 1, 2] + 6*[3, 2, 1]
sage: a^2 == 6*a
True
sage: b = QS3([3, 1, 2])
sage: b
[3, 1, 2]
sage: b*a
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: b*a == a
True

```

We now construct the symmetric group algebra by providing explicitly the underlying group:

```

sage: SGA = SymmetricGroupAlgebra(QQ, Permutations(4)); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()

```

```

Standard permutations of 4
sage: SGA.an_element()
[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 3*[1, 3, 2, 4] + [4, 1, 2, 3]

sage: SGA = SymmetricGroupAlgebra(QQ, SymmetricGroup(4)); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()
Symmetric group of order 4! as a permutation group
sage: SGA.an_element()
() + 2*(1,2) + 4*(1,2,3,4)

sage: SGA = SymmetricGroupAlgebra(QQ, WeylGroup(["A",3], prefix='s')); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()
Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space)
sage: SGA.an_element()
2*s1*s2*s3*s2*s1 + 3*s1*s2*s3*s1 + s1*s2*s3 + 1

```

The preferred way to construct the symmetric group algebra is to go through the usual algebra method:

```

sage: SGA = Permutations(3).algebra(QQ); SGA
Symmetric group algebra of order 3 over Rational Field
sage: SGA.group()
Standard permutations of 3

sage: SGA = SymmetricGroup(3).algebra(QQ); SGA
Symmetric group algebra of order 3 over Rational Field
sage: SGA.group()
Symmetric group of order 3! as a permutation group

```

The canonical embedding from the symmetric group algebra of order n to the symmetric group algebra of order $p > n$ is available as a coercion:

```

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.coerce_map_from(QS3)
Generic morphism:
  From: Symmetric group algebra of order 3 over Rational Field
  To:   Symmetric group algebra of order 4 over Rational Field

sage: x3 = QS3([3,1,2]) + 2 * QS3([2,3,1]); x3
2*[2, 3, 1] + [3, 1, 2]
sage: QS4(x3)
2*[2, 3, 1, 4] + [3, 1, 2, 4]

```

This allows for mixed expressions:

```

sage: x4 = 3*QS4([3, 1, 4, 2])
sage: x3 + x4
2*[2, 3, 1, 4] + [3, 1, 2, 4] + 3*[3, 1, 4, 2]

sage: QS0 = SymmetricGroupAlgebra(QQ, 0)
sage: QS1 = SymmetricGroupAlgebra(QQ, 1)
sage: x0 = QS0([])
sage: x1 = QS1([1])
sage: x0 * x1
[1]
sage: x3 - (2*x0 + x1) - x4

```

```
-3*[1, 2, 3, 4] + 2*[2, 3, 1, 4] + [3, 1, 2, 4] - 3*[3, 1, 4, 2]
```

Caveat: to achieve this, constructing `SymmetricGroupAlgebra(QQ, 10)` currently triggers the construction of all symmetric group algebras of smaller order. Is this a feature we really want to have?

Warning: The semantics of multiplication in symmetric group algebras with index set `Permutations(n)` is determined by the order in which permutations are multiplied, which currently defaults to “in such a way that multiplication is associative with permutations acting on integers from the right”, but can be changed to the opposite order at runtime by setting the global variable `Permutations.options['mult']` (see `sage.combinat.permutation.Permutations.options()`). On the other hand, the semantics of multiplication in symmetric group algebras with index set `SymmetricGroup(n)` does not depend on this global variable. (This has the awkward consequence that the coercions between these two sorts of symmetric group algebras do not respect multiplication when this global variable is set to 'r2l'.) In view of this, it is recommended that code not rely on the usual multiplication function, but rather use the methods `left_action_product()` and `right_action_product()` for multiplying permutations (these methods don't depend on the setting). See [trac ticket #14885](#) for more information.

We conclude by constructing the algebra of the symmetric group as a monoid algebra:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3, category=Monoids())
sage: QS3.category()
Category of finite dimensional monoid algebras over Rational Field
sage: TestSuite(QS3).run()
```

class `sage.combinat.symmetric_group_algebra.SymmetricGroupAlgebra_n(R, W, category)`

Bases: `sage.algebras.group_algebra.GroupAlgebra_class`

algebra_generators()

Return generators of this group algebra (as algebra) as a list of permutations.

The generators used for the group algebra of S_n are the transposition $(2, 1)$ and the n -cycle $(1, 2, \dots, n)$, unless $n \leq 1$ (in which case no generators are needed).

EXAMPLES:

```
sage: SymmetricGroupAlgebra(ZZ, 5).algebra_generators()
Family ([2, 1, 3, 4, 5], [2, 3, 4, 5, 1])

sage: SymmetricGroupAlgebra(QQ, 0).algebra_generators()
Family ()

sage: SymmetricGroupAlgebra(QQ, 1).algebra_generators()
Family ()
```

antipode(x)

Return the image of the element x of `self` under the antipode of the Hopf algebra `self` (where the comultiplication is the usual one on a group algebra).

Explicitly, this is obtained by replacing each permutation σ by σ^{-1} in x while keeping all coefficients as they are.

EXAMPLES:

```
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.antipode(2 * QS4([1, 3, 4, 2]) - 1/2 * QS4([1, 4, 2, 3]))
```

```

-1/2*[1, 3, 4, 2] + 2*[1, 4, 2, 3]
sage: all( QS4.antipode(QS4(p)) == QS4(p.inverse())
....:     for p in Permutations(4) )
True

sage: ZS3 = SymmetricGroupAlgebra(ZZ, 3)
sage: ZS3.antipode(ZS3.zero())
0
sage: ZS3.antipode(-ZS3(Permutation([2, 3, 1])))
-[3, 1, 2]

```

binary_unshuffle_sum(*k*)

Return the k -th binary unshuffle sum in the group algebra `self`.

The k -th binary unshuffle sum in the symmetric group algebra RS_n over a ring R is defined as the sum of all permutations $\sigma \in S_n$ satisfying $\sigma(1) < \sigma(2) < \dots < \sigma(k)$ and $\sigma(k+1) < \sigma(k+2) < \dots < \sigma(n)$.

This element has the property that, if it is denoted by t_k , and if the k -th semi-RSW element (see [semi_rsw_element\(\)](#)) is denoted by s_k , then $s_k S(t_k)$ and $t_k S(s_k)$ both equal the k -th Reiner-Saliola-Welker shuffling element of RS_n (see [rsw_shuffling_element\(\)](#)).

The k -th binary unshuffle sum is the image of the complete non-commutative symmetric function $S^{(k, n-k)}$ in the ring of non-commutative symmetric functions under the canonical projection on the symmetric group algebra (through the descent algebra).

EXAMPLES:

The binary unshuffle sums on QS_3 :

```

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.binary_unshuffle_sum(0)
[1, 2, 3]
sage: QS3.binary_unshuffle_sum(1)
[1, 2, 3] + [2, 1, 3] + [3, 1, 2]
sage: QS3.binary_unshuffle_sum(2)
[1, 2, 3] + [1, 3, 2] + [2, 3, 1]
sage: QS3.binary_unshuffle_sum(3)
[1, 2, 3]
sage: QS3.binary_unshuffle_sum(4)
0

```

Let us check the relation with the k -th Reiner-Saliola-Welker shuffling element stated in the docstring:

```

sage: def test_rsw(n):
....:     ZSn = SymmetricGroupAlgebra(ZZ, n)
....:     for k in range(1, n):
....:         a = ZSn.semi_rsw_element(k)
....:         b = ZSn.binary_unshuffle_sum(k)
....:         c = ZSn.left_action_product(a, ZSn.antipode(b))
....:         d = ZSn.left_action_product(b, ZSn.antipode(a))
....:         e = ZSn.rsw_shuffling_element(k)
....:         if c != e or d != e:
....:             return False
....:     return True
sage: test_rsw(3)
True
sage: test_rsw(4) # long time
True

```

```
sage: test_rsw(5) # long time
True
```

Let us also check the statement about the complete non-commutative symmetric function:

```
sage: def test_rsw_ncsf(n):
....:     ZSn = SymmetricGroupAlgebra(ZZ, n)
....:     NSym = NonCommutativeSymmetricFunctions(ZZ)
....:     S = NSym.S()
....:     for k in range(1, n):
....:         a = S(Composition([k, n-k])).to_symmetric_group_algebra()
....:         if a != ZSn.binary_unshuffle_sum(k):
....:             return False
....:     return True
sage: test_rsw_ncsf(3)
True
sage: test_rsw_ncsf(4)
True
sage: test_rsw_ncsf(5) # long time
True
```

canonical_embedding (*other*)

Return the canonical coercion of `self` into a symmetric group algebra `other`.

INPUT:

- `other` – a symmetric group algebra with order p satisfying $p \geq n$, where n is the order of `self`, over a ground ring into which the ground ring of `self` coerces.

EXAMPLES:

```
sage: QS2 = SymmetricGroupAlgebra(QQ, 2)
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: phi = QS2.canonical_embedding(QS4); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Rational Field
  To:   Symmetric group algebra of order 4 over Rational Field

sage: x = QS2([2,1]) + 2 * QS2([1,2])
sage: phi(x)
2*[1, 2, 3, 4] + [2, 1, 3, 4]

sage: loads(dumps(phi))
Generic morphism:
  From: Symmetric group algebra of order 2 over Rational Field
  To:   Symmetric group algebra of order 4 over Rational Field

sage: ZS2 = SymmetricGroupAlgebra(ZZ, 2)
sage: phi = ZS2.canonical_embedding(QS4); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Integer Ring
  To:   Symmetric group algebra of order 4 over Rational Field

sage: phi = ZS2.canonical_embedding(QS2); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Integer Ring
  To:   Symmetric group algebra of order 2 over Rational Field

sage: QS4.canonical_embedding(QS2)
```

```

Traceback (most recent call last):
...
ValueError: There is no canonical embedding from Symmetric group
algebra of order 2 over Rational Field to Symmetric group
algebra of order 4 over Rational Field

sage: QS4g = SymmetricGroup(4).algebra(QQ)
sage: QS4.canonical_embedding(QS4g) (QS4([1, 3, 2, 4]))
(2, 3)
sage: QS4g.canonical_embedding(QS4) (QS4g((2, 3)))
[1, 3, 2, 4]
sage: ZS2.canonical_embedding(QS4g) (ZS2([2, 1]))
(1, 2)
sage: ZS2g = SymmetricGroup(2).algebra(ZZ)
sage: ZS2g.canonical_embedding(QS4) (ZS2g((1, 2)))
[2, 1, 3, 4]

```

cpi(*p*)

Return the centrally primitive idempotent for the symmetric group of order n corresponding to the irreducible representation indexed by the partition *p*.

EXAMPLES:

```

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.cpi([2, 1])
2/3*[1, 2, 3] - 1/3*[2, 3, 1] - 1/3*[3, 1, 2]
sage: QS3.cpi([3])
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2]
↪ + 1/6*[3, 2, 1]
sage: QS3.cpi([1, 1, 1])
1/6*[1, 2, 3] - 1/6*[1, 3, 2] - 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2]
↪ - 1/6*[3, 2, 1]

sage: QS0 = SymmetricGroupAlgebra(QQ, 0)
sage: QS0.cpi(Partition([]))
[]

```

cpis()

Return a list of the centrally primitive idempotents of *self*.

EXAMPLES:

```

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: a = QS3.cpis()
sage: a[0] # [3]
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2]
↪ + 1/6*[3, 2, 1]
sage: a[1] # [2, 1]
2/3*[1, 2, 3] - 1/3*[2, 3, 1] - 1/3*[3, 1, 2]

```

dft (*form*='seminormal', *mult*='l2r')

Return the discrete Fourier transform for *self*.

INPUT:

- *mult* – string (default: *l2r*). If set to *r2l*, this causes the method to use the antipodes (*antipode*()) of the seminormal basis instead of the seminormal basis.

EXAMPLES:

```

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.dft()
[ 1 1 1 1 1 1]
[ 1 1/2 -1 -1/2 -1/2 1/2]
[ 0 3/4 0 3/4 -3/4 -3/4]
[ 0 1 0 -1 1 -1]
[ 1 -1/2 1 -1/2 -1/2 -1/2]
[ 1 -1 -1 1 1 -1]

```

epsilon_ik (*itab*, *ktab*, *star=0*, *mult='l2r'*)

Return the seminormal basis element of `self` corresponding to the pair of tableaux `itab` and `ktab` (or restrictions of these tableaux, if the optional variable `star` is set).

INPUT:

- `itab`, `ktab` – two standard tableaux of size n .
- `star` – integer (default: 0).
- `mult` – string (default: `l2r`). If set to `r2l`, this causes the method to return the antipode (`antipode()`) of $\epsilon(I, K)$ instead of $\epsilon(I, K)$ itself.

OUTPUT:

The element $\epsilon(I, K)$, where I and K are the tableaux obtained by removing all entries higher than $n - \text{star}$ from `itab` and `ktab`, respectively. Here, we are using the notations from `seminormal_basis()`.

EXAMPLES:

```

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: a = QS3.epsilon_ik([[1,2,3]], [[1,2,3]]); a
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2]
↪ + 1/6*[3, 2, 1]
sage: QS3.dft()*vector(a)
(1, 0, 0, 0, 0, 0)
sage: a = QS3.epsilon_ik([[1,2],[3]], [[1,2],[3]]); a
1/3*[1, 2, 3] - 1/6*[1, 3, 2] + 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2]
↪ - 1/6*[3, 2, 1]
sage: QS3.dft()*vector(a)
(0, 0, 0, 0, 1, 0)

```

Let us take some properties of the seminormal basis listed in the docstring of `seminormal_basis()`, and verify them on the situation of S_3 .

First, check the formula

$$\epsilon(T) = \frac{1}{K_{\text{sh}(T)}} \epsilon(\overline{T}) e(T) \epsilon(\overline{T}).$$

In fact:

```

sage: from sage.combinat.symmetric_group_algebra import e
sage: def test_sn1(n):
....:     QSn = SymmetricGroupAlgebra(QQ, n)
....:     QSn1 = SymmetricGroupAlgebra(QQ, n - 1)
....:     for T in StandardTableaux(n):
....:         TT = T.restrict(n-1)
....:         eTT = QSn1.epsilon_ik(TT, TT)
....:         eT = QSn.epsilon_ik(T, T)
....:         kT = prod(T.shape().hooks())
....:         if kT * eT != eTT * e(T) * eTT:

```

```

....:         return False
....:         return True
sage: test_sn1(3)
True
sage: test_sn1(4)    # long time
True

```

Next, we check the identity

$$\epsilon(T, S) = \frac{1}{\kappa_{\text{sh}(T)}} \epsilon(\overline{S}) \pi_{T, S} e(T) \epsilon(\overline{T})$$

which we used to define $\epsilon(T, S)$. In fact:

```

sage: from sage.combinat.symmetric_group_algebra import e
sage: def test_sn2(n):
....:     QSn = SymmetricGroupAlgebra(QQ, n)
....:     mul = QSn.left_action_product
....:     QSn1 = SymmetricGroupAlgebra(QQ, n - 1)
....:     for lam in Partitions(n):
....:         k = prod(lam.hooks())
....:         for T in StandardTableaux(lam):
....:             for S in StandardTableaux(lam):
....:                 TT = T.restrict(n-1)
....:                 SS = S.restrict(n-1)
....:                 eTT = QSn1.epsilon_ik(TT, TT)
....:                 eSS = QSn1.epsilon_ik(SS, SS)
....:                 eTS = QSn.epsilon_ik(T, S)
....:                 piTS = [0] * n
....:                 for (i, j) in T.cells():
....:                     piTS[T[i][j] - 1] = S[i][j]
....:                 piTS = QSn(Permutation(piTS))
....:                 if k * eTS != mul(mul(eSS, piTS), mul(e(T), eTT)):
....:                     return False
....:     return True
sage: test_sn2(3)
True
sage: test_sn2(4)    # long time
True

```

Let us finally check the identity

$$\epsilon(T, S) \epsilon(U, V) = \delta_{T, V} \epsilon(U, S)$$

In fact:

```

sage: def test_sn3(lam):
....:     n = lam.size()
....:     QSn = SymmetricGroupAlgebra(QQ, n)
....:     mul = QSn.left_action_product
....:     for T in StandardTableaux(lam):
....:         for S in StandardTableaux(lam):
....:             for U in StandardTableaux(lam):
....:                 for V in StandardTableaux(lam):
....:                     lhs = mul(QSn.epsilon_ik(T, S), QSn.epsilon_ik(U,
↪ V))
....:                     if T == V:
....:                         rhs = QSn.epsilon_ik(U, S)

```

```

.....:         else:
.....:             rhs = QSn.zero()
.....:             if rhs != lhs:
.....:                 return False
.....:         return True
sage: all( test_sn3(lam) for lam in Partitions(3) )
True
sage: all( test_sn3(lam) for lam in Partitions(4) )    # long time
True

```

jucys_murphy (*k*)

Return the Jucys-Murphy element J_k (also known as a Young-Jucys-Murphy element) for the symmetric group algebra `self`.

The Jucys-Murphy element J_k in the symmetric group algebra RS_n is defined for every $k \in \{1, 2, \dots, n\}$ by

$$J_k = (1, k) + (2, k) + \cdots + (k-1, k) \in RS_n,$$

where the addends are transpositions in S_n (regarded as elements of RS_n). We note that there is not a dependence on n , so it is often suppressed in the notation.

EXAMPLES:

```

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.jucys_murphy(1)
0
sage: QS3.jucys_murphy(2)
[2, 1, 3]
sage: QS3.jucys_murphy(3)
[1, 3, 2] + [3, 2, 1]

sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: j3 = QS4.jucys_murphy(3); j3
[1, 3, 2, 4] + [3, 2, 1, 4]
sage: j4 = QS4.jucys_murphy(4); j4
[1, 2, 4, 3] + [1, 4, 3, 2] + [4, 2, 3, 1]
sage: j3*j4 == j4*j3
True

sage: QS5 = SymmetricGroupAlgebra(QQ, 5)
sage: QS5.jucys_murphy(4)
[1, 2, 4, 3, 5] + [1, 4, 3, 2, 5] + [4, 2, 3, 1, 5]

```

left_action_product (*left, right*)

Return the product of two elements `left` and `right` of `self`, where multiplication is defined in such a way that for two permutations p and q , the product pq is the permutation obtained by first applying q and then applying p . This definition of multiplication is tailored to make multiplication of permutations associative with their action on numbers if permutations are to act on numbers from the left.

EXAMPLES:

```

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: p1 = Permutation([2, 1, 3])
sage: p2 = Permutation([3, 1, 2])
sage: QS3.left_action_product(QS3(p1), QS3(p2))
[3, 2, 1]
sage: x = QS3([1, 2, 3]) - 2*QS3([1, 3, 2])

```

```

sage: y = 1/2 * QS3([3, 1, 2]) + 3*QS3([1, 2, 3])
sage: QS3.left_action_product(x, y)
3*[1, 2, 3] - 6*[1, 3, 2] - [2, 1, 3] + 1/2*[3, 1, 2]
sage: QS3.left_action_product(0, x)
0

```

The method coerces its input into the algebra `self`:

```

sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.left_action_product(QS3([1, 2, 3]), QS3([2, 1, 3]))
[2, 1, 3, 4]
sage: QS4.left_action_product(1, Permutation([4, 1, 2, 3]))
[4, 1, 2, 3]

```

Warning: Note that coercion presently works from permutations of n into the n -th symmetric group algebra, and also from all smaller symmetric group algebras into the n -th symmetric group algebra, but not from permutations of integers smaller than n into the n -th symmetric group algebra.

monomial_from_smaller_permutation (*permutation*)

Convert *permutation* into a permutation, possibly extending it to the appropriate size, and return the corresponding basis element of `self`.

EXAMPLES:

```

sage: QS5 = SymmetricGroupAlgebra(QQ, 5)
sage: QS5.monomial_from_smaller_permutation([])
[1, 2, 3, 4, 5]
sage: QS5.monomial_from_smaller_permutation(Permutation([3, 1, 2]))
[3, 1, 2, 4, 5]
sage: QS5.monomial_from_smaller_permutation([5, 3, 4, 1, 2])
[5, 3, 4, 1, 2]
sage: QS5.monomial_from_smaller_permutation(SymmetricGroup(2)((1, 2)))
[2, 1, 3, 4, 5]

sage: QS5g = SymmetricGroup(5).algebra(QQ)
sage: QS5g.monomial_from_smaller_permutation([2, 1])
(1, 2)

```

retract_direct_product (*f*, *m*)

Return the direct-product retract of the element $f \in RS_n$ to RS_m , where $m \leq n$ (and where RS_n is `self`).

If m is a nonnegative integer less or equal to n , then the direct-product retract from S_n to S_m is defined as an R -linear map $S_n \rightarrow S_m$ which sends every permutation $p \in S_n$ to

$$\begin{cases} \text{dret}(p) & \text{if } \text{dret}(p) \text{ is defined;} \\ 0 & \text{otherwise} \end{cases}.$$

Here $\text{dret}(p)$ denotes the direct-product retract of the permutation p to S_m , which is defined in `retract_direct_product()`.

EXAMPLES:

```

sage: SGA3 = SymmetricGroupAlgebra(QQ, 3)
sage: SGA3.retract_direct_product(2*SGA3([1, 2, 3]) - 4*SGA3([2, 1, 3]) +
↪ 7*SGA3([1, 3, 2]), 2)

```

```

2*[1, 2] - 4*[2, 1]
sage: SGA3.retract_direct_product(2*SGA3([1, 3, 2]) - 5*SGA3([2, 3, 1]), 2)
0

sage: SGA5 = SymmetricGroupAlgebra(QQ, 5)
sage: SGA5.retract_direct_product(8*SGA5([1, 4, 2, 5, 3]) - 6*SGA5([1, 3, 2, 5, 4]) +
↪ 11*SGA5([3, 2, 1, 4, 5]), 4)
11*[3, 2, 1, 4]
sage: SGA5.retract_direct_product(8*SGA5([1, 4, 2, 5, 3]) - 6*SGA5([1, 3, 2, 5, 4]) +
↪ 11*SGA5([3, 2, 1, 4, 5]), 3)
-6*[1, 3, 2] + 11*[3, 2, 1]
sage: SGA5.retract_direct_product(8*SGA5([1, 4, 2, 5, 3]) - 6*SGA5([1, 3, 2, 5, 4]) +
↪ 11*SGA5([3, 2, 1, 4, 5]), 2)
0
sage: SGA5.retract_direct_product(8*SGA5([1, 4, 2, 5, 3]) - 6*SGA5([1, 3, 2, 5, 4]) +
↪ 11*SGA5([3, 2, 1, 4, 5]), 1)
2*[1]

sage: SGA5.retract_direct_product(8*SGA5([1, 2, 3, 4, 5]) - 6*SGA5([1, 3, 2, 4, 5]),
↪ 3)
8*[1, 2, 3] - 6*[1, 3, 2]
sage: SGA5.retract_direct_product(8*SGA5([1, 2, 3, 4, 5]) - 6*SGA5([1, 3, 2, 4, 5]),
↪ 1)
2*[1]
sage: SGA5.retract_direct_product(8*SGA5([1, 2, 3, 4, 5]) - 6*SGA5([1, 3, 2, 4, 5]),
↪ 0)
2*[]

```

See also:

`retract_plain()`, `retract_okounkov_vershik()`

retract_okounkov_vershik(f, m)

Return the Okounkov-Vershik retract of the element $f \in RS_n$ to RS_m , where $m \leq n$ (and where RS_n is self).

If m is a nonnegative integer less or equal to n , then the Okounkov-Vershik retract from S_n to S_m is defined as an R -linear map $S_n \rightarrow S_m$ which sends every permutation $p \in S_n$ to the Okounkov-Vershik retract of the permutation p to S_m , which is defined in `retract_okounkov_vershik()`.

EXAMPLES:

```

sage: SGA3 = SymmetricGroupAlgebra(QQ, 3)
sage: SGA3.retract_okounkov_vershik(2*SGA3([1, 2, 3]) - 4*SGA3([2, 1, 3]) +
↪ 7*SGA3([1, 3, 2]), 2)
9*[1, 2] - 4*[2, 1]
sage: SGA3.retract_okounkov_vershik(2*SGA3([1, 3, 2]) - 5*SGA3([2, 3, 1]), 2)

`retract_plain()`, `retract_direct_product()`

retract_plain(f, m)

Return the plain retract of the element $f \in RS_n$ to RS_m , where $m \leq n$ (and where RS_n is self).

If m is a nonnegative integer less or equal to n , then the plain retract from S_n to S_m is defined as an R -linear map $S_n \rightarrow S_m$ which sends every permutation $p \in S_n$ to

$$\begin{cases} \text{pret}(p) & \text{if } \text{pret}(p) \text{ is defined;} \\ 0 & \text{otherwise} \end{cases}.$$

Here $\text{pret}(p)$ denotes the plain retract of the permutation p to S_m , which is defined in `retract_plain()`.

EXAMPLES:

```

sage: SGA3 = SymmetricGroupAlgebra(QQ, 3)
sage: SGA3.retract_plain(2*SGA3([1,2,3]) - 4*SGA3([2,1,3]) + 7*SGA3([1,3,2]),
↪ 2)
2*[1, 2] - 4*[2, 1]
sage: SGA3.retract_plain(2*SGA3([1,3,2]) - 5*SGA3([2,3,1]), 2)
0

sage: SGA5 = SymmetricGroupAlgebra(QQ, 5)
sage: SGA5.retract_plain(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) +
↪ 11*SGA5([3,2,1,4,5]), 4)
11*[3, 2, 1, 4]
sage: SGA5.retract_plain(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) +
↪ 11*SGA5([3,2,1,4,5]), 3)
11*[3, 2, 1]
sage: SGA5.retract_plain(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) +
↪ 11*SGA5([3,2,1,4,5]), 2)
0
sage: SGA5.retract_plain(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) +
↪ 11*SGA5([3,2,1,4,5]), 1)
0

sage: SGA5.retract_plain(8*SGA5([1,2,3,4,5]) - 6*SGA5([1,3,2,4,5]), 3)
8*[1, 2, 3] - 6*[1, 3, 2]
sage: SGA5.retract_plain(8*SGA5([1,2,3,4,5]) - 6*SGA5([1,3,2,4,5]), 1)
8*[1]
sage: SGA5.retract_plain(8*SGA5([1,2,3,4,5]) - 6*SGA5([1,3,2,4,5]), 0)
8*[]

```

See also:

`retract_direct_product()`, `retract_okounkov_vershik()`

right_action_product (*left*, *right*)

Return the product of two elements *left* and *right* of *self*, where multiplication is defined in such a way that for two permutations p and q , the product pq is the permutation obtained by first applying p and then applying q . This definition of multiplication is tailored to make multiplication of permutations associative with their action on numbers if permutations are to act on numbers from the right.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: p1 = Permutation([2, 1, 3])
sage: p2 = Permutation([3, 1, 2])
sage: QS3.right_action_product(QS3(p1), QS3(p2))
[1, 3, 2]
sage: x = QS3([1, 2, 3]) - 2*QS3([1, 3, 2])
sage: y = 1/2 * QS3([3, 1, 2]) + 3*QS3([1, 2, 3])
sage: QS3.right_action_product(x, y)
3*[1, 2, 3] - 6*[1, 3, 2] + 1/2*[3, 1, 2] - [3, 2, 1]
sage: QS3.right_action_product(0, x)
0
```

The method coerces its input into the algebra *self*:

```
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.right_action_product(QS3([1, 2, 3]), QS3([2, 1, 3]))
[2, 1, 3, 4]
sage: QS4.right_action_product(1, Permutation([4, 1, 2, 3]))
[4, 1, 2, 3]
```

Warning: Note that coercion presently works from permutations of n into the n -th symmetric group algebra, and also from all smaller symmetric group algebras into the n -th symmetric group algebra, but not from permutations of integers smaller than n into the n -th symmetric group algebra.

rsw_shuffling_element (k)

Return the k -th Reiner-Saliola-Welker shuffling element in the group algebra *self*.

The k -th Reiner-Saliola-Welker shuffling element in the symmetric group algebra RS_n over a ring R is defined as the sum $\sum_{\sigma \in S_n} \text{noninv}_k(\sigma) \cdot \sigma$, where for every permutation σ , the number $\text{noninv}_k(\sigma)$ is the number of all k -noninversions of σ (that is, the number of all k -element subsets of $\{1, 2, \dots, n\}$ on which σ restricts to a strictly increasing map). See `sage.combinat.permutation.number_of_noninversions()` for the `noninv` map.

This element is more or less the operator $\nu_{k, 1^{n-k}}$ introduced in [RSW2011]; more precisely, $\nu_{k, 1^{n-k}}$ is the left multiplication by this element.

It is a nontrivial theorem (Theorem 1.1 in [RSW2011]) that the operators $\nu_{k, 1^{n-k}}$ (for fixed n and varying k) pairwise commute. It is a conjecture (Conjecture 1.2 in [RSW2011]) that all their eigenvalues are integers (which, in light of their commutativity and easily established symmetry, yields that they can be simultaneously diagonalized over $\mathbb{Q}$ with only integer eigenvalues).

EXAMPLES:

The Reiner-Saliola-Welker shuffling elements on QS_3 :

```

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.rsw_shuffling_element(0)
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: QS3.rsw_shuffling_element(1)
3*[1, 2, 3] + 3*[1, 3, 2] + 3*[2, 1, 3] + 3*[2, 3, 1] + 3*[3, 1, 2] + 3*[3, 2,
↪ 1]
sage: QS3.rsw_shuffling_element(2)
3*[1, 2, 3] + 2*[1, 3, 2] + 2*[2, 1, 3] + [2, 3, 1] + [3, 1, 2]
sage: QS3.rsw_shuffling_element(3)
[1, 2, 3]
sage: QS3.rsw_shuffling_element(4)
0

```

Checking the commutativity of Reiner-Saliola-Welker shuffling elements (we leave out the ones for which it is trivial):

```

sage: def test_rsw_comm(n):
....:     QSn = SymmetricGroupAlgebra(QQ, n)
....:     rsws = [QSn.rsw_shuffling_element(k) for k in range(2, n)]
....:     return all( all( rsws[i] * rsws[j] == rsws[j] * rsws[i]
....:                     for j in range(i) )
....:                 for i in range(len(rsws)) )
sage: test_rsw_comm(3)
True
sage: test_rsw_comm(4)
True
sage: test_rsw_comm(5)    # long time
True

```

Note: For large k (relative to n), it might be faster to call `QSn.left_action_product(QSn.semi_rsw_element(k), QSn.antipode(binary_unshuffle_sum(k)))` than `QSn.rsw_shuffling_element(n)`.

See also:

`semi_rsw_element()`, `binary_unshuffle_sum()`

semi_rsw_element(k)

Return the k -th semi-RSW element in the group algebra `self`.

The k -th semi-RSW element in the symmetric group algebra RS_n over a ring R is defined as the sum of all permutations $\sigma \in S_n$ satisfying $\sigma(1) < \sigma(2) < \dots < \sigma(k)$.

This element has the property that, if it is denoted by s_k , then $s_k S(s_k)$ is $(n-k)!$ times the k -th Reiner-Saliola-Welker shuffling element of RS_n (see `rsw_shuffling_element()`). Here, S denotes the antipode of the group algebra RS_n .

The k -th semi-RSW element is the image of the complete non-commutative symmetric function $S^{(k, 1^{n-k})}$ in the ring of non-commutative symmetric functions under the canonical projection on the symmetric group algebra (through the descent algebra).

EXAMPLES:

The semi-RSW elements on QS_3 :

```

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.semi_rsw_element(0)
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]

```

```

sage: QS3.semi_rsw_element(1)
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: QS3.semi_rsw_element(2)
[1, 2, 3] + [1, 3, 2] + [2, 3, 1]
sage: QS3.semi_rsw_element(3)
[1, 2, 3]
sage: QS3.semi_rsw_element(4)
0

```

Let us check the relation with the k -th Reiner-Saliola-Welker shuffling element stated in the docstring:

```

sage: def test_rsw(n):
....:     ZSn = SymmetricGroupAlgebra(ZZ, n)
....:     for k in range(1, n):
....:         a = ZSn.semi_rsw_element(k)
....:         b = ZSn.left_action_product(a, ZSn.antipode(a))
....:         if factorial(n-k) * ZSn.rsw_shuffling_element(k) != b:
....:             return False
....:     return True
sage: test_rsw(3)
True
sage: test_rsw(4)
True
sage: test_rsw(5) # long time
True

```

Let us also check the statement about the complete non-commutative symmetric function:

```

sage: def test_rsw_ncsf(n):
....:     ZSn = SymmetricGroupAlgebra(ZZ, n)
....:     NSym = NonCommutativeSymmetricFunctions(ZZ)
....:     S = NSym.S()
....:     for k in range(1, n):
....:         a = S(Composition([k] + [1]*(n-k))).to_symmetric_group_algebra()
....:         if a != ZSn.semi_rsw_element(k):
....:             return False
....:     return True
sage: test_rsw_ncsf(3)
True
sage: test_rsw_ncsf(4)
True
sage: test_rsw_ncsf(5) # long time
True

```

seminormal_basis (*mult='l2r'*)

Return a list of the seminormal basis elements of `self`.

The seminormal basis of a symmetric group algebra is defined as follows:

Let n be a nonnegative integer. Let R be a $\mathbf{Q}$ -algebra. In the following, we will use the “left action” convention for multiplying permutations. This means that for all permutations p and q in S_n , the product pq is defined in such a way that $(pq)(i) = p(q(i))$ for each $i \in \{1, 2, \dots, n\}$ (this is the same convention as in `left_action_product()`, but not the default semantics of the `*` operator on permutations in Sage). Thus, for instance, s_2s_1 is the permutation obtained by first transposing 1 with 2 and then transposing 2 with 3 (where $s_i = (i, i+1)$).

For every partition λ of n , let

$$\kappa_\lambda = \frac{n!}{f^\lambda}$$

where f^λ is the number of standard Young tableaux of shape λ . Note that κ_λ is an integer, namely the product of all hook lengths of λ (by the hook length formula). In Sage, this integer can be computed by using `sage.combinat.symmetric_group_algebra.kappa()`.

Let T be a standard tableau of size n .

Let $a(T)$ denote the formal sum (in RS_n) of all permutations in S_n which stabilize the rows of T (as sets), i. e., which map each entry i of T to an entry in the same row as i . (See `sage.combinat.symmetric_group_algebra.a()` for an implementation of this.)

Let $b(T)$ denote the signed formal sum (in RS_n) of all permutations in S_n which stabilize the columns of T (as sets). Here, “signed” means that each permutation is multiplied with its sign. (This is implemented in `sage.combinat.symmetric_group_algebra.b()`.)

Define an element $e(T)$ of RS_n to be $a(T)b(T)$. (This is implemented in `sage.combinat.symmetric_group_algebra.e()` for $R = \mathbf{Q}$.)

Let $\text{sh}(T)$ denote the shape of T . (See `shape()`.)

Let $\bar{T}$ denote the standard tableau of size $n - 1$ obtained by removing the letter n (along with its cell) from T (if $n \geq 1$).

Now, we define an element $\epsilon(T)$ of RS_n . We define it by induction on the size n of T , so we set $\epsilon(\emptyset) = 1$ and only need to define $\epsilon(T)$ for $n \geq 1$, assuming that $\epsilon(\bar{T})$ is already defined. We do this by setting

$$\epsilon(T) = \frac{1}{\kappa_{\text{sh}(T)}} \epsilon(\bar{T}) e(T) \epsilon(\bar{T}).$$

This element $\epsilon(T)$ is implemented as `sage.combinat.symmetric_group_algebra.epsilon()` for $R = \mathbf{Q}$, but it is also a particular case of the elements $\epsilon(T, S)$ defined below.

Now let S be a further tableau of the same shape as T (possibly equal to T). Let $\pi_{T,S}$ denote the permutation in S_n such that applying this permutation to the entries of T yields the tableau S . Define an element $\epsilon(T, S)$ of RS_n by

$$\epsilon(T, S) = \frac{1}{\kappa_{\text{sh}(T)}} \epsilon(\bar{S}) \pi_{T,S} e(T) \epsilon(\bar{T}) = \frac{1}{\kappa_{\text{sh}(T)}} \epsilon(\bar{S}) a(S) \pi_{T,S} b(T) \epsilon(\bar{T}).$$

This element $\epsilon(T, S)$ is called *Young’s seminormal unit corresponding to the bitableau (T, S)* , and is the return value of `epsilon_ik()` applied to T and S . Note that $\epsilon(T, T) = \epsilon(T)$.

If we let λ run through all partitions of n , and (T, S) run through all pairs of tableaux of shape λ , then the elements $\epsilon(T, S)$ form a basis of RS_n . This basis is called *Young’s seminormal basis* and has the properties that

$$\epsilon(T, S) \epsilon(U, V) = \delta_{T,V} \epsilon(U, S)$$

(where δ stands for the Kronecker delta).

Warning: Because of our convention, we are multiplying our elements in reverse of those given in some papers, for example [Ram1997]. Using the other convention of multiplying permutations, we would instead have $\epsilon(U, V) \epsilon(T, S) = \delta_{T,V} \epsilon(U, S)$.

In other words, Young's seminormal basis consists of the matrix units in a (particular) Artin-Wedderburn decomposition of RS_n into a direct product of matrix algebras over $\mathbf{Q}$.

The output of `seminormal_basis()` is a list of all elements of the seminormal basis of `self`.

INPUT:

- `mult` – string (default: 'l2r'). If set to 'r2l', this causes the method to return the list of the antipodes (`antipode()`) of all $\epsilon(T, S)$ instead of the $\epsilon(T, S)$ themselves.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.seminormal_basis()
[1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2]
↪ 2] + 1/6*[3, 2, 1],
1/3*[1, 2, 3] + 1/6*[1, 3, 2] - 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2]
↪ + 1/6*[3, 2, 1],
1/3*[1, 3, 2] + 1/3*[2, 3, 1] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1],
1/4*[1, 3, 2] - 1/4*[2, 3, 1] + 1/4*[3, 1, 2] - 1/4*[3, 2, 1],
1/3*[1, 2, 3] - 1/6*[1, 3, 2] + 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2]
↪ - 1/6*[3, 2, 1],
1/6*[1, 2, 3] - 1/6*[1, 3, 2] - 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2]
↪ - 1/6*[3, 2, 1]]
```

REFERENCES:

`sage.combinat.symmetric_group_algebra.a` (`tableau`, `star=0`, `base_ring=Rational Field`)

The row projection operator corresponding to the Young tableau `tableau` (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

This is the sum (in the group algebra of the relevant symmetric group over $\mathbf{Q}$) of all the permutations which preserve the rows of `tableau`. It is called a_{tableau} in [ETRT], Section 4.2.

REFERENCES:

INPUT:

- `tableau` – Young tableau which contains every integer from 1 to its size precisely once.
- `star` – nonnegative integer (default: 0). When this optional variable is set, the method computes not the row projection operator of `tableau`, but the row projection operator of the restriction of `tableau` to the entries `1, 2, ..., tableau.size() - star` instead.
- `base_ring` – commutative ring (default: $\mathbf{QQ}$). When this optional variable is set, the row projection operator is computed over a user-determined base ring instead of $\mathbf{Q}$. (Note that symmetric group algebras currently don't preserve coercion, so e. g. a symmetric group algebra over $\mathbf{Z}$ does not coerce into the corresponding one over $\mathbf{Q}$; so convert manually or choose your base rings wisely!)

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import a
sage: a([[1, 2]])
[1, 2] + [2, 1]
sage: a([[1], [2]])
[1, 2]
sage: a([])
[]
sage: a([[1, 5], [2, 3], [4]])
[1, 2, 3, 4, 5] + [1, 3, 2, 4, 5] + [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
sage: a([[1, 4], [2, 3]], base_ring=ZZ)
[1, 2, 3, 4] + [1, 3, 2, 4] + [4, 2, 3, 1] + [4, 3, 2, 1]
```

`sage.combinat.symmetric_group_algebra.b(tableau, star=0, base_ring=Rational Field)`

The column projection operator corresponding to the Young tableau `tableau` (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

This is the signed sum (in the group algebra of the relevant symmetric group over $\mathbf{Q}$) of all the permutations which preserve the column of `tableau` (where the signs are the usual signs of the permutations). It is called b_{tableau} in [EtRT], Section 4.2.

INPUT:

- `tableau` – Young tableau which contains every integer from 1 to its size precisely once.
- `star` – nonnegative integer (default: 0). When this optional variable is set, the method computes not the column projection operator of `tableau`, but the column projection operator of the restriction of `tableau` to the entries `1, 2, ..., tableau.size() - star` instead.
- `base_ring` – commutative ring (default: $\mathbf{QQ}$). When this optional variable is set, the column projection operator is computed over a user-determined base ring instead of $\mathbf{Q}$. (Note that symmetric group algebras currently don't preserve coercion, so e. g. a symmetric group algebra over $\mathbf{Z}$ does not coerce into the corresponding one over $\mathbf{Q}$; so convert manually or choose your base rings wisely!)

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import b
sage: b([[1,2]])
[1, 2]
sage: b([[1],[2]])
[1, 2] - [2, 1]
sage: b([])
[]
sage: b([[1, 2, 4], [5, 3]])
[1, 2, 3, 4, 5] - [1, 3, 2, 4, 5] - [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
sage: b([[1, 4], [2, 3]], base_ring=ZZ)
[1, 2, 3, 4] - [1, 2, 4, 3] - [2, 1, 3, 4] + [2, 1, 4, 3]
sage: b([[1, 4], [2, 3]], base_ring=Integers(5))
[1, 2, 3, 4] + 4*[1, 2, 4, 3] + 4*[2, 1, 3, 4] + [2, 1, 4, 3]
```

With the `l2r` setting for multiplication, the unnormalized Young symmetrizer `e(tableau)` should be the product `b(tableau) * a(tableau)` for every `tableau`. Let us check this on the standard tableaux of size 5:

```
sage: from sage.combinat.symmetric_group_algebra import a, b, e
sage: all( e(t) == b(t) * a(t) for t in StandardTableaux(5) )
True
```

`sage.combinat.symmetric_group_algebra.e(tableau, star=0)`

The unnormalized Young projection operator corresponding to the Young tableau `tableau` (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

If n is a nonnegative integer, and T is a Young tableau containing every integer from 1 to n exactly once, then the unnormalized Young projection operator $e(T)$ is defined by

$$e(T) = a(T)b(T) \in \mathbf{Q}S_n,$$

where $a(T) \in \mathbf{Q}S_n$ is the sum of all permutations in S_n which fix the rows of T (as sets), and $b(T) \in \mathbf{Q}S_n$ is the signed sum of all permutations in S_n which fix the columns of T (as sets). Here, “signed” means that each permutation is multiplied with its sign; and the product on the group S_n is defined in such a way that $(pq)(i) = p(q(i))$ for any permutations p and q and any $1 \leq i \leq n$.

Note that the definition of $e(T)$ is not uniform across literature. Others define it as $b(T)a(T)$ instead, or include certain scalar factors (we do not, whence “unnormalized”).

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e
sage: e([[1, 2]])
[1, 2] + [2, 1]
sage: e([[1], [2]])
[1, 2] - [2, 1]
sage: e([])
[]
```

There are differing conventions for the order of the symmetrizers and antisymmetrizers. This example illustrates our conventions:

```
sage: e([[1, 2], [3]])
[1, 2, 3] + [2, 1, 3] - [3, 1, 2] - [3, 2, 1]
```

To obtain the product $b(T)a(T)$, one has to take the antipode of this:

```
sage: QS3 = parent(e([[1, 2], [3]]))
sage: QS3.antipode(e([[1, 2], [3]]))
[1, 2, 3] + [2, 1, 3] - [2, 3, 1] - [3, 2, 1]
```

See also:

`e_hat()`

`sage.combinat.symmetric_group_algebra.e_hat(tab, star=0)`

The Young projection operator corresponding to the Young tableau `tab` (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard). This is an idempotent in the rational group algebra.

If n is a nonnegative integer, and T is a Young tableau containing every integer from 1 to n exactly once, then the Young projection operator $\hat{e}(T)$ is defined by

$$\hat{e}(T) = \frac{1}{\kappa_\lambda} a(T)b(T) \in \mathbf{Q}S_n,$$

where λ is the shape of T , where κ_λ is $n!$ divided by the number of standard tableaux of shape λ , where $a(T) \in \mathbf{Q}S_n$ is the sum of all permutations in S_n which fix the rows of T (as sets), and where $b(T) \in \mathbf{Q}S_n$ is the signed sum of all permutations in S_n which fix the columns of T (as sets). Here, “signed” means that each permutation is multiplied with its sign; and the product on the group S_n is defined in such a way that $(pq)(i) = p(q(i))$ for any permutations p and q and any $1 \leq i \leq n$.

Note that the definition of $\hat{e}(T)$ is not uniform across literature. Others define it as $\frac{1}{\kappa_\lambda} b(T)a(T)$ instead.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e_hat
sage: e_hat([[1, 2, 3]])
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] + 1/
↪ 6*[3, 2, 1]
sage: e_hat([[1], [2]])
1/2*[1, 2] - 1/2*[2, 1]
```

There are differing conventions for the order of the symmetrizers and antisymmetrizers. This example illustrates our conventions:

```
sage: e_hat([[1,2],[3]])
1/3*[1, 2, 3] + 1/3*[2, 1, 3] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1]
```

See also:

`e()`

`sage.combinat.symmetric_group_algebra.e_ik(itab, ktab, star=0)`

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e_ik
sage: e_ik([[1,2,3]], [[1,2,3]])
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: e_ik([[1,2,3]], [[1,2,3]], star=1)
[1, 2] + [2, 1]
```

`sage.combinat.symmetric_group_algebra.epsilon(tab, star=0)`

The (T, T) -th element of the seminormal basis of the group algebra $\mathbb{Q}[S_n]$, where T is the tableau `tab` (with its `star` highest entries removed if the optional variable `star` is set).

See the docstring of `seminormal_basis()` for the notation used herein.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import epsilon
sage: epsilon([[1,2]])
1/2*[1, 2] + 1/2*[2, 1]
sage: epsilon([[1],[2]])
1/2*[1, 2] - 1/2*[2, 1]
```

`sage.combinat.symmetric_group_algebra.epsilon_ik(itab, ktab, star=0)`

Return the seminormal basis element of the symmetric group algebra $\mathbb{Q}S_n$ corresponding to the pair of tableaux `itab` and `ktab` (or restrictions of these tableaux, if the optional variable `star` is set).

INPUT:

- `itab, ktab` – two standard tableaux of same size.
- `star` – integer (default: 0).

OUTPUT:

The element $\epsilon(I, K) \in \mathbb{Q}S_n$, where I and K are the tableaux obtained by removing all entries higher than $n - \text{star}$ from `itab` and `ktab`, respectively (where n is the size of `itab` and `ktab`). Here, we are using the notations from `seminormal_basis()`.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import epsilon_ik
sage: epsilon_ik([[1,2],[3]], [[1,3],[2]])
1/4*[1, 3, 2] - 1/4*[2, 3, 1] + 1/4*[3, 1, 2] - 1/4*[3, 2, 1]
sage: epsilon_ik([[1,2],[3]], [[1,3],[2]], star=1)
Traceback (most recent call last):
...
ValueError: the two tableaux must be of the same shape
```

`sage.combinat.symmetric_group_algebra.kappa(alpha)`

Return κ_α , which is $n!$ divided by the number of standard tableaux of shape α (where α is a partition of n).

INPUT:

- `alpha` – integer partition (can be encoded as a list).

OUTPUT:

The factorial of the size of `alpha`, divided by the number of standard tableaux of shape `alpha`. Equivalently, the product of all hook lengths of `alpha`.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import kappa
sage: kappa(Partition([2,1]))
3
sage: kappa([2,1])
3
```

`sage.combinat.symmetric_group_algebra.pi_ik(itab, ktab)`

Return the permutation p which sends every entry of the tableau `itab` to the respective entry of the tableau `ktab`, as an element of the corresponding symmetric group algebra.

This assumes that `itab` and `ktab` are tableaux (possibly given just as lists of lists) of the same shape.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import pi_ik
sage: pi_ik([[1,3],[2]], [[1,2],[3]])
[1, 3, 2]
```

`sage.combinat.symmetric_group_algebra.seminormal_test(n)`

Run a variety of tests to verify that the construction of the seminormal basis works as desired. The numbers appearing are results in James and Kerber's 'Representation Theory of the Symmetric Group' [[JamesKerber](#)].

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import seminormal_test
sage: seminormal_test(3)
True
```

5.1.321 Representations of the Symmetric Group

Todo

- construct the product of two irreducible representations.
- implement Induction/Restriction of representations.

Warning: This code uses a different convention than in Sagan's book "The Symmetric Group"

```
class sage.combinat.symmetric_group_representations.SpechtRepresentation(partition,
                                                                           ring=None,
                                                                           cache_matrices=True)
    Bases: sage.combinat.symmetric_group_representations.
            SymmetricGroupRepresentation_generic_class
```

An irreducible representation of the symmetric group corresponding to `partition`.

For more information, see the documentation for `SymmetricGroupRepresentation()`.

EXAMPLES:

```

sage: spc = SymmetricGroupRepresentation([3])
sage: spc([3,2,1])
[1]
sage: spc == loads(dumps(spc))
True

sage: spc = SymmetricGroupRepresentation([3], cache_matrices=False)
sage: spc([3,2,1])
[1]
sage: spc == loads(dumps(spc))
True

```

representation_matrix(*permutation*)

Returns the matrix representing the permutation in this irreducible representation.

Note: This method caches the results.

EXAMPLES:

```

sage: spc = SymmetricGroupRepresentation([3,1], 'specht')
sage: spc.representation_matrix(Permutation([2,1,3,4]))
[ 0 -1  0]
[-1  0  0]
[ 0  0  1]
sage: spc.representation_matrix(Permutation([3,2,1,4]))
[0 0 1]
[0 1 0]
[1 0 0]

```

scalar_product(*u*, *v*)

Return 0 if $u+v$ is not a permutation, and the signature of the permutation otherwise.

This is the scalar product of a vertex u of the underlying Yang-Baxter graph with the vertex v in the ‘dual’ Yang-Baxter graph.

EXAMPLES:

```

sage: spc = SymmetricGroupRepresentation([3,2], 'specht')
sage: spc.scalar_product((1,0,2,1,0), (0,3,0,3,0))
-1
sage: spc.scalar_product((1,0,2,1,0), (3,0,0,3,0))
0

```

scalar_product_matrix(*permutation=None*)

Return the scalar product matrix corresponding to permutation.

The entries are given by the scalar products of u and $\text{permutation.action}(v)$, where u is a vertex in the underlying Yang-Baxter graph and v is a vertex in the dual graph.

EXAMPLES:

```

sage: spc = SymmetricGroupRepresentation([3,1], 'specht')
sage: spc.scalar_product_matrix()
[ 1  0  0]
[ 0 -1  0]
[ 0  0  1]

```

```
class sage.combinat.symmetric_group_representations.SpechtRepresentations(n,
                                                                    ring=None,
                                                                    cache_matrices=True)
```

Bases: `sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations_class`

Irreducible representations of the symmetric group.

See the documentation for `SymmetricGroupRepresentations()` for more information.

EXAMPLES:

```
sage: snorm = SymmetricGroupRepresentations(3, "seminormal")
sage: snorm == loads(dumps(snorm))
True
```

object_class

alias of `SpechtRepresentation`

```
sage.combinat.symmetric_group_representations.SymmetricGroupRepresentation(partition,
im-
ple-
men-
ta-
tion='specht',
ring=None,
cache_matrices=True)
```

The irreducible representation of the symmetric group corresponding to `partition`.

INPUT:

- `partition` – a partition of a positive integer
- **implementation** – string (default: "specht"), one of:
 - "seminormal" - for Young's seminormal representation
 - "orthogonal" - for Young's orthogonal representation
 - "specht" - for Specht's representation
- `ring` – the ring over which the representation is defined.
- `cache_matrices` – boolean (default: True) if True, then any representation matrices that are computed are cached.

EXAMPLES:

Young's orthogonal representation: the matrices are orthogonal.

```
sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal"); orth
Orthogonal representation of the symmetric group corresponding to [2, 1]
sage: all(a*a.transpose() == a.parent().identity_matrix() for a in orth)
True
```

```
sage: orth = SymmetricGroupRepresentation([3,2], "orthogonal"); orth
Orthogonal representation of the symmetric group corresponding to [3, 2]
sage: orth([2,1,3,4,5])
[ 1  0  0  0  0]
[ 0  1  0  0  0]
[ 0  0 -1  0  0]
[ 0  0  0  1  0]
[ 0  0  0  0 -1]
```

```

sage: orth([1,3,2,4,5])
[
  1      0      0      0      0
  0      -1/2  1/2*sqrt(3)  0      0
  0      1/2*sqrt(3)  1/2      0      0
  0      0      0      -1/2  1/2*sqrt(3)
  0      0      0      1/2*sqrt(3)  1/2
sage: orth([1,2,4,3,5])
[
  -1/3  2/3*sqrt(2)      0      0      0
  2/3*sqrt(2)      1/3      0      0      0
  0      0      1      0      0
  0      0      0      1      0
  0      0      0      0      -1]

```

The Specht Representation:

```

sage: spc = SymmetricGroupRepresentation([3,2], "specht")
sage: spc.scalar_product_matrix(Permutation([1,2,3,4,5]))
[ 1  0  0  0  0]
[ 0 -1  0  0  0]
[ 0  0  1  0  0]
[ 0  0  0  1  0]
[-1  0  0  0 -1]
sage: spc.scalar_product_matrix(Permutation([5,4,3,2,1]))
[ 1 -1  0  1  0]
[ 0  0  1  0 -1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[-1  0  0  0 -1]
sage: spc([5,4,3,2,1])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
sage: spc.verify_representation()
True

```

By default, any representation matrices that are computed are cached:

```

sage: spc = SymmetricGroupRepresentation([3,2], "specht")
sage: spc([5,4,3,2,1])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
sage: spc._cache__representation_matrix
{((([5, 4, 3, 2, 1]),), ()): [ 1 -1  0  1  0]
 [ 0  0 -1  0  1]
 [ 0  0  0 -1  1]
 [ 0  1 -1 -1  1]
 [ 0  1  0 -1  1]}

```

This can be turned off with the keyword `cache_matrices`:

```

sage: spc = SymmetricGroupRepresentation([3,2], "specht", cache_matrices=False)
sage: spc([5,4,3,2,1])
[ 1 -1  0  1  0]

```

```
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
sage: hasattr(spc, '_cache__representation_matrix')
False
```

Note: The implementation is based on the paper [\[Las\]](#).

REFERENCES:

AUTHORS:

•Franco Saliola (2009-04-23)

class sage.combinat.symmetric_group_representations.SymmetricGroupRepresentation_generic_class

Bases: sage.structure.sage_object.SageObject

Generic methods for a representation of the symmetric group.

to_character()

Return the character of the representation.

EXAMPLES:

The trivial character:

```
sage: rho = SymmetricGroupRepresentation([3])
sage: chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
sage: chi.values()
[1, 1, 1]
sage: all(chi(g) == 1 for g in SymmetricGroup(3))
True
```

The sign character:

```
sage: rho = SymmetricGroupRepresentation([1,1,1])
sage: chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
sage: chi.values()
[1, -1, 1]
sage: all(chi(g) == g.sign() for g in SymmetricGroup(3))
True
```

The defining representation:

```
sage: triv = SymmetricGroupRepresentation([4])
sage: hook = SymmetricGroupRepresentation([3,1])
sage: def_rep = lambda p : triv(p).block_sum(hook(p)).trace()
sage: list(map(def_rep, Permutations(4)))
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 1, 1, 2, 0, 0]
sage: [p.to_matrix().trace() for p in Permutations(4)]
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]
```

verify_representation()

Verify the representation: tests that the images of the simple transpositions are involutions and tests that the braid relations hold.

EXAMPLES:

```
sage: spc = SymmetricGroupRepresentation([1,1,1])
sage: spc.verify_representation()
True
sage: spc = SymmetricGroupRepresentation([4,2,1])
sage: spc.verify_representation()
True
```

```
sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations(n,
im-
ple-
men-
ta-
tion='specht',
ring=None,
cache_matrices=True)
```

Irreducible representations of the symmetric group.

INPUT:

- **n** – positive integer
- **implementation** – string (default: "specht"), one of:
 - "seminormal" - for Young's seminormal representation
 - "orthogonal" - for Young's orthogonal representation
 - "specht" - for Specht's representation
- **ring** – the ring over which the representation is defined.
- **cache_matrices** – boolean (default: True) if True, then any representation matrices that are computed are cached.

EXAMPLES:

Young's orthogonal representation: the matrices are orthogonal.

```
sage: orth = SymmetricGroupRepresentations(3, "orthogonal"); orth
Orthogonal representations of the symmetric group of order 3! over Symbolic Ring
sage: orth.list()
[Orthogonal representation of the symmetric group corresponding to [3],
↪Orthogonal representation of the symmetric group corresponding to [2, 1],
↪Orthogonal representation of the symmetric group corresponding to [1, 1, 1]]
sage: orth([2,1])([1,2,3])
[1 0]
[0 1]
```

Young's seminormal representation.

```
sage: snorm = SymmetricGroupRepresentations(3, "seminormal"); snorm
Seminormal representations of the symmetric group of order 3! over Rational Field
sage: sgn = snorm([1,1,1]); sgn
Seminormal representation of the symmetric group corresponding to [1, 1, 1]
sage: list(map(sgn, Permutations(3)))
[[1], [-1], [-1], [1], [1], [-1]]
```

The Specht Representation.

```
sage: spc = SymmetricGroupRepresentations(5, "specht"); spc
Specht representations of the symmetric group of order 5! over Integer Ring
sage: spc([3,2])([5,4,3,2,1])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
```

Note: The implementation is based on the paper [\[Las\]](#).

AUTHORS:

•Franco Saliola (2009-04-23)

```
class sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations_class(n,
                                                                                          ring=None,
                                                                                          cache_matrices=True)
```

Bases: `sage.combinat.combinat.CombinatorialClass`

Generic methods for the CombinatorialClass of irreducible representations of the symmetric group.

```
class sage.combinat.symmetric_group_representations.YoungRepresentation_Orthogonal(partition,
                                                                                      ring=None,
                                                                                      cache_matrices=True)
```

Bases: `sage.combinat.symmetric_group_representations.YoungRepresentation_generic`

An irreducible representation of the symmetric group corresponding to partition.

For more information, see the documentation for `SymmetricGroupRepresentation()`.

EXAMPLES:

```
sage: spc = SymmetricGroupRepresentation([3])
sage: spc([3,2,1])
[1]
sage: spc == loads(dumps(spc))
True

sage: spc = SymmetricGroupRepresentation([3], cache_matrices=False)
sage: spc([3,2,1])
[1]
sage: spc == loads(dumps(spc))
True
```

```
class sage.combinat.symmetric_group_representations.YoungRepresentation_Seminormal(partition,
                                                                                      ring=None,
                                                                                      cache_matrices=True)
```

Bases: `sage.combinat.symmetric_group_representations.YoungRepresentation_generic`

An irreducible representation of the symmetric group corresponding to partition.

For more information, see the documentation for `SymmetricGroupRepresentation()`.

EXAMPLES:

```

sage: spc = SymmetricGroupRepresentation([3])
sage: spc([3,2,1])
[1]
sage: spc == loads(dumps(spc))
True

sage: spc = SymmetricGroupRepresentation([3], cache_matrices=False)
sage: spc([3,2,1])
[1]
sage: spc == loads(dumps(spc))
True

```

class `sage.combinat.symmetric_group_representations.YoungRepresentation_generic` (*partition*, *ring=None*, *cache_matrices=True*)

Bases: `sage.combinat.symmetric_group_representations.SymmetricGroupRepresentation_generic_class`

Generic methods for Young's representations of the symmetric group.

representation_matrix (*permutation*)

Return the matrix representing permutation.

EXAMPLES:

```

sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal")
sage: orth.representation_matrix(Permutation([2,1,3]))
[ 1  0]
[ 0 -1]
sage: orth.representation_matrix(Permutation([1,3,2]))
[ -1/2  1/2*sqrt(3)]
[ 1/2*sqrt(3)  1/2]

```

```

sage: norm = SymmetricGroupRepresentation([2,1], "seminormal")
sage: p = PermutationGroupElement([2,1,3])
sage: norm.representation_matrix(p)
[ 1  0]
[ 0 -1]
sage: p = PermutationGroupElement([1,3,2])
sage: norm.representation_matrix(p)
[-1/2  3/2]
[ 1/2  1/2]

```

representation_matrix_for_simple_transposition (*i*)

Return the matrix representing the transposition that swaps *i* and *i*+1.

EXAMPLES:

```

sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal")
sage: orth.representation_matrix_for_simple_transposition(1)
[ 1  0]
[ 0 -1]
sage: orth.representation_matrix_for_simple_transposition(2)
[ -1/2  1/2*sqrt(3)]
[ 1/2*sqrt(3)  1/2]

sage: norm = SymmetricGroupRepresentation([2,1], "seminormal")
sage: norm.representation_matrix_for_simple_transposition(1)
[ 1  0]

```

```
[ 0 -1]
sage: norm.representation_matrix_for_simple_transposition(2)
[-1/2  3/2]
[ 1/2  1/2]
```

class sage.combinat.symmetric_group_representations.**YoungRepresentations_Orthogonal**(*n*,
ring=None,
cache_matrix=True)

Bases: `sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations_class`

Irreducible representations of the symmetric group.

See the documentation for `SymmetricGroupRepresentations()` for more information.

EXAMPLES:

```
sage: snorm = SymmetricGroupRepresentations(3, "seminormal")
sage: snorm == loads(dumps(snorm))
True
```

object_class

alias of `YoungRepresentation_Orthogonal`

class sage.combinat.symmetric_group_representations.**YoungRepresentations_Seminormal**(*n*,
ring=None,
cache_matrix=True)

Bases: `sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations_class`

Irreducible representations of the symmetric group.

See the documentation for `SymmetricGroupRepresentations()` for more information.

EXAMPLES:

```
sage: snorm = SymmetricGroupRepresentations(3, "seminormal")
sage: snorm == loads(dumps(snorm))
True
```

object_class

alias of `YoungRepresentation_Seminormal`

sage.combinat.symmetric_group_representations.**partition_to_vector_of_contents**(*partition*,
re-verse=False)

Returns the “vector of contents” associated to partition.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_representations import partition_to_
      ↪vector_of_contents
sage: partition_to_vector_of_contents([3,2])
(0, 1, 2, -1, 0)
```

5.1.322 Tableaux

AUTHORS:

- Mike Hansen (2007): initial version

- Jason Bandlow (2011): updated to use Parent/Element model, and many minor fixes
- Andrew Mathas (2012-13): completed the transition to the parent/element model begun by Jason Bandlow
- Travis Scrimshaw (11-22-2012): Added tuple options, changed **katabolism** to **catabolism**. Cleaned up documentation.

This file consists of the following major classes:

Element classes:

- *SemistandardTableaux_size_inf*
- *SemistandardTableaux_size_weight*
- *SemistandardTableaux_shape*
- *SemistandardTableaux_shape_inf*
- *SemistandardTableaux_shape_weight*
- *StandardTableaux_all* (facade class)
- *StandardTableaux_size*
- *StandardTableaux_shape*

For display options, see *Tableaux.options()*.

Todo

- Move methods that only apply to semistandard tableaux from tableau to semistandard tableau
 - Copy/move functionality to skew tableaux
 - Add a class for tableaux of a given shape (eg *Tableaux_shape*)
-

class `sage.combinat.tableau.SemistandardTableau` (*parent*, *t*)

Bases: *sage.combinat.tableau.Tableau*

A class to model a semistandard tableau.

INPUT:

- `t` – a tableau, a list of iterables, or an empty list

OUTPUT:

- A `SemistandardTableau` object constructed from `t`.

A semistandard tableau is a tableau whose entries are positive integers, which are weakly increasing in rows and strictly increasing down columns.

EXAMPLES:

```
sage: t = SemistandardTableau([[1,2,3],[2,3]]); t
[[1, 2, 3], [2, 3]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty print
1 2 3
2 3
sage: t = Tableau([[1,2],[2]])
sage: s = SemistandardTableau(t); s
[[1, 2], [2]]
sage: SemistandardTableau([]) # The empty tableau
[]
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a `SemistandardTableau` from the appropriate `Parent` object:

```
sage: SST = SemistandardTableaux()
sage: SST([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

See also:

- [`Tableaux`](#)
- [`Tableau`](#)
- [`SemistandardTableaux`](#)
- [`StandardTableaux`](#)
- [`StandardTableau`](#)

class `sage.combinat.tableau.SemistandardTableaux` (***kws*)

Bases: [`sage.combinat.tableau.Tableaux`](#)

A factory class for the various classes of semistandard tableaux.

INPUT:

Keyword arguments:

- `size` – The size of the tableaux
- `shape` – The shape of the tableaux
- `eval` – The weight (also called content or evaluation) of the tableaux
- `max_entry` – A maximum entry for the tableaux. This can be a positive integer or infinity (`oo`). If `size` or `shape` are specified, `max_entry` defaults to be `size` or the size of `shape`.

Positional arguments:

- The first argument is interpreted as either `size` or `shape` according to whether it is an integer or a partition
- The second keyword argument will always be interpreted as `eval`

OUTPUT:

- The appropriate class, after checking basic consistency tests. (For example, specifying `eval` implies a value for *max_{entry}*).

A semistandard tableau is a tableau whose entries are positive integers, which are weakly increasing in rows and strictly increasing down columns. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

Classes of semistandard tableaux can be iterated over if and only if there is some restriction.

EXAMPLES:

```
sage: SST = SemistandardTableaux([2,1]); SST
Semistandard tableaux of shape [2, 1] and maximum entry 3
sage: SST.list()
[[[1, 1], [2]],
 [1, 1], [3]],
 [[1, 2], [2]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[1, 3], [3]],
 [[2, 2], [3]],
 [[2, 3], [3]]]

sage: SST = SemistandardTableaux(3); SST
Semistandard tableaux of size 3 and maximum entry 3
sage: SST.list()
[[[1, 1, 1]],
 [1, 1, 2]],
 [1, 1, 3]],
 [1, 2, 2]],
 [1, 2, 3]],
 [1, 3, 3]],
 [2, 2, 2]],
 [2, 2, 3]],
 [2, 3, 3]],
 [3, 3, 3]],
 [[1, 1], [2]],
 [[1, 1], [3]],
 [[1, 2], [2]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[1, 3], [3]],
 [[2, 2], [3]],
 [[2, 3], [3]],
 [[1], [2], [3]]]

sage: SST = SemistandardTableaux(3, max_entry=2); SST
Semistandard tableaux of size 3 and maximum entry 2
sage: SST.list()
[[[1, 1, 1]],
 [1, 1, 2]],
 [1, 2, 2]],
 [2, 2, 2]],
```

```

[[1, 1], [2]],
[[1, 2], [2]]]

sage: SST = SemistandardTableaux(3, max_entry=oo); SST
Semistandard tableaux of size 3
sage: SST[123]
[[3, 4], [6]]

sage: SemistandardTableaux(max_entry=2)[11]
[[1, 1], [2]]

sage: SemistandardTableaux()[0]
[]

```

See also:

- [Tableaux](#)
- [Tableau](#)
- [SemistandardTableau](#)
- [StandardTableaux](#)
- [StandardTableau](#)

Element

alias of [SemistandardTableau](#)

class `sage.combinat.tableau.SemistandardTableaux_all(max_entry=None)`
 Bases: `sage.combinat.tableau.SemistandardTableaux`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`
 All semistandard tableaux.

Warning: Input is not checked; please use [SemistandardTableaux](#) to ensure the options are properly parsed.

list()

class `sage.combinat.tableau.SemistandardTableaux_shape(p, max_entry=None)`
 Bases: `sage.combinat.tableau.SemistandardTableaux`

Semistandard tableaux of fixed shape p with a given max entry.

A semistandard tableau with max entry i is required to have all its entries less or equal to i . It is not required to actually contain an entry i .

INPUT:

- p – A partition
- `max_entry` – The max entry; defaults to the size of p .

Warning: Input is not checked; please use [SemistandardTableaux](#) to ensure the options are properly parsed.

cardinality (*algorithm*='hook')

Return the cardinality of `self`.

INPUT:

• *algorithm* – (default: 'hook') any one of the following:

- 'hook' – use Stanley's hook length formula
- 'sum' – sum over the compositions of `max_entry` the number of semistandard tableau with shape and given weight vector

This is computed using *Stanley's hook length formula*:

$$f_{\lambda} = \prod_{u \in \lambda} \frac{n + c(u)}{h(u)}.$$

where n is the `max_entry`, $c(u)$ is the content of u , and $h(u)$ is the hook length of u . See [Sta-EC2] Corollary 7.21.4.

EXAMPLES:

```
sage: SemistandardTableaux([2,1]).cardinality()
8
sage: SemistandardTableaux([2,2,1]).cardinality()
75
sage: SymmetricFunctions(QQ).schur()([2,2,1]).expand(5)(1,1,1,1,1) # cross_
↪check
75
sage: SemistandardTableaux([5]).cardinality()
126
sage: SemistandardTableaux([3,2,1]).cardinality()
896
sage: SemistandardTableaux([3,2,1], max_entry=7).cardinality()
2352
sage: SemistandardTableaux([6,5,4,3,2,1], max_entry=30).cardinality()
208361017592001331200
sage: ssts = [SemistandardTableaux(p, max_entry=6) for p in Partitions(5)]
sage: all(sst.cardinality() == sst.cardinality(algorithm='sum')
....:      for sst in ssts)
True
```

random_element ()

Return a uniformly distributed random tableau of the given shape and `max_entry`.

Uses the algorithm from [Krat99] based on the Novelli-Pak-Stoyanovskii bijection

EXAMPLES:

```
sage: SemistandardTableaux([2, 2, 1, 1]).random_element()
[[1, 1], [2, 3], [3], [5]]
sage: SemistandardTableaux([2, 2, 1, 1], max_entry=7).random_element()
[[1, 4], [5, 5], [6], [7]]
```

REFERENCES:

class `sage.combinat.tableau.SemistandardTableaux_shape_inf(p)`

Bases: `sage.combinat.tableau.SemistandardTableaux`

Semistandard tableaux of fixed shape p and no maximum entry.

Warning: Input is not checked; please use `SemistandardTableaux` to ensure the options are properly parsed.

class `sage.combinat.tableau.SemistandardTableaux_shape_weight` (p, μ)

Bases: `sage.combinat.tableau.SemistandardTableaux_shape`

Semistandard tableaux of fixed shape p and weight μ .

Warning: Input is not checked; please use `SemistandardTableaux` to ensure the options are properly parsed.

cardinality()

Returns the number of semistandard tableaux of the given shape and weight, as computed by `kostka_number` function of `symmetrica`.

EXAMPLES:

```
sage: SemistandardTableaux([2,2], [2, 1, 1]).cardinality()
1
sage: SemistandardTableaux([2,2,2], [2, 2, 1,1]).cardinality()
1
sage: SemistandardTableaux([2,2,2], [2, 2, 2]).cardinality()
1
sage: SemistandardTableaux([3,2,1], [2, 2, 2]).cardinality()
2
```

list()

Return a list of all semistandard tableaux in `self` generated by `symmetrica`.

EXAMPLES:

```
sage: SemistandardTableaux([2,2], [2, 1, 1]).list()
[[[1, 1], [2, 3]]]
sage: SemistandardTableaux([2,2,2], [2, 2, 1,1]).list()
[[[1, 1], [2, 2], [3, 4]]]
sage: SemistandardTableaux([2,2,2], [2, 2, 2]).list()
[[[1, 1], [2, 2], [3, 3]]]
sage: SemistandardTableaux([3,2,1], [2, 2, 2]).list()
[[[1, 1, 2], [2, 3], [3]], [[1, 1, 3], [2, 2], [3]]]
```

class `sage.combinat.tableau.SemistandardTableaux_size` ($n, \text{max\_entry}=\text{None}$)

Bases: `sage.combinat.tableau.SemistandardTableaux`

Semistandard tableaux of fixed size n .

Warning: Input is not checked; please use `SemistandardTableaux` to ensure the options are properly parsed.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```

sage: SemistandardTableaux(3).cardinality()
19
sage: SemistandardTableaux(4).cardinality()
116
sage: SemistandardTableaux(4, max_entry=2).cardinality()
9
sage: SemistandardTableaux(4, max_entry=10).cardinality()
4225
sage: ns = list(range(1, 6))
sage: ssts = [ SemistandardTableaux(n) for n in ns ]
sage: all(sst.cardinality() == len(sst.list()) for sst in ssts)
True

```

random_element()

Generate a random *SemistandardTableau* with uniform probability.

The RSK algorithm gives a bijection between symmetric $k \times k$ matrices of nonnegative integers that sum to n and semistandard tableaux with size n and maximum entry k .

The number of $k \times k$ symmetric matrices of nonnegative integers having sum of elements on the diagonal i and sum of elements above the diagonal j is $\binom{k+i-1}{k-1} \binom{\binom{k}{2}+j-1}{\binom{k}{2}-1}$. We first choose the sum of the elements on the diagonal randomly weighted by the number of matrices having that trace. We then create random integer vectors of length k having that sum and use them to generate a $k \times k$ diagonal matrix. Then we take a random integer vector of length $\binom{k}{2}$ summing to half the remainder and distribute it symmetrically to the remainder of the matrix.

Applying RSK to the random symmetric matrix gives us a pair of identical *SemistandardTableau* of which we choose the first.

EXAMPLES:

```

sage: SemistandardTableaux(6).random_element() # random
[[1, 1, 2], [3, 5, 5]]
sage: SemistandardTableaux(6, max_entry=7).random_element() # random
[[2, 4, 4, 6, 6, 6]]

```

class sage.combinat.tableau.SemistandardTableaux_size_inf(n)

Bases: *sage.combinat.tableau.SemistandardTableaux*

Semistandard tableaux of fixed size n with no maximum entry.

Warning: Input is not checked; please use *SemistandardTableaux* to ensure the options are properly parsed.

list()

class sage.combinat.tableau.SemistandardTableaux_size_weight(n, μ)

Bases: *sage.combinat.tableau.SemistandardTableaux*

Semistandard tableaux of fixed size n and weight μ .

Warning: Input is not checked; please use *SemistandardTableaux* to ensure the options are properly parsed.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: SemistandardTableaux(3, [2,1]).cardinality()
2
sage: SemistandardTableaux(4, [2,2]).cardinality()
3
```

class `sage.combinat.tableau.StandardTableau` (*parent, t*)

Bases: `sage.combinat.tableau.SemistandardTableau`

A class to model a standard tableau.

INPUT:

- `t` – a Tableau, a list of iterables, or an empty list

OUTPUT:

- A `StandardTableau` object constructed from `t`.

A standard tableau is a semistandard tableau whose entries are exactly the positive integers from 1 to n , where n is the size of the tableau.

EXAMPLES:

```
sage: t = StandardTableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty print
1 2 3
4 5
sage: t.is_standard()
True
sage: StandardTableau([]) # The empty tableau
[]
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a `StandardTableau` from the appropriate `Parent` object:

```
sage: ST = StandardTableaux()
sage: ST([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

See also:

- `Tableaux`
- `Tableau`
- `SemistandardTableaux`
- `SemistandardTableau`
- `StandardTableaux`

```
sage: StandardTableau([[1,2,3],[4,4]]) Traceback (most recent call last): ... ValueError: the entries in a standard tableau must be in bijection with 1,2,...,n
sage: StandardTableau([[1,3,2]]) Traceback (most recent call last): ... ValueError: the entries in each row of a semistandard tableau must be weakly increasing
```

dominates (*t*)

Return True if *self* dominates the tableau *t*.

That is, if the shape of the tableau restricted to k dominates the shape of *t* restricted to k , for $k = 1, 2, \dots, n$.

When the two tableaux have the same shape, then this ordering coincides with the Bruhat ordering for the corresponding permutations.

INPUT:

- *t* – a tableau

EXAMPLES:

```
sage: s=StandardTableau([[1,2,3],[4,5]])
sage: t=StandardTableau([[1,2],[3,5],[4]])
sage: s.dominates(t)
True
sage: t.dominates(s)
False
sage: all(StandardTableau(s).dominates(t) for t in StandardTableaux([3,2]))
True
sage: s.dominates([[1,2,3,4,5]])
False
```

down ()

An iterator for all the standard tableaux that can be obtained from *self* by removing a cell. Note that this iterates just over a single tableau (or nothing if *self* is empty).

EXAMPLES:

```
sage: t = StandardTableau([[1,2],[3]])
sage: [x for x in t.down()]
[[[1, 2]]]
sage: t = StandardTableau([])
sage: [x for x in t.down()]
[]
```

down_list ()

Return a list of all the standard tableaux that can be obtained from *self* by removing a cell. Note that this is just a singleton list if *self* is nonempty, and an empty list otherwise.

EXAMPLES:

```
sage: t = StandardTableau([[1,2],[3]])
sage: t.down_list()
[[[1, 2]]]
sage: t = StandardTableau([])
sage: t.down_list()
[]
```

is_standard ()

Return True since *self* is a standard tableau.

EXAMPLES:

```
sage: StandardTableau([[1, 3], [2, 4]]).is_standard()
True
```

promotion ($n=None$)

Return the image of `self` under the promotion operator.

The promotion operator, applied to a standard tableau t , does the following:

Remove the letter n from t , thus leaving a hole where it used to be. Apply jeu de taquin to move this hole southwest (in French notation) until it reaches the inner boundary of t . Fill 0 into the hole once jeu de taquin has completed. Finally, add 1 to each letter in the tableau. The resulting standard tableau is the image of t under the promotion operator.

This definition of promotion is precisely the one given in [Hai1992] (p. 90). It is the inverse of the maps called “promotion” in [Sg2011] (p. 23) and in [Stan2009].

See the `promotion()` method for a more general operator.

EXAMPLES:

```
sage: ST = StandardTableaux(7)
sage: all( st.promotion().promotion_inverse() == st for st in ST ) # long time
True
sage: all( st.promotion_inverse().promotion() == st for st in ST ) # long time
True
sage: st = StandardTableau([[1,2,5],[3,4]])
sage: parent(st.promotion())
Standard tableaux
```

promotion_inverse ($n=None$)

Return the image of `self` under the inverse promotion operator. The optional variable m should be set to the size of `self` minus 1 for a minimal speedup; otherwise, it defaults to this number.

The inverse promotion operator, applied to a standard tableau t , does the following:

Remove the letter 1 from t , thus leaving a hole where it used to be. Apply jeu de taquin to move this hole northeast (in French notation) until it reaches the outer boundary of t . Fill $n + 1$ into this hole, where n is the size of t . Finally, subtract 1 from each letter in the tableau. This yields a new standard tableau.

This definition of inverse promotion is the map called “promotion” in [Sg2011] (p. 23) and in [Stan2009], and is the inverse of the map called “promotion” in [Hai1992] (p. 90).

See the `promotion_inverse()` method for a more general operator.

EXAMPLES:

```
sage: t = StandardTableau([[1,3],[2,4]])
sage: t.promotion_inverse()
[[1, 2], [3, 4]]
```

We check the equivalence of two definitions of inverse promotion on standard tableaux:

```
sage: ST = StandardTableaux(7)
sage: def bk_promotion_inverse7(st):
....:     st2 = st
....:     for i in range(1, 7):
....:         st2 = st2.bender_knuth_involution(i, check=False)
....:     return st2
sage: all( bk_promotion_inverse7(st) == st.promotion_inverse() for st in ST )
↪ # long time
True
```

standard_descents ()

Return a list of the integers i such that i appears strictly further north than $i + 1$ in `self` (this is not to say

that i and $i + 1$ must be in the same column). The list is sorted in increasing order.

EXAMPLES:

```
sage: StandardTableau( [[1,3,4],[2,5]] ).standard_descents()
[1, 4]
sage: StandardTableau( [[1,2],[3,4]] ).standard_descents()
[2]
sage: StandardTableau( [[1,2,5],[3,4],[6,7],[8],[9]] ).standard_descents()
[2, 5, 7, 8]
sage: StandardTableau( [] ).standard_descents()
[]
```

standard_major_index()

Return the major index of the standard tableau `self` in the standard meaning of the word. The major index is defined to be the sum of the descents of `self` (see [standard_descents\(\)](#) for their definition).

EXAMPLES:

```
sage: StandardTableau( [[1,4,5],[2,6],[3]] ).standard_major_index()
8
sage: StandardTableau( [[1,2],[3,4]] ).standard_major_index()
2
sage: StandardTableau( [[1,2,3],[4,5]] ).standard_major_index()
3
```

standard_number_of_descents()

Return the number of all integers i such that i appears strictly further north than $i + 1$ in `self` (this is not to say that i and $i + 1$ must be in the same column). A list of these integers can be obtained using the [standard_descents\(\)](#) method.

EXAMPLES:

```
sage: StandardTableau( [[1,2],[3,4],[5]] ).standard_number_of_descents()
2
sage: StandardTableau( [] ).standard_number_of_descents()
0
sage: tabs = StandardTableaux(5)
sage: all( t.standard_number_of_descents() == t.schuetzenberger_involution().
↪standard_number_of_descents() for t in tabs )
True
```

up()

An iterator for all the standard tableaux that can be obtained from `self` by adding a cell.

EXAMPLES:

```
sage: t = StandardTableau([[1,2]])
sage: [x for x in t.up()]
[[[1, 2, 3]], [[1, 2], [3]]]
```

up_list()

Return a list of all the standard tableaux that can be obtained from `self` by adding a cell.

EXAMPLES:

```
sage: t = StandardTableau([[1,2]])
sage: t.up_list()
[[[1, 2, 3]], [[1, 2], [3]]]
```

class `sage.combinat.tableau.StandardTableaux` (***kws*)
Bases: `sage.combinat.tableau.SemistandardTableaux`

A factory for the various classes of standard tableaux.

INPUT:

- Either a non-negative integer (possibly specified with the keyword `n`) or a partition.

OUTPUT:

- With no argument, the class of all standard tableaux
- With a non-negative integer argument, `n`, the class of all standard tableaux of size `n`
- With a partition argument, the class of all standard tableaux of that shape.

A standard tableau is a semistandard tableaux which contains each of the entries from 1 to `n` exactly once.

All classes of standard tableaux are iterable.

EXAMPLES:

```
sage: ST = StandardTableaux(3); ST
Standard tableaux of size 3
sage: ST.first()
[[1, 2, 3]]
sage: ST.last()
[[1], [2], [3]]
sage: ST.cardinality()
4
sage: ST.list()
[[[1, 2, 3]], [[1, 3], [2]], [[1, 2], [3]], [[1], [2], [3]]]
```

See also:

- `Tableaux`
- `Tableau`
- `SemistandardTableaux`
- `SemistandardTableau`
- `StandardTableau`
- `StandardSkewTableaux`

Element

alias of `StandardTableau`

class `sage.combinat.tableau.StandardTableaux_all`
Bases: `sage.combinat.tableau.StandardTableaux`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`

All standard tableaux.

class `sage.combinat.tableau.StandardTableaux_shape` (`p`)
Bases: `sage.combinat.tableau.StandardTableaux`
Semistandard tableaux of a fixed shape `p`.

Warning: Input is not checked; please use `SemistandardTableaux` to ensure the options are properly parsed.

cardinality()

Return the number of standard Young tableaux of this shape.

This method uses the so-called *hook length formula*, a formula for the number of Young tableaux associated with a given partition. The formula says the following: Let λ be a partition. For each cell c of the Young diagram of λ , let the *hook length* of c be defined as 1 plus the number of cells horizontally to the right of c plus the number of cells vertically below c . The number of standard Young tableaux of shape λ is then $n!$ divided by the product of the hook lengths of the shape of λ , where $n = |\lambda|$.

For example, consider the partition $[3, 2, 1]$ of 6 with Ferrers diagram:

```
# # #
# #
#
```

When we fill in the cells with their respective hook lengths, we obtain:

```
5 3 1
3 1
1
```

The hook length formula returns

$$\frac{6!}{5 \cdot 3 \cdot 1 \cdot 3 \cdot 1 \cdot 1} = 16.$$

EXAMPLES:

```
sage: StandardTableaux([3,2,1]).cardinality()
16
sage: StandardTableaux([2,2]).cardinality()
2
sage: StandardTableaux([5]).cardinality()
1
sage: StandardTableaux([6,5,5,3]).cardinality()
6651216
sage: StandardTableaux([]).cardinality()
1
```

REFERENCES:

- <http://mathworld.wolfram.com/HookLengthFormula.html>

list()

Return a list of the standard Young tableaux of the specified shape.

EXAMPLES:

```
sage: StandardTableaux([2,2]).list()
[[[1, 3], [2, 4]], [[1, 2], [3, 4]]]
sage: StandardTableaux([5]).list()
[[[1, 2, 3, 4, 5]]]
sage: StandardTableaux([3,2,1]).list()
[[[1, 4, 6], [2, 5], [3]],
 [[1, 3, 6], [2, 5], [4]],
 [[1, 2, 6], [3, 5], [4]]]
```

```
[[1, 3, 6], [2, 4], [5]],
[[1, 2, 6], [3, 4], [5]],
[[1, 4, 5], [2, 6], [3]],
[[1, 3, 5], [2, 6], [4]],
[[1, 2, 5], [3, 6], [4]],
[[1, 3, 4], [2, 6], [5]],
[[1, 2, 4], [3, 6], [5]],
[[1, 2, 3], [4, 6], [5]],
[[1, 3, 5], [2, 4], [6]],
[[1, 2, 5], [3, 4], [6]],
[[1, 3, 4], [2, 5], [6]],
[[1, 2, 4], [3, 5], [6]],
[[1, 2, 3], [4, 5], [6]]]
```

random_element()

Return a random standard tableau of the given shape using the Greene-Nijenhuis-Wilf Algorithm.

EXAMPLES:

```
sage: StandardTableaux([2,2]).random_element()
[[1, 2], [3, 4]]
sage: StandardTableaux([]).random_element()
[]
```

class sage.combinat.tableau.**StandardTableaux_size**(*n*)

Bases: [sage.combinat.tableau.StandardTableaux](#)

Standard tableaux of fixed size *n*.

Warning: Input is not checked; please use [StandardTableaux](#) to ensure the options are properly parsed.

cardinality()

Return the number of all standard tableaux of size *n*.

The number of standard tableaux of size *n* is equal to the number of involutions in the symmetric group S_n . This is a consequence of the symmetry of the RSK correspondence, that if $\sigma \mapsto (P, Q)$, then $\sigma^{-1} \mapsto (Q, P)$. For more information, see [Wikipedia article Robinson-Schensted-Knuth_correspondence#Symmetry](#).

ALGORITHM:

The algorithm uses the fact that standard tableaux of size *n* are in bijection with the involutions of size *n*, (see page 41 in section 4.1 of [\[Ful1997\]](#)). For each number of fixed points, you count the number of ways to choose those fixed points multiplied by the number of perfect matchings on the remaining values.

REFERENCES:

EXAMPLES:

```
sage: StandardTableaux(3).cardinality()
4
sage: ns = [1,2,3,4,5,6]
sage: sts = [StandardTableaux(n) for n in ns]
sage: all(st.cardinality() == len(st.list()) for st in sts)
True
sage: StandardTableaux(50).cardinality()
27886995605342342839104615869259776
```

random_element()

Return a random `StandardTableau` with uniform probability.

This algorithm uses the fact that the Robinson-Schensted correspondence returns a pair of identical standard Young tableaux (SYTs) if and only if the permutation was an involution. Thus, generating a random SYT is equivalent to generating a random involution.

To generate an involution, we first need to choose its number of fixed points k (if the size of the involution is even, the number of fixed points will be even, and if the size is odd, the number of fixed points will be odd). To do this, we choose a random integer r between 0 and the number N of all involutions of size n . We then decompose the interval $\{1, 2, \dots, N\}$ into subintervals whose lengths are the numbers of involutions of size n with respectively 0, 1, $\dots$, $\lfloor N/2 \rfloor$ fixed points. The interval in which our random integer r lies then decides how many fixed points our random involution will have. We then place those fixed points randomly and then compute a perfect matching (an involution without fixed points) on the remaining values.

EXAMPLES:

```
sage: StandardTableaux(5).random_element() # random
[[1, 4, 5], [2], [3]]
sage: StandardTableaux(0).random_element()
[]
sage: StandardTableaux(1).random_element()
[[1]]
```

class `sage.combinat.tableau.Tableau`(*parent, t*)
 Bases: `sage.structure.list_clone.ClonableList`

A class to model a tableau.

INPUT:

- t – a Tableau, a list of iterables, or an empty list

OUTPUT:

- A Tableau object constructed from t .

A tableau is abstractly a mapping from the cells in a partition to arbitrary objects (called entries). It is often represented as a finite list of nonempty lists (or, more generally, an iterator of iterables) of weakly decreasing lengths. This list, in particular, can be empty, representing the empty tableau.

Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

EXAMPLES:

```
sage: t = Tableau([[1, 2, 3], [4, 5]]); t
[[1, 2, 3], [4, 5]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty print
1 2 3
4 5
sage: t.is_standard()
True

sage: Tableau([['a', 'c', 'b'], [[], (2, 1)]])
[['a', 'c', 'b'], [[], (2, 1)]]
sage: Tableau([]) # The empty tableau
[]
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a Tableau from the appropriate Parent object:

```
sage: T = Tableaux()
sage: T([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

See also:

- *Tableaux*
- *SemistandardTableaux*
- *SemistandardTableau*
- *StandardTableaux*
- *StandardTableau*

add_entry (*cell*, *m*)

Return the result of setting the entry in cell *cell* equal to *m* in the tableau *self*.

This tableau has larger size than *self* if *cell* does not belong to the shape of *self*; otherwise, the tableau has the same shape as *self* and has the appropriate entry replaced.

INPUT:

- *cell* – a pair of nonnegative integers

OUTPUT:

The tableau *self* with the entry in cell *cell* set to *m*. This entry overwrites an existing entry if *cell* already belongs to *self*, or is added to the tableau if *cell* is a cocorner of the shape *self*. (Either way, the input is not modified.)

Note: Both coordinates of *cell* are interpreted as starting at 0. So, *cell* == (0, 0) corresponds to the northwesternmost cell.

EXAMPLES:

```
sage: s = StandardTableau([[1,2,5],[3,4]]); s.pp()
 1 2 5
 3 4
sage: t = s.add_entry( (1,2), 6); t.pp()
 1 2 5
 3 4 6
sage: t.category()
Category of elements of Standard tableaux
sage: s.add_entry( (2,0), 6).pp()
 1 2 5
 3 4
 6
sage: u = s.add_entry( (1,2), 3); u.pp()
 1 2 5
 3 4 3
sage: u.category()
Category of elements of Tableaux
sage: s.add_entry( (2,2), 3)
Traceback (most recent call last):
```

```
...
IndexError: (2, 2) is not an addable cell of the tableau
```

anti_restrict(*n*)

Return the skew tableau formed by removing all of the cells from `self` that are filled with a number at most *n*.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.anti_restrict(1)
[[None, 2, 3], [4, 5]]
sage: t.anti_restrict(2)
[[None, None, 3], [4, 5]]
sage: t.anti_restrict(3)
[[None, None, None], [4, 5]]
sage: t.anti_restrict(4)
[[None, None, None], [None, 5]]
sage: t.anti_restrict(5)
[[None, None, None], [None, None]]
```

atom()

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).atom()
[2, 2]
sage: Tableau([[1,2,3],[4,5],[6]]).atom()
[3, 2, 1]
```

bender_knuth_involution(*k*, *rows=None*, *check=True*)

Return the image of `self` under the *k*-th Bender–Knuth involution, assuming `self` is a semistandard tableau.

Let *T* be a tableau, then a *lower free* '*k*' in '*T*' means a cell of *T* which is filled with the integer *k* and whose direct lower neighbor is not filled with the integer *k* + 1 (in particular, this lower neighbor might not exist at all). Let an *upper free* '*k* + 1' in '*T*' mean a cell of *T* which is filled with the integer *k* + 1 and whose direct upper neighbor is not filled with the integer *k* (in particular, this neighbor might not exist at all). It is clear that for any row *r* of *T*, the lower free *k*'s and the upper free *k* + 1's in *r* together form a contiguous interval or *r*.

The '*k*'-th Bender–Knuth switch at row '*i*' changes the entries of the cells in this interval in such a way that if it used to have *a* entries of *k* and *b* entries of *k* + 1, it will now have *b* entries of *k* and *a* entries of *k* + 1. For fixed *k*, the *k*-th Bender–Knuth switches for different *i* commute. The composition of the *k*-th Bender–Knuth switches for all rows is called the '*k*'-th Bender–Knuth involution. This is used to show that the Schur functions defined by semistandard tableaux are symmetric functions.

INPUT:

- *k* – an integer
- *rows* – (Default `None`) When set to `None`, the method computes the *k*-th Bender–Knuth involution as defined above. When an iterable, this computes the composition of the *k*-th Bender–Knuth switches at row *i* over all *i* in *rows*. When set to an integer *i*, the method computes the *k*-th Bender–Knuth switch at row *i*. Note the indexing of the rows starts with 1.
- *check* – (Default: `True`) Check to make sure `self` is semistandard. Set to `False` to avoid this check.

OUTPUT:

The image of `self` under either the k -th Bender–Knuth involution, the k -th Bender–Knuth switch at a certain row, or the composition of such switches, as detailed in the INPUT section.

EXAMPLES:

```
sage: t = Tableau([[1,1,3,4,4,5,6,7],[2,2,4,6,7,7,7],[3,4,5,8,8,9],[6,6,7,10],
↪[7,8,8,11],[8]])
sage: t.bender_knuth_involution(1) == t
True
sage: t.bender_knuth_involution(2)
[[1, 1, 2, 4, 4, 5, 6, 7], [2, 3, 4, 6, 7, 7, 7], [3, 4, 5, 8, 8, 9], [6, 6, ↪
↪7, 10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(3)
[[1, 1, 3, 3, 3, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 4, 5, 8, 8, 9], [6, 6, ↪
↪7, 10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(4)
[[1, 1, 3, 4, 5, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 5, 5, 8, 8, 9], [6, 6, ↪
↪7, 10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(5)
[[1, 1, 3, 4, 4, 5, 6, 7], [2, 2, 4, 5, 7, 7, 7], [3, 4, 6, 8, 8, 9], [5, 5, ↪
↪7, 10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(666) == t
True
sage: t.bender_knuth_involution(4, 2) == t
True
sage: t.bender_knuth_involution(4, 3)
[[1, 1, 3, 4, 4, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 5, 5, 8, 8, 9], [6, 6, ↪
↪7, 10], [7, 8, 8, 11], [8]]
```

The `rows` keyword can be an iterator:

```
sage: t.bender_knuth_involution(6, iter([1,2])) == t
False
sage: t.bender_knuth_involution(6, iter([3,4])) == t
True
```

The Bender–Knuth involution is an involution:

```
sage: T = SemistandardTableaux(shape=[3,1,1], max_entry=4)
sage: all(all(t.bender_knuth_involution(k).bender_knuth_involution(k) == t, ↪
↪for k in range(1,5)) for t in T)
True
```

The same holds for the single switches:

```
sage: all(all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j) ↪
↪== t for k in range(1,5) for j in range(1, 5)) for t in T)
True
```

Locality of the Bender–Knuth involutions:

```
sage: all(all(t.bender_knuth_involution(k).bender_knuth_involution(1) == t, ↪
↪bender_knuth_involution(1).bender_knuth_involution(k) for k in range(1,5) ↪
↪for l in range(1,5) if abs(k - l) > 1) for t in T)
True
```

Berenstein and Kirillov [*BerKilGGI*] have shown that $(s_1 s_2)^6 = id$ (for tableaux of straight shape):

```
sage: p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k_
↪+ 1)
sage: all(p(p(p(p(p(p(t,1),1),1),1),1),1) == t for t in T)
True
```

However, $(s_2 s_3)^6 = id$ is false:

```
sage: p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k_
↪+ 1)
sage: t = Tableau([[1,2,2],[3,4]])
sage: x = t
sage: for i in range(6): x = p(x, 2)
sage: x
[[1, 2, 3], [2, 4]]
sage: x == t
False
```

REFERENCES:

bump(*x*)

Insert *x* into *self* using Schensted's row-bumping (or row-insertion) algorithm.

EXAMPLES:

```
sage: t = Tableau([[1,2],[3]])
sage: t.bump(1)
[[1, 1], [2], [3]]
sage: t
[[1, 2], [3]]
sage: t.bump(2)
[[1, 2, 2], [3]]
sage: t.bump(3)
[[1, 2, 3], [3]]
sage: t
[[1, 2], [3]]
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t.bump(2)
[[1, 2, 2, 2], [2, 3, 3, 5], [4, 4, 5], [5, 6, 6]]
sage: t.bump(1)
[[1, 1, 2, 3], [2, 2, 5, 5], [3, 4, 6], [4, 6], [5]]
```

bump_multiply(*left*, *right*)

Multiply two tableaux using Schensted's bump.

This product makes the set of semistandard tableaux into an associative monoid. The empty tableau is the unit in this monoid. See pp. 11-12 of [\[Ful1997\]](#).

The same product operation is implemented in a different way in `slide_multiply()`.

EXAMPLES:

```
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t2 = Tableau([[1,2],[3]])
sage: t.bump_multiply(t2)
[[1, 1, 2, 2, 3], [2, 2, 3, 5], [3, 4, 5], [4, 6, 6], [5]]
```

catabolism()

Remove the top row of *self* and insert it back in using column Schensted insertion (starting with the largest letter).

EXAMPLES:

```
sage: Tableau([]).catabolism()
[]
sage: Tableau([[1,2,3,4,5]]).catabolism()
[[1, 2, 3, 4, 5]]
sage: Tableau([[1,1,3,3],[2,3],[3]]).catabolism()
[[1, 1, 2, 3, 3, 3], [3]]
sage: Tableau([[1, 1, 2, 3, 3, 3], [3]]).catabolism()
[[1, 1, 2, 3, 3, 3, 3]]
```

catabolism_projector(*parts*)

EXAMPLES:

```
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.catabolism_projector([[4,2,1]])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.catabolism_projector([[1]])
[]
sage: t.catabolism_projector([[2,1],[1]])
[]
sage: t.catabolism_projector([[1,1],[4,1]])
[[1, 1, 3, 3], [2, 3], [3]]
```

catabolism_sequence()

Perform *catabolism*() on *self* until it returns a tableau consisting of a single row.

EXAMPLES:

```
sage: t = Tableau([[1,2,3,4,5,6,8],[7,9]])
sage: t.catabolism_sequence()
[[[1, 2, 3, 4, 5, 6, 8], [7, 9]],
 [[1, 2, 3, 4, 5, 6, 7, 9], [8]],
 [[1, 2, 3, 4, 5, 6, 7, 8], [9]],
 [[1, 2, 3, 4, 5, 6, 7, 8, 9]]]
sage: Tableau([]).catabolism_sequence()
[[]]
```

cells()

Return a list of the coordinates of the cells of *self*.

Coordinates start at 0, so the northwesternmost cell (in English notation) has coordinates (0,0).

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).cells()
[(0, 0), (0, 1), (1, 0), (1, 1)]
```

cells_containing(*i*)

Return the list of cells in which the letter *i* appears in the tableau *self*. The list is ordered with cells appearing from left to right.

Cells are given as pairs of coordinates (*a*, *b*), where both rows and columns are counted from 0 (so *a* = 0 means the cell lies in the leftmost column of the tableau, etc.).

EXAMPLES:

```
sage: t = Tableau([[1,1,3],[2,3,5],[4,5]])
sage: t.cells_containing(5)
[(2, 1), (1, 2)]
```

```

sage: t.cells_containing(4)
[(2, 0)]
sage: t.cells_containing(6)
[]

sage: t = Tableau([[1,1,2,4],[2,4,4],[4]])
sage: t.cells_containing(4)
[(2, 0), (1, 1), (1, 2), (0, 3)]

sage: t = Tableau([[1,1,2,8,9],[2,5,6,11],[3,7,7,13],[4,8,9],[5],[13],[14]])
sage: t.cells_containing(8)
[(3, 1), (0, 3)]

sage: Tableau([]).cells_containing(3)
[]

```

charge()

Return the charge of the reading word of `self`. See [charge\(\)](#) for more information.

EXAMPLES:

```

sage: Tableau([[1,1],[2,2],[3]]).charge()
0
sage: Tableau([[1,1,3],[2,2]]).charge()
1
sage: Tableau([[1,1,2],[2],[3]]).charge()
1
sage: Tableau([[1,1,2],[2,3]]).charge()
2
sage: Tableau([[1,1,2,3],[2]]).charge()
2
sage: Tableau([[1,1,2,2],[3]]).charge()
3
sage: Tableau([[1,1,2,2,3]]).charge()
4

```

check()

Check that `self` is a valid straight-shape tableau.

EXAMPLES:

```

sage: t = Tableau([[1,1],[2]])
sage: t.check()

sage: t = Tableau([[None, None, 1], [2, 4], [3, 4, 5]])
Traceback (most recent call last):
...
ValueError: A tableau must be a list of iterables of weakly decreasing length.

```

cocharge()

Return the cocharge of the reading word of `self`. See [cocharge\(\)](#) for more information.

EXAMPLES:

```

sage: Tableau([[1,1],[2,2],[3]]).cocharge()
4
sage: Tableau([[1,1,3],[2,2]]).cocharge()
3
sage: Tableau([[1,1,2],[2],[3]]).cocharge()

```

```

3
sage: Tableau([[1, 1, 2], [2, 3]]).cocharge()
2
sage: Tableau([[1, 1, 2, 3], [2]]).cocharge()
2
sage: Tableau([[1, 1, 2, 2], [3]]).cocharge()
1
sage: Tableau([[1, 1, 2, 2, 3]]).cocharge()
0

```

codegree (*e*, *multicharge*=(0,))

Return the Brundan-Kleshchev-Wang [BKW11] codegree of the standard tableau *self*.

The *coderee* of a tableau is an integer that is defined recursively by successively stripping off the number k , for $k = n, n-1, \dots, 1$ and at stage adding the number of addable cell of the same residue minus the number of removable cells of the same residue as k and are above k in the diagram.

The codegree of the tableau T gives the degree of “dual” homogeneous basis element of the Graded Specht module that is indexed by T .

INPUT:

- *e* – the *quantum characteristic*
- *multicharge* – (default: [0]) the *multicharge*

OUTPUT:

The codegree of the tableau *self*, which is an integer.

EXAMPLES:

```

sage: StandardTableau([[1, 3, 5], [2, 4]]).codegree(3)
0
sage: StandardTableau([[1, 2, 5], [3, 4]]).codegree(3)
1
sage: StandardTableau([[1, 2, 5], [3, 4]]).codegree(4)
0

```

REFERENCES:

- [BKW11] J. Brundan, A. Kleshchev, and W. Wang, *Graded Specht modules*, J. Reine Angew. Math., 655 (2011), 61-87.

column_stabilizer ()

Return the *PermutationGroup* corresponding to the column stabilizer of *self*.

This assumes that every integer from 1 to the size of *self* appears exactly once in *self*.

EXAMPLES:

```

sage: cs = Tableau([[1, 2, 3], [4, 5]]).column_stabilizer()
sage: cs.order() == factorial(2)*factorial(2)
True
sage: PermutationGroupElement([(1, 3, 2), (4, 5)]) in cs
False
sage: PermutationGroupElement([(1, 4)]) in cs
True

```

components ()

This function returns a list containing itself. It exists mainly for compatibility with *TableauTuple* as it allows constructions like the example below.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[4,5]]);
sage: for s in t.components(): print(s.to_list())
[[1, 2, 3], [4, 5]]
```

conjugate()

Return the conjugate of `self`.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).conjugate()
[[1, 3], [2, 4]]
sage: c = StandardTableau([[1,2],[3,4]]).conjugate()
sage: c.parent()
Standard tableaux
```

content (k , *multicharge*=[0])

Return the content of k in the standard tableau `self`.

The content of k is $c - r$ if k appears in row r and column c of the tableau.

The *multicharge* is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with `sage.combinat.tableau_tuple.TableauTuple()`.

EXAMPLES:

```
sage: StandardTableau([[1,2],[3,4]]).content(3)
-1

sage: StandardTableau([[1,2],[3,4]]).content(6)
Traceback (most recent call last):
...
ValueError: 6 does not appear in tableau
```

corners()

Return the corners of the tableau `self`.

EXAMPLES:

```
sage: Tableau([[1, 4, 6], [2, 5], [3]]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Tableau([[1, 3], [2, 4]]).corners()
[(1, 1)]
```

degree (e , *multicharge*=(0,))

Return the Brundan-Kleshchev-Wang [BKW11] degree of `self`.

The *degree* is an integer that is defined recursively by successively stripping off the number k , for $k = n, n - 1, \dots, 1$ and at stage adding the number of addable cell of the same residue minus the number of removable cells of the same residue as k and which are below k in the diagram.

The degrees of the tableau T gives the degree of the homogeneous basis element of the graded Specht module that is indexed by T .

INPUT:

- e – the *quantum characteristic*
- *multicharge* – (default: [0]) the *multicharge*

OUTPUT:

The degree of the tableau `self`, which is an integer.

EXAMPLES:

```
sage: StandardTableau([[1,2,5],[3,4]]).degree(3)
0
sage: StandardTableau([[1,2,5],[3,4]]).degree(4)
1
```

REFERENCES:

descents()

Return a list of the cells (i, j) such that `self[i][j] > self[i-1][j]`.

Warning: This is not to be confused with the descents of a standard tableau.

EXAMPLES:

```
sage: Tableau( [[1,4],[2,3]] ).descents()
[(1, 0)]
sage: Tableau( [[1,2],[3,4]] ).descents()
[(1, 0), (1, 1)]
sage: Tableau( [[1,2,3],[4,5]] ).descents()
[(1, 0), (1, 1)]
```

entries()

Return the tuple of all entries of `self`, in the order obtained by reading across the rows from top to bottom (in English notation).

EXAMPLES:

```
sage: t = Tableau([[1,3],[2]])
sage: t.entries()
(1, 3, 2)
```

entry(*cell*)

Returns the entry of cell `cell` in the tableau `self`. Here, `cell` should be given as a tuple (i, j) of zero-based coordinates (so the northwesternmost cell in English notation is $(0, 0)$).

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,4]])
sage: t.entry( (0,0) )
1
sage: t.entry( (1,1) )
4
```

evacuation(*n=None, check=True*)

Return the evacuation of the tableau `self`.

This is an alias for `schuetzenberger_involution()`.

This method relies on the analogous method on words, which reverts the word and then complements all letters within the underlying ordered alphabet. If n is specified, the underlying alphabet is assumed to be $[1, 2, \dots, n]$. If no alphabet is specified, n is the maximal letter appearing in `self`.

INPUT:

- `n` – an integer specifying the maximal letter in the alphabet (optional)
- `check` – (Default: `True`) Check to make sure `self` is semistandard. Set to `False` to avoid this check. (optional)

OUTPUT:

- a tableau, the evacuation of `self`

EXAMPLES:

```
sage: t = Tableau([[1,1,1],[2,2]])
sage: t.evacuation(3)
[[2, 2, 3], [3, 3]]

sage: t = Tableau([[1,2,3],[4,5]])
sage: t.evacuation()
[[1, 2, 5], [3, 4]]

sage: t = Tableau([[1,3,5,7],[2,4,6],[8,9]])
sage: t.evacuation()
[[1, 2, 6, 8], [3, 4, 9], [5, 7]]

sage: t = Tableau([])
sage: t.evacuation()
[]

sage: t = StandardTableau([[1,2,3],[4,5]])
sage: s = t.evacuation()
sage: s.parent()
Standard tableaux
```

evaluation()

Return the weight of the tableau `self`. Trailing zeroes are omitted when returning the weight.

The weight of a tableau T is the sequence $(a_1, a_2, a_3, \dots)$, where a_k is the number of entries of T equal to k . This sequence contains only finitely many nonzero entries.

The weight of a tableau T is the same as the weight of the reading word of T , for any reading order.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).weight()
[1, 1, 1, 1]

sage: Tableau([]).weight()
[]

sage: Tableau([[1,3,3,7],[4,2],[2,3]]).weight()
[1, 2, 3, 1, 0, 0, 1]
```

first_column_descent()

Return the first cell where `self` is not column standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell (r, c) with r and c minimal such that the entry in position (r, c) is bigger than the entry in position $(r, c + 1)$. If there is no such cell then `None` is returned - in this case the tableau is column strict.

OUTPUT:

The first cell which there is a descent or `None` if no such cell exists.

EXAMPLES:

```
sage: Tableau([[1, 4, 5], [2, 3]]).first_column_descent()
(0, 1)
sage: Tableau([[1, 2, 3], [4]]).first_column_descent() is None
True
```

first_row_descent()

Return the first cell where the tableau `self` is not row standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell (r, c) with r and c minimal such that the entry in position (r, c) is bigger than the entry in position $(r, c + 1)$. If there is no such cell then `None` is returned - in this case the tableau is row strict.

OUTPUT:

The first cell which there is a descent or `None` if no such cell exists.

EXAMPLES:

```
sage: t=Tableau([[1, 3, 2], [4]]); t.first_row_descent()
(0, 1)
sage: Tableau([[1, 2, 3], [4]]).first_row_descent() is None
True
```

flush()

Return the number of flush segments in `self`, as in [S14].

Let $1 \leq i < k \leq r + 1$ and suppose ℓ is the smallest integer greater than k such that there exists an ℓ -segment in the $(i + 1)$ -st row of T . A k -segment in the i -th row of T is called *flush* if the leftmost box in the k -segment and the leftmost box of the ℓ -segment are in the same column of T . If, however, no such ℓ exists, then this k -segment is said to be *flush* if the number of boxes in the k -segment is equal to θ_i , where $\theta_i = \lambda_i - \lambda_{i+1}$ and the shape of T is $\lambda = (\lambda_1 > \lambda_2 > \dots > \lambda_r)$. Denote the number of flush k -segments in T by $\text{flush}(T)$.

EXAMPLES:

```
sage: t = Tableau([[1, 1, 2, 3, 5], [2, 3, 5, 5], [3, 4]])
sage: t.flush()
3

sage: B = crystals.Tableaux("A4", shape=[4, 3, 2, 1])
sage: t = B[32].to_tableau()
sage: t.flush()
4
```

height()

Return the height of `self`.

EXAMPLES:

```
sage: Tableau([[1, 2, 3], [4, 5]]).height()
2
sage: Tableau([[1, 2, 3]]).height()
1
sage: Tableau([]).height()
0
```

insert_word(w, left=False)

Insert the word `w` into the tableau `self` letter by letter using Schensted insertion. By default, the word `w`

is being processed from left to right, and the insertion used is row insertion. If the optional keyword `left` is set to `True`, the word `w` is being processed from right to left, and column insertion is used instead.

EXAMPLES:

```
sage: t0 = Tableau([])
sage: w = [1,1,2,3,3,3,3]
sage: t0.insert_word(w)
[[1, 1, 2, 3, 3, 3, 3]]
sage: t0.insert_word(w, left=True)
[[1, 1, 2, 3, 3, 3, 3]]
sage: w.reverse()
sage: t0.insert_word(w)
[[1, 1, 3, 3], [2, 3], [3]]
sage: t0.insert_word(w, left=True)
[[1, 1, 3, 3], [2, 3], [3]]
sage: t1 = Tableau([[1,3],[2]])
sage: t1.insert_word([4,5])
[[1, 3, 4, 5], [2]]
sage: t1.insert_word([4,5], left=True)
[[1, 3], [2, 5], [4]]
```

inversion_number()

Return the inversion number of `self`.

The inversion number is defined to be the number of inversions of `self` minus the sum of the arm lengths of the descents of `self` (see the [inversions\(\)](#) and [descents\(\)](#) methods for the relevant definitions).

Warning: This has none of the meanings in which the word “inversion” is used in the theory of standard tableaux.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[2,5]])
sage: t.inversion_number()
0
sage: t = Tableau([[1,2,4],[3,5]])
sage: t.inversion_number()
0
```

inversions()

Return a list of the inversions of `self`.

Let T be a tableau. An inversion is an attacking pair (c, d) of the shape of T (see [attacking_pairs\(\)](#) for a definition of this) such that the entry of c in T is greater than the entry of d .

Warning: Do not mistake this for the inversions of a standard tableau.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[2,5]])
sage: t.inversions()
[(1, 1), (0, 0)]
sage: t = Tableau([[1,4,3],[5,2],[2,6],[3]])
```

```
sage: t.inversions()
[(0, 1), (0, 2), (1, 0), (1, 1), (1, 1), (0, 0), (2, 1), (1, 0)]
```

is_column_increasing(*weak=False*)

Return True if the entries in each column are in increasing order, and False otherwise.

By default, this checks for strictly increasing columns. Set *weak* to True to test for weakly increasing columns.

EXAMPLES:

```
sage: T = Tableau([[1, 1, 3], [1, 2]])
sage: T.is_column_increasing(weak=True)
True
sage: T.is_column_increasing()
False
sage: Tableau([[2], [1]]).is_column_increasing(weak=True)
False
```

is_column_strict()

Return True if self is a column strict tableau and False otherwise.

A tableau is column strict if the entries in each column are in (strictly) increasing order.

EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_column_strict()
True
sage: Tableau([[1, 2], [2, 4]]).is_column_strict()
True
sage: Tableau([[2, 3], [2, 4]]).is_column_strict()
False
sage: Tableau([[5, 3], [2, 4]]).is_column_strict()
False
sage: Tableau([]).is_column_strict()
True
sage: Tableau([[1, 4, 2]]).is_column_strict()
True
sage: Tableau([[1, 4, 2], [2, 5]]).is_column_strict()
True
sage: Tableau([[1, 4, 2], [2, 3]]).is_column_strict()
False
```

is_increasing()

Return True if self is an increasing tableau and False otherwise.

A tableau is increasing if it is both row strict and column strict.

EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_increasing()
True
sage: Tableau([[1, 2], [2, 4]]).is_increasing()
True
sage: Tableau([[2, 3], [2, 4]]).is_increasing()
False
sage: Tableau([[5, 3], [2, 4]]).is_increasing()
False
sage: Tableau([[1, 2, 3], [2, 3], [3]]).is_increasing()
True
```

is_k_tableau(*k*)

Checks whether `self` is a valid weak k -tableau.

EXAMPLES:

```
sage: t = Tableau([[1, 2, 3], [2, 3], [3]])
sage: t.is_k_tableau(3)
True
sage: t = Tableau([[1, 1, 3], [2, 2], [3]])
sage: t.is_k_tableau(3)
False
```

is_key_tableau()

Return `True` if `self` is a key tableau or `False` otherwise.

A tableau is a *key tableau* if the set of entries in the j -th column is a subset of the set of entries in the $(j - 1)$ -st column.

REFERENCES:

EXAMPLES:

```
sage: t = Tableau([[1, 1, 1], [2, 3], [3]])
sage: t.is_key_tableau()
True
sage: t = Tableau([[1, 1, 2], [2, 3], [3]])
sage: t.is_key_tableau()
False
```

is_rectangular()

Return `True` if the tableau `self` is rectangular and `False` otherwise.

EXAMPLES:

```
sage: Tableau([[1, 2], [3, 4]]).is_rectangular()
True
sage: Tableau([[1, 2, 3], [4, 5], [6]]).is_rectangular()
False
sage: Tableau([]).is_rectangular()
True
```

is_row_increasing(*weak=False*)

Return `True` if the entries in each row are in increasing order, and `False` otherwise.

By default, this checks for strictly increasing rows. Set `weak` to `True` to test for weakly increasing rows.

EXAMPLES:

```
sage: T = Tableau([[1, 1, 3], [1, 2]])
sage: T.is_row_increasing(weak=True)
True
sage: T.is_row_increasing()
False
sage: Tableau([[2, 1]]).is_row_increasing(weak=True)
False
```

is_row_strict()

Return `True` if `self` is a row strict tableau and `False` otherwise.

A tableau is row strict if the entries in each row are in (strictly) increasing order.

EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_row_strict()
True
sage: Tableau([[1, 2], [2, 4]]).is_row_strict()
True
sage: Tableau([[2, 3], [2, 4]]).is_row_strict()
True
sage: Tableau([[5, 3], [2, 4]]).is_row_strict()
False
```

is_semistandard()

Return True if self is a semistandard tableau, and False otherwise.

A tableau is semistandard if its rows weakly increase and its columns strictly increase.

EXAMPLES:

```
sage: Tableau([[1, 1], [1, 2]]).is_semistandard()
False
sage: Tableau([[1, 2], [1, 2]]).is_semistandard()
False
sage: Tableau([[1, 1], [2, 2]]).is_semistandard()
True
sage: Tableau([[1, 2], [2, 3]]).is_semistandard()
True
sage: Tableau([[4, 1], [3, 2]]).is_semistandard()
False
```

is_standard()

Return True if self is a standard tableau and False otherwise.

EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_standard()
True
sage: Tableau([[1, 2], [2, 4]]).is_standard()
False
sage: Tableau([[2, 3], [2, 4]]).is_standard()
False
sage: Tableau([[5, 3], [2, 4]]).is_standard()
False
```

k_weight(k)

Return the k -weight of self.

A tableau has k -weight $\alpha = (\alpha_1, \dots, \alpha_n)$ if there are exactly α_i distinct residues for the cells occupied by the letter i for each i . The residue of a cell in position (a, b) is $a - b$ modulo $k + 1$.

This definition is the one used in [Ive2012] (p. 12).

REFERENCES:

EXAMPLES:

```
sage: Tableau([[1, 2], [2, 3]]).k_weight(1)
[1, 1, 1]
sage: Tableau([[1, 2], [2, 3]]).k_weight(2)
[1, 2, 1]
```

```

sage: t = Tableau([[1,1,1,2,5],[2,3,6],[3],[4]])
sage: t.k_weight(1)
[2, 1, 1, 1, 1, 1]
sage: t.k_weight(2)
[3, 2, 2, 1, 1, 1]
sage: t.k_weight(3)
[3, 1, 2, 1, 1, 1]
sage: t.k_weight(4)
[3, 2, 2, 1, 1, 1]
sage: t.k_weight(5)
[3, 2, 2, 1, 1, 1]

```

lambda_catabolism(*part*)

Return the *part*-catabolism of *self*, where *part* is a partition (which can be just given as an array).

For a partition λ and a tableau T , the λ -catabolism of T is defined by performing the following steps.

1. Truncate the parts of λ so that λ is contained in the shape of T . Let m be the length of this partition.
2. Let T_a be the first m rows of T , and T_b be the remaining rows.
3. Let S_a be the skew tableau T_a/λ .
4. Concatenate the reading words of S_a and T_b , and insert into a tableau.

EXAMPLES:

```

sage: Tableau([[1,1,3],[2,4,5]]).lambda_catabolism([2,1])
[[3, 5], [4]]
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.lambda_catabolism([])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.lambda_catabolism([1])
[[1, 2, 3, 3, 3], [3]]
sage: t.lambda_catabolism([1,1])
[[1, 3, 3, 3], [3]]
sage: t.lambda_catabolism([2,1])
[[3, 3, 3, 3]]
sage: t.lambda_catabolism([4,2,1])
[]
sage: t.lambda_catabolism([5,1])
[[3, 3]]
sage: t.lambda_catabolism([4,1])
[[3, 3]]

```

last_letter_lequal(*tab2*)

Return True if *self* is less than or equal to *tab2* in the last letter ordering.

EXAMPLES:

```

sage: st = StandardTableaux([3,2])
sage: f = lambda b: 1 if b else 0
sage: matrix( [ [ f(t1.last_letter_lequal(t2)) for t2 in st] for t1 in st] )
[1 1 1 1 1]
[0 1 1 1 1]
[0 0 1 1 1]
[0 0 0 1 1]
[0 0 0 0 1]

```

left_key_tableau()

Return the left key tableau of `self`.

The left key tableau of a tableau T is the key tableau whose entries are weakly lesser than the corresponding entries in T , and whose column reading word is subject to certain conditions. See [LS90] for the full definition.

ALGORITHM:

The following algorithm follows [Willis10]. Note that if T is a key tableau then the output of the algorithm is T .

To compute the left key tableau L of a tableau T we iterate over the columns of T . Let T_j be the j -th column of T and iterate over the entries in T_j from bottom to top. Initialize the corresponding entry k in L as the largest entry in T_j . Scan the columns to the left of T_j and with each column update k to be the lowest entry in that column which is weakly less than k . Update T_j and all columns to the left by removing all scanned entries.

See also:

- `is_key_tableau()`

EXAMPLES:

```
sage: t = Tableau([[1, 2], [2, 3]])
sage: t.left_key_tableau()
[[1, 1], [2, 2]]
sage: t = Tableau([[1, 1, 2, 4], [2, 3, 3], [4], [5]])
sage: t.left_key_tableau()
[[1, 1, 1, 2], [2, 2, 2], [4], [5]]
```

leq(secondtab)

Check whether each entry of `self` is less-or-equal to the corresponding entry of a further tableau `secondtab`.

INPUT:

- `secondtab` – a tableau of the same shape as `self`

EXAMPLES:

```
sage: T = Tableau([[1, 2], [3]]) sage: S = Tableau([[1, 3], [3]]) sage: G = Tableau([[2, 1], [4]])
sage: H = Tableau([[1, 2], [4]]) sage: T.leq(S) True sage: T.leq(T) True sage: T.leq(G) False sage:
T.leq(H) True sage: S.leq(T) False sage: S.leq(G) False sage: S.leq(H) False sage: G.leq(H) False
sage: H.leq(G) False
```

level()

Returns the level of `self`, which is always 1.

This function exists mainly for compatibility with `TableauTuple`.

EXAMPLES:

```
sage: Tableau([[1, 2, 3], [4, 5]]).level()
1
```

major_index()

Return the major index of `self`.

The major index of a tableau T is defined to be the sum of the number of descents of T (defined in `descents()`) with the sum of their legs' lengths.

Warning: This is not to be confused with the major index of a standard tableau.

EXAMPLES:

```
sage: Tableau( [[1,4],[2,3]] ).major_index()
1
sage: Tableau( [[1,2],[3,4]] ).major_index()
2
```

If the major index would be defined in the sense of standard tableaux theory, then the following would give 3 for a result:

```
sage: Tableau( [[1,2,3],[4,5]] ).major_index()
2
```

pp()

Returns a pretty print string of the tableau.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[3,4],[5]])
sage: T.pp()
1 2 3
3 4
5
sage: Tableaux.options.convention="french"
sage: T.pp()
5
3 4
1 2 3
sage: Tableaux.options._reset()
```

promotion(n)

Return the image of `self` under the promotion operator.

Warning: You might know this operator as the inverse promotion operator – literature does not agree on the name. You might also be looking for the Lapointe-Lascoux-Morse promotion operator ([promotion_operator\(\)](#)).

The promotion operator, applied to a tableau t , does the following:

Iterate over all letters $n + 1$ in the tableau t , from left to right. For each of these letters, do the following:

- Remove the letter from t , thus leaving a hole where it used to be.
- Apply jeu de taquin to move this hole southwest (in French notation) until it reaches the inner boundary of t .
- Fill 0 into the hole once jeu de taquin has completed.

Once this all is done, add 1 to each letter in the tableau. This is not always well-defined. Restricted to the class of semistandard tableaux whose entries are all $\leq n + 1$, this is the usual promotion operator defined on this class.

When `self` is a standard tableau of size $n + 1$, this definition of promotion is precisely the one given in [Hai1992] (p. 90). It is the inverse of the maps called “promotion” in [Sg2011] (p. 23) and in [Stan2009].

Warning: To my (Darij’s) knowledge, the fact that the above promotion operator really is the inverse of the “inverse promotion operator” `promotion_inverse()` for semistandard tableaux has never been proven in literature. Corrections are welcome.

REFERENCES:

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,3]])
sage: t.promotion(2)
[[1, 1], [2, 3]]

sage: t = Tableau([[1,1,1],[2,2,3],[3,4,4]])
sage: t.promotion(3)
[[1, 1, 2], [2, 2, 3], [3, 4, 4]]

sage: t = Tableau([[1,2],[2]])
sage: t.promotion(3)
[[2, 3], [3]]

sage: t = Tableau([[1,1,3],[2,2]])
sage: t.promotion(2)
[[1, 2, 2], [3, 3]]

sage: t = Tableau([[1,1,3],[2,3]])
sage: t.promotion(2)
[[1, 1, 2], [2, 3]]

sage: t = Tableau([])
sage: t.promotion(2)
[]
```

promotion_inverse(*n*)

Return the image of `self` under the inverse promotion operator.

Warning: You might know this operator as the promotion operator (without “inverse”) – literature does not agree on the name.

The inverse promotion operator, applied to a tableau *t*, does the following:

Iterate over all letters *l* in the tableau *t*, from right to left. For each of these letters, do the following:

- Remove the letter from *t*, thus leaving a hole where it used to be.
- Apply jeu de taquin to move this hole northeast (in French notation) until it reaches the outer boundary of *t*.
- Fill $n + 2$ into the hole once jeu de taquin has completed.

Once this all is done, subtract 1 from each letter in the tableau. This is not always well-defined. Restricted to the class of semistandard tableaux whose entries are all $\leq n + 1$, this is the usual inverse promotion operator defined on this class.

When `self` is a standard tableau of size $n + 1$, this definition of inverse promotion is the map called “promotion” in [Sg2011] (p. 23) and in [Stan2009], and is the inverse of the map called “promotion” in [Hai1992] (p. 90).

Warning: To my (Darij's) knowledge, the fact that the above “inverse promotion operator” really is the inverse of the promotion operator `promotion()` for semistandard tableaux has never been proven in literature. Corrections are welcome.

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,3]])
sage: t.promotion_inverse(2)
[[1, 2], [2, 3]]

sage: t = Tableau([[1,2],[2,3]])
sage: t.promotion_inverse(2)
[[1, 1], [2, 3]]

sage: t = Tableau([[1,2,5],[3,3,6],[4,7]])
sage: t.promotion_inverse(8)
[[1, 2, 4], [2, 5, 9], [3, 6]]

sage: t = Tableau([])
sage: t.promotion_inverse(2)
[]
```

promotion_operator(*i*)

Return a list of semistandard tableaux obtained by the *i*-th Lapointe-Lascoux-Morse promotion operator from the semistandard tableau `self`.

Warning: This is not Schuetzenberger's jeu-de-taquin promotion! For the latter, see `promotion()` and `promotion_inverse()`.

This operator is defined by taking the maximum entry m of T , then adding a horizontal i -strip to T in all possible ways, each time filling this strip with $m + 1$'s, and finally letting the permutation $\sigma_1\sigma_2\cdots\sigma_m = (2, 3, \dots, m+1, 1)$ act on each of the resulting tableaux via the Lascoux-Schuetzenberger action (`symmetric_group_action_on_values()`). This method returns the list of all resulting tableaux. See [LLM01] for the purpose of this operator.

REFERENCES:

EXAMPLES:

```
sage: t = Tableau([[1,2],[3]])
sage: t.promotion_operator(1)
[[[1, 2], [3], [4]], [[1, 2], [3, 4]], [[1, 2, 4], [3]]]
sage: t.promotion_operator(2)
[[[1, 1], [2, 3], [4]],
 [[1, 1, 2], [3], [4]],
 [[1, 1, 4], [2, 3]],
 [[1, 1, 2, 4], [3]]]
sage: Tableau([[1]]).promotion_operator(2)
[[[1, 1], [2]], [[1, 1, 2]]]
sage: Tableau([[1,1],[2]]).promotion_operator(3)
[[[1, 1, 1], [2, 2], [3]],
 [[1, 1, 1, 2], [2], [3]],
 [[1, 1, 1, 3], [2, 2]],
 [[1, 1, 1, 2, 3], [2]]]
```

The example from [\[LLM01\]](#) p. 12:

```
sage: Tableau([[1,1],[2,2]]).promotion_operator(3)
[[[1, 1, 1], [2, 2], [3, 3]],
 [[1, 1, 1, 3], [2, 2], [3]],
 [[1, 1, 1, 3, 3], [2, 2]]]
```

raise_action_from_words(*f*, **args*)

EXAMPLES:

```
sage: from sage.combinat.tableau import symmetric_group_action_on_values
sage: import functools
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: f = functools.partial(t.raise_action_from_words, symmetric_group_action_
↪ on_values)
sage: f([1,2,3])
[[1, 1, 3, 3], [2, 3], [3]]
sage: f([3,2,1])
[[1, 1, 1, 1], [2, 3], [3]]
sage: f([1,3,2])
[[1, 1, 2, 2], [2, 2], [3]]
```

reading_word_permutation()

Return the permutation obtained by reading the entries of the standardization of `self` row by row, starting with the bottommost row (in English notation).

EXAMPLES:

```
sage: StandardTableau([[1,2],[3,4]]).reading_word_permutation()
[3, 4, 1, 2]
```

Check that [trac ticket #14724](#) is fixed:

```
sage: SemistandardTableau([[1,1]]).reading_word_permutation()
[1, 2]
```

reduced_column_word()

Return the lexicographically minimal reduced expression for the permutation that maps the conjugate of the `initial_tableau()` to `self`.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the columns of the tableau in order from top to bottom.

EXAMPLES:

```
sage: StandardTableau([[1,4,6],[2,5],[3]]).reduced_column_word()
[]
sage: StandardTableau([[1,4,5],[2,6],[3]]).reduced_column_word()
[5]
sage: StandardTableau([[1,3,6],[2,5],[4]]).reduced_column_word()
[3]
sage: StandardTableau([[1,3,5],[2,6],[4]]).reduced_column_word()
[3, 5]
sage: StandardTableau([[1,2,5],[3,6],[4]]).reduced_column_word()
[3, 2, 5]
```

reduced_lambda_catabolism(*part*)

EXAMPLES:

```

sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.reduced_lambda_catabolism([])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.reduced_lambda_catabolism([1])
[[1, 2, 3, 3, 3], [3]]
sage: t.reduced_lambda_catabolism([1,1])
[[1, 3, 3, 3], [3]]
sage: t.reduced_lambda_catabolism([2,1])
[[3, 3, 3, 3]]
sage: t.reduced_lambda_catabolism([4,2,1])
[]
sage: t.reduced_lambda_catabolism([5,1])
0
sage: t.reduced_lambda_catabolism([4,1])
0

```

reduced_row_word()

Return the lexicographically minimal reduced expression for the permutation that maps the `initial_tableau()` to `self`.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the rows of the tableau in order from top to bottom.

EXAMPLES:

```

sage: StandardTableau([[1,2,3],[4,5],[6]]).reduced_row_word()
[]
sage: StandardTableau([[1,2,3],[4,6],[5]]).reduced_row_word()
[5]
sage: StandardTableau([[1,2,4],[3,6],[5]]).reduced_row_word()
[3, 5]
sage: StandardTableau([[1,2,5],[3,6],[4]]).reduced_row_word()
[3, 5, 4]
sage: StandardTableau([[1,2,6],[3,5],[4]]).reduced_row_word()
[3, 4, 5, 4]

```

residue(*k*, *e*, *multicharge*=(0,))

Return the residue of the integer *k* in the tableau `self`.

The *residue* of *k* in a standard tableau is $c - r + m$ in $\mathbf{Z}/e\mathbf{Z}$, where *k* appears in row *r* and column *c* of the tableau with multicharge *m*.

INPUT:

- *k* – an integer in $\{1, 2, \dots, n\}$
- *e* – an integer in $\{0, 2, 3, 4, 5, \dots\}$
- *multicharge* – (default: `[0]`) a list of length 1

Here *n* is its size of `self`.

The *multicharge* is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with `residue()`.

OUTPUT:

The residue in $\mathbf{Z}/e\mathbf{Z}$.

EXAMPLES:

```

sage: StandardTableau([[1,2,5],[3,4]]).residue(1,3)
0
sage: StandardTableau([[1,2,5],[3,4]]).residue(2,3)
1
sage: StandardTableau([[1,2,5],[3,4]]).residue(3,3)
2
sage: StandardTableau([[1,2,5],[3,4]]).residue(4,3)
0
sage: StandardTableau([[1,2,5],[3,4]]).residue(5,3)
2
sage: StandardTableau([[1,2,5],[3,4]]).residue(6,3)
Traceback (most recent call last):
...
ValueError: 6 does not appear in the tableau

```

residue_sequence (*e*, *multicharge*=(0,))

Return the `sage.combinat.tableau_residues.ResidueSequence` of the tableau `self`.

INPUT:

- *e* – an integer in $\{0, 2, 3, 4, 5, \dots\}$
- *multicharge* – (default: [0]) a sequence of integers of length 1

The *multicharge* is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with `residue()`.

OUTPUT:

The corresponding residue sequence of the tableau; see `ResidueSequence`.

EXAMPLES:

```

sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(2)
2-residue sequence (0,1,1,0) with multicharge (0)
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(3)
3-residue sequence (0,1,2,0) with multicharge (0)
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(4)
4-residue sequence (0,1,3,0) with multicharge (0)

```

restrict (*n*)

Return the restriction of the semistandard tableau `self` to *n*. If possible, the restricted tableau will have the same parent as this tableau.

If *T* is a semistandard tableau and *n* is a nonnegative integer, then the restriction of *T* to *n* is defined as the (semistandard) tableau obtained by removing all cells filled with entries greater than *n* from *T*.

Note: If only the shape of the restriction, rather than the whole restriction, is needed, then the faster method `restriction_shape()` is preferred.

EXAMPLES:

```

sage: Tableau([[1,2],[3],[4]]).restrict(3)
[[1, 2], [3]]
sage: StandardTableau([[1,2],[3],[4]]).restrict(2)
[[1, 2]]
sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(0)
[]
sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(2)

```

```

[[1, 2], [2]]
sage: Tableau([[1, 2, 3], [2, 4, 4], [3]]).restrict(3)
[[1, 2, 3], [2], [3]]
sage: Tableau([[1, 2, 3], [2, 4, 4], [3]]).restrict(5)
[[1, 2, 3], [2, 4, 4], [3]]

```

If possible the restricted tableau will belong to the same category as the original tableau:

```

sage: S=StandardTableau([[1, 2, 4, 7], [3, 5], [6]]); S.category()
Category of elements of Standard tableaux
sage: S.restrict(4).category()
Category of elements of Standard tableaux
sage: SS=StandardTableaux([4, 2, 1])([[1, 2, 4, 7], [3, 5], [6]]); SS.category()
Category of elements of Standard tableaux of shape [4, 2, 1]
sage: SS.restrict(4).category()
Category of elements of Standard tableaux

sage: Tableau([[1, 2], [3], [4]]).restrict(3)
[[1, 2], [3]]
sage: Tableau([[1, 2], [3], [4]]).restrict(2)
[[1, 2]]
sage: SemistandardTableau([[1, 1], [2]]).restrict(1)
[[1, 1]]
sage: _.category()
Category of elements of Semistandard tableaux

```

restriction_shape(*n*)

Return the shape of the restriction of the semistandard tableau *self* to *n*.

If *T* is a semistandard tableau and *n* is a nonnegative integer, then the restriction of *T* to *n* is defined as the (semistandard) tableau obtained by removing all cells filled with entries greater than *n* from *T*.

This method computes merely the shape of the restriction. For the restriction itself, use `restrict()`.

EXAMPLES:

```

sage: Tableau([[1, 2], [2, 3], [3, 4]]).restriction_shape(3)
[2, 2, 1]
sage: StandardTableau([[1, 2], [3], [4], [5]]).restriction_shape(2)
[2]
sage: Tableau([[1, 3, 3, 5], [2, 4, 4], [17]]).restriction_shape(0)
[]
sage: Tableau([[1, 3, 3, 5], [2, 4, 4], [17]]).restriction_shape(2)
[1, 1]
sage: Tableau([[1, 3, 3, 5], [2, 4, 4], [17]]).restriction_shape(3)
[3, 1]
sage: Tableau([[1, 3, 3, 5], [2, 4, 4], [17]]).restriction_shape(5)
[4, 3]

sage: all( T.restriction_shape(i) == T.restrict(i).shape()
....:      for T in StandardTableaux(5) for i in range(1, 5) )
True

```

reverse_bump(*loc*)

Reverse row bump the entry of *self* at the specified location *loc* (given as a row index or a corner (*r*, *c*) of the tableau).

This is the reverse of Schensted's row-insertion algorithm. See Section 1.1, page 8, of Fulton's [\[Ful1997\]](#).

INPUT:

• `loc` – Can be either of the following:

- The coordinates (r, c) of the square to reverse-bump (which must be a corner of the tableau);
- The row index r of this square.

Note that both r and c are 0-based, i.e., the topmost row and the leftmost column are the 0-th row and the 0-th column.

OUTPUT:

An ordered pair consisting of:

1. The resulting (smaller) tableau;
2. The entry bumped out at the end of the process.

See also:

`bump()`

EXAMPLES:

This is the reverse of Schensted's bump:

```
sage: T = Tableau([[1, 1, 2, 2, 4], [2, 3, 3], [3, 4], [4]])
sage: T.reverse_bump(2)
([[1, 1, 2, 3, 4], [2, 3, 4], [3], [4]], 2)
sage: T == T.reverse_bump(2)[0].bump(2)
True
sage: T.reverse_bump((3, 0))
([[1, 2, 2, 2, 4], [3, 3, 3], [4, 4]], 1)
```

Some errors caused by wrong input:

```
sage: T.reverse_bump((3, 1))
Traceback (most recent call last):
...
ValueError: invalid corner
sage: T.reverse_bump(4)
Traceback (most recent call last):
...
IndexError: list index out of range
sage: Tableau([[2, 2, 1], [3, 3]]).reverse_bump(0)
Traceback (most recent call last):
...
ValueError: Reverse bumping is only defined for semistandard tableaux
```

Some edge cases:

```
sage: Tableau([[1]]).reverse_bump(0)
([], 1)
sage: Tableau([[1, 1]]).reverse_bump(0)
([[1]], 1)
sage: Tableau([]).reverse_bump(0)
Traceback (most recent call last):
...
IndexError: list index out of range
```

Note: Reverse row bumping is only implemented for tableaux with weakly increasing and strictly increas-

ing columns (though the tableau does not need to be an instance of class `SemistandardTableau`).

`right_key_tableau()`

Return the right key tableau of `self`.

The right key tableau of a tableau T is a key tableau whose entries are weakly greater than the corresponding entries in T , and whose column reading word is subject to certain conditions. See [LS90] for the full definition.

ALGORITHM:

The following algorithm follows [Willis10]. Note that if T is a key tableau then the output of the algorithm is T .

To compute the right key tableau R of a tableau T we iterate over the columns of T . Let T_j be the j -th column of T and iterate over the entries in T_j from bottom to top. Initialize the corresponding entry k in R to be the largest entry in T_j . Scan the bottom of each column of T to the right of T_j , updating k to be the scanned entry whenever the scanned entry is weakly greater than k . Update T_j and all columns to the right by removing all scanned entries.

See also:

- `is_key_tableau()`

EXAMPLES:

```
sage: t = Tableau([[1,2],[2,3]])
sage: t.right_key_tableau()
[[2, 2], [3, 3]]
sage: t = Tableau([[1,1,2,4],[2,3,3],[4],[5]])
sage: t.right_key_tableau()
[[2, 2, 2, 4], [3, 4, 4], [4], [5]]
```

`rotate_180()`

Return the tableau obtained by rotating `self` by 180 degrees.

This only works for rectangular tableaux.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).rotate_180()
[[4, 3], [2, 1]]
```

`row_stabilizer()`

Return the `PermutationGroup` corresponding to the row stabilizer of `self`.

This assumes that every integer from 1 to the size of `self` appears exactly once in `self`.

EXAMPLES:

```
sage: rs = Tableau([[1,2,3],[4,5]]).row_stabilizer()
sage: rs.order() == factorial(3)*factorial(2)
True
sage: PermutationGroupElement([(1,3,2),(4,5)]) in rs
True
sage: PermutationGroupElement([(1,4)]) in rs
False
sage: rs = Tableau([[1, 2],[3]]).row_stabilizer()
sage: PermutationGroupElement([(1,2),(3,)] in rs
True
```

```

sage: rs.one().domain()
[1, 2, 3]
sage: rs = Tableau([[1],[2],[3]]).row_stabilizer()
sage: rs.order()
1
sage: rs = Tableau([[2,4,5],[1,3]]).row_stabilizer()
sage: rs.order()
12
sage: rs = Tableau([]).row_stabilizer()
sage: rs.order()
1

```

schensted_insert (*i*, *left=False*)

Insert *i* into *self* using Schensted's row-bumping (or row-insertion) algorithm.

INPUT:

- *i* – a number to insert
- *left* – (default: *False*) boolean; if set to *True*, the insertion will be done from the left. That is, if one thinks of the algorithm as appending a letter to the reading word of *self*, we append the letter to the left instead of the right

EXAMPLES:

```

sage: t = Tableau([[3,5],[7]])
sage: t.schensted_insert(8)
[[3, 5, 8], [7]]
sage: t.schensted_insert(8, left=True)
[[3, 5], [7], [8]]

```

schuetzenberger_involution (*n=None*, *check=True*)

Return the Schuetzenberger involution of the tableau *self*.

This method relies on the analogous method on words, which reverts the word and then complements all letters within the underlying ordered alphabet. If *n* is specified, the underlying alphabet is assumed to be $[1, 2, \dots, n]$. If no alphabet is specified, *n* is the maximal letter appearing in *self*.

INPUT:

- *n* – an integer specifying the maximal letter in the alphabet (optional)
- *check* – (Default: *True*) Check to make sure *self* is semistandard. Set to *False* to avoid this check. (optional)

OUTPUT:

- a tableau, the Schuetzenberger involution of *self*

EXAMPLES:

```

sage: t = Tableau([[1,1,1],[2,2]])
sage: t.schuetzenberger_involution(3)
[[2, 2, 3], [3, 3]]

sage: t = Tableau([[1,2,3],[4,5]])
sage: t.schuetzenberger_involution()
[[1, 2, 5], [3, 4]]

sage: t = Tableau([[1,3,5,7],[2,4,6],[8,9]])
sage: t.schuetzenberger_involution()

```

```

[[1, 2, 6, 8], [3, 4, 9], [5, 7]]

sage: t = Tableau([])
sage: t.schuetzenberger_involution()
[]

sage: t = StandardTableau([[1, 2, 3], [4, 5]])
sage: s = t.schuetzenberger_involution()
sage: s.parent()
Standard tableaux

```

seg()

Return the total number of segments in `self`, as in [SI14].

Let T be a tableaux. We define a k -segment of T (in the i -th row) to be a maximal consecutive sequence of k -boxes in the i -th row for any $i + 1 \leq k \leq r + 1$. Denote the total number of k -segments in T by $\text{seg}(T)$.

REFERENCES:

EXAMPLES:

```

sage: t = Tableau([[1, 1, 2, 3, 5], [2, 3, 5, 5], [3, 4]])
sage: t.seg()
6

sage: B = crystals.Tableaux("A4", shape=[4, 3, 2, 1])
sage: t = B[31].to_tableau()
sage: t.seg()
3

```

shape()

Return the shape of a tableau `self`.

EXAMPLES:

```

sage: Tableau([[1, 2, 3], [4, 5], [6]]).shape()
[3, 2, 1]

```

size()

Return the size of the shape of the tableau `self`.

EXAMPLES:

```

sage: Tableau([[1, 4, 6], [2, 5], [3]]).size()
6
sage: Tableau([[1, 3], [2, 4]]).size()
4

```

slide_multiply(left, right)

Multiply two tableaux using jeu de taquin.

This product makes the set of semistandard tableaux into an associative monoid. The empty tableau is the unit in this monoid.

See pp. 15 of [Ful1997].

The same product operation is implemented in a different way in `bump_multiply()`.

EXAMPLES:

```
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t2 = Tableau([[1,2],[3]])
sage: t.slide_multiply(t2)
[[1, 1, 2, 2, 3], [2, 2, 3, 5], [3, 4, 5], [4, 6, 6], [5]]
```

socle()

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).socle()
2
sage: Tableau([[1,2,3,4]]).socle()
4
```

standardization (*check=True*)

Return the standardization of *self*, assuming *self* is a semistandard tableau.

The standardization of a semistandard tableau T is the standard tableau $st(T)$ of the same shape as T whose reversed reading word is the standardization of the reversed reading word of T .

The standardization of a word w can be formed by replacing all 1's in w by $1, 2, \dots, k_1$ from left to right, all 2's in w by $k_1 + 1, k_1 + 2, \dots, k_2$, and repeating for all letters which appear in w . See also `Word.standard_permutation()`.

INPUT:

- *check* – (Default: `True`) Check to make sure *self* is semistandard. Set to `False` to avoid this check.

EXAMPLES:

```
sage: t = Tableau([[1,3,3,4],[2,4,4],[5,16]])
sage: t.standardization()
[[1, 3, 4, 7], [2, 5, 6], [8, 9]]
```

Standard tableaux are fixed under standardization:

```
sage: all((t == t.standardization() for t in StandardTableaux(6)))
True
sage: t = Tableau([])
sage: t.standardization()
[]
```

The reading word of the standardization is the standardization of the reading word:

```
sage: T = SemistandardTableaux(shape=[6,3,3,1], max_entry=5)
sage: all(t.to_word().standard_permutation() == t.standardization().reading_
↪ word_permutation() for t in T) # long time
True
```

symmetric_group_action_on_entries (*w*)

Return the tableau obtained from this tableau by acting by the permutation w .

Let T be a standard tableau of size n , then the action of $w \in S_n$ is defined by permuting the entries of T (recall they are $1, 2, \dots, n$). In particular, suppose the entry at cell (i, j) is a , then the entry becomes $w(a)$. In general, the resulting tableau wT may *not* be standard.

Note: This is different than `symmetric_group_action_on_values()` which is defined on semi-standard tableaux and is guaranteed to return a semistandard tableau.

INPUT:

•w – a permutation

EXAMPLES:

```
sage: StandardTableau([[1,2,4],[3,5]]).symmetric_group_action_on_entries(_
↳Permutation(((4,5))) )
[[1, 2, 5], [3, 4]]
sage: _.category()
Category of elements of Standard tableaux
sage: StandardTableau([[1,2,4],[3,5]]).symmetric_group_action_on_entries(_
↳Permutation(((1,2))) )
[[2, 1, 4], [3, 5]]
sage: _.category()
Category of elements of Tableaux
```

symmetric_group_action_on_values (*perm*)

Return the image of the semistandard tableau *self* under the action of the permutation *perm* using the Lascoux-Schuetzenberger action of the symmetric group S_n on the semistandard tableaux with ceiling n .

If n is a nonnegative integer, then the Lascoux-Schuetzenberger action is a group action of the symmetric group S_n on the set of semistandard Young tableaux with ceiling n (that is, with entries taken from the set $\{1, 2, \dots, n\}$). It is defined as follows:

Let $i \in \{1, 2, \dots, n-1\}$, and let T be a semistandard tableau with ceiling n . Let w be the reading word (*to_word()*) of T . Replace all letters i in w by closing parentheses, and all letters $i+1$ in w by opening parentheses. Whenever an opening parenthesis stands left of a closing parenthesis without there being any parentheses in between (it is allowed to have letters in-between as long as they are not parentheses), consider these two parentheses as matched with each other, and replace them back by the letters $i+1$ and i . Repeat this procedure until there are no more opening parentheses standing left of closing parentheses. Then, let a be the number of opening parentheses in the word, and b the number of closing parentheses (notice that all opening parentheses are left of all closing parentheses). Replace the first a parentheses by the letters i , and replace the remaining b parentheses by the letters $i+1$. Let w' be the resulting word. Let T' be the tableau with the same shape as T but with reading word w' . This tableau T' can be shown to be semistandard. We define the image of T under the action of the simple transposition $s_i = (i, i+1) \in S_n$ to be this tableau T' . It can be shown that these actions $s_1, s_2, \dots, s_{n-1}$ satisfy the Moore-Coxeter relations of S_n , and thus this extends to a unique action of the symmetric group S_n on the set of semistandard tableaux with ceiling n . This is the Lascoux-Schuetzenberger action.

This action of the symmetric group S_n on the set of all semistandard tableaux of given shape λ with entries in $\{1, 2, \dots, n\}$ is the one defined in [Loth02] Theorem 5.6.3. In particular, the action of s_i is denoted by σ_i in said source. (Beware of the typo in the definition of σ_i : it should say $\sigma_i(a_i^r a_{i+1}^s) = a_i^s a_{i+1}^r$, not $\sigma_i(a_i^r a_{i+1}^s) = a_i^s a_{i+1}^s$.)

EXAMPLES:

```
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.symmetric_group_action_on_values([1,2,3])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.symmetric_group_action_on_values([2,1,3])
[[1, 2, 3, 3], [2, 3], [3]]
sage: t.symmetric_group_action_on_values([3,1,2])
[[1, 2, 2, 2], [2, 3], [3]]
sage: t.symmetric_group_action_on_values([2,3,1])
[[1, 1, 1, 1], [2, 2], [3]]
sage: t.symmetric_group_action_on_values([3,2,1])
[[1, 1, 1, 1], [2, 3], [3]]
```

```
sage: t.symmetric_group_action_on_values([1,3,2])
[[1, 1, 2, 2], [2, 2], [3]]
```

to_Gelfand_Tsetlin_pattern()

Return the *Gelfand-Tsetlin pattern* corresponding to self when semistandard.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[2,3],[3]])
sage: G = T.to_Gelfand_Tsetlin_pattern(); G
[[3, 2, 1], [2, 1], [1]]
sage: G.to_tableau() == T
True
sage: T = Tableau([[1,3],[2]])
sage: T.to_Gelfand_Tsetlin_pattern()
[[2, 1, 0], [1, 1], [1]]
```

to_chain(max_entry=None)

Return the chain of partitions corresponding to the (semi)standard tableau self.

The optional keyword parameter `max_entry` can be used to customize the length of the chain. Specifically, if this parameter is set to a nonnegative integer n , then the chain is constructed from the positions of the letters $1, 2, \dots, n$ in the tableau.

EXAMPLES:

```
sage: Tableau([[1,2],[3],[4]]).to_chain()
[[], [1], [2], [2, 1], [2, 1, 1]]
sage: Tableau([[1,1],[2]]).to_chain()
[[], [2], [2, 1]]
sage: Tableau([[1,1],[3]]).to_chain()
[[], [2], [2], [2, 1]]
sage: Tableau([]).to_chain()
[[]]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=2)
[[], [2], [2, 1]]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=3)
[[], [2], [2, 1], [2, 1, 1]]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=4)
[[], [2], [2, 1], [2, 1, 1], [2, 1, 1]]
sage: Tableau([[1,1,2],[2,3],[4,5]]).to_chain(max_entry=6)
[[], [2], [3, 1], [3, 2], [3, 2, 1], [3, 2, 2], [3, 2, 2]]
```

to_list()

Return self as a list of lists (not tuples!).

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,4]])
sage: l = t.to_list(); l
[[1, 2], [3, 4]]
sage: l[0][0] = 2
sage: t
[[1, 2], [3, 4]]
```

to_sign_matrix(max_entry=None)

Return the sign matrix of self.

A sign matrix is an $m \times n$ matrix of 0's, 1's and -1's such that the partial sums of each column is either 0 or 1 and the partial sums of each row is non-negative. [Aval2008]

INPUT:

- `max_entry` – A non-negative integer, the maximum allowable number in the tableau. Defaults to the largest entry in the tableau if not specified.

EXAMPLES:

```
sage: t = SemistandardTableau([[1,1,1,2,4],[3,3,4],[4,5],[6,6]])
sage: t.to_sign_matrix(6)
[ 0  0  0  1  0  0]
[ 0  1  0 -1  0  0]
[ 1 -1  0  1  0  0]
[ 0  0  1 -1  1  1]
[ 0  0  0  1 -1  0]
sage: t = Tableau([[1,2,4],[3,5]])
sage: t.to_sign_matrix(7)
[ 0  0  0  1  0  0  0]
[ 0  1  0 -1  1  0  0]
[ 1 -1  1  0 -1  0  0]
sage: t=Tableau([(4,5,4,3),(2,1,3)])
sage: t.to_sign_matrix(5)
[ 0  0  1  0  0]
[ 0  0  0  1  0]
[ 1  0 -1 -1  1]
[-1  1  0  1 -1]
sage: s=Tableau([(1,0,-2,4),(3,4,5)])
sage: s.to_sign_matrix(6)
Traceback (most recent call last):
...
ValueError: the entries must be non-negative integers
```

REFERENCES:

`to_word()`

An alias for `to_word_by_row()`.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).to_word()
word: 3412
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word()
word: 325146
```

`to_word_by_column()`

Return the word obtained from a column reading of the tableau `self` (starting with the leftmost column, reading every column from bottom to top).

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).to_word_by_column()
word: 3142
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word_by_column()
word: 321546
```

`to_word_by_row()`

Return the word obtained from a row reading of the tableau `self` (starting with the lowermost row, reading every row from left to right).

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).to_word_by_row()
word: 3412
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word_by_row()
word: 325146
```

vertical_flip()

Return the tableau obtained by vertically flipping the tableau *self*.

This only works for rectangular tableaux.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).vertical_flip()
[[3, 4], [1, 2]]
```

weight()

Return the weight of the tableau *self*. Trailing zeroes are omitted when returning the weight.

The weight of a tableau T is the sequence $(a_1, a_2, a_3, \dots)$, where a_k is the number of entries of T equal to k . This sequence contains only finitely many nonzero entries.

The weight of a tableau T is the same as the weight of the reading word of T , for any reading order.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).weight()
[1, 1, 1, 1]

sage: Tableau([]).weight()
[]

sage: Tableau([[1,3,3,7],[4,2],[2,3]]).weight()
[1, 2, 3, 1, 0, 0, 1]
```

class sage.combinat.tableau.**Tableau_class**(parent, t)

Bases: *sage.combinat.tableau.Tableau*

This exists solely for unpickling Tableau_class objects.

class sage.combinat.tableau.**Tableaux**

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

A factory class for the various classes of tableaux.

INPUT:

- *n* (optional) – a non-negative integer

OUTPUT:

- If *n* is specified, the class of tableaux of size *n*. Otherwise, the class of all tableaux.

A tableau in Sage is a finite list of lists, whose lengths are weakly decreasing, or an empty list, representing the empty tableau. The entries of a tableau can be any Sage objects. Because of this, no enumeration through the set of Tableaux is possible.

EXAMPLES:

```

sage: T = Tableaux(); T
Tableaux
sage: T3 = Tableaux(3); T3
Tableaux of size 3
sage: [['a', 'b']] in T
True
sage: [['a', 'b']] in T3
False
sage: t = T3([[1, 1, 1]]); t
[[1, 1, 1]]
sage: t in T
True
sage: t.parent()
Tableaux of size 3
sage: T([]) # the empty tableau
[]
sage: T.category()
Category of sets

```

- *SemistandardTableau*
- *StandardTableaux*
- *StandardTableau*

Element

alias of *Tableau*

global_options (*args, **kws)

Deprecated: Use *options()* instead. See [trac ticket #18555](#) for details.

options (*get_value, **set_value)

Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- *ascii_art* – (default: repr) Controls the ascii art output for tableaux
 - compact – minimal length ascii art
 - repr – display using the diagram string representation
 - table – display as a table
- *convention* – (default: English) Sets the convention used for displaying tableaux and partitions
 - English – use the English convention
 - French – use the French convention
- *display* – (default: list) Controls the way in which tableaux are printed
 - array – alias for diagram
 - compact – minimal length string representation
 - diagram – display as Young diagram (similar to *pp()*)

- ferrers_diagram – alias for diagram
- list – print tableaux as lists
- young_diagram – alias for diagram
- latex – (default: diagram) Controls the way in which tableaux are latexed
- array – alias for diagram
- diagram – as a Young diagram
- ferrers_diagram – alias for diagram
- list – as a list
- young_diagram – alias for diagram
- notation – alternative name for convention

Note: Changing the `convention` for tableaux also changes the `convention` for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.options.display="array"
sage: T
 1  2  3
 4  5
sage: Tableaux.options.convention="french"
sage: T
 4  5
 1  2  3
```

Changing the `convention` for tableaux also changes the `convention` for partitions and vice versa:

```
sage: P = Partition([3,3,1])
sage: print(P.ferrers_diagram())
*
***
***
sage: Partitions.options.convention="english"
sage: print(P.ferrers_diagram())
***
***
*
sage: T
 1  2  3
 4  5
```

The ASCII art can also be changed:

```
sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
 1  2  3
 4  5
sage: Tableaux.options.ascii_art="table"
```

```

sage: ascii_art(t)
+---+---+
| 4 | 5 |
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
sage: Tableaux.options.ascii_art="compact"
sage: ascii_art(t)
|4|5|
|1|2|3|
sage: Tableaux.options._reset()

```

See `GlobalOptions` for more features of these options.

class `sage.combinat.tableau.Tableaux_all`

Bases: `sage.combinat.tableau.Tableaux`

Initializes the class of all tableaux

an_element()

Returns a particular element of the class.

class `sage.combinat.tableau.Tableaux_size(n)`

Bases: `sage.combinat.tableau.Tableaux`

Tableaux of a fixed size n .

an_element()

Returns a particular element of the class.

`sage.combinat.tableau.from_chain(chain)`

Returns a semistandard tableau from a chain of partitions.

EXAMPLES:

```

sage: from sage.combinat.tableau import from_chain
sage: from_chain([[1], [2], [2, 1], [3, 2, 1]])
[[1, 1, 3], [2, 3], [3]]

```

`sage.combinat.tableau.from_shape_and_word(shape, w, convention='French')`

Returns a tableau from a shape and word.

INPUT:

- `shape` – a partition
- `w` – a word whose length equals that of the partition
- `convention` – a string which can take values "French" or "English"; the default is "French"

OUTPUT:

A tableau, whose shape is `shape` and whose reading word is `w`. If the `convention` is specified as "French", the reading word is to be read starting from the top row in French convention (= the bottom row in English convention). If the `convention` is specified as "English", the reading word is to be read starting with the top row in English convention.

EXAMPLES:

```

sage: from sage.combinat.tableau import from_shape_and_word
sage: t = Tableau([[1, 3], [2], [4]])
sage: shape = t.shape(); shape

```

```

[2, 1, 1]
sage: word = t.to_word(); word
word: 4213
sage: from_shape_and_word(shape, word)
[[1, 3], [2], [4]]
sage: word = Word(flatten(t))
sage: from_shape_and_word(shape, word, convention = "English")
[[1, 3], [2], [4]]

```

sage.combinat.tableau.**symmetric_group_action_on_values**(word, perm)

EXAMPLES:

```

sage: from sage.combinat.tableau import symmetric_group_action_on_values
sage: symmetric_group_action_on_values([1, 1, 1], [1, 3, 2])
[1, 1, 1]
sage: symmetric_group_action_on_values([1, 1, 1], [2, 1, 3])
[2, 2, 2]
sage: symmetric_group_action_on_values([1, 2, 1], [2, 1, 3])
[2, 2, 1]
sage: symmetric_group_action_on_values([2, 2, 2], [2, 1, 3])
[1, 1, 1]
sage: symmetric_group_action_on_values([2, 1, 2], [2, 1, 3])
[2, 1, 1]
sage: symmetric_group_action_on_values([2, 2, 3, 1, 1, 2, 2, 3], [1, 3, 2])
[2, 3, 3, 1, 1, 2, 3, 3]
sage: symmetric_group_action_on_values([2, 1, 1], [2, 1])
[2, 1, 2]
sage: symmetric_group_action_on_values([2, 2, 1], [2, 1])
[1, 2, 1]
sage: symmetric_group_action_on_values([1, 2, 1], [2, 1])
[2, 2, 1]

```

sage.combinat.tableau.**unmatched_places**(w, open, close)

EXAMPLES:

```

sage: from sage.combinat.tableau import unmatched_places
sage: unmatched_places([2, 2, 2, 1, 1, 1], 2, 1)
([], [])
sage: unmatched_places([1, 1, 1, 2, 2, 2], 2, 1)
([0, 1, 2], [3, 4, 5])
sage: unmatched_places([], 2, 1)
([], [])
sage: unmatched_places([1, 2, 4, 6, 2, 1, 5, 3], 2, 1)
([0], [1])
sage: unmatched_places([2, 2, 1, 2, 4, 6, 2, 1, 5, 3], 2, 1)
([], [0, 3])
sage: unmatched_places([3, 1, 1, 1, 2, 1, 2], 2, 1)
([1, 2, 3], [6])

```

5.1.323 Residue sequences of tableaux

A *residue sequence* for a *StandardTableau*, or *StandardTableauTuple*, of size n is an n -tuple $(i_1, i_2, \dots, i_n)$ of elements of $\mathbb{Z}/e\mathbb{Z}$ for some positive integer $e \geq 1$. Such sequences arise in the representation theory of the symmetric group and the closely related cyclotomic Hecke algebras, and cyclotomic quiver Hecke algebras, where the residue sequences play a similar role to weights in the representations of Lie groups and Lie algebras. These Hecke algebras are semisimple when e is “large enough” and in these cases residue sequences are essentially the

same as content sequences (see `sage.combinat.partition.Partition.content()`) and it is not difficult to see that residue sequences are in bijection with the set of standard tableaux. In the non-semisimple case, when e is “small”, different standard tableaux can have the same residue sequence. In this case the residue sequences describe how to decompose modules into generalised eigenspaces for the Jucys-Murphy elements for these algebras.

By definition, if t is a `StandardTableau` of size n then the residue sequence of t is the n -tuple $(i_1, \dots, i_n)$ where $i_m = c - r + e\mathbb{Z}$, if m appears in row r and column c of t . If p is prime then such sequence arise in the representation theory of the symmetric group n characteristic p . More generally, e -residue sequences arise in the representation theory of the Iwahori-Hecke algebra (see `IwahoriHeckeAlgebra`) the symmetric group with Hecke parameter at an e -th root of unity.

More generally, the e -residue sequence of a `StandardTableau` of size n and level l is the n -tuple $(i_1, \dots, i_n)$ determined by e and a *multicharge* $\kappa = (\kappa_1, \dots, \kappa_l)$ by setting $i_m = \kappa_k + c - r + e\mathbb{Z}$, if m appears in component k , row r and column c of t . These sequences arise in the representation theory of the cyclotomic Hecke algebras of type A, which are also known as Ariki-Koike algebras.

The residue classes are constructed from standard tableaux:

```
sage: StandardTableau([[1,2],[3,4]]).residue_sequence(2)
2-residue sequence (0,1,1,0) with multicharge (0)
sage: StandardTableau([[1,2],[3,4]]).residue_sequence(3)
3-residue sequence (0,1,2,0) with multicharge (0)

sage: StandardTableauTuple([[5]],[[1,2],[3,4]]).residue_sequence(3,[0,0])
3-residue sequence (0,1,2,0,0) with multicharge (0,0)
sage: StandardTableauTuple([[5]],[[1,2],[3,4]]).residue_sequence(3,[0,1])
3-residue sequence (1,2,0,1,0) with multicharge (0,1)
sage: StandardTableauTuple([[5]],[[1,2],[3,4]]).residue_sequence(3,[0,2])
3-residue sequence (2,0,1,2,0) with multicharge (0,2)
```

One of the most useful functions of a `ResidueSequence` is that it can return the `StandardTableaux_residue` and `StandardTableaux_residue_shape` that contain all of the tableaux with this residue sequence. Again, these are best accessed via the standard tableaux classes:

```
sage: res = StandardTableau([[1,2],[3,4]]).residue_sequence(2)
sage: res.standard_tableaux()
Standard tableaux with 2-residue sequence (0,1,1,0) and multicharge (0)
sage: res.standard_tableaux()[:]
[[[1, 2, 4], [3]],
 [[1, 2], [3, 4]],
 [[1, 2], [3], [4]],
 [[1, 3, 4], [2]],
 [[1, 3], [2, 4]],
 [[1, 3], [2], [4]]]
sage: res.standard_tableaux(shape=[4])
Standard (4)-tableaux with 2-residue sequence (0,1,1,0) and multicharge (0)
sage: res.standard_tableaux(shape=[4])[:]
[]

sage: res=StandardTableauTuple([[5]],[[1,2],[3,4]]).residue_sequence(3,[0,0])
sage: res.standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,0,0) and multicharge (0,0)
sage: res.standard_tableaux(shape=[[1],[2,2]])[:]
[[[5]],[[1, 2], [3, 4]]], ([[4]],[[1, 2], [3, 5]])]
```

These residue sequences are particularly useful in the graded representation theory of the cyclotomic Hecke algebras of type A [BK].

This module implements the following classes:

- *ResidueSequence*
- *ResidueSequences*

See also:

- *PartitionTuples*
- *Partitions*
- *StandardTableau*
- *StandardTableaux_residue_shape*
- *StandardTableaux_residue*
- *StandardTableaux*
- *Tableau*
- *Tableaux*

Todo

Strictly speaking this module implements residue sequences of type $A_e^{(1)}$. Residue sequences of other types also need to be implemented.

AUTHORS:

- Andrew Mathas (2016-07-01): Initial version

class `sage.combinat.tableau_residues.ResidueSequence` (*parent, residues, check*)

Bases: `sage.structure.list_clone.ClonableArray`

A residue sequence.

The *residue sequence* of a tableau t (of partition or partition tuple shape) is the sequence $(i_1, i_2, \dots, i_n)$ where i_k is the residue of l in t , for $k = 1, 2, \dots, n$, where n is the size of t . Residue sequences are important in the representation theory of the cyclotomic Hecke algebras of type $G(r, 1, n)$, and of the cyclotomic quiver Hecke algebras, because they determine the eigenvalues of the Jucys-Murphy elements upon all modules. More precisely, they index and completely determine the irreducible representations of the (cyclotomic) Gelfand-Tsetlin algebras.

Rather than being called directly, residue sequences are best accessed via the standard tableaux classes *StandardTableau* and *StandardTableauTuple*.

INPUT:

Can be of the form:

- `ResidueSequence(e, res)`,
- `ResidueSequence(e, multicharge, res)`,

where e is a positive integer not equal to 1 and res is a sequence of integers (the residues).

EXAMPLES:

```
sage: res = StandardTableauTuple([[1, 3], [6]], [[2, 7], [4], [5]]).residue_  
↪sequence(3, (0, 5))  
sage: res  
3-residue sequence (0, 2, 1, 1, 0, 2, 0) with multicharge (0, 2)  
sage: res.quantum_characteristic()  
3
```

```

sage: res.level()
2
sage: res.size()
7
sage: res.residues()
[0, 2, 1, 1, 0, 2, 0]
sage: res.restrict(2)
3-residue sequence (0,2) with multicharge (0,2)
sage: res.standard_tableaux([[2,1],[1],[2,1,1]])
Standard (2,1|1|2,1^2)-tableaux with 3-residue sequence (0,2,1,1,0,2,0) and
↳multicharge (0,2)
sage: res.standard_tableaux([[2,2],[3]]).list()
[]
sage: res.standard_tableaux([[2,2],[3]])[: ]
[]
sage: res.standard_tableaux()
Standard tableaux with 3-residue sequence (0,2,1,1,0,2,0) and multicharge (0,2)
sage: res.standard_tableaux()[:10]
[[[1, 3, 6, 7], [2, 5], [4]], []],
 [[1, 3, 6], [2, 5], [4], [7]], []],
 [[1, 3], [2, 5], [4, 6], [7]], []],
 [[1, 3], [2, 5], [4], [7]], [[6]],
 [[1, 3], [2, 5], [4]], [[6, 7]]],
 [[1, 3, 6, 7], [2], [4], [5]], []],
 [[1, 3, 6], [2, 7], [4], [5]], []],
 [[1, 3], [2, 7], [4], [5], [6]], []],
 [[1, 3], [2, 7], [4], [5]], [[6]],
 [[1, 3], [2], [4], [5]], [[6, 7]]]

```

The TestSuite fails `_test_pickling` because `__getitem__` does not support slices, so we skip this.

base_ring()

Return the base ring for the residue sequence.

If the `quantum_characteristic()` of the residue sequence `self` is e then the base ring for the sequence is $\mathbb{Z}/e\mathbb{Z}$, or $\mathbb{Z}$ if $e = 0$.

EXAMPLES:

```

sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).base_ring()
Ring of integers modulo 3

```

block()

Return a dictionary β that determines the block associated to the residue sequence `self`.

In more detail, in tis dictionary $\beta[i]$ is equal to the number of nodes of residue i . This corresponds to

$$\sum_{i \in I} \beta_i \alpha_i \in Q^+,$$

a element of the positive root lattice of the corresponding Kac-Moody algebra.

This is a useful statistics because two Specht modules for a cyclotomic Hecke algebra of type A belong to the same block if and only if they correspond to same element β of the root lattice, given above.

We return a dictionary because when the quantum characteristic is 0, the Cartan type is A_∞ , in which case the simple roots are indexed by the integers.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,0], [0,1,2,0,1,2,0,1,2]).block()
{0: 3, 1: 3, 2: 3}
```

check()

Raise a ValueError if self is not a residue sequence.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,1], [0,0,1,1,2,2,3,3]).check()
sage: ResidueSequence(3, [0,0,1], [2,0,1,1,2,2,3,3]).check()
```

level()

Return the level of the residue sequence. That is, the level of the corresponding (tuples of) standard tableaux.

The *level* of a residue sequence is the length of its `multicharge()`. This is the same as the level of the `standard_tableaux()` that belong to the residue class of tableaux determined by self.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).level()
3
```

multicharge()

Return the multicharge for the residue sequence self.

The e -residue sequences are associated with a cyclotomic Hecke algebra with Hecke parameter q of `quantum_characteristic()` e and multicharge $(\kappa_1, \dots, \kappa_l)$. This means that the cyclotomic parameters of the Hecke algebra are $q^{\kappa_1}, \dots, q^{\kappa_l}$. Equivalently, the Hecke algebra is determined by the dominant weight

$$\sum_{r \in \mathbb{Z}/e\mathbb{Z}} \kappa_r \Lambda_r \in P^+.$$

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).multicharge()
(0, 0, 1)
```

negative()

Return the negative of the residue sequence self.

That is, if self is the residue sequence $(i_1, \dots, i_n)$ then return $(-i_1, \dots, -i_n)$. Taking the negative residue sequences is a shadow of tensoring with the sign representation from the cyclotomic Hecke algebras of type A .

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,1], [0,0,1,1,2,2,3,3]).negative()
3-residue sequence (0,0,2,2,1,1,0,0) with multicharge (0,0,1)
```

quantum_characteristic()

Return the quantum characteristic of the residue sequence self.

The e -residue sequences are associated with a cyclotomic Hecke algebra that has a parameter q of *quantum characteristic* e . This is the smallest positive integer such that $1 + q + \cdots + q^{e-1} = 0$, or $e = 0$ if no such integer exists.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).quantum_characteristic()
3
```

residues()

Return a list of the residue sequence.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).residues()
[0, 0, 1, 1, 2, 2, 0, 0]
```

restrict(m)

Return the subsequence of this sequence of length m .

The residue sequence `self` is of the form $(r_1, \dots, r_n)$. The function returns the residue sequence $(r_1, \dots, r_m)$, with the same *quantum_characteristic()* and *multicharge()*.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).restrict(7)
3-residue sequence (0,0,1,1,2,2,0) with multicharge (0,0,1)
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).restrict(6)
3-residue sequence (0,0,1,1,2,2) with multicharge (0,0,1)
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).restrict(4)
3-residue sequence (0,0,1,1) with multicharge (0,0,1)
```

size()

Return the size of the residue sequence.

This is the size, or length, of the residue sequence, which is the same as the size of the *standard_tableaux()* that belong to the residue class of tableaux determined by `self`.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).size()
8
```

standard_tableaux($shape=None$)

Return the residue-class of standard tableaux that have residue sequence `self`.

INPUT:

- `shape` – (optional) a partition or partition tuple of the correct level

OUTPUT:

An iterator for the standard tableaux with this residue sequence. If the `shape` is given then only tableaux of this shape are returned, otherwise all of the full residue-class of standard tableaux, or standard tableaux tuples, is returned. The residue sequence `self` specifies the *multicharge()* of the tableaux which, in turn, determines the *level()* of the tableaux in the residue class.

EXAMPLES:

```

sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,0), [0,1,2,0,1,2,0,1,2]).standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and multicharge_
↪ (0,0,0)
sage: ResidueSequence(3, (0,0,0), [0,1,2,0,1,2,0,1,2]).standard_tableaux([[3],
↪ [3], [3]])
Standard (3|3|3)-tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and_
↪ multicharge (0,0,0)

```

swap_residues (*i*, *j*)

Return the *new* residue sequence obtained by swapping the residues for *i* and *j*.

INPUT:

- *i* and *j* – two integers between 1 and the length of the residue sequence

If residue sequence *self* is of Te form $(r_1, \dots, r_n)$, and $i < j$, then the residue sequence $(r_1, \dots, r_j, \dots, r_i, \dots, r_m)$, with the same `quantum_characteristic()` and `multicharge()`, is returned.

EXAMPLES:

```

sage: from sage.combinat.tableau_residues import ResidueSequence
sage: res = ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]); res
3-residue sequence (0,0,1,1,2,2,0,0) with multicharge (0,0,1)
sage: ser = res.swap_residues(2,6); ser
3-residue sequence (0,2,1,1,2,0,0,0) with multicharge (0,0,1)
sage: res == ser
False

```

class `sage.combinat.tableau_residues.ResidueSequences` (*e*, *multicharge*=(0,))

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

A parent class for `ResidueSequence`.

This class exists because `ResidueSequence` needs to have a parent. Apart from being a parent the only useful method that it provides is `cell_residue()`, which is a short-hand for computing the residue of a cell using the `ResidueSequence.quantum_characteristic()` and `ResidueSequence.multicharge()` for the residue class.

EXAMPLES:

```

sage: from sage.combinat.tableau_residues import ResidueSequences
sage: ResidueSequences(e=0, multicharge=(0,1,2))
0-residue sequences with multicharge (0, 1, 2)
sage: ResidueSequences(e=0, multicharge=(0,1,2)) == ResidueSequences(e=0,
↪ multicharge=(0,1,2))
True
sage: ResidueSequences(e=0, multicharge=(0,1,2)) == ResidueSequences(e=3,
↪ multicharge=(0,1,2))
False
sage: ResidueSequences(e=0, multicharge=(0,1,2)).element_class
<class 'sage.combinat.tableau_residues.ResidueSequences_with_category.element_
↪ class'>

```

Element

alias of `ResidueSequence`

an_element()

Return a particular element of `self`.

EXAMPLES:

```
sage: TableauTuples().an_element()
([[1]], [[2]], [[3]], [[4]], [[5]], [[6]], [[7]])
```

cell_residue(*args)

Return the residue a cell with respect to the quantum characteristic and the multicharge of the residue sequence.

INPUT:

- `r` and `c` – the row and column indices in level one
- `k`, `r` and `c` – the component, row and column indices in higher levels

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequences
sage: ResidueSequences(3).cell_residue(1,1)
0
sage: ResidueSequences(3).cell_residue(2,1)
2
sage: ResidueSequences(3).cell_residue(3,1)
1
sage: ResidueSequences(3).cell_residue(3,2)
2
sage: ResidueSequences(3, (0,1,2)).cell_residue(0,0,0)
0
sage: ResidueSequences(3, (0,1,2)).cell_residue(0,1,0)
2
sage: ResidueSequences(3, (0,1,2)).cell_residue(0,1,2)
1
sage: ResidueSequences(3, (0,1,2)).cell_residue(1,0,0)
1
sage: ResidueSequences(3, (0,1,2)).cell_residue(1,1,0)
0
sage: ResidueSequences(3, (0,1,2)).cell_residue(1,0,1)
2
sage: ResidueSequences(3, (0,1,2)).cell_residue(2,0,0)
2
sage: ResidueSequences(3, (0,1,2)).cell_residue(2,1,0)
1
sage: ResidueSequences(3, (0,1,2)).cell_residue(2,0,1)
0
```

check_element(element)

Check that `element` is a residue sequence with multicharge `self.multicharge()`.

This is weak criteria in that we only require that `element` is a tuple of elements in the underlying base ring of `self`. Such a sequence is always a valid residue sequence, although there may be no tableaux with this residue sequence.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]) # indirect doctest
3-residue sequence (0,0,1,1,2,2,0,0) with multicharge (0,0,1)
sage: ResidueSequence(3, (0,0,1), [2,0,1,4,2,2,5,3]) # indirect doctest

sage: ResidueSequence(3, (0,0,1), [2,0,1,1,2,2,3,3]) # indirect doctest
3-residue sequence (2,0,1,1,2,2,0,0) with multicharge (0,0,1)
```

5.1.324 TableauTuples

A *TableauTuple* is a tuple of tableaux. These objects arise naturally in representation theory of the wreath products of cyclic groups and the symmetric groups where the standard tableau tuples index bases for the ordinary irreducible representations. This generalises the well-known fact the ordinary irreducible representations of the symmetric groups have bases indexed by the standard tableaux of a given shape. More generally, *TableauTuples*, or multitableaux, appear in the representation theory of the degenerate and non-degenerate cyclotomic Hecke algebras and in the crystal theory of the integral highest weight representations of the affine special linear groups.

A *TableauTuple* is an ordered tuple $(t^{(1)}, t^{(2)}, \dots, t^{(l)})$ of tableaux. The length of the tuple is its *level* and the tableaux $t^{(1)}, t^{(2)}, \dots, t^{(l)}$ are the components of the *TableauTuple*.

A tableau can be thought of as the labelled diagram of a partition. Analogously, a *TableauTuple* is the labelled diagram of a *PartitionTuple*. That is, a *TableauTuple* is a tableau of *PartitionTuple* shape. As much as possible, *TableauTuples* behave in exactly the same way as *Tableaux*. There are obvious differences in that the cells of a partition are ordered pairs (r, c) , where r is a row index and c a column index, whereas the cells of a *PartitionTuple* are ordered triples (k, r, c) , with r and c as before and k indexes the component.

Frequently, we will call a *TableauTuple* a tableau, or a tableau of *PartitionTuple* shape. If the shape of the tableau is known this should not cause any confusion.

Warning: In sage the convention is that the (k, r, c) -th entry of a tableau tuple t is the entry in row r , column c and component k of the tableau. This is because it makes much more sense to let $t[k]$ be component of the tableau. In particular, we want $t(k, r, c) == t[k][r][c]$. In the literature, the cells of a tableau tuple are usually written in the form (r, c, k) , where r is the row index, c is the column index, and k is the component index.

The same convention applies to the cells of *PartitionTuples*.

Note: As with partitions and tableaux, the cells are 0-based. For example, the (lexicographically) first cell in any non-empty tableau tuple is $[0, 0, 0]$.

EXAMPLES:

```
sage: TableauTuple([[1,2,3],[4,5]])
[[1, 2, 3], [4, 5]]
sage: t = TableauTuple([ [[6,7],[8,9]], [[1,2,3],[4,5]] ]); t
([[6, 7], [8, 9]], [[1, 2, 3], [4, 5]])
sage: t.pp()
 6 7   1 2 3
 8 9   4 5
sage: t(0,0,1)
7
sage: t(1,0,1)
2
sage: t.shape()
([2, 2], [3, 2])
sage: t.size()
9
sage: t.level()
```

```

2
sage: t.components()
[[[6, 7], [8, 9]], [[1, 2, 3], [4, 5]]]
sage: t.entries()
[6, 7, 8, 9, 1, 2, 3, 4, 5]
sage: t.parent()
Tableau tuples
sage: t.category()
Category of elements of Tableau tuples

```

One reason for implementing *TableauTuples* is to be able to consider *StandardTableauTuples*. These objects arise in many areas of algebraic combinatorics. In particular, they index bases for the Specht modules of the cyclotomic Hecke algebras of type $G(r, 1, n)$. A *StandardTableauTuple* of tableau whose entries are increasing along rows and down columns in each component and which contain the numbers $1, 2, \dots, n$, where the shape of the *StandardTableauTuple* is a *PartitionTuple* of n .

```

sage: s = StandardTableauTuple([ [[1,2],[3]], [[4,5]] ])
sage: s.category()
Category of elements of Standard tableau tuples
sage: t = TableauTuple([ [[1,2],[3]], [[4,5]] ])
sage: t.is_standard(), t.is_column_strict(), t.is_row_strict()
(True, True, True)
sage: t.category()
Category of elements of Tableau tuples
sage: s == t
True
sage: s is t
False
sage: s == StandardTableauTuple(t)
True
sage: StandardTableauTuples([ [2,1],[1] ]):[:]
([([1, 2], [3]), ([4])],
 ([([1, 3], [2]), ([4])],
 ([([1, 2], [4]), ([3])],
 ([([1, 3], [4]), ([2])],
 ([([2, 3], [4]), ([1])],
 ([([1, 4], [2]), ([3])],
 ([([1, 4], [3]), ([2])],
 ([([2, 4], [3]), ([1])])

```

As tableaux (of partition shape) are in natural bijection with 1-tuples of tableaux all of the *TableauTuple* classes return an ordinary *Tableau* when given *TableauTuple* of level 1.

```

sage: TableauTuples( level=1 ) is Tableaux()
True
sage: TableauTuple([ [1,2,3], [4,5] ])
[[1, 2, 3], [4, 5]]
sage: TableauTuple([ [1,2,3], [4,5] ])
[[1, 2, 3], [4, 5]]
sage: TableauTuple([ [1,2,3], [4,5] ]) == Tableau([ [1,2,3], [4,5] ])
True

```

There is one situation where a 1-tuple of tableau is not actually a *Tableau*; tableaux generated by the *StandardTableauTuples()* iterators must have the correct parents, so in this one case 1-tuples of tableaux are different from *Tableaux*:

```
sage: StandardTableauTuples()[:10]
[(),
 ([[1]]),
 ([], []),
 ([[1, 2]]),
 ([[1], [2]]),
 ([[1]], []),
 ([], [[1]]),
 ([], [], []),
 ([[1, 2, 3]]),
 ([[1, 3], [2]])]
```

AUTHORS:

- Andrew Mathas (2012-10-09): Initial version – heavily based on `tableau.py` by Mike Hansen (2007) and Jason Bandlow (2011).

This file consists of the following major classes:

Todo

Implement semistandard tableau tuples as defined in [DJM].

Much of the combinatorics implemented here is motivated by this and subsequent papers on the representation theory of these algebras.

REFERENCES:

class `sage.combinat.tableau_tuple.StandardTableauTuple` (*parent*, *t*)

Bases: `sage.combinat.tableau_tuple.TableauTuple`

A class to model a standard tableau of shape a partition tuple. This is a tuple of standard tableau with entries $1, 2, \dots, n$, where n is the size of the underlying partition tuple, such that the entries increase along rows and down columns in each component of the tuple.

Note: The tableaux appearing in a `StandardTableauTuple` are both row and column strict, but individually they are not standard tableaux because the entries in any single component of a `StandardTableauTuple` will typically not be in bijection with $\{1, 2, \dots, n\}$.

INPUT:

- *t* – a tableau, a list of (standard) tableau or an equivalent list

OUTPUT:

- A `StandardTableauTuple` object constructed from *t*.

Note: Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with `PartitionTuple`, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is $[0, 0, 0]$. Further, the coordinates $[k, r, c]$ in a `TableauTuple` refer to the component, row and column indices, respectively.

EXAMPLES:

```
sage: t=TableauTuple([ [[1,3,4],[7,9]], [[2,8,11],[6]], [[5,10]] ]); t
([ [1, 3, 4], [7, 9]], [ [2, 8, 11], [6]], [ [5, 10]])
sage: t[0][0][0]
1
sage: t[1][1][0]
6
sage: t[2][0][0]
5
sage: t[2][0][1]
10

sage: t = StandardTableauTuple([[[4,5],[7]], [[1,2,3],[6,8]], [[9]]]); t
([ [4, 5], [7]], [ [1, 2, 3], [6, 8]], [ [9]])
sage: t.pp()
 4 5      1 2 3      9
 7      6 8
sage: t.shape()
([2, 1], [3, 2], [1])
sage: t[0].pp() # pretty print
```

```

4 5
7
sage: t.is_standard()
True
sage: t[0].is_standard()
False
sage: StandardTableauTuple([], [], []) # An empty tableau tuple
([], [], [])

```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a *StandardTableauTuple* from the appropriate parent object:

```

sage: STT = StandardTableauTuples()
sage: STT([[[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]]])
([[[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]]])

```

See also:

- *Tableau*
- *Tableaux*
- *TableauTuples*
- *TableauTuple*
- *StandardTableauTuples*

codegree (*e*, *multicharge*)

Return the Brundan-Kleshchev-Wang [BKW11] codegree of the standard tableau *self*.

The *codegree* of a tableau is an integer that is defined recursively by successively stripping off the number k , for $k = n, n-1, \dots, 1$ and at stage adding the number of addable cell of the same residue minus the number of removable cells of the same residue as k and which are above k in the diagram.

The codegree of the tableau *self* gives the degree of “dual” homogeneous basis element of the graded Specht module which is indexed by *self*.

INPUT:

- *e* – the *quantum characteristic*
- *multicharge* – the *multicharge*

OUTPUT:

The codegree of the tableau *self*, which is an integer.

EXAMPLES:

```

sage: StandardTableauTuple([[[1]], [], []]).codegree(0, (0, 0, 0))
0
sage: StandardTableauTuple([], [[1]], []).codegree(0, (0, 0, 0))
1
sage: StandardTableauTuple([], [], [[1]]).codegree(0, (0, 0, 0))
2
sage: StandardTableauTuple([[[1]], [[2]], []).codegree(0, (0, 0, 0))
-1
sage: StandardTableauTuple([[[1]], [], [[2]]]).codegree(0, (0, 0, 0))
0
sage: StandardTableauTuple([], [[1]], [[2]]).codegree(0, (0, 0, 0))

```

```

1
sage: StandardTableauTuple([[2]], [[1]], []).codegree(0, (0, 0, 0))
1
sage: StandardTableauTuple([[2]], [], [[1]]).codegree(0, (0, 0, 0))
2
sage: StandardTableauTuple([], [2], [[1]]).codegree(0, (0, 0, 0))
3

```

degree (*e*, *multicharge*)

Return the Brundan-Kleshchev-Wang [\[BKW11\]](#) degree of the standard tableau `self`.

The *degree* of a tableau is an integer that is defined recursively by successively stripping off the number k , for $k = n, n-1, \dots, 1$, and at stage adding the count of the number of addable cell of the same residue minus the number of removable cells of them same residue as k and that are below k in the diagram.

Note that even though this degree function was defined by Brundan-Kleshchev-Wang [\[BKW11\]](#) the underlying combinatorics is much older, going back at least to Misra and Miwa.

The degrees of the tableau T gives the degree of the homogeneous basis element of the graded Specht module which is indexed by T .

INPUT:

- *e* – the *quantum characteristic* e
- *multicharge* – (default: `[0]`) the multicharge

OUTPUT:

The degree of the tableau `self`, which is an integer.

EXAMPLES:

```

sage: StandardTableauTuple([[1]], [], []).degree(0, (0, 0, 0))
2
sage: StandardTableauTuple([], [1], []).degree(0, (0, 0, 0))
1
sage: StandardTableauTuple([], [], [1]).degree(0, (0, 0, 0))
0
sage: StandardTableauTuple([[1]], [2], []).degree(0, (0, 0, 0))
3
sage: StandardTableauTuple([[1]], [], [2]).degree(0, (0, 0, 0))
2
sage: StandardTableauTuple([], [1], [2]).degree(0, (0, 0, 0))
1
sage: StandardTableauTuple([[2]], [1], []).degree(0, (0, 0, 0))
1
sage: StandardTableauTuple([[2]], [], [1]).degree(0, (0, 0, 0))
0
sage: StandardTableauTuple([], [2], [1]).degree(0, (0, 0, 0))
-1

```

dominates (*t*)

Return True if the tableau (tuple) `self` dominates the tableau `t`. The two tableaux do not need to be of the same shape.

EXAMPLES:

```

sage: s=StandardTableauTuple([[1,2,3],[4,5]])
sage: t=StandardTableauTuple([[1,2],[3,5],[4]])
sage: s.dominates(t)
True
sage: t.dominates(s)
False

```

inverse (*k*)

Return the cell containing *k* in the tableau tuple self.

EXAMPLES:

```

sage: StandardTableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]) .
↪inverse(1)
(0, 0, 0)
sage: StandardTableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]) .
↪inverse(2)
(0, 0, 1)
sage: StandardTableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]) .
↪inverse(3)
(0, 1, 0)
sage: StandardTableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]) .
↪inverse(12)
(2, 2, 0)

```

residue_sequence (*e*, *multicharge*)

Return the `sage.combinat.tableau_residues.ResidueSequence` of the tableau self.

INPUT:

- *e* – integer in $\{0, 2, 3, 4, 5, \dots\}$
- *multicharge* – a sequence of integers of length equal to the level/length of self

OUTPUT:

The *residue sequence* of the tableau.

EXAMPLES:

```

sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]) .residue_sequence(3,[0,0])
3-residue sequence (0,1,2,0,0) with multicharge (0,0)
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]) .residue_sequence(3,[0,1])
3-residue sequence (1,2,0,1,0) with multicharge (0,1)
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]) .residue_sequence(3,[0,2])
3-residue sequence (2,0,1,2,0) with multicharge (0,2)

```

restrict (*m=None*)

Returns the restriction of the standard tableau self to *m*, which defaults to one less than the current `size()`.

EXAMPLES:

```

sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]) .restrict(6)
([5], [[1, 2], [3, 4]])
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]) .restrict(5)
([5], [[1, 2], [3, 4]])
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]) .restrict(4)
([], [[1, 2], [3, 4]])
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]) .restrict(3)

```

```
([], [[1, 2], [3]])
sage: StandardTableauTuple([[[5]], [[1, 2], [3, 4]]]).restrict(2)
([], [[1, 2]])
sage: StandardTableauTuple([[[5]], [[1, 2], [3, 4]]]).restrict(1)
([], [[1]])
sage: StandardTableauTuple([[[5]], [[1, 2], [3, 4]]]).restrict(0)
([], [])
```

Where possible the restricted tableau belongs to the same category as the tableau self:

```
sage: TableauTuple([[[5]], [[1, 2], [3, 4]]]).restrict(3).category()
Category of elements of Tableau tuples
sage: StandardTableauTuple([[[5]], [[1, 2], [3, 4]]]).restrict(3).category()
Category of elements of Standard tableau tuples
sage: StandardTableauTuples([([1], [2, 2])], ([[5]], [[1, 2], [3, 4]]]).restrict(3).
↪category()
Category of elements of Standard tableau tuples
sage: StandardTableauTuples(level=2)([[[5]], [[1, 2], [3, 4]]]).restrict(3).
↪category()
Category of elements of Standard tableau tuples of level 2
```

to_chain()

Returns the chain of partitions corresponding to the standard tableau tuple self.

EXAMPLES:

```
sage: StandardTableauTuple([[[5]], [[1, 2], [3, 4]]]).to_chain()
[([], []),
 ([], [1]),
 ([], [2]),
 ([], [2, 1]),
 ([], [2, 2]),
 ([1], [2, 2])]
```

class sage.combinat.tableau_tuple.**StandardTableauTuples**

Bases: *sage.combinat.tableau_tuple.TableauTuples*

A factory class for the various classes of tuples of standard tableau.

INPUT:

There are three optional arguments:

- **level** – The *level()* of the tuples of tableaux
- **size** – The *size()* of the tuples of tableaux
- **shape** – A list or a partition tuple specifying the *shape()* of the standard tableau tuples

It is not necessary to use the keywords. If they are not used then the first integer argument specifies the *level()* and the second the *size()* of the tableau tuples.

OUTPUT:

The appropriate subclass of *StandardTableauTuples*.

A tuple of standard tableau is a tableau whose entries are positive integers which increase from left to down along the rows, and from top to bottom down the columns, in each component. The entries do NOT need to increase from left to right along the components.

Note: Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with *PartitionTuple*, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is [0, 0, 0].

EXAMPLES:

```
sage: tabs=StandardTableauTuples([[2],[1],[1,1]]); tabs
Standard tableau tuples of shape ([2], [1], [1, 1])
sage: tabs.cardinality()
30
sage: tabs.list()
[[[1, 2]], [[3]], [[4], [5]]],
 [[1, 3]], [[2]], [[4], [5]]],
 [[2, 3]], [[1]], [[4], [5]]],
 [[1, 2]], [[4]], [[3], [5]]],
 [[1, 3]], [[4]], [[2], [5]]],
 [[2, 3]], [[4]], [[1], [5]]],
 [[1, 4]], [[2]], [[3], [5]]],
 [[2, 4]], [[1]], [[3], [5]]],
 [[1, 4]], [[3]], [[2], [5]]],
 [[2, 4]], [[3]], [[1], [5]]],
 [[3, 4]], [[1]], [[2], [5]]],
 [[3, 4]], [[2]], [[1], [5]]],
 [[1, 2]], [[5]], [[3], [4]]],
 [[1, 3]], [[5]], [[2], [4]]],
 [[2, 3]], [[5]], [[1], [4]]],
 [[1, 4]], [[5]], [[2], [3]]],
 [[2, 4]], [[5]], [[1], [3]]],
 [[3, 4]], [[5]], [[1], [2]]],
 [[1, 5]], [[2]], [[3], [4]]],
 [[2, 5]], [[1]], [[3], [4]]],
 [[1, 5]], [[3]], [[2], [4]]],
 [[2, 5]], [[3]], [[1], [4]]],
 [[3, 5]], [[1]], [[2], [4]]],
 [[3, 5]], [[2]], [[1], [4]]],
 [[1, 5]], [[4]], [[2], [3]]],
 [[2, 5]], [[4]], [[1], [3]]],
 [[3, 5]], [[4]], [[1], [2]]],
 [[4, 5]], [[1]], [[2], [3]]],
 [[4, 5]], [[2]], [[1], [3]]],
 [[4, 5]], [[3]], [[1], [2]]]]

sage: tabs=StandardTableauTuples(level=3); tabs
Standard tableau tuples of level 3
sage: tabs[100]
[[1, 2], [3]], [], [[4]]

sage: StandardTableauTuples()[0]
()
```

See also:

- [Tableau](#)
- [StandardTableau](#)

•*StandardTableauTuples*

Element

alias of *StandardTableauTuple*

an_element()

Returns a particular element of the class.

EXAMPLES:

```
sage: StandardTableauTuples().an_element()
([[1]], [[2, 3]], [[4, 5, 6, 7]])
```

level_one_parent_class

alias of *StandardTableaux_all*

shape()

Return the shape of the set of *StandardTableauTuples*, or None if it is not defined.

EXAMPLES:

```
sage: tabs=StandardTableauTuples(shape=[[5,2],[3,2],[],[1,1,1],[3]]); tabs
Standard tableau tuples of shape ([5, 2], [3, 2], [], [1, 1, 1], [3])
sage: tabs.shape()
([5, 2], [3, 2], [], [1, 1, 1], [3])
sage: StandardTableauTuples().shape() is None
True
```

class sage.combinat.tableau_tuple.**StandardTableauTuples_all**

Bases: *sage.combinat.tableau_tuple.StandardTableauTuples*

Default class of all *StandardTableauTuples* with an arbitrary *level()* and *size()*.

class sage.combinat.tableau_tuple.**StandardTableauTuples_level**(*level*)

Bases: *sage.combinat.tableau_tuple.StandardTableauTuples*

Class of all *StandardTableauTuples* with a fixed *level* and arbitrary size.

an_element()

Returns a particular element of the class.

EXAMPLES:

```
sage: StandardTableauTuples(2).an_element()
([[1]], [[2, 3]])
sage: StandardTableauTuples(3).an_element()
([[1]], [[2, 3]], [[4, 5, 6, 7]])
```

class sage.combinat.tableau_tuple.**StandardTableauTuples_level_size**(*level*, *size*)

Bases: *sage.combinat.tableau_tuple.StandardTableauTuples*

Class of all *StandardTableauTuples* with a fixed *level* and a fixed size.

an_element()

Returns a particular element of the class.

EXAMPLES:

```
sage: StandardTableauTuples(5,size=2).an_element()
([], [], [], [], [[1], [2]])
sage: StandardTableauTuples(2,size=4).an_element()
([[1]], [[2, 3], [4]])
```

cardinality()

Returns the number of elements in this set of tableaux.

EXAMPLES:

```
sage: StandardTableauTuples(3,2).cardinality()
12
sage: StandardTableauTuples(4,6).cardinality()
31936
```

class sage.combinat.tableau_tuple.**StandardTableauTuples_shape**(shape)Bases: *sage.combinat.tableau_tuple.StandardTableauTuples*Class of all *StandardTableauTuples* of a fixed shape.**an_element()**

Returns a particular element of the class.

EXAMPLES:

```
sage: StandardTableauTuples([[2],[2,1]]).an_element()
([[2, 4]], [[1, 3], [5]])
sage: StandardTableauTuples([[10],[],[ ]]).an_element()
([[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]], [[ ], [ ]])
```

cardinality()Returns the number of standard Young tableau tuples of with the same shape as the partition tuple *self*.

Let $\mu = (\mu^{(1)}, \dots, \mu^{(l)})$ be the shape of the tableaux in *self* and let $m_k = |\mu^{(k)}|$, for $1 \leq k \leq l$. Multiplying by a (unique) coset representative of the Young subgroup $S_{m_1} \times \dots \times S_{m_l}$ inside the symmetric group S_n , we can assume that t is standard and the numbers $1, 2, \dots, n$ are entered in order from right to left along the components of the tableau. Therefore, there are

$$\binom{n}{m_1, \dots, m_l} \prod_{k=1}^l |\text{Std}(\mu^{(k)})|$$

standard tableau tuples of this shape, where $|\text{Std}(\mu^{(k)})|$ is the number of standard tableau of shape $\mu^{(k)}$, for $1 \leq k \leq l$. This is given by the hook length formula.

EXAMPLES:

```
sage: StandardTableauTuples([[3,2,1],[ ]]).cardinality()
16
sage: StandardTableauTuples([[1],[1],[1]]).cardinality()
6
sage: StandardTableauTuples([[2,1],[1],[1]]).cardinality()
40
sage: StandardTableauTuples([[3,2,1],[3,2]]).cardinality()
36960
```

last()

Returns the last standard tableau tuple in *self*, with respect to the order that they are generated by the iterator. This is just the standard tableau tuple with the numbers $1, 2, \dots, n$, where n is *size()*, entered in order down the columns from right to left along the components.

EXAMPLES:

```
sage: StandardTableauTuples([[2],[2,2]]).last().pp()
5 6      1 3
      2 4
```

random_element()

Returns a random standard tableau in *self*.

We do this by randomly selecting addable nodes to place $1, 2, \dots, n$. Of course we could do this recursively, but it's more efficient to keep track of the (changing) list of addable nodes as we go.

EXAMPLES:

```
sage: StandardTableauTuples([[2],[2,1]]).random_element() # random
([[1, 2]], [[3, 4], [5]])
```

class sage.combinat.tableau_tuple.**StandardTableauTuples_size**(*size*)

Bases: *sage.combinat.tableau_tuple.StandardTableauTuples*

Class of all *StandardTableauTuples* with an arbitrary level and a fixed size.

an_element()

Returns a particular element of the class.

EXAMPLES:

```
sage: StandardTableauTuples(size=2).an_element()
([[1]], [[2]], [], [])
sage: StandardTableauTuples(size=4).an_element()
([[1]], [[2, 3, 4]], [], [])
```

class sage.combinat.tableau_tuple.**StandardTableaux_residue**(*residue*)

Bases: *sage.combinat.tableau_tuple.StandardTableauTuples*

Class of all standard tableau tuples with a fixed residue sequence.

Implicitly, this also specifies the quantum characteristic, multicharge and hence the level and size of the tableaux.

Note: This class is not intended to be called directly, but rather, it is accessed through the standard tableaux.

EXAMPLES:

```
sage: StandardTableau([[1,2,3],[4,5]]).residue_sequence(2).standard_tableaux()
Standard tableaux with 2-residue sequence (0,1,0,1,0) and multicharge (0)
sage: StandardTableau([[1,2,3],[4,5]]).residue_sequence(3).standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,2,0) and multicharge (0)
sage: StandardTableauTuple([[5,6],[7]], [[1,2,3],[4]]).residue_sequence(2,(0,0)).
↪standard_tableaux()
Standard tableaux with 2-residue sequence (0,1,0,1,0,1,1) and multicharge (0,0)
sage: StandardTableauTuple([[5,6],[7]], [[1,2,3],[4]]).residue_sequence(3,(0,1)).
↪standard_tableaux()
Standard tableaux with 3-residue sequence (1,2,0,0,0,1,2) and multicharge (0,1)
```

an_element()

Return a particular element of *self*.

EXAMPLES:

```
sage: T = StandardTableau([[1,2],[3]]).residue_sequence(3,(0,1)).standard_
↪tableaux()
sage: T.an_element()
([[1, 2, 3]], [])
```

class `sage.combinat.tableau_tuple.StandardTableaux_residue_shape` (*residue, shape*)
 Bases: `sage.combinat.tableau_tuple.StandardTableauTuples`

All standard tableau tuples with a fixed residue and shape.

INPUT:

- *shape* – the shape of the partitions or partition tuples
- *residue* – the residue sequence of the label

EXAMPLES:

```
sage: res = StandardTableauTuple([[[1, 3], [6]], [[2, 7], [4], [5]]]).residue_
↪sequence(3, (0, 0))
sage: tabs = res.standard_tableaux([[2, 1], [2, 1, 1]])
sage: tabs
Standard (2, 1|2, 1^2)-tableaux with 3-residue sequence (0, 0, 1, 2, 1, 2, 1) and_
↪multicharge (0, 0)
sage: tabs.shape()
([2, 1], [2, 1, 1])
sage: tabs.level()
2
sage: tabs.cardinality()
12
sage: tabs.list()
([([2, 7], [6]), ([1, 3], [4], [5])],
 ([1, 7], [6]), ([2, 3], [4], [5])),
 ([2, 3], [6]), ([1, 7], [4], [5])),
 ([1, 3], [6]), ([2, 7], [4], [5])),
 ([2, 5], [6]), ([1, 3], [4], [7])),
 ([1, 5], [6]), ([2, 3], [4], [7])),
 ([2, 3], [6]), ([1, 5], [4], [7])),
 ([1, 3], [6]), ([2, 5], [4], [7])),
 ([2, 5], [4]), ([1, 3], [6], [7])),
 ([1, 5], [4]), ([2, 3], [6], [7])),
 ([2, 3], [4]), ([1, 5], [6], [7])),
 ([1, 3], [4]), ([2, 5], [6], [7]))]
```

an_element()

Return a particular element of *self*.

EXAMPLES:

```
sage: T = StandardTableau([([1, 3], [2])]).residue_sequence(3).standard_
↪tableaux([2, 1])
sage: T.an_element()
[[1, 3], [2]]
```

class `sage.combinat.tableau_tuple.TableauTuple` (*parent, t*)
 Bases: `sage.combinat.combinat.CombinatorialElement`

A class to model a tuple of tableaux.

INPUT:

- *t* – a list or tuple of *Tableau*, a list or tuple of lists of lists

OUTPUT:

- The Tableau tuple object constructed from *t*.

A *TableauTuple* is a tuple of tableau of shape a *PartitionTuple*. These combinatorial objects are useful in several areas of algebraic combinatorics. In particular, they are important in:

- the representation theory of the complex reflection groups of type $G(l, 1, n)$ and the representation theory of the associated (degenerate and non-degenerate) Hecke algebras. See, for example, [DJM]
- the crystal theory of (quantum) affine special linear groups and its integral highest weight modules and their canonical bases. See, for example, [BK].

These apparently different and unrelated contexts are, in fact, intimately related as in characteristic zero the cyclotomic Hecke algebras categorify the canonical bases of the integral highest weight modules of the quantum affine special linear groups.

The *level()* of a tableau tuple is the length of the tuples. This corresponds to the level of the corresponding highest weight module.

In sage a *TableauTuple* looks and behaves like a real tuple of (level 1) *Tableaux*. Many of the operations which are defined on *Tableau* extend to *TableauTuples*. Tableau tuples of level 1 are just ordinary *Tableau*.

In sage, the entries of *Tableaux* can be very general, including arbitrarily nested lists, so some lists can be interpreted either as a tuple of tableaux or simply as tableaux. If it is possible to interpret the input to *TableauTuple* as a tuple of tableaux then *TableauTuple* returns the corresponding tuple. Given a 1-tuple of tableaux the tableau itself is returned.

EXAMPLES:

```
sage: t = TableauTuple([ [[6,9,10],[11]], [[1,2,3],[4,5]], [[7],[8]] ]); t
([ [6, 9, 10], [11]], [ [1, 2, 3], [4, 5]], [ [7], [8]] )
sage: t.level()
3
sage: t.size()
11
sage: t.shape()
([3, 1], [3, 2], [1, 1])
sage: t.is_standard()
True
sage: t.pp() # pretty print
  6  9 10      1  2  3      7
 11           4  5          8
sage: t.category()
Category of elements of Tableau tuples
sage: t.parent()
Tableau tuples

sage: s = TableauTuple([ [['a','c','b'],['d','e']], [(2,1)]]); s
([ ['a', 'c', 'b'], ['d', 'e']], [(2, 1)])
sage: s.shape()
([3, 2], [1])
sage: s.size()
6

sage: TableauTuple([[],[],[]]) # The empty 3-tuple of tableaux
([], [], [])

sage: TableauTuple([ [1,2,3], [4,5] ])
[ [1, 2, 3], [4, 5] ]
sage: TableauTuple([ [1,2,3], [4,5] ]) == Tableau([ [1,2,3], [4,5] ])
True
```

- `Tableaux`

Element

alias of `Tableau`

`add_entry` (*cell*, *m*)

Set the entry in *cell* equal to *m*. If the cell does not exist then extend the tableau, otherwise just replace the entry.

EXAMPLES:

```
sage: s=StandardTableauTuple([ [[3,4,7],[6,8]], [[9,13],[12]], [[1,5],[2,11]],
↪[10]] ]); s.pp()
  3  4  7      9 13      1  5
  6  8      12      2 11
                    10

sage: t=s.add_entry( (0,0,3),14); t.pp(); t.category()
  3  4  7 14      9 13      1  5
  6  8      12      2 11
                    10
Category of elements of Standard tableau tuples
sage: t=s.add_entry( (0,0,3),15); t.pp(); t.category()
  3  4  7 15      9 13      1  5
  6  8      12      2 11
                    10
Category of elements of Tableau tuples
sage: t=s.add_entry( (1,1,1),14); t.pp(); t.category()
  3  4  7      9 13      1  5
  6  8      12 14      2 11
                    10
Category of elements of Standard tableau tuples
sage: t=s.add_entry( (2,1,1),14); t.pp(); t.category()
  3  4  7      9 13      1  5
  6  8      12      2 14
                    10
Category of elements of Tableau tuples
sage: t=s.add_entry( (2,1,2),14); t.pp(); t.category()
Traceback (most recent call last):
...
IndexError: (2, 1, 2) is not an addable cell of the tableau
```

`cells_containing` (*m*)

Return the list of cells in which the letter *m* appears in the tableau *self*.

The list is ordered with cells appearing from left to right.

EXAMPLES:

```
sage: t = TableauTuple([[4,5]], [[1,1,2,4], [2,4,4], [4]], [[1,3,4], [3,4]])
sage: t.cells_containing(4)
[(0, 0, 0),
 (1, 2, 0),
 (1, 1, 1),
 (1, 1, 2),
 (1, 0, 3),
 (2, 1, 1),
 (2, 0, 2)]
sage: t.cells_containing(6)
[]
```

charge()

Return the charge of the reading word of *self*.

See [charge\(\)](#) for more information.

EXAMPLES:

```
sage: TableauTuple([[4,5]], [[1,1,2,4], [2,4,4], [4]], [[1,3,4], [3,4]]).charge()
4
```

cocharge()

Return the cocharge of the reading word of *self*.

See [cocharge\(\)](#) for more information.

EXAMPLES:

```
sage: TableauTuple([[4,5]], [[1,1,2,4], [2,4,4], [4]], [[1,3,4], [3,4]]).cocharge()
4
```

column_stabilizer()

Return the *PermutationGroup* corresponding to *self*. That is, return subgroup of the symmetric group of degree [size\(\)](#) which is the column stabilizer of *self*.

EXAMPLES:

```
sage: cs = TableauTuple([[1,2,3], [4,5]], [[6,7]], [[8], [9]]).column_
↪stabilizer()
sage: cs.order()
8
sage: PermutationGroupElement([(1,3,2), (4,5)]) in cs
False
sage: PermutationGroupElement([(1,4)]) in cs
True
```

components()

Return a list of the components of tableau tuple *self*. The *components* are the individual *Tableau* which are contained in the tuple *self*.

For compatibility with *TableauTuples* of [level\(\)](#) 1, [components\(\)](#) should be used to iterate over the components of *TableauTuples*.

EXAMPLES:

```
sage: for t in TableauTuple([[1,2,3], [4,5]]).components(): t.pp()
1 2 3
```

```

4 5
sage: for t in TableauTuple([ [[1,2,3],[4,5]], [[6,7],[8,9]] ]).components():
↳ t.pp()
1 2 3
4 5
6 7
8 9

```

conjugate()

Return the conjugate of the tableau tuple `self`.

The conjugate tableau tuple T' is the `TableauTuple` obtained from T by reversing the order of the components and conjugating each component – that is, swapping the rows and columns of the all of `Tableau` in T (see `sage.combinat.tableau.Tableau.conjugate()`).

EXAMPLES:

```

sage: TableauTuple([ [[1,2],[3,4]], [[5,6,7],[8]], [[9,10],[11],[12]] ]).
↳ conjugate()
([ [9, 11, 12], [10]], [[5, 8], [6], [7]], [[1, 3], [2, 4]])

```

content(k , $multicharge$)

Return the content k in `self`.

The content of k in a standard tableau. That is, if k appears in row r and column c of the tableau, then we return $c - r + a_k$, where the multicharge is $(a_1, a_2, \dots, a_l)$ and l is the level of the tableau.

The multicharge determines the dominant weight

$$\Lambda = \sum_{i=1}^l \Lambda_{a_i}$$

of the affine special linear group. In the combinatorics, the multicharge simply offsets the contents in each component so that the cell (k, r, c) has content $a_k + c - r$.

INPUT:

- k – an integer in $\{1, 2, \dots, n\}$
- `multicharge` – a sequence of integers of length l

Here l is the `level()` and n is the `size()` of `self`.

EXAMPLES:

```

sage: StandardTableauTuple([ [[5]], [[1,2],[3,4]] ]).content(3, [0,0])
-1
sage: StandardTableauTuple([ [[5]], [[1,2],[3,4]] ]).content(3, [0,1])
0
sage: StandardTableauTuple([ [[5]], [[1,2],[3,4]] ]).content(3, [0,2])
1
sage: StandardTableauTuple([ [[5]], [[1,2],[3,4]] ]).content(6, [0,2])
Traceback (most recent call last):
...
ValueError: 6 must be contained in the tableaux

```

entries()

Return a sorted list of all entries of `self`, in the order obtained by reading across the rows.

EXAMPLES:

```
sage: TableauTuple([[1,2],[3,4]],[5,6,7],[8]],[9,10],[11],[12]]).entries()
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]
sage: TableauTuple([[1,2],[3,4]],[9,10],[11],[12]],[5,6,7],[8]]).entries()
[1, 2, 3, 4, 9, 10, 11, 12, 5, 6, 7, 8]
```

entry(l, r, c)

Return the entry of the cell (l, r, c) in self.

A cell is a tuple (l, r, c) of coordinates, where l is the component index, r is the row index, and c is the column index.

EXAMPLES:

```
sage: t = TableauTuple([[1,2],[3,4]],[5,6,7],[8]],[9,10],[11],[12]])
sage: t.entry(1, 0, 0)
5
sage: t.entry(1, 1, 1)
Traceback (most recent call last):
...
IndexError: tuple index out of range
```

first_column_descent()

Return the first cell of self is not column standard.

Cells are ordered left to right along the rows and then top to bottom. That is, return the cell (k, r, c) with (k, r, c) minimal such that the entry in position (k, r, c) is bigger than the entry in position $(k, r, c + 1)$. If there is no such cell then None is returned - in this case the tableau is column strict.

OUTPUT:

The cell corresponding to the first column descent or None if the tableau is column strict.

EXAMPLES:

```
sage: TableauTuple([[3,5,6],[2,4,5]],[1,4,5],[2,3]]).first_column_descent()
(0, 0, 0)
sage: Tableau([[1,2,3],[4]],[5,6,7],[8,9]]).first_column_descent() is None
True
```

first_row_descent()

Return the first cell of self that is not row standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell minimal (k, r, c) such that the entry in position (k, r, c) is bigger than the entry in position $(k, r, c + 1)$. If there is no such cell then None is returned - in this case the tableau is row strict.

OUTPUT:

The cell corresponding to the first row descent or None if the tableau is row strict.

EXAMPLES:

```
sage: TableauTuple([[5,6,7],[1,2]],[1,3,2],[4]]).first_row_descent()
(1, 0, 1)
sage: TableauTuple([[1,2,3],[4]],[6,7,8],[1,2,3]],[1,11]]).first_row_
↪ descent() is None
True
```

is_column_strict()

Return True if the tableau self is column strict and False otherwise.

A tableau tuple is *column strict* if the entries in each column of each component are in increasing order, when read from top to bottom.

EXAMPLES:

```
sage: TableauTuple([[5,7],[8]],[[1, 3], [2, 4]],[[6]]).is_column_strict()
True
sage: TableauTuple([[1, 2], [2, 4]],[[4,5,6],[7,8]]).is_column_strict()
True
sage: TableauTuple([[1]],[[2, 3], [2, 4]]).is_column_strict()
False
sage: TableauTuple([[1]],[[2, 2], [4,5]]).is_column_strict()
True
sage: TableauTuple([[1,2],[6,7]],[[4,8], [6, 9]],[[]]).is_column_strict()
True
```

is_row_strict()

Return True if the tableau `self` is row strict and False otherwise.

A tableau tuple is *row strict* if the entries in each row of each component are in increasing order, when read from left to right.

EXAMPLES:

```
sage: TableauTuple([[5,7],[8]],[[1, 3], [2, 4]],[[6]]).is_row_strict()
True
sage: TableauTuple([[1, 2], [2, 4]],[[4,5,6],[7,8]]).is_row_strict()
True
sage: TableauTuple([[1]],[[2, 3], [2, 4]]).is_row_strict()
True
sage: TableauTuple([[1]],[[2, 2], [4,5]]).is_row_strict()
False
sage: TableauTuple([[1,2],[6,7]],[[4,8], [6, 9]],[[]]).is_row_strict()
True
```

is_standard()

Return True if the tableau `self` is a standard tableau and False otherwise.

A tableau tuple is *standard* if it is row standard, column standard and the entries in the tableaux are $1, 2, \dots, n$, where n is the `size()` of the underlying partition tuple of `self`.

EXAMPLES:

```
sage: TableauTuple([[5,7],[8]],[[1, 3], [2, 4]],[[6]]).is_standard()
True
sage: TableauTuple([[1, 2], [2, 4]],[[4,5,6],[7,8]]).is_standard()
False
sage: TableauTuple([[1]],[[2, 3], [2, 4]]).is_standard()
False
sage: TableauTuple([[1]],[[2, 2], [4,5]]).is_row_strict()
False
sage: TableauTuple([[1,2],[6,7]],[[4,8], [6, 9]],[[]]).is_standard()
False
```

level()

Return the level of the tableau `self`, which is just the number of components in the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([[7,8,9]],[],[[1,2,3],[4,5],[6]]).level()
3
```

pp()

Pretty printing for the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([ [[1,2,3],[4,5]], [[1,2,3],[4,5]] ]).pp()
 1 2 3      1 2 3
 4 5      4 5

sage: TableauTuple([ [[1,2],[3],[4]], [], [[6,7,8],[10,11],[12],[13]] ]).pp()
 1 2      -      6 7 8
 3      10 11
 4      12
      13

sage: t = TableauTuple([ [[1,2,3],[4,5],[6],[9]], [[1,2,3],[4,5,8]], [[11,12,
↪13],[14]] ])
sage: t.pp()
 1 2 3      1 2 3      11 12 13
 4 5      4 5 8      14
 6
 9

sage: TableauTuples.options(convention="french")
sage: t.pp()
 9
 6
 4 5      4 5 8      14
 1 2 3      1 2 3      11 12 13
sage: TableauTuples.options._reset()
```

reduced_column_word()

Return the lexicographically minimal reduced expression for the permutation that maps the `initial_column_tableau()` to `self`.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the rows of the tableau from top to bottom in each component, and then left to right along the components.

EXAMPLES:

```
sage: StandardTableauTuple([[[7,9],[8]], [[1,4,6],[2,5],[3]]]).reduced_column_
↪word()
[]

sage: StandardTableauTuple([[[7,9],[8]], [[1,3,6],[2,5],[4]]]).reduced_column_
↪word()
[3]

sage: StandardTableauTuple([[[6,9],[8]], [[1,3,7],[2,5],[4]]]).reduced_column_
↪word()
[3, 6]

sage: StandardTableauTuple([[[6,8],[9]], [[1,3,7],[2,5],[4]]]).reduced_column_
↪word()
[3, 6, 8]

sage: StandardTableauTuple([[[5,8],[9]], [[1,3,7],[2,6],[4]]]).reduced_column_
↪word()
[3, 6, 5, 8]
```

reduced_row_word()

Return the lexicographically minimal reduced expression for the permutation that maps the

`initial_tableau()` to `self`.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the rows of the tableau from top to bottom in each component, and then left to right along the components.

EXAMPLES:

```
sage: StandardTableauTuple([[ [1,2], [3] ], [ [4,5,6], [7,8], [9] ] ]).reduced_row_
↪word()
[]
sage: StandardTableauTuple([[ [1,2], [3] ], [ [4,5,6], [7,9], [8] ] ]).reduced_row_
↪word()
[8]
sage: StandardTableauTuple([[ [1,2], [3] ], [ [4,5,7], [6,9], [8] ] ]).reduced_row_
↪word()
[6, 8]
sage: StandardTableauTuple([[ [1,2], [3] ], [ [4,5,8], [6,9], [7] ] ]).reduced_row_
↪word()
[6, 8, 7]
sage: StandardTableauTuple([[ [1,2], [3] ], [ [4,5,9], [6,8], [7] ] ]).reduced_row_
↪word()
[6, 7, 8, 7]
sage: StandardTableauTuple([[ [7,9], [8] ], [ [1,3,5], [2,6], [4] ] ]).reduced_row_
↪word()
[2, 3, 2, 1, 4, 3, 2, 5, 4, 3, 6, 5, 4, 3, 2, 7, 6, 5, 8, 7, 6, 5, 4]
```

residue (*k*, *e*, *multicharge*)

Return the *residue* of the integer *k* in the tableau `self`.

The *residue* of *k* is $c - r + a_k$ in $\mathbf{Z}/e\mathbf{Z}$, where *k* appears in row *r* and column *c* of the tableau and the multicharge is $(a_1, a_2, \dots, a_l)$.

The multicharge determines the dominant weight

$$\sum_{i=1}^l \Lambda_{a_i}$$

for the affine special linear group. In the combinatorics, it simply offsets the contents in each component so that the cell $(k, 0, 0)$ has content a_k .

INPUT:

- *k* – an integer in $\{1, 2, \dots, n\}$
- *e* – an integer in $\{0, 2, 3, 4, 5, \dots\}$
- *multicharge* – a list of integers of length *l*

Here *l* is the `level()` and *n* is the `size()` of `self`.

OUTPUT:

The residue of *k* in a standard tableau. That is,

EXAMPLES:

```
sage: StandardTableauTuple([[ [5] ], [ [1,2], [3,4] ] ]).residue(1, 3, [0,0])
0
sage: StandardTableauTuple([[ [5] ], [ [1,2], [3,4] ] ]).residue(1, 3, [0,1])
1
sage: StandardTableauTuple([[ [5] ], [ [1,2], [3,4] ] ]).residue(1, 3, [0,2])
```

```

2
sage: StandardTableauTuple([[5]], [[1, 2], [3, 4]]).residue(6, 3, [0, 2])
Traceback (most recent call last):
...
ValueError: 6 must be contained in the tableaux

```

restrict (*m=None*)

Returns the restriction of the standard tableau *self* to *m*.

The restriction is the subtableau of *self* whose entries are less than or equal to *m*.

By default, *m* is one less than the current size.

EXAMPLES:

```

sage: TableauTuple([[5]], [[1, 2], [3, 4]]).restrict()
([], [[1, 2], [3, 4]])
sage: TableauTuple([[5]], [[1, 2], [3, 4]]).restrict(6)
([[5]], [[1, 2], [3, 4]])
sage: TableauTuple([[5]], [[1, 2], [3, 4]]).restrict(5)
([[5]], [[1, 2], [3, 4]])
sage: TableauTuple([[5]], [[1, 2], [3, 4]]).restrict(4)
([], [[1, 2], [3, 4]])
sage: TableauTuple([[5]], [[1, 2], [3, 4]]).restrict(3)
([], [[1, 2], [3]])
sage: TableauTuple([[5]], [[1, 2], [3, 4]]).restrict(2)
([], [[1, 2]])
sage: TableauTuple([[5]], [[1, 2], [3, 4]]).restrict(1)
([], [[1]])
sage: TableauTuple([[5]], [[1, 2], [3, 4]]).restrict(0)
([], [])

```

Where possible the restricted tableau belongs to the same category as the original tableaux:

```

sage: TableauTuple([[5]], [[1, 2], [3, 4]]).restrict(3).category()
Category of elements of Tableau tuples
sage: TableauTuple([[5]], [[1, 2], [3, 4]]).restrict(3).category()
Category of elements of Tableau tuples
sage: TableauTuples(level=2)([[5]], [[1, 2], [3, 4]]).restrict(3).category()
Category of elements of Tableau tuples of level 2

```

row_stabilizer ()

Return the PermutationGroup corresponding to *self*. That is, return subgroup of the symmetric group of degree *size()* which is the row stabilizer of *self*.

EXAMPLES:

```

sage: rs = TableauTuple([[1, 2, 3], [4, 5]], [[6, 7]], [[8], [9]]).row_stabilizer()
sage: rs.order()
24
sage: PermutationGroupElement([(1, 3, 2), (4, 5)]) in rs
True
sage: PermutationGroupElement([(1, 4)]) in rs
False
sage: rs.one().domain()
[1, 2, 3, 4, 5, 6, 7, 8, 9]

```

shape ()

Returns the *PartitionTuple* which is the shape of the tableau tuple *self*.

EXAMPLES:

```
sage: TableauTuple([[7,8,9]], [], [[1,2,3], [4,5], [6]]) .shape()
([3], [], [3, 2, 1])
```

size()

Returns the size of the tableau tuple `self`, which is just the number of boxes, or the size, of the underlying *PartitionTuple*.

EXAMPLES:

```
sage: TableauTuple([[7,8,9]], [], [[1,2,3], [4,5], [6]]) .size()
9
```

symmetric_group_action_on_entries(*w*)

Return the action of a permutation *w* on `self`.

Consider a standard tableau tuple $T = (t^{(1)}, t^{(2)}, \dots, t^{(l)})$ of size n , then the action of $w \in S_n$ is defined by permuting the entries of T (recall they are $1, 2, \dots, n$). In particular, suppose the entry at cell (k, i, j) is a , then the entry becomes $w(a)$. In general, the resulting tableau tuple wT may *not* be standard.

INPUT:

• *w* – a permutation

EXAMPLES:

```
sage: TableauTuple([[1,2], [4]], [[3,5]]) .symmetric_group_action_on_entries(
↪ Permutation((4,5)))
([[1, 2], [5]], [[3, 4]])
sage: TableauTuple([[1,2], [4]], [[3,5]]) .symmetric_group_action_on_entries(
↪ Permutation((1,2)))
([[2, 1], [4]], [[3, 5]])
```

to_list()

Return the list representation of the tableaux tuple `self`.

EXAMPLES:

```
sage: TableauTuple([ [1,2,3], [4,5]], [[6,7], [8,9]] ) .to_list()
[[1, 2, 3], [4, 5], [6, 7], [8, 9]]
```

to_permutation()

Returns a permutation with the entries in the tableau tuple `self` which is obtained by `self` obtained by reading the entries of the tableau tuple in order from left to right along the rows, and then top to bottom, in each component and then left to right along the components.

EXAMPLES:

```
sage: TableauTuple([[1,2], [3,4]], [[5,6,7], [8]], [[9,10], [11], [12]]) .to_
↪ permutation()
[12, 11, 9, 10, 8, 5, 6, 7, 3, 4, 1, 2]
```

to_word()

Returns a word obtained from a row reading of the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([[1,2], [3,4]], [[5,6,7], [8]], [[9,10], [11], [12]]) .to_word_
↪ by_row()
word: 12, 11, 9, 10, 8, 5, 6, 7, 3, 4, 1, 2
```

to_word_by_column()

Returns the word obtained from a column reading of the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([[1,2],[3,4]],[5,6,7],[8]],[9,10],[11],[12]]).to_word_
↳by_column()
word: 12,11,9,10,8,5,6,7,3,1,4,2
```

to_word_by_row()

Returns a word obtained from a row reading of the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([[1,2],[3,4]],[5,6,7],[8]],[9,10],[11],[12]]).to_word_
↳by_row()
word: 12,11,9,10,8,5,6,7,3,4,1,2
```

up ($n=None$)

An iterator for all the *TableauTuple* that can be obtained from `self` by adding a cell with the label `n`. If `n` is not specified then a cell with label `n` will be added to the tableau tuple, where `n-1` is the size of the tableau tuple before any cells are added.

EXAMPLES:

```
sage: list(TableauTuple([[1,2]],[3]]).up())
([1, 2, 4], [3]),
([1, 2], [4], [3]),
([1, 2], [3, 4]),
([1, 2], [3], [4])
```

class sage.combinat.tableau_tuple.**TableauTuples**

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

A factory class for the various classes of tableau tuples.

INPUT:

There are three optional arguments:

- `shape` – determines a *PartitionTuple* which gives the shape of the *TableauTuples*
- `level` – the level of the tableau tuples (positive integer)
- `size` – the size of the tableau tuples (non-negative integer)

It is not necessary to use the keywords. If they are not specified then the first integer argument specifies the `level` and the second the `size` of the tableaux.

OUTPUT:

- The corresponding class of tableau tuples.

The entries of a tableau can be any sage object. Because of this, no enumeration of the set of *TableauTuples* is possible.

EXAMPLES:

```

sage: T3 = TableauTuples(3); T3
Tableau tuples of level 3
sage: [['a', 'b']] in TableauTuples()
True
sage: [['a', 'b']] in TableauTuples(level=3)
False
sage: t = TableauTuples(level=3)([], [[1, 1, 1]], []); t
([], [[1, 1, 1]], [])
sage: t in T3
True
sage: t in TableauTuples()
True
sage: t in TableauTuples(size=3)
True
sage: t in TableauTuples(size=4)
False
sage: t in StandardTableauTuples()
False
sage: t.parent()
Tableau tuples of level 3
sage: t.category()
Category of elements of Tableau tuples of level 3

```

See also:

- [Tableau](#)
- [StandardTableau](#)
- [StandardTableauTuples](#)

Element

alias of [TableauTuple](#)

global_options(*args, **kws)

Deprecated: Use [options\(\)](#) instead. See [trac ticket #18555](#) for details.

level()

Return the level of a tableau tuple in self, or None if different tableau tuples in self can have different sizes. The level of a tableau tuple is just the level of the underlying [PartitionTuple](#).

EXAMPLES:

```

sage: TableauTuples().level() is None
True
sage: TableauTuples(7).level()
7

```

level_one_parent_class

alias of [Tableaux_all](#)

list()

If the set of tableau tuples self is finite then this function returns the list of these tableau tuples. If the class is infinite an error is returned.

EXAMPLES:

```

sage: StandardTableauTuples([[2, 1], [2]]).list()
[[[1, 2], [3]], [[4, 5]],

```

```

([[1, 3], [2]], [[4, 5]]),
([[1, 2], [4]], [[3, 5]]),
([[1, 3], [4]], [[2, 5]]),
([[2, 3], [4]], [[1, 5]]),
([[1, 4], [2]], [[3, 5]]),
([[1, 4], [3]], [[2, 5]]),
([[2, 4], [3]], [[1, 5]]),
([[1, 2], [5]], [[3, 4]]),
([[1, 3], [5]], [[2, 4]]),
([[2, 3], [5]], [[1, 4]]),
([[1, 4], [5]], [[2, 3]]),
([[2, 4], [5]], [[1, 3]]),
([[3, 4], [5]], [[1, 2]]),
([[1, 5], [2]], [[3, 4]]),
([[1, 5], [3]], [[2, 4]]),
([[2, 5], [3]], [[1, 4]]),
([[1, 5], [4]], [[2, 3]]),
([[2, 5], [4]], [[1, 3]]),
([[3, 5], [4]], [[1, 2]])]

```

options (*get_value, **set_value)

Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- **ascii_art** – (default: repr) Controls the ascii art output for tableaux
 - compact – minimal length ascii art
 - repr – display using the diagram string representation
 - table – display as a table
- **convention** – (default: English) Sets the convention used for displaying tableaux and partitions
 - English – use the English convention
 - French – use the French convention
- **display** – (default: list) Controls the way in which tableaux are printed
 - array – alias for diagram
 - compact – minimal length string representation
 - diagram – display as Young diagram (similar to `pp()`)
 - ferrers_diagram – alias for diagram
 - list – print tableaux as lists
 - young_diagram – alias for diagram
- **latex** – (default: diagram) Controls the way in which tableaux are latexed
 - array – alias for diagram
 - diagram – as a Young diagram
 - ferrers_diagram – alias for diagram
 - list – as a list
 - young_diagram – alias for diagram

•notation – alternative name for convention

Note: Changing the convention for tableaux also changes the convention for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.options.display="array"
sage: T
  1  2  3
  4  5
sage: Tableaux.options.convention="french"
sage: T
  4  5
  1  2  3
```

Changing the convention for tableaux also changes the convention for partitions and vice versa:

```
sage: P = Partition([3,3,1])
sage: print(P.ferrers_diagram())
*
***
***
sage: Partitions.options.convention="english"
sage: print(P.ferrers_diagram())
***
***
*
sage: T
  1  2  3
  4  5
```

The ASCII art can also be changed:

```
sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
  1  2  3
  4  5
sage: Tableaux.options.ascii_art="table"
sage: ascii_art(t)
+---+---+
| 4 | 5 |
+---+---+
| 1 | 2 | 3 |
+---+---+
sage: Tableaux.options.ascii_art="compact"
sage: ascii_art(t)
|4|5|
|1|2|3|
sage: Tableaux.options._reset()
```

See GlobalOptions for more features of these options.

size()

Return the size of a tableau tuple in `self`, or `None` if different tableau tuples in `self` can have different sizes. The size of a tableau tuple is just the size of the underlying *PartitionTuple*.

EXAMPLES:

```
sage: TableauTuples(size=14).size()
14
```

class `sage.combinat.tableau_tuple.TableauTuples_all`

Bases: *sage.combinat.tableau_tuple.TableauTuples*

The parent class of all *TableauTuples*, with arbitrary level and size.

an_element()

Returns a particular element of the class.

EXAMPLES:

```
sage: TableauTuples().an_element()
([[1]], [[2]], [[3]], [[4]], [[5]], [[6]], [[7]])
```

class `sage.combinat.tableau_tuple.TableauTuples_level(level)`

Bases: *sage.combinat.tableau_tuple.TableauTuples*

Class of all *TableauTuples* with a fixed level and arbitrary size.

an_element()

Returns a particular element of the class.

EXAMPLES:

```
sage: TableauTuples(3).an_element()
([], [], [])
sage: TableauTuples(5).an_element()
([], [], [], [], [])
sage: T = TableauTuples(0)
Traceback (most recent call last):
...
ValueError: the level must be a positive integer
```

class `sage.combinat.tableau_tuple.TableauTuples_level_size(level, size)`

Bases: *sage.combinat.tableau_tuple.TableauTuples*

Class of all *TableauTuples* with a fixed level and a fixed size.

an_element()

Returns a particular element of the class.

EXAMPLES:

```
sage: TableauTuples(3,0).an_element()
([], [], [])
sage: TableauTuples(3,1).an_element()
([[1]], [], [])
sage: TableauTuples(3,2).an_element()
([[1, 2]], [], [])
```

class `sage.combinat.tableau_tuple.TableauTuples_size(size)`

Bases: *sage.combinat.tableau_tuple.TableauTuples*

Class of all *TableauTuples* with a arbitrary level and fixed size.

`an_element()`

Returns a particular element of the class.

EXAMPLES:

```
sage: TableauTuples(size=3).an_element()
([], [[1, 2, 3]], [])
sage: TableauTuples(size=0).an_element()
([], [], [])
```

5.1.325 Generalized Tamari lattices

These lattices depend on three parameters a , b and m , where a and b are coprime positive integers and m is a nonnegative integer.

The elements are *Dyck paths* in the $(a \times b)$ -rectangle. The order relation depends on m .

To use the provided functionality, you should import Generalized Tamari lattices by typing:

```
sage: from sage.combinat.tamari_lattices import GeneralizedTamariLattice
```

Then,

```
sage: GeneralizedTamariLattice(3,2)
Finite lattice containing 2 elements
sage: GeneralizedTamariLattice(4,3)
Finite lattice containing 5 elements
```

The classical **Tamari lattices** are special cases of this construction and are also available directly using the catalogue of posets, as follows:

```
sage: posets.TamariLattice(3)
Finite lattice containing 5 elements
```

See also:

For more detailed information see `TamariLattice()`, `GeneralizedTamariLattice()`.

`sage.combinat.tamari_lattices.GeneralizedTamariLattice(a, b, m=1)`

Return the (a, b) -Tamari lattice of parameter m .

INPUT:

- a and b coprime integers with $a \geq b$
- m a nonnegative integer such that $a \geq b \times m$

OUTPUT:

- a finite lattice (the lattice property is only conjectural in general)

The elements of the lattice are *Dyck paths* in the $(a \times b)$ -rectangle.

The parameter m (slope) is used only to define the covering relations. When the slope m is 0, two paths are comparable if and only if one is always above the other.

The usual **Tamari lattice** of index b is the special case $a = b + 1$ and $m = 1$.

Other special cases give the m -Tamari lattices studied in [BMFPR].

EXAMPLES:

```

sage: from sage.combinat.tamari_lattices import GeneralizedTamariLattice
sage: GeneralizedTamariLattice(3,2)
Finite lattice containing 2 elements
sage: GeneralizedTamariLattice(4,3)
Finite lattice containing 5 elements
sage: GeneralizedTamariLattice(4,4)
Traceback (most recent call last):
...
ValueError: The numbers a and b must be coprime with a>=b.
sage: GeneralizedTamariLattice(7,5,2)
Traceback (most recent call last):
...
ValueError: The condition a>=b*m does not hold.
sage: P = GeneralizedTamariLattice(5,3);P
Finite lattice containing 7 elements

```

REFERENCES:

`sage.combinat.tamari_lattices.TamariLattice(n)`
Return the n -th Tamari lattice.

INPUT:

- n a nonnegative integer

OUTPUT:

- a finite lattice

The elements of the lattice are *Dyck paths* in the $(n+1 \times n)$ -rectangle.

See [Tamari lattice](#) for mathematical background.

EXAMPLES:

```

sage: posets.TamariLattice(3)
Finite lattice containing 5 elements

```

`sage.combinat.tamari_lattices.paths_in_triangle(i,j,a,b)`
Return all Dyck paths from $(0,0)$ to (i,j) in the $(a \times b)$ -rectangle.

This means that at each step of the path, one has $ay \geq bx$.

A path is represented by a sequence of 0 and 1, where 0 is an horizontal step $(1,0)$ and 1 is a vertical step $(0,1)$.

INPUT:

- a and b coprime integers with $a \geq b$
- i and j nonnegative integers with $1 \geq \frac{j}{b} \geq \frac{bi}{a} \geq 0$

OUTPUT:

- a list of paths

EXAMPLES:

```

sage: from sage.combinat.tamari_lattices import paths_in_triangle
sage: paths_in_triangle(2,2,2,2)
[(1, 0, 1, 0), (1, 1, 0, 0)]
sage: paths_in_triangle(2,3,4,4)
[(1, 0, 1, 0, 1), (1, 1, 0, 0, 1), (1, 0, 1, 1, 0),
(1, 1, 0, 1, 0), (1, 1, 1, 0, 0)]

```

```

sage: paths_in_triangle(2,1,4,4)
Traceback (most recent call last):
...
ValueError: The endpoint is not valid.
sage: paths_in_triangle(3,2,5,3)
[(1, 0, 1, 0, 0), (1, 1, 0, 0, 0)]

```

`sage.combinat.tamari_lattices.swap(p, i, m=1)`

Perform a covering move in the (a, b) -Tamari lattice of parameter m .

The letter at position i in p must be a 0, followed by at least one 1.

INPUT:

- p a Dyck path in the $(a \times b)$ -rectangle
- i an integer between 0 and $a + b - 1$

OUTPUT:

- a Dyck path in the $(a \times b)$ -rectangle

EXAMPLES:

```

sage: from sage.combinat.tamari_lattices import swap
sage: swap((1,0,1,0),1)
(1, 1, 0, 0)
sage: swap((1,0,1,0),6)
Traceback (most recent call last):
...
ValueError: The index is greater than the length of the path.
sage: swap((1,1,0,0,1,1,0,0),3)
(1, 1, 0, 1, 1, 0, 0, 0)
sage: swap((1,1,0,0,1,1,0,0),2)
Traceback (most recent call last):
...
ValueError: There is no such covering move.

```

5.1.326 Tiling Solver

Tiling a n -dimensional polyomino with n -dimensional polyominoes.

This module defines two classes:

- `sage.combinat.tiling.Polyomino` class, to represent polyominoes in arbitrary dimension. The goal of this class is to return all the rotated, reflected and/or translated copies of a polyomino that are contained in a certain box.
- `sage.combinat.tiling.TilingSolver` class, to solve the problem of tiling a n -dimensional polyomino with a set of n -dimensional polyominoes. One can specify if rotations and reflections are allowed or not and if pieces can be reused or not. This class convert the tiling data into rows of a matrix that are passed to the DLX solver. It also allows to compute the number of solutions.

This uses dancing links code which is in Sage. Dancing links were originally introduced by Donald Knuth in 2000 [Knuth1]. Knuth used dancing links to solve tilings of a region by 2d pentaminoes. Here we extend the method to any dimension.

In particular, the `sage.games.quantumino` module is based on the Tiling Solver and allows to solve the 3d Quantumino puzzle.

AUTHOR:

- Sebastien Labbe, June 2011, initial version
- Sebastien Labbe, July 2015, count solutions up to rotations
- Sebastien Labbe, April 2017, tiling a polyomino, not only a rectangular box

EXAMPLES:

2d Easy Example

Here is a 2d example. Let us try to fill the 3×2 rectangle with a 1×2 rectangle and a 2×2 square. Obviously, there are two solutions:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0), (0,1)])
sage: q = Polyomino([(0,0), (0,1), (1,0), (1,1)])
sage: T = TilingSolver([p,q], box=[3,2])
sage: it = T.solve()
sage: next(it)
[Polyomino: [(0, 0), (0, 1), (1, 0), (1, 1)], Color: gray, Polyomino: [(2, 0), (2, 1)], Color: gray]
sage: next(it)
[Polyomino: [(1, 0), (1, 1), (2, 0), (2, 1)], Color: gray, Polyomino: [(0, 0), (0, 1)], Color: gray]
sage: next(it)
Traceback (most recent call last):
...
StopIteration
sage: T.number_of_solutions()
2
```

Scott's pentomino problem

As mentioned in the introduction of [\[Knuth1\]](#), Scott's pentomino problem consists in tiling a chessboard leaving the center four squares vacant with the 12 distinct pentominoes.

The 12 pentominoes:

```
sage: from sage.combinat.tiling import Polyomino
sage: I = Polyomino([(0,0), (1,0), (2,0), (3,0), (4,0)], color='brown')
sage: N = Polyomino([(1,0), (1,1), (1,2), (0,2), (0,3)], color='yellow')
sage: L = Polyomino([(0,0), (1,0), (0,1), (0,2), (0,3)], color='magenta')
sage: U = Polyomino([(0,0), (1,0), (0,1), (0,2), (1,2)], color='violet')
sage: X = Polyomino([(1,0), (0,1), (1,1), (1,2), (2,1)], color='pink')
sage: W = Polyomino([(2,0), (2,1), (1,1), (1,2), (0,2)], color='green')
sage: P = Polyomino([(1,0), (2,0), (0,1), (1,1), (2,1)], color='orange')
sage: F = Polyomino([(1,0), (1,1), (0,1), (2,1), (2,2)], color='gray')
sage: Z = Polyomino([(0,0), (1,0), (1,1), (1,2), (2,2)], color='yellow')
sage: T = Polyomino([(0,0), (0,1), (1,1), (2,1), (0,2)], color='red')
sage: Y = Polyomino([(0,0), (1,0), (2,0), (3,0), (2,1)], color='green')
sage: V = Polyomino([(0,0), (0,1), (0,2), (1,0), (2,0)], color='blue')
```

A 8×8 chessboard leaving the center four squares vacant:

```

sage: import itertools
sage: s = set(itertools.product(range(8), repeat=2))
sage: s.difference_update([(3,3), (3,4), (4,3), (4,4)])
sage: chessboard = Polyomino(s)
sage: len(chessboard)
60

```

This problem is represented by a matrix made of 1568 rows and 72 columns. It has 65 different solutions up to isometries:

```

sage: from sage.combinat.tiling import TilingSolver
sage: T = TilingSolver([I,N,L,U,X,W,P,F,Z,T,Y,V], box=chessboard, reflection=True)
sage: T
Tiling solver of 12 pieces into a box of size 60
Rotation allowed: True
Reflection allowed: True
Reusing pieces allowed: False
sage: len(T.rows())           # long time
1568
sage: T.number_of_solutions() # long time
520
sage: 520 / 8
65

```

Showing one solution:

```

sage: solution = next(T.solve())           # long time
sage: G = sum([piece.show2d() for piece in solution], Graphics()) # long time
sage: G.show(aspect_ratio=1, axes=False)   # long time

```

1d Easy Example

Here is an easy one dimensional example where we try to tile a stick of length 6 with three sticks of length 1, 2 and 3. There are six solutions:

```

sage: p = Polyomino([[0]])
sage: q = Polyomino([[0],[1]])
sage: r = Polyomino([[0],[1],[2]])
sage: T = TilingSolver([p,q,r], box=[6])
sage: len(T.rows())
15
sage: it = T.solve()
sage: next(it)
[Polyomino: [(0)], Color: gray, Polyomino: [(1), (2)], Color: gray, Polyomino: [(3), (4), (5)], Color: gray]
sage: next(it)
[Polyomino: [(0)], Color: gray, Polyomino: [(1), (2), (3)], Color: gray, Polyomino: [(4), (5)], Color: gray]
sage: T.number_of_solutions()
6

```

2d Puzzle allowing reflections

The following is a puzzle owned by Florent Hivert:

```

sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: L = []
sage: L.append(Polyomino([(0,0), (0,1), (0,2), (0,3), (1,0), (1,1), (1,2), (1,3)], 'yellow'))
sage: L.append(Polyomino([(0,0), (0,1), (0,2), (0,3), (1,0), (1,1), (1,2)], 'black'))
sage: L.append(Polyomino([(0,0), (0,1), (0,2), (0,3), (1,0), (1,1), (1,3)], 'gray'))
sage: L.append(Polyomino([(0,0), (0,1), (0,2), (0,3), (1,0), (1,3)], 'cyan'))
sage: L.append(Polyomino([(0,0), (0,1), (0,2), (0,3), (1,0), (1,1)], 'red'))
sage: L.append(Polyomino([(0,0), (0,1), (0,2), (0,3), (1,1), (1,2)], 'blue'))
sage: L.append(Polyomino([(0,0), (0,1), (0,2), (0,3), (1,1), (1,3)], 'green'))
sage: L.append(Polyomino([(0,1), (0,2), (0,3), (1,0), (1,1), (1,3)], 'magenta'))
sage: L.append(Polyomino([(0,1), (0,2), (0,3), (1,0), (1,1), (1,2)], 'orange'))
sage: L.append(Polyomino([(0,0), (0,1), (0,2), (1,0), (1,1), (1,2)], 'pink'))

```

By default, rotations are allowed and reflections are not. In this case, there are no solution for tiling a 8×8 rectangular box:

```

sage: T = TilingSolver(L, box=(8,8))
sage: T.number_of_solutions()                                # long time (2.5 s)
0

```

If reflections are allowed, there are solutions. Solve the puzzle and show one solution:

```

sage: T = TilingSolver(L, box=(8,8), reflection=True)
sage: solution = next(T.solve())                             # long time (7s)
sage: G = sum([piece.show2d() for piece in solution], Graphics()) # long time (<1s)
sage: G.show(aspect_ratio=1, axes=False)                     # long time (2s)

```

Compute the number of solutions:

```

sage: T.number_of_solutions()                                # long time (2.6s)
328

```

Create a animation of all the solutions:

```

sage: a = T.animate()                                       # not tested
sage: a                                                       # not tested
Animation with 328 frames

```

3d Puzzle

The same thing done in 3d *without* allowing reflections this time:

```

sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: L = []
sage: L.append(Polyomino([(0,0,0), (0,1,0), (0,2,0), (0,3,0), (1,0,0), (1,1,0), (1,2,0), (1,
↪ 3,0)]))
sage: L.append(Polyomino([(0,0,0), (0,1,0), (0,2,0), (0,3,0), (1,0,0), (1,1,0), (1,2,0)]))
sage: L.append(Polyomino([(0,0,0), (0,1,0), (0,2,0), (0,3,0), (1,0,0), (1,1,0), (1,3,0)]))
sage: L.append(Polyomino([(0,0,0), (0,1,0), (0,2,0), (0,3,0), (1,0,0), (1,3,0)]))
sage: L.append(Polyomino([(0,0,0), (0,1,0), (0,2,0), (0,3,0), (1,1,0), (1,2,0)]))
sage: L.append(Polyomino([(0,0,0), (0,1,0), (0,2,0), (0,3,0), (1,1,0), (1,3,0)]))
sage: L.append(Polyomino([(0,1,0), (0,2,0), (0,3,0), (1,0,0), (1,1,0), (1,3,0)]))
sage: L.append(Polyomino([(0,1,0), (0,2,0), (0,3,0), (1,0,0), (1,1,0), (1,2,0)]))
sage: L.append(Polyomino([(0,0,0), (0,1,0), (0,2,0), (1,0,0), (1,1,0), (1,2,0)]))

```

Solve the puzzle and show one solution:

```
sage: T = TilingSolver(L, box=(8,8,1))
sage: solution = next(T.solve()) # long time (8s)
sage: G = sum([p.show3d(size=0.85) for p in solution], Graphics()) # long time (<1s)
sage: G.show(aspect_ratio=1, viewer='tachyon') # long time (2s)
```

Let us compute the number of solutions:

```
sage: T.number_of_solutions() # long time (3s)
328
```

Donald Knuth example : the Y pentamino

Donald Knuth [Knuth1] considered the problem of packing 45 Y pentaminoes into a 15×15 square:

```
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: y = Polyomino([(0,0), (1,0), (2,0), (3,0), (2,1)])
sage: T = TilingSolver([y], box=(5,10), reusable=True, reflection=True)
sage: T.number_of_solutions()
10
sage: solution = next(T.solve())
sage: G = sum([p.show2d() for p in solution], Graphics())
sage: G.show(aspect_ratio=1) # long time (2s)
```

```
sage: T = TilingSolver([y], box=(15,15), reusable=True, reflection=True)
sage: T.number_of_solutions() # not tested
212
```

Animation of Donald Knuth's dancing links

Animation of the solutions:

```
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: Y = Polyomino([(0,0), (1,0), (2,0), (3,0), (2,1)], color='yellow')
sage: T = TilingSolver([Y], box=(15,15), reusable=True, reflection=True)
sage: a = T.animate(stop=40) # long time # optional -- ImageMagick
sage: a # long time # optional -- ImageMagick
Animation with 40 frames
```

Incremental animation of the solutions (one piece is removed/added at a time):

```
sage: a = T.animate('incremental', stop=40) # long time # optional -- ImageMagick
sage: a # long time # optional -- ImageMagick
Animation with 40 frames
sage: a.show(delay=50, iterations=1) # long time # optional -- ImageMagick
```

5d Easy Example

Here is a 5d example. Let us try to fill the $2 \times 2 \times 2 \times 2 \times 2$ rectangle with reusable $1 \times 1 \times 1 \times 1 \times 1$ rectangles. Obviously, there is one solution:

```

sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: p = Polyomino([(0,0,0,0,0)])
sage: T = TilingSolver([p], box=(2,2,2,2,2), reusable=True)
sage: rows = T.rows()                                     # long time (3s)
sage: rows                                                # long time (fast)
[[0], [1], [2], [3], [4], [5], [6], [7], [8], [9], [10], [11], [12], [13], [14], [15],
↪ [16], [17], [18], [19], [20], [21], [22], [23], [24], [25], [26], [27], [28], [29],
↪ [30], [31]]
sage: T.number_of_solutions()                             # long time (fast)
1

```

REFERENCES:

class sage.combinat.tiling.**Polyomino**(coords, color='gray')

Bases: sage.structure.sage_object.SageObject

A polyomino in $\mathbb{Z}^d$.

The polyomino is the union of the unit square (or cube, or n-cube) centered at those coordinates. Such an object should be connected, but the code does not make this assumption.

INPUT:

- coords – iterable of integer coordinates in $\mathbb{Z}^d$
- color – string (default: 'gray'), color for display

EXAMPLES:

```

sage: from sage.combinat.tiling import Polyomino
sage: Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
Polyomino: [(0, 0, 0), (0, 1, 0), (1, 1, 0), (1, 1, 1)], Color: blue

```

boundary()

Return the boundary of a 2d polyomino.

INPUT:

- self - a 2d polyomino

OUTPUT:

- list of edges (an edge is a pair of adjacent 2d coordinates)

EXAMPLES:

```

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0), (1,0), (0,1), (1,1)])
sage: p.boundary()
[((0.5, 1.5), (1.5, 1.5)), ((-0.5, -0.5), (0.5, -0.5)), ((0.5, -0.5), (1.5, -
↪ 0.5)), ((-0.5, 1.5), (0.5, 1.5)), ((-0.5, 0.5), (-0.5, 1.5)), ((-0.5, -0.5),
↪ (-0.5, 0.5)), ((1.5, 0.5), (1.5, 1.5)), ((1.5, -0.5), (1.5, 0.5))]
sage: len(_)
8
sage: p = Polyomino([(5,5)])
sage: p.boundary()
[((4.5, 5.5), (5.5, 5.5)), ((4.5, 4.5), (5.5, 4.5)), ((4.5, 4.5), (4.5, 5.5)),
↪ ((5.5, 4.5), (5.5, 5.5))]

```

bounding_box()

EXAMPLES:

```

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (1,0,0), (1,1,0), (1,1,1), (1,2,0)], color='deeppink
↪')
sage: p.bounding_box()
[[0, 0, 0], [1, 2, 1]]

```

canonical()

Returns the translated copy of self having minimal and nonnegative coordinates

EXAMPLES:

```

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (1,0,0), (1,1,0), (1,1,1), (1,2,0)], color='deeppink
↪')
sage: p
Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color: ↪
↪deeppink
sage: p.canonical()
Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color: ↪
↪deeppink

```

canonical_isometric_copies (*orientation_preserving=True, mod_box_isometries=False*)

Return the set of image of self under isometries of the n -cube where the coordinates are all nonnegative and minimal.

INPUT:

- *orientation_preserving* – bool (optional, default: True), If True, the group of isometries of the n -cube is restricted to those that preserve the orientation, i.e. of determinant 1.
- *mod_box_isometries* – bool (default: False), whether to quotient the group of isometries of the n -cube by the subgroup of isometries of the $a_1 \times a_2 \cdots \times a_n$ rectangular box where the a_i are assumed to be distinct.

OUTPUT:

set of Polyomino

EXAMPLES:

```

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: s = p.canonical_isometric_copies()
sage: len(s)
12

```

With the non orientation-preserving:

```

sage: s = p.canonical_isometric_copies(orientation_preserving=False)
sage: len(s)
24

```

Modulo rotation by angle 180 degrees:

```

sage: s = p.canonical_isometric_copies(mod_box_isometries=True)
sage: len(s)
3

```

canonical_orthogonals (**args, **kws*)

Deprecated: Use `canonical_isometric_copies()` instead. See [trac ticket #19107](#) for details.

center()

Return the center of the polyomino.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,0,1)])
sage: p.center()
(0, 0, 1/2)
```

In 3d:

```
sage: p = Polyomino([(0,0,0), (1,0,0), (1,1,0), (1,1,1), (1,2,0)], color='deeppink',
↪)
sage: p.center()
(4/5, 4/5, 1/5)
```

In 2d:

```
sage: p = Polyomino([(0,0), (1,0), (1,1), (1,2)])
sage: p.center()
(3/4, 3/4)
```

color()

Return the color of the polyomino.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: p.color()
'blue'
```

frozenset()

Return the elements of $\mathbb{Z}^d$ in the polyomino as a frozenset.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='red')
sage: p.frozenset()
frozenset({(0, 0, 0), (0, 1, 0), (1, 1, 0), (1, 1, 1)})
```

isometric_copies(box, orientation_preserving=True, mod_box_isometries=False)

Return the translated and isometric images of self that lies in the box.

INPUT:

- **box** – Polyomino or tuple of integers (size of a box)
- **orientation_preserving** – bool (optional, default: True), If True, the group of isometries of the n -cube is restricted to those that preserve the orientation, i.e. of determinant 1.
- **mod_box_isometries** – bool (default: False), whether to quotient the group of isometries of the n -cube by the subgroup of isometries of the $a_1 \times a_2 \cdots \times a_n$ rectangular box where the a_i are assumed to be distinct.

EXAMPLES:

```

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (1,0,0), (1,1,0), (1,1,1), (1,2,0)], color='deeppink
↪')
sage: L = list(p.isometric_copies(box=(5,8,2)))
sage: len(L)
360

```

```

sage: p = Polyomino([(0,0,0), (1,0,0), (1,1,0), (1,2,0), (1,2,1)], color='orange')
sage: L = list(p.isometric_copies(box=(5,8,2)))
sage: len(L)
180
sage: L = list(p.isometric_copies((5,8,2), False))
sage: len(L)
360
sage: L = list(p.isometric_copies((5,8,2), mod_box_isometries=True))
sage: len(L)
45

```

```

sage: p = Polyomino([(0,0), (1,0), (0,1)])
sage: b = Polyomino([(0,0), (1,0), (2,0), (0,1), (1,1), (0,2)])
sage: list(p.isometric_copies(b))
[Polyomino: [(0, 0), (1, 0), (1, 1)], Color: gray,
Polyomino: [(0, 0), (0, 1), (1, 0)], Color: gray,
Polyomino: [(0, 1), (0, 2), (1, 1)], Color: gray,
Polyomino: [(1, 0), (1, 1), (2, 0)], Color: gray,
Polyomino: [(0, 0), (0, 1), (1, 1)], Color: gray,
Polyomino: [(0, 1), (1, 0), (1, 1)], Color: gray]

```

neighbor_edges()

Return an iterator over the pairs of neighbor coordinates inside of the polyomino.

Two points P and Q in the polyomino are neighbor if $P - Q$ has one coordinate equal to $+1$ or -1 and zero everywhere else.

EXAMPLES:

```

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,0,1)])
sage: list(sorted(edge) for edge in p.neighbor_edges())
[[ (0, 0, 0), (0, 0, 1) ]]

```

In 3d:

```

sage: p = Polyomino([(0,0,0), (1,0,0), (1,1,0), (1,1,1), (1,2,0)], color='deeppink
↪')
sage: L = sorted(sorted(edge) for edge in p.neighbor_edges())
sage: for a in L: a
[(0, 0, 0), (1, 0, 0)]
[(1, 0, 0), (1, 1, 0)]
[(1, 1, 0), (1, 1, 1)]
[(1, 1, 0), (1, 2, 0)]

```

In 2d:

```

sage: p = Polyomino([(0,0), (1,0), (1,1), (1,2)])
sage: L = sorted(sorted(edge) for edge in p.neighbor_edges())
sage: for a in L: a
[(0, 0), (1, 0)]

```

```
[(1, 0), (1, 1)]
[(1, 1), (1, 2)]
```

show2d (*size=0.7, color='black', thickness=1*)

Returns a 2d Graphic object representing the polyomino.

INPUT:

- *self* - a polyomino of dimension 2
- *size* - number (optional, default: 0.7), the size of each square.
- *color* - color (optional, default: 'black'), color of the boundary line.
- *thickness* - number (optional, default: 1), how thick the boundary line is.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0), (1,0), (1,1), (1,2)], color='deeppink')
sage: p.show2d() # long time (0.5s)
Graphics object consisting of 17 graphics primitives
```

show3d (*size=1*)

Returns a 3d Graphic object representing the polyomino.

INPUT:

- *self* - a polyomino of dimension 3
- *size* - number (optional, default: 1), the size of each 1 \times 1 \times 1 cube. This does a homothety with respect to the center of the polyomino.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: p.show3d() # long time (2s)
Graphics3d Object
```

sorted_list ()

Return the color of the polyomino.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: p.sorted_list()
[(0, 0, 0), (0, 1, 0), (1, 1, 0), (1, 1, 1)]
```

translated (*args, **kws)

Deprecated: Use `translated_copies()` instead. See [trac ticket #19107](#) for details.

translated_copies (box)

Returns an iterator over the translated images of self inside a polyomino.

INPUT:

- *box* – Polyomino or tuple of integers (size of a box)

OUTPUT:

iterator of 3d polyominoes

EXAMPLES:

```

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (1,0,0), (1,1,0), (1,1,1), (1,2,0)], color='deeppink
↳')
sage: for t in p.translated_copies(box=(5,8,2)): t
Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color:↳
↳deeppink
Polyomino: [(0, 1, 0), (1, 1, 0), (1, 2, 0), (1, 2, 1), (1, 3, 0)], Color:↳
↳deeppink
Polyomino: [(0, 2, 0), (1, 2, 0), (1, 3, 0), (1, 3, 1), (1, 4, 0)], Color:↳
↳deeppink
Polyomino: [(0, 3, 0), (1, 3, 0), (1, 4, 0), (1, 4, 1), (1, 5, 0)], Color:↳
↳deeppink
Polyomino: [(0, 4, 0), (1, 4, 0), (1, 5, 0), (1, 5, 1), (1, 6, 0)], Color:↳
↳deeppink
Polyomino: [(0, 5, 0), (1, 5, 0), (1, 6, 0), (1, 6, 1), (1, 7, 0)], Color:↳
↳deeppink
Polyomino: [(1, 0, 0), (2, 0, 0), (2, 1, 0), (2, 1, 1), (2, 2, 0)], Color:↳
↳deeppink
Polyomino: [(1, 1, 0), (2, 1, 0), (2, 2, 0), (2, 2, 1), (2, 3, 0)], Color:↳
↳deeppink
Polyomino: [(1, 2, 0), (2, 2, 0), (2, 3, 0), (2, 3, 1), (2, 4, 0)], Color:↳
↳deeppink
Polyomino: [(1, 3, 0), (2, 3, 0), (2, 4, 0), (2, 4, 1), (2, 5, 0)], Color:↳
↳deeppink
Polyomino: [(1, 4, 0), (2, 4, 0), (2, 5, 0), (2, 5, 1), (2, 6, 0)], Color:↳
↳deeppink
Polyomino: [(1, 5, 0), (2, 5, 0), (2, 6, 0), (2, 6, 1), (2, 7, 0)], Color:↳
↳deeppink
Polyomino: [(2, 0, 0), (3, 0, 0), (3, 1, 0), (3, 1, 1), (3, 2, 0)], Color:↳
↳deeppink
Polyomino: [(2, 1, 0), (3, 1, 0), (3, 2, 0), (3, 2, 1), (3, 3, 0)], Color:↳
↳deeppink
Polyomino: [(2, 2, 0), (3, 2, 0), (3, 3, 0), (3, 3, 1), (3, 4, 0)], Color:↳
↳deeppink
Polyomino: [(2, 3, 0), (3, 3, 0), (3, 4, 0), (3, 4, 1), (3, 5, 0)], Color:↳
↳deeppink
Polyomino: [(2, 4, 0), (3, 4, 0), (3, 5, 0), (3, 5, 1), (3, 6, 0)], Color:↳
↳deeppink
Polyomino: [(2, 5, 0), (3, 5, 0), (3, 6, 0), (3, 6, 1), (3, 7, 0)], Color:↳
↳deeppink
Polyomino: [(3, 0, 0), (4, 0, 0), (4, 1, 0), (4, 1, 1), (4, 2, 0)], Color:↳
↳deeppink
Polyomino: [(3, 1, 0), (4, 1, 0), (4, 2, 0), (4, 2, 1), (4, 3, 0)], Color:↳
↳deeppink
Polyomino: [(3, 2, 0), (4, 2, 0), (4, 3, 0), (4, 3, 1), (4, 4, 0)], Color:↳
↳deeppink
Polyomino: [(3, 3, 0), (4, 3, 0), (4, 4, 0), (4, 4, 1), (4, 5, 0)], Color:↳
↳deeppink
Polyomino: [(3, 4, 0), (4, 4, 0), (4, 5, 0), (4, 5, 1), (4, 6, 0)], Color:↳
↳deeppink
Polyomino: [(3, 5, 0), (4, 5, 0), (4, 6, 0), (4, 6, 1), (4, 7, 0)], Color:↳
↳deeppink

```

This method is independant of the translation of the polyomino:

```

sage: q = Polyomino([(0,0,0), (1,0,0)])
sage: list(q.translated_copies((2,2,1)))

```

```
[Polyomino: [(0, 0, 0), (1, 0, 0)], Color: gray, Polyomino: [(0, 1, 0), (1, 1,
↪ 0)], Color: gray]
sage: q = Polyomino([(34,7,-9), (35,7,-9)])
sage: list(q.translated_copies((2,2,1)))
[Polyomino: [(0, 0, 0), (1, 0, 0)], Color: gray, Polyomino: [(0, 1, 0), (1, 1,
↪ 0)], Color: gray]
```

Inside smaller boxes:

```
sage: list(p.translated_copies(box=(2,2,3)))
[]
sage: list(p.translated_copies(box=(2,3,2)))
[Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color: ↪
↪ deeppink]
sage: list(p.translated_copies(box=(3,2,2)))
[]
sage: list(p.translated_copies(box=(1,1,1)))
[]
```

Using a Polyomino as input:

```
sage: b = Polyomino([(0,0), (0,1), (0,2), (1,0), (1,1), (1,2)])
sage: p = Polyomino([(0,0)])
sage: list(p.translated_copies(b))
[Polyomino: [(0, 0)], Color: gray,
Polyomino: [(0, 1)], Color: gray,
Polyomino: [(0, 2)], Color: gray,
Polyomino: [(1, 0)], Color: gray,
Polyomino: [(1, 1)], Color: gray,
Polyomino: [(1, 2)], Color: gray]
```

```
sage: p = Polyomino([(0,0), (1,0), (0,1)])
sage: b = Polyomino([(0,0), (1,0), (2,0), (0,1), (1,1), (0,2)])
sage: list(p.translated_copies(b))
[Polyomino: [(0, 0), (0, 1), (1, 0)], Color: gray,
Polyomino: [(0, 1), (0, 2), (1, 1)], Color: gray,
Polyomino: [(1, 0), (1, 1), (2, 0)], Color: gray]
```

translated_orthogonals (*args, **kws)

Deprecated: Use *isometric_copies*() instead. See [trac ticket #19107](#) for details.

class sage.combinat.tiling.**TilingSolver**(pieces, box, rotation=True, reflection=False, reusable=False)

Bases: sage.structure.sage_object.SageObject

Tiling solver

Solve the problem of tiling a rectangular box with a certain number of pieces, called polyominoes, where each polyomino must be used exactly once.

INPUT:

- pieces – iterable of Polyominoes
- box – Polyomino or tuple of integers (size of a box)
- rotation – bool (optional, default: True), whether to allow rotations
- reflection – bool (optional, default: False), whether to allow reflections
- reusable – bool (optional, default: False), whether to allow the pieces to be reused

EXAMPLES:

By default, rotations are allowed and reflections are not allowed:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T
Tiling solver of 3 pieces into a box of size 6
Rotation allowed: True
Reflection allowed: False
Reusing pieces allowed: False
```

Solutions are given by an iterator:

```
sage: it = T.solve()
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2)], Color: gray
Polyomino: [(0, 0, 3), (0, 0, 4), (0, 0, 5)], Color: gray
```

Another solution:

```
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2), (0, 0, 3)], Color: gray
Polyomino: [(0, 0, 4), (0, 0, 5)], Color: gray
```

Tiling of a polyomino by polyominoes:

```
sage: b = Polyomino([(0,0), (1,0), (1,1), (2,1), (1,2), (2,2), (0,3), (1,3)])
sage: p = Polyomino([(0,0), (1,0)])
sage: T = TilingSolver([p], box=b, reusable=True)
sage: T.number_of_solutions()
2
```

animate (*partial=None, stop=None, size=0.75, axes=False*)

Return an animation of evolving solutions.

INPUT:

- **partial** - string (optional, default: None), whether to include partial (incomplete) solutions. It can be one of the following:
 - None - include only complete solutions
 - 'common_prefix' - common prefix between two consecutive solutions
 - 'incremental' - one piece change at a time
- **stop** - integer (optional, default:None), number of frames
- **size** - number (optional, default: 0.75), the size of each 1 \times 1 square. This does a homothety with respect to the center of each polyomino.
- **axes** - bool (optional, default:False), whether the x and y axes are shown.

EXAMPLES:

```

sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: y = Polyomino([(0,0), (1,0), (2,0), (3,0), (2,1)], color='cyan')
sage: T = TilingSolver([y], box=(5,10), reusable=True, reflection=True)
sage: a = T.animate()
sage: a                                # optional -- ImageMagick
Animation with 10 frames

```

Include partial solutions (common prefix between two consecutive solutions):

```

sage: a = T.animate('common_prefix')
sage: a                                # optional -- ImageMagick
Animation with 19 frames

```

Incremental solutions (one piece removed or added at a time):

```

sage: a = T.animate('incremental')      # long time (2s)
sage: a                                # long time (2s) # optional -- ImageMagick
Animation with 123 frames

```

```

sage: a.show()                          # optional -- ImageMagick

```

The show function takes arguments to specify the delay between frames (measured in hundredths of a second, default value 20) and the number of iterations (default value 0, which means to iterate forever). To iterate 4 times with half a second between each frame:

```

sage: a.show(delay=50, iterations=4)   # optional -- ImageMagick

```

Limit the number of frames:

```

sage: a = T.animate('incremental', stop=13) # not tested
sage: a                                    # not tested
Animation with 13 frames

```

`coord_to_int_dict()`

Returns a dictionary mapping coordinates to integers.

OUTPUT:

dict

EXAMPLES:

```

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: A = T.coord_to_int_dict()
sage: sorted(A.items())
[((0, 0, 0), 3), ((0, 0, 1), 4), ((0, 0, 2), 5), ((0, 0, 3), 6), ((0, 0, 4), 7), ((0, 0, 5), 8)]

```

Reusable pieces:

```

sage: p = Polyomino([(0,0), (0,1)])
sage: q = Polyomino([(0,0), (0,1), (1,0), (1,1)])
sage: T = TilingSolver([p,q], box=[3,2], reusable=True)

```

```

sage: B = T.coord_to_int_dict()
sage: sorted(B.items())
[(0, 0), 0), ((0, 1), 1), ((1, 0), 2), ((1, 1), 3), ((2, 0), 4), ((2, 1), 5)]

```

dlx_solver()

Return the sage DLX solver of that tiling problem.

OUTPUT:

DLX Solver

EXAMPLES:

```

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.dlx_solver()
Dancing links solver for 9 columns and 15 rows

```

int_to_coord_dict()

Returns a dictionary mapping integers to coordinates.

EXAMPLES:

```

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: B = T.int_to_coord_dict()
sage: sorted(B.items())
[(3, (0, 0, 0)), (4, (0, 0, 1)), (5, (0, 0, 2)), (6, (0, 0, 3)), (7, (0, 0, 4)), (8, (0, 0, 5))]

```

Reusable pieces:

```

sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: p = Polyomino([(0,0), (0,1)])
sage: q = Polyomino([(0,0), (0,1), (1,0), (1,1)])
sage: T = TilingSolver([p,q], box=[3,2], reusable=True)
sage: B = T.int_to_coord_dict()
sage: sorted(B.items())
[(0, (0, 0)), (1, (0, 1)), (2, (1, 0)), (3, (1, 1)), (4, (2, 0)), (5, (2, 1))]

```

is_suitable()

Return whether the volume of the box is equal to sum of the volume of the polyominoes and the number of rows sent to the DLX solver is larger than zero.

If these conditions are not verified, then the problem is not suitable in the sense that there are no solution.

EXAMPLES:

```

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.is_suitable()

```

```
True
sage: T = TilingSolver([p,q,r], box=(1,1,7))
sage: T.is_suitable()
False
```

nrows_per_piece()

Return the number of rows necessary by each piece.

OUTPUT:

list

EXAMPLES:

```
sage: from sage.games.quantumino import QuantuminoSolver
sage: q = QuantuminoSolver(0)
sage: T = q.tiling_solver()
sage: T.nrows_per_piece()           # long time (10s)
[360, 360, 360, 360, 360, 180, 180, 672, 672, 360, 360, 180, 180, 360, 360,
↪180]
```

number_of_solutions()

Return the number of distinct solutions.

OUTPUT:

integer

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0)])
sage: q = Polyomino([(0,0), (0,1)])
sage: r = Polyomino([(0,0), (0,1), (0,2)])
sage: T = TilingSolver([p,q,r], box=(1,6))
sage: T.number_of_solutions()
6
```

```
sage: T = TilingSolver([p,q,r], box=(1,7))
sage: T.number_of_solutions()
0
```

pieces()

Return the list of pieces.

OUTPUT:

list of 3d polyominoes

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: for p in T._pieces: p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 0), (0, 0, 1)], Color: gray
Polyomino: [(0, 0, 0), (0, 0, 1), (0, 0, 2)], Color: gray
```

row_to_polyomino (*row_number*)

Return a polyomino associated to a row.

INPUT:

- *row_number* – integer, the *i*-th row

OUTPUT:

polyomino

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: a = Polyomino([(0,0,0), (0,0,1), (1,0,0)], color='blue')
sage: b = Polyomino([(0,0,0), (1,0,0), (0,1,0)], color='red')
sage: T = TilingSolver([a,b], box=(2,1,3))
sage: len(T.rows())
16
```

```
sage: T.row_to_polyomino(7)
Polyomino: [(0, 0, 1), (1, 0, 1), (1, 0, 2)], Color: blue
```

```
sage: T.row_to_polyomino(13)
Polyomino: [(0, 0, 1), (0, 0, 2), (1, 0, 1)], Color: red
```

rows ()

Creation of the rows

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: rows = T.rows()
sage: for row in rows: row
[0, 3]
[0, 4]
[0, 5]
[0, 6]
[0, 7]
[0, 8]
[1, 3, 4]
[1, 4, 5]
[1, 5, 6]
[1, 6, 7]
[1, 7, 8]
[2, 3, 4, 5]
[2, 4, 5, 6]
[2, 5, 6, 7]
[2, 6, 7, 8]
```

rows_for_piece (*i*, *mod_box_isometries=False*)Return the rows for the *i*-th piece.

INPUT:

- *i* – integer, the *i*-th piece

- `mod_box_isometries` – bool (default: False), whether to consider only rows for positions up to the action of the quotient the group of isometries of the n -cube by the subgroup of isometries of the $a_1 \times a_2 \cdots \times a_n$ rectangular box where the a_i are assumed to be distinct.

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.rows_for_piece(0)
[[0, 3], [0, 4], [0, 5], [0, 6], [0, 7], [0, 8]]
sage: T.rows_for_piece(1)
[[1, 3, 4], [1, 4, 5], [1, 5, 6], [1, 6, 7], [1, 7, 8]]
sage: T.rows_for_piece(2)
[[2, 3, 4, 5], [2, 4, 5, 6], [2, 5, 6, 7], [2, 6, 7, 8]]
```

Less rows when using `mod_box_isometries=True`:

```
sage: a = Polyomino([(0,0,0), (0,0,1), (1,0,0)])
sage: b = Polyomino([(0,0,0), (1,0,0), (0,1,0)])
sage: T = TilingSolver([a,b], box=(2,1,3))
sage: T.rows_for_piece(0)
[[0, 3, 5, 6],
 [0, 4, 6, 7],
 [0, 2, 3, 6],
 [0, 3, 4, 7],
 [0, 2, 3, 5],
 [0, 3, 4, 6],
 [0, 2, 5, 6],
 [0, 3, 6, 7]]
sage: T.rows_for_piece(0, mod_box_isometries=True)
[[0, 2, 3, 6], [0, 3, 4, 7]]
sage: T.rows_for_piece(1, mod_box_isometries=True)
[[1, 2, 3, 6], [1, 3, 4, 7]]
```

solve (*partial=None*)

Returns an iterator of list of polyominoes that are an exact cover of the box.

INPUT:

- `partial` - string (optional, default: None), whether to include partial (incomplete) solutions. It can be one of the following:
 - None - include only complete solution
 - 'common_prefix' - common prefix between two consecutive solutions
 - 'incremental' - one piece change at a time

OUTPUT:

iterator of list of polyominoes

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
```

```

sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: it = T.solve()
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2)], Color: gray
Polyomino: [(0, 0, 3), (0, 0, 4), (0, 0, 5)], Color: gray
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2), (0, 0, 3)], Color: gray
Polyomino: [(0, 0, 4), (0, 0, 5)], Color: gray
sage: for p in next(it): p
Polyomino: [(0, 0, 0), (0, 0, 1)], Color: gray
Polyomino: [(0, 0, 2), (0, 0, 3), (0, 0, 4)], Color: gray
Polyomino: [(0, 0, 5)], Color: gray

```

Including the partial solutions:

```

sage: it = T.solve(partial='common_prefix')
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2)], Color: gray
Polyomino: [(0, 0, 3), (0, 0, 4), (0, 0, 5)], Color: gray
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2), (0, 0, 3)], Color: gray
Polyomino: [(0, 0, 4), (0, 0, 5)], Color: gray
sage: for p in next(it): p
sage: for p in next(it): p
Polyomino: [(0, 0, 0), (0, 0, 1)], Color: gray
Polyomino: [(0, 0, 2), (0, 0, 3), (0, 0, 4)], Color: gray
Polyomino: [(0, 0, 5)], Color: gray

```

Colors are preserved when the polyomino can be reused:

```

sage: p = Polyomino([(0,0,0)], color='yellow')
sage: q = Polyomino([(0,0,0), (0,0,1)], color='yellow')
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)], color='yellow')
sage: T = TilingSolver([p,q,r], box=(1,1,6), reusable=True)
sage: it = T.solve()
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: yellow
Polyomino: [(0, 0, 1)], Color: yellow
Polyomino: [(0, 0, 2)], Color: yellow
Polyomino: [(0, 0, 3)], Color: yellow
Polyomino: [(0, 0, 4)], Color: yellow
Polyomino: [(0, 0, 5)], Color: yellow

```

space()

Returns an iterator over all the non negative integer coordinates contained in the space to tile.

EXAMPLES:

```

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])

```

```
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: list(T.space())
[(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 0, 3), (0, 0, 4), (0, 0, 5)]
```

starting_rows()

Return the starting rows for each piece.

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.starting_rows()
[0, 6, 11, 15]
```

`sage.combinat.tiling.ncube_isometry_group(n, orientation_preserving=True)`

Return the isometry group of the n -cube as a list of matrices.

INPUT:

- n – positive integer, dimension of the space
- `orientation_preserving` – bool (optional, default: True), whether the orientation is preserved

OUTPUT:

list of matrices

EXAMPLES:

```
sage: from sage.combinat.tiling import ncube_isometry_group
sage: ncube_isometry_group(2)
[
[1 0] [ 0 1] [-1 0] [ 0 -1]
[0 1], [-1 0], [ 0 -1], [ 1 0]
]
sage: ncube_isometry_group(2, orientation_preserving=False)
[
[1 0] [ 0 -1] [ 1 0] [ 0 1] [0 1] [-1 0] [ 0 -1] [-1 0]
[0 1], [-1 0], [ 0 -1], [-1 0], [1 0], [ 0 -1], [ 1 0], [ 0 1]
]
]
```

There are 24 orientation preserving isometries of the 3-cube:

```
sage: ncube_isometry_group(3)
[
[1 0 0] [ 1 0 0] [-1 0 0] [-1 0 0] [0 0 1] [ 0 0 -1]
[0 1 0] [ 0 -1 0] [ 0 1 0] [ 0 -1 0] [1 0 0] [ 1 0 0]
[0 0 1], [ 0 0 -1], [ 0 0 -1], [ 0 0 1], [0 1 0], [ 0 -1 0],

[ 0 0 -1] [ 0 0 1] [0 1 0] [ 0 -1 0] [ 0 1 0] [ 0 -1 0]
[-1 0 0] [-1 0 0] [0 0 1] [ 0 0 -1] [ 0 0 -1] [ 0 0 1]
[ 0 1 0], [ 0 -1 0], [1 0 0], [ 1 0 0], [-1 0 0], [-1 0 0],

[ 0 1 0] [ 0 -1 0] [ 0 1 0] [ 0 -1 0] [ 1 0 0] [ 1 0 0]
[ 1 0 0] [ 1 0 0] [-1 0 0] [-1 0 0] [ 0 0 -1] [ 0 0 1]
[ 0 0 -1], [ 0 0 1], [ 0 0 1], [ 0 0 -1], [ 0 1 0], [ 0 -1 0],
]
```

```

[-1  0  0] [-1  0  0] [ 0  0 -1] [ 0  0  1] [ 0  0  1] [ 0  0 -1]
[ 0  0  1] [ 0  0 -1] [ 0  1  0] [ 0 -1  0] [ 0  1  0] [ 0 -1  0]
[ 0  1  0], [ 0 -1  0], [ 1  0  0], [ 1  0  0], [-1  0  0], [-1  0  0]
]

```

`sage.combinat.tiling.ncube_isometry_group_cosets(n, orientation_preserving=True)`

Return the quotient of the isometry group of the n -cube by the the isometry group of the rectangular parallelepiped.

INPUT:

- n – positive integer, dimension of the space
- `orientation_preserving` – bool (optional, default: True), whether the orientation is preserved

OUTPUT:

list of cosets, each coset being a sorted list of matrices

EXAMPLES:

```

sage: from sage.combinat.tiling import ncube_isometry_group_cosets
sage: sorted(ncube_isometry_group_cosets(2))
[[
[-1  0] [1 0]
[ 0 -1], [0 1]
], [
[ 0 -1] [ 0  1]
[ 1  0], [-1  0]
]]
sage: sorted(ncube_isometry_group_cosets(2, False))
[[
[-1  0] [-1  0] [ 1  0] [1 0]
[ 0 -1], [ 0  1], [ 0 -1], [0 1]
], [
[ 0 -1] [ 0 -1] [ 0  1] [0 1]
[-1  0], [ 1  0], [-1  0], [1 0]
]]

```

```

sage: sorted(ncube_isometry_group_cosets(3))
[[
[-1  0  0] [-1  0  0] [ 1  0  0] [1 0 0]
[ 0 -1  0] [ 0  1  0] [ 0 -1  0] [0 1 0]
[ 0  0  1], [ 0  0 -1], [ 0  0 -1], [0 0 1]
], [
[-1  0  0] [-1  0  0] [ 1  0  0] [ 1  0  0]
[ 0  0 -1] [ 0  0  1] [ 0  0 -1] [ 0  0  1]
[ 0 -1  0], [ 0  1  0], [ 0  1  0], [ 0 -1  0]
], [
[ 0 -1  0] [ 0 -1  0] [ 0  1  0] [ 0  1  0]
[-1  0  0] [ 1  0  0] [-1  0  0] [ 1  0  0]
[ 0  0 -1], [ 0  0  1], [ 0  0  1], [ 0  0 -1]
], [
[ 0 -1  0] [ 0 -1  0] [ 0  1  0] [0 1 0]
[ 0  0 -1] [ 0  0  1] [ 0  0 -1] [0 0 1]
[ 1  0  0], [-1  0  0], [-1  0  0], [1 0 0]
], [
[ 0  0 -1] [ 0  0 -1] [ 0  0  1] [0 0 1]
[-1  0  0] [ 1  0  0] [-1  0  0] [1 0 0]
[ 0  1  0], [ 0 -1  0], [ 0 -1  0], [0 1 0]
]]

```

```
], [
[ 0 0 -1] [ 0 0 -1] [ 0 0 1] [ 0 0 1]
[ 0 -1 0] [ 0 1 0] [ 0 -1 0] [ 0 1 0]
[-1 0 0], [ 1 0 0], [ 1 0 0], [-1 0 0]
]]
```

5.1.327 Transitive ideal closure tool.

`sage.combinat.tools.transitive_ideal(f, x)`

Return a list of all elements reachable from x in the abstract reduction system whose reduction relation is given by the function f .

In more elementary terms:

If S is a set, and f is a function sending every element of S to a list of elements of S , then we can define a digraph on the vertex set S by drawing an edge from s to t for every $s \in S$ and every $t \in f(s)$.

If $x \in S$, then an element $y \in S$ is said to be reachable from x if there is a path $x \rightarrow y$ in this graph.

Given f and x , this method computes the list of all elements of S reachable from x .

Note that if there are infinitely many such elements, then this method will never halt.

For more powerful versions, see `sage.combinat.backtrack`

EXAMPLES:

```
sage: f = lambda x: [x-1] if x > 0 else []
sage: sage.combinat.tools.transitive_ideal(f, 10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

5.1.328 Tuples

`sage.combinat.tuple.Tuples(S, k)`

Returns the combinatorial class of ordered tuples of S of length k .

An ordered tuple of length k of set S is an ordered selection with repetition and is represented by a list of length k containing elements of S .

EXAMPLES:

```
sage: S = [1,2]
sage: Tuples(S,3).list()
[[1, 1, 1], [2, 1, 1], [1, 2, 1], [2, 2, 1], [1, 1, 2], [2, 1, 2], [1, 2, 2], [2, ↵
↵2, 2]]
sage: mset = ["s","t","e","i","n"]

Bases: *sage.combinat.combinat.CombinatorialClass*

cardinality()

EXAMPLES:

```

sage: S = [1,2,3,4,5]
sage: Tuples(S,2).cardinality()
25
sage: S = [1,1,2,3,4,5]
sage: Tuples(S,2).cardinality()
25

```

sage.combinat.tuple.UnorderedTuples(S, k)

Returns the combinatorial class of unordered tuples of S of length k .

An unordered tuple of length k of set is a unordered selection with repetitions of set and is represented by a sorted list of length k containing elements from set.

EXAMPLES:

```

sage: S = [1,2]
sage: UnorderedTuples(S,3).list()
[[1, 1, 1], [1, 1, 2], [1, 2, 2], [2, 2, 2]]
sage: UnorderedTuples(["a","b","c"],2).list()
[['a', 'a'], ['a', 'b'], ['a', 'c'], ['b', 'b'], ['b', 'c'], ['c', 'c']]

```

5.1.329 Introduction to combinatorics in Sage

This thematic tutorial is a translation by Hugh Thomas of the combinatorics chapter written by Nicolas M. Thiéry in the book “Calcul Mathématique avec Sage” [CMS2012]. It covers mainly the treatment in Sage of the following combinatorial problems: enumeration (how many elements are there in a set S ?), listing (generate all the elements of

S , or iterate through them), and random selection (choosing an element at random from a set S according to a given distribution, for example the uniform distribution). These questions arise naturally in the calculation of probabilities (what is the probability in poker of obtaining a straight or a four-of-a-kind of aces?), in statistical physics, and also in computer algebra (the number of elements in a finite field), or in the analysis of algorithms. Combinatorics covers a much wider domain (partial orders, representation theory, ...) for which we only give a few pointers towards the possibilities offered by Sage.

Todo

Add link to some thematic tutorial on graphs

A characteristic of computational combinatorics is the profusion of types of objects and sets that one wants to manipulate. It would be impossible to describe them all or, a fortiori, to implement them all. After some *Initial examples*, this chapter illustrates the underlying method: supplying the basic building blocks to describe common combinatorial sets *Common enumerated sets*, tools for combining them to construct new examples *Constructions*, and generic algorithms for solving uniformly a large class of problems *Generic algorithms*.

This is a domain in which Sage has much more extensive capabilities than most computer algebra systems, and it is rapidly expanding; at the same time, it is still quite new, and has many unnecessary limitations and incoherences.

Initial examples

Poker and probability

We begin by solving a classic problem: enumerating certain combinations of cards in the game of poker, in order to deduce their probability.

A card in a poker deck is characterized by a suit (hearts, diamonds, spades, or clubs) and a value (2, 3, ..., 10, jack, queen, king, ace). The game is played with a full deck, which consists of the Cartesian product of the set of suits and the set of values:

$$\text{Cards} = \text{Suits} \times \text{Values} = \{(s, v) \mid s \in \text{Suits} \text{ et } v \in \text{Values}\}.$$

We construct these examples in Sage:

```
sage: Suits = Set(["Hearts", "Diamonds", "Spades", "Clubs"])
sage: Values = Set([2, 3, 4, 5, 6, 7, 8, 9, 10,
....:               "Jack", "Queen", "King", "Ace"])
sage: Cards = cartesian_product([Values, Suits])
```

There are 4 suits and 13 possible values, and therefore $4 \times 13 = 52$ cards in the poker deck:

```
sage: Suits.cardinality()
4
sage: Values.cardinality()
13
sage: Cards.cardinality()
52
```

Draw a card at random:

```
sage: Cards.random_element()
(6, 'Clubs') # random
```

Now we can define a set of cards:

```
sage: Set([Cards.random_element(), Cards.random_element()]) # random
{(2, 'Hearts'), (4, 'Spades')}
```

This problem should eventually disappear: it is planned to change the implementation of Cartesian products so that their elements are immutable by default.

Returning to our main topic, we will be considering a simplified version of poker, in which each player directly draws five cards, which form his *hand*. The cards are all distinct and the order in which they are drawn is irrelevant; a hand is therefore a subset of size 5 of the set of cards. To draw a hand at random, we first construct the set of all possible hands, and then we ask for a randomly chosen element:

```
sage: Hands = Subsets(Cards, 5)
sage: Hands.random_element() # random
{(4, 'Hearts', 4), (9, 'Diamonds'), (8, 'Spades'),
 (9, 'Clubs'), (7, 'Hearts')}
```

The total number of hands is given by the number of subsets of size 5 of a set of size 52, which is given by the binomial coefficient $\binom{52}{5}$:

```
sage: binomial(52, 5)
2598960
```

One can also ignore the method of calculation, and simply ask for the size of the set of hands:

```
sage: Hands.cardinality()
2598960
```

The strength of a poker hand depends on the particular combination of cards present. One such combination is the *flush*; this is a hand all of whose cards have the same suit. (In principle, straight flushes should be excluded; this will be the goal of an exercise given below.) Such a hand is therefore characterized by the choice of five values from among the thirteen possibilities, and the choice of one of four suits. We will construct the set of all flushes, so as to determine how many there are:

```
sage: Flushes = cartesian_product([Subsets(Values, 5), Suits])
sage: Flushes.cardinality()
5148
```

The probability of obtaining a flush when drawing a hand at random is therefore:

```
sage: Flushes.cardinality() / Hands.cardinality()
33/16660
```

or about two in a thousand:

```
sage: 1000.0 * Flushes.cardinality() / Hands.cardinality()
1.98079231692677
```

We will now attempt a little numerical simulation. The following function tests whether a given hand is a flush or not:

```
sage: def is_flush(hand):
....:     return len(set(suit for (val, suit) in hand)) == 1
```

We now draw 10000 hands at random, and count the number of flushes obtained (this takes about 10 seconds):

```
sage: n = 10000
sage: nflush = 0
sage: for i in range(n): # long time
```

```

....:     hand = Hands.random_element()
....:     if is_flush(hand):
....:         nflush += 1
sage: n, nflush                                     # random
(10000, 18)

```

Exercises

A hand containing four cards of the same value is called a *four of a kind*. Construct the set of four of a kind hands (Hint: use `Arrangements` to choose a pair of distinct values at random, then choose a suit for the first value). Calculate the number of four of a kind hand, list them, and then determine the probability of obtaining a four of a kind when drawing a hand at random.

A hand all of whose cards have the same suit, and whose values are consecutive, is called a *straight flush* rather than a *flush*. Count the number of straight flushes, and then deduce the correct probability of obtaining a flush when drawing a hand at random.

Calculate the probability of each of the poker hands (see [Wikipedia article Poker_hands](#)), and compare them with the results of simulations.

Enumeration of trees using generating functions

In this section, we discuss the example of complete binary trees, and illustrate in this context many techniques of enumeration in which formal power series play a natural role. These techniques are quite general, and can be applied whenever the combinatorial objects in question admit a recursive definition (grammar) (see [Species](#), [decomposable combinatorial classes](#) for an automated treatment). The goal is not a formal presentation of these methods; the calculations are rigorous, but most of the justifications will be skipped.

A *complete binary tree* is either a leaf L , or a node to which two complete binary trees are attached (see [Figure: The five complete binary trees with four leaves](#)).

Fig. 5.1: Figure: The five complete binary trees with four leaves

Exercise: enumeration of binary trees

Find by hand all the complete binary trees with $n = 1, 2, 3, 4, 5$ leaves (see [Exercise: complete binary tree iterator](#) to find them using Sage).

Our goal is to determine the number c_n of complete binary trees with n leaves (in this section, except when explicitly stated otherwise, “trees” always means complete binary trees). This is a typical situation in which one is not only interested in a single set, but in a family of sets, typically parameterized by $n \in \mathbb{N}$.

According to the solution of [Exercise: enumeration of binary trees](#), the first terms are given by $c_1, \dots, c_5 = 1, 1, 2, 5, 14$. The simple fact of knowing these few numbers is already very valuable. In fact, this permits research in

a gold mine of information: the [Online Encyclopedia of Integer Sequences](#), commonly called “Sloane”, the name of its principal author, which contains more than 190000 sequences of integers:

```
sage: oeis([1,1,2,5,14]) # optional -- internet
0: A000108: Catalan numbers: C(n) = binomial(2n,n)/(n+1) = (2n)!/(n!(n+1)!). Also
↳ called Segner numbers.
1: A120588: G.f. satisfies: 3*A(x) = 2 + x + A(x)^2, with a(0) = 1.
2: A080937: Number of Catalan paths (nonnegative, starting and ending at 0, step +/-
↳ 1) of 2*n steps with all values <= 5.
```

The result suggests that the trees are counted by one of the most famous sequences, the Catalan numbers. Looking through the references supplied by the Encyclopedia, we see that this is really the case: the few numbers above form a digital fingerprint of our objects, which enable us to find, in a few seconds, a precise result from within an abundant literature.

Our next goal is to recover this result using Sage. Let C_n be the set of trees with n leaves, so that $c_n = |C_n|$; by convention, we will define $C_0 = \emptyset$ and $c_0 = 0$. The set of all trees is then the disjoint union of the sets C_n :

$$C = \bigsqcup_{n \in \mathbb{N}} C_n.$$

Having named the set C of all trees, we can translate the recursive definition of trees into a set-theoretic equation:

$$C \approx \{L\} \uplus C \times C.$$

In words: a tree t (which is by definition in C) is either a leaf (so in $\{L\}$) or a node to which two trees t_1 and t_2 have been attached, and which we can therefore identify with the pair (t_1, t_2) (in the Cartesian product $C \times C$).

The founding idea of algebraic combinatorics, introduced by Euler in a letter to Goldbach of 1751 to treat a similar problem, is to manipulate all the numbers c_n simultaneously, by encoding them as coefficients in a formal power series, called the *generating function* of the c_n 's:

$$C(z) = \sum_{n \in \mathbb{N}} c_n z^n,$$

where z is a formal variable (which means that we do not have to worry about questions of convergence). The beauty of this idea is that set-theoretic operations ($A \uplus B$, $A \times B$) translate naturally into algebraic operations on the corresponding series ($A(z) + B(z)$, $A(z) \cdot B(z)$), in such a way that the set-theoretic equation satisfied by C can be translated directly into an algebraic equation satisfied by $C(z)$:

$$C(z) = z + C(z) \cdot C(z).$$

Now we can solve this equation with Sage. In order to do so, we introduce two variables, C and z , and we define the equation:

```
sage: C, z = var('C, z');
sage: sys = [ C == z + C*C ]
```

There are two solutions, which happen to have closed forms:

```
sage: sol = solve(sys, C, solution_dict=True); sol
[{C: -1/2*sqrt(-4*z + 1) + 1/2}, {C: 1/2*sqrt(-4*z + 1) + 1/2}]
sage: s0 = sol[0][C]; s1 = sol[1][C]
```

and whose Taylor series begin as follows:

```
sage: s0.series(z, 6)
1*z + 1*z^2 + 2*z^3 + 5*z^4 + 14*z^5 + Order(z^6)
sage: s1.series(z, 6)
1 + (-1)*z + (-1)*z^2 + (-2)*z^3 + (-5)*z^4 + (-14)*z^5
+ Order(z^6)
```

The second solution is clearly aberrant, while the first one gives the expected coefficients. Therefore, we set:

```
sage: C = s0
```

We can now calculate the next terms:

```
sage: C.series(z, 11)
1*z + 1*z^2 + 2*z^3 + 5*z^4 + 14*z^5 + 42*z^6 +
132*z^7 + 429*z^8 + 1430*z^9 + 4862*z^10 + Order(z^11)
```

or calculate, more or less instantaneously, the 100-th coefficient:

```
sage: C.series(z, 101).coefficient(z, 100)
227508830794229349661819540395688853956041682601541047340
```

It is unfortunate to have to recalculate everything if at some point we wanted the 101-st coefficient. Lazy power series (see [sage.combinat.species.series](#)) come into their own here, in that one can define them from a system of equations without solving it, and, in particular, without needing a closed form for the answer. We begin by defining the ring of lazy power series:

```
sage: L.<z> = LazyPowerSeriesRing(QQ)
```

Then we create a “free” power series, which we name, and which we then define by a recursive equation:

```
sage: C = L()
sage: C._name = 'C'
sage: C.define( z + C * C );
```

```
sage: [C.coefficient(i) for i in range(11)]
[0, 1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
```

At any point, one can ask for any coefficient without having to redefine C :

```
sage: C.coefficient(100)
227508830794229349661819540395688853956041682601541047340
sage: C.coefficient(200)
12901315806442911400122290766967667513434953055272888249981085159890141901334831904553458085084773552
```

We now return to the closed form of $C(z)$:

```
sage: z = var('z');
sage: C = s0; C
-1/2*sqrt(-4*z + 1) + 1/2
```

The n -th coefficient in the Taylor series for $C(z)$ being given by $\frac{1}{n!}C(z)^{(n)}(0)$, we look at the successive derivatives $C(z)^{(n)}(z)$:

```
sage: derivative(C, z, 1)
1/sqrt(-4*z + 1)
sage: derivative(C, z, 2)
2/(-4*z + 1)^(3/2)
```

```
sage: derivative(C, z, 3)
12/(-4*z + 1)^(5/2)
```

This suggests the existence of a simple explicit formula, which we will now seek. The following small function returns $d_n = n!c_n$:

```
sage: def d(n): return derivative(s0, n).subs(z=0)
```

Taking successive quotients:

```
sage: [ (d(n+1) / d(n)) for n in range(1,17) ]
[2, 6, 10, 14, 18, 22, 26, 30, 34, 38, 42, 46, 50, 54, 58, 62]
```

we observe that d_n satisfies the recurrence relation $d_{n+1} = (4n - 2)d_n$, from which we deduce that c_n satisfies the recurrence relation $c_{n+1} = \frac{(4n-2)}{n+1}c_n$. Simplifying, we find that c_n is the $(n - 1)$ -th Catalan number:

$$c_n = \text{Catalan}(n - 1) = \frac{1}{n} \binom{2(n-1)}{n-1}.$$

We check this:

```
sage: n = var('n');
sage: c = 1/n*binomial(2*(n-1),n-1)
sage: [c.subs(n=k) for k in range(1, 11)]
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
sage: [catalan_number(k-1) for k in range(1, 11)]
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
```

We can now calculate coefficients much further; here we calculate c_{100000} which has more than 60000 digits:

```
sage: cc = c(n = 100000)
```

This takes a couple of seconds:

```
sage: %time cc = c(100000) # not tested
CPU times: user 2.34 s, sys: 0.00 s, total: 2.34 s
Wall time: 2.34 s
sage: ZZ(cc).ndigits()
60198
```

The methods which we have used generalize to all recursively defined objects: the system of set-theoretic equations can be translated into a system of equations on the generating function, which enables the recursive calculation of its coefficients. If the set-theoretic equations are simple enough (for example, if they only involve Cartesian products and disjoint unions), the equation for $C(z)$ is algebraic. This equation has, in general, no closed-form solution. However, using *confinement*, one can deduce a *linear* differential equation which $C(z)$ satisfies. This differential equation, in turn, can be translated into a recurrence relation of fixed length on its coefficients c_n . In this case, the series is called *D-finite*. After the initial calculation of this recurrence relation, the calculation of coefficients is very fast. All these steps are purely algorithmic, and it is planned to port into Sage the implementations which exist in Maple (the `gfun` and `combstruct` packages) or MuPAD-Combinat (the `decomposableObjects` library).

For the moment, we illustrate this general procedure in the case of complete binary trees. The generating function $C(z)$ is a solution to an algebraic equation $P(z, C(z)) = 0$, where $P = P(x, y)$ is a polynomial with coefficients in $\mathbb{Q}$. In the present case, $P = y^2 - y + x$. We formally differentiate this equation with respect to z :

```
sage: x, y, z = var('x, y, z')
sage: P = function('P')(x, y)
sage: C = function('C')(z)
```

```
sage: equation = P(x=z, y=C) == 0
sage: diff(equation, z)
diff(C(z), z)*D[1](P)(z, C(z)) + D[0](P)(z, C(z)) == 0
```

or, in a more readable format,

$$\frac{dC(z)}{dz} \frac{\partial P}{\partial y}(z, C(z)) + \frac{\partial P}{\partial x}(z, C(z)) = 0$$

From this we deduce:

$$\frac{dC(z)}{dz} = -\frac{\frac{\partial P}{\partial x}(z, C(z))}{\frac{\partial P}{\partial y}(z, C(z))}.$$

In the case of complete binary trees, this gives:

```
sage: P = y^2 - y + x
sage: Px = diff(P, x); Py = diff(P, y)
sage: - Px / Py
-1/(2*y - 1)
```

Recall that $P(z, C(z)) = 0$. Thus, we can calculate this fraction mod P and, in this way, express the derivative of $C(z)$ as a polynomial in $C(z)$ with coefficients in $\mathbb{Q}(z)$. In order to achieve this, we construct the quotient ring $R = \mathbb{Q}(x)[y]/(P)$:

```
sage: Qx = QQ['x'].fraction_field()
sage: Qxy = Qx['y']
sage: R = Qxy.quo(P); R
Univariate Quotient Polynomial Ring in ybar
over Fraction Field of Univariate Polynomial Ring in x
over Rational Field with modulus y^2 - y + x
```

Note: `ybar` is the name of the variable y in the quotient ring.

Todo

add link to some tutorial on quotient rings

We continue the calculation of this fraction in R :

```
sage: fraction = - R(Px) / R(Py); fraction
(1/2/(x - 1/4))*ybar - 1/4/(x - 1/4)
```

Note: The following variant does not work yet:

```
sage: fraction = R( - Px / Py ); fraction # todo: not implemented
Traceback (most recent call last):
...
TypeError: denominator must be a unit
```

We lift the result to $\mathbb{Q}(x)[y]$ and then substitute z and $C(z)$ to obtain an expression for $\frac{d}{dz}C(z)$:

```
sage: fraction = fraction.lift(); fraction
(1/2/(x - 1/4))*y - 1/4/(x - 1/4)
sage: fraction(x=z, y=C)
2*C(z)/(4*z - 1) - 1/(4*z - 1)
```

or, more legibly,

$$\frac{\partial C(z)}{\partial z} = \frac{1}{1-4z} - \frac{2}{1-4z}C(z).$$

In this simple case, we can directly deduce from this expression a linear differential equation with coefficients in $\mathbf{Q}[z]$:

```
sage: equadiff = diff(C,z) == fraction(x=z, y=C)
sage: equadiff
diff(C(z), z) == 2*C(z)/(4*z - 1) - 1/(4*z - 1)
sage: equadiff = equadiff.simplify_rational()
sage: equadiff = equadiff * equadiff.rhs().denominator()
sage: equadiff = equadiff - equadiff.rhs()
sage: equadiff
(4*z - 1)*diff(C(z), z) - 2*C(z) + 1 == 0
```

or, more legibly,

$$(1-4z)\frac{\partial C(z)}{\partial z} + 2C(z) - 1 = 0.$$

It is trivial to verify this equation on the closed form:

```
sage: Cf = sage.symbolic.function_factory.function('C')
sage: equadiff.substitute_function(Cf, s0)
doctest:...: DeprecationWarning:...
(4*z - 1)/sqrt(-4*z + 1) + sqrt(-4*z + 1) == 0
sage: bool(equadiff.substitute_function(Cf, s0))
True
```

In the general case, one continues to calculate successive derivatives of $C(z)$. These derivatives are *confined* in the quotient ring $\mathbf{Q}(z)[C]/(P)$ which is of finite dimension $\deg P$ over $\mathbf{Q}(z)$. Therefore, one will eventually find a linear relation among the first $\deg P$ derivatives of $C(z)$. Putting it over a single denominator, we obtain a linear differential equation of degree $\leq \deg P$ with coefficients in $\mathbf{Q}[z]$. By extracting the coefficient of z^n in the differential equation, we obtain the desired recurrence relation on the coefficients; in this case we recover the relation we had already found, based on the closed form:

$$c_{n+1} = \frac{(4n-2)}{n+1}c_n$$

After fixing the correct initial conditions, it becomes possible to calculate the coefficients of $C(z)$ recursively:

```
sage: def C(n): return 1 if n <= 1 else (4*n-6)/n * C(n-1)
sage: [ C(i) for i in range(10) ]
[1, 1, 1, 2, 5, 14, 42, 132, 429, 1430]
```

If n is too large for the explicit calculation of c_n , a sequence asymptotically equivalent to the sequence of coefficients c_n may be sought. Here again, there are generic techniques. The central tool is complex analysis, specifically, the study of the generating function around its singularities. In the present instance, the singularity is at $z_0 = 1/4$ and one would obtain $c_n \sim \frac{4^n}{n^{3/2}\sqrt{\pi}}$.

Summary

We see here a general phenomenon of computer algebra: the best *data structure* to describe a complicated mathematical object (a real number, a sequence, a formal power series, a function, a set) is often an equation defining the object (or a system of equations, typically with some initial conditions). Attempting to find a closed-form solution to this equation is not necessarily of interest: on the one hand, such a closed form rarely exists (e.g., the problem of

solving a polynomial by radicals), and on the other hand, the equation, in itself, contains all the necessary information to calculate algorithmically the properties of the object under consideration (e.g., a numerical approximation, the initial terms or elements, an asymptotic equivalent), or to calculate with the object itself (e.g., performing arithmetic on power series). Therefore, instead of solving the equation, we look for the equation describing the object which is best suited to the problem we want to solve.

As we saw in our example, confinement (for example, in a finite dimensional vector space) is a fundamental tool for studying such equations. This notion of confinement is widely applicable in elimination techniques (linear algebra, Gröbner bases, and their algebro-differential generalizations). The same tool is central in algorithms for automatic summation and automatic verification of identities (Gosper's algorithm, Zeilberger's algorithm, and their generalizations; see also *Exercise: alternating sign matrices*).

Todo

add link to some tutorial on summation

All these techniques and their many generalizations are at the heart of very active topics of research: automatic combinatorics and analytic combinatorics, with major applications in the analysis of algorithms. It is likely, and desirable, that they will be progressively implemented in Sage.

Common enumerated sets

First example: the subsets of a set

Fix a set E of size n and consider the subsets of E of size k . We know that these subsets are counted by the binomial coefficients $\binom{n}{k}$. We can therefore calculate the number of subsets of size $k = 2$ of $E = \{1, 2, 3, 4\}$ with the function `binomial`:

```
sage: binomial(4, 2)
6
```

Alternatively, we can *construct* the set $\mathcal{P}_2(E)$ of all the subsets of size 2 of E , then ask its cardinality:

```
sage: S = Subsets([1, 2, 3, 4], 2)
sage: S.cardinality()
6
```

Once S has been constructed, we can also obtain the list of its elements:

```
sage: S.list()
[{1, 2}, {1, 3}, {1, 4}, {2, 3}, {2, 4}, {3, 4}]
```

or select an element at random:

```
sage: S.random_element()
{1, 4} # random
```

More precisely, the object S models the set $\mathcal{P}_2(E)$ equipped with a fixed order (here, lexicographic order). It is therefore possible to ask for its 5-th element, keeping in mind that, as with Python lists, the first element is numbered zero:

```
sage: S.unrank(4)
{2, 4}
```

As a shortcut, in this setting, one can also use the notation:

```
sage: S[4]
{2, 4}
```

but this should be used with care because some sets have a natural indexing other than by $(0, 1, \dots)$.

Conversely, one can calculate the position of an object in this order:

```
sage: s = S([2, 4]); s
{2, 4}
sage: S.rank(s)
4
```

Note that S is *not* the list of its elements. One can, for example, model the set $\mathcal{P}(\mathcal{P}(\mathcal{P}(E)))$ and calculate its cardinality (2^{2^4}) :

```
sage: E = Set([1, 2, 3, 4])
sage: S = Subsets(Subsets(Subsets(E))); S
Subsets of Subsets of Subsets of {1, 2, 3, 4}
sage: n = S.cardinality(); n
2003529930406846464979072351560255750447825475569751419265016973...
```

which is roughly $2 \cdot 10^{19728}$:

```
sage: n.ndigits()
19729
```

or ask for its 237102124-th element:

```
sage: S.unrank(237102123)
{{{2, 4}, {1, 4}, {}, {1, 3, 4}, {1, 2, 4}, {4}, {2, 3}, {1, 3}, {2}},
 {{1, 3}, {2, 4}, {1, 2, 4}, {}, {3, 4}}}
```

It would be physically impossible to construct explicitly all the elements of S , as there are many more of them than there are particles in the universe (estimated at 10^{82}).

Remark: it would be natural in Python to use `len(S)` to ask for the cardinality of S . This is not possible because Python requires that the result of `len` be an integer of type `int`; this could cause overflows, and would not permit the return of `{Infinity}` for infinite sets:

```
sage: len(S)
Traceback (most recent call last):
...
OverflowError: Python int too large to convert to C long
```

Partitions of integers

We now consider another classic problem: given a positive integer n , in how many ways can it be written in the form of a sum $n = i_1 + i_2 + \dots + i_\ell$, where $i_1, \dots, i_\ell$ are positive integers? There are two cases to distinguish:

- the order of the elements in the sum is not important, in which case we call $(i_1, \dots, i_\ell)$ a *partition* of n ;
- the order of the elements in the sum is important, in which case we call $(i_1, \dots, i_\ell)$ a *composition* of n .

We will begin with the partitions of $n = 5$; as before, we begin by constructing the set of these partitions:

```
sage: P5 = Partitions(5); P5
Partitions of the integer 5
```

then we ask for its cardinality:

```
sage: P5.cardinality()
7
```

We look at these 7 partitions; the order being irrelevant, the entries are ordered, by convention, in decreasing order.

```
sage: P5.list()
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1],
 [1, 1, 1, 1, 1]]
```

The calculation of the number of partitions uses the Rademacher formula ([Wikipedia article Partition_\(number_theory\)](#)), implemented in C and highly optimized, which makes it very fast:

```
sage: Partitions(100000).cardinality()
2749351056977569651267751632098635268817342931598005475820312598430214732811496417305505074166073662
```

Partitions of integers are combinatorial objects naturally equipped with many operations. They are therefore returned as objects that are richer than simple lists:

```
sage: P7 = Partitions(7)
sage: p = P7.unrank(5); p
[4, 2, 1]
sage: type(p)
<class 'sage.combinat.partition.Partitions_n_with_category.element_class'>
```

For example, they can be represented graphically by a Ferrers diagram:

```
sage: print(p.ferrers_diagram())
****
**
*
```

We leave it to the user to explore by introspection the available operations.

Note that we can also construct a partition directly by:

```
sage: Partition([4,2,1])
[4, 2, 1]
```

or:

```
sage: P7([4,2,1])
[4, 2, 1]
```

If one wants to restrict the possible values of the parts $i_1, \dots, i_\ell$ of the partition as, for example, when giving change, one can use `WeightedIntegerVectors`. For example, the following calculation:

```
sage: WeightedIntegerVectors(8, [2,3,5]).list()
[[0, 1, 1], [1, 2, 0], [4, 0, 0]]
```

shows that to make 8 dollars using 2, 3, and 5 dollar bills, one can use a 3 and a 5 dollar bill, or a 2 and two 3 dollar bills, or four 2 dollar bills.

Compositions of integers are manipulated the same way:

```
sage: C5 = Compositions(5); C5
Compositions of 5
sage: C5.cardinality()
```

```

16
sage: C5.list()
[[1, 1, 1, 1, 1], [1, 1, 1, 2], [1, 1, 2, 1], [1, 1, 3],
 [1, 2, 1, 1], [1, 2, 2], [1, 3, 1], [1, 4], [2, 1, 1, 1],
 [2, 1, 2], [2, 2, 1], [2, 3], [3, 1, 1], [3, 2], [4, 1], [5]]

```

The number 16 above seems significant and suggests the existence of a formula. We look at the number of compositions of n ranging from 0 to 9:

```

sage: [ Compositions(n).cardinality() for n in range(10) ]
[1, 1, 2, 4, 8, 16, 32, 64, 128, 256]

```

Similarly, if we consider the number of compositions of 5 by length, we find a line of Pascal's triangle:

```

sage: x = var('x')
sage: sum( x^len(c) for c in C5 )
x^5 + 4*x^4 + 6*x^3 + 4*x^2 + x

```

The above example uses a functionality which we have not seen yet: `C5` being iterable, it can be used like a list in a `for` loop or a comprehension (*Set comprehension and iterators*).

Prove the formulas suggested by the above examples for the number of compositions of n and the number of compositions of n of length k ; investigate by introspection whether Sage uses these formulas for calculating cardinalities.

Some other finite enumerated sets

Essentially, the principle is the same for all the finite sets with which one wants to do combinatorics in Sage; begin by constructing an object which models this set, and then supply appropriate methods, following a uniform interface¹. We now give a few more typical examples.

Intervals of integers:

```

sage: C = IntegerRange(3, 21, 2); C
{3, 5, ..., 19}
sage: C.cardinality()
9
sage: C.list()
[3, 5, 7, 9, 11, 13, 15, 17, 19]

```

Permutations:

```

sage: C = Permutations(4); C
Standard permutations of 4
sage: C.cardinality()
24
sage: C.list()
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 3, 2, 4], [1, 3, 4, 2],
 [1, 4, 2, 3], [1, 4, 3, 2], [2, 1, 3, 4], [2, 1, 4, 3],
 [2, 3, 1, 4], [2, 3, 4, 1], [2, 4, 1, 3], [2, 4, 3, 1],
 [3, 1, 2, 4], [3, 1, 4, 2], [3, 2, 1, 4], [3, 2, 4, 1],
 [3, 4, 1, 2], [3, 4, 2, 1], [4, 1, 2, 3], [4, 1, 3, 2],
 [4, 2, 1, 3], [4, 2, 3, 1], [4, 3, 1, 2], [4, 3, 2, 1]]

```

Set partitions:

¹ Or at least that should be the case; there are still many corners to clean up.

```

sage: C = SetPartitions([1,2,3])
sage: C
Set partitions of {1, 2, 3}
sage: C.cardinality()
5
sage: C.list()
[[{1, 2, 3}], [{1}, {2, 3}], [{1, 3}, {2}], [{1, 2}, {3}],
 [{1}, {2}, {3}]]

```

Partial orders on a set of 8 elements, up to isomorphism:

```

sage: C = Posets(8); C
Posets containing 8 elements
sage: C.cardinality()
16999

```

```

sage: C.unrank(20).plot()
Graphics object consisting of 20 graphics primitives

```

One can iterate through all graphs up to isomorphism. For example, there are 34 simple graphs with 5 vertices:

```
sage: len(list(graphs(5)))
34
```

Here are those with at most 4 edges:

```
sage: up_to_four_edges = list(graphs(5, lambda G: G.size() <= 4))
sage: pretty_print(*up_to_four_edges)
```

However, the *set* C of these graphs is not yet available in Sage; as a result, the following commands are not yet implemented:

```
sage: C = Graphs(5) # todo: not implemented
sage: C.cardinality() # todo: not implemented
```

```

34
sage: Graphs(19).cardinality()      # todo: not implemented
24637809253125004524383007491432768
sage: Graphs(19).random_element()  # todo: not implemented
Graph on 19 vertices

```

What we have seen so far also applies, in principle, to finite algebraic structures like the dihedral groups:

```

sage: G = DihedralGroup(4); G
Dihedral group of order 8 as a permutation group
sage: G.cardinality()
8
sage: G.list()
[(), (1,4)(2,3), (1,2,3,4), (1,3)(2,4), (1,3), (2,4), (1,4,3,2), (1,2)(3,4)]

```

or the algebra of 2×2 matrices over the finite field $\mathbf{Z}/2\mathbf{Z}$:

```

sage: C = MatrixSpace(GF(2), 2)
sage: C.list()
[
[0 0] [1 0] [0 1] [0 0] [0 0] [1 1] [1 0] [1 0] [0 1] [0 1]
[0 0], [0 0], [0 0], [1 0], [0 1], [0 0], [1 0], [0 1], [1 0], [0 1],

[0 0] [1 1] [1 1] [1 0] [0 1] [1 1]
[1 1], [1 0], [0 1], [1 1], [1 1], [1 1]
]
sage: C.cardinality()
16

```

Exercise

List all the monomials of degree 5 in three variables (see `IntegerVectors`). Manipulate the ordered set partitions `OrderedSetPartitions` and standard tableaux (`StandardTableaux`).

Exercise

List the alternating sign matrices of size 3, 4, and 5 (`AlternatingSignMatrices`), and try to guess the definition. The discovery and proof of the formula for the enumeration of these matrices (see the method `cardinality`), motivated by calculations of determinants in physics, is quite a story. In particular, the first proof, given by Zeilberger in 1992 was automatically produced by a computer program. It was 84 pages long, and required nearly a hundred people to verify it.

Exercise

Calculate by hand the number of vectors in $(\mathbf{Z}/2\mathbf{Z})^5$, and the number of matrices in $GL_3(\mathbf{Z}/2\mathbf{Z})$ (that is to say, the number of invertible 3×3 matrices with coefficients in $\mathbf{Z}/2\mathbf{Z}$). Verify your answer with Sage. Generalize to $GL_n(\mathbf{Z}/q\mathbf{Z})$.

Set comprehension and iterators

We will now show some of the possibilities offered by Python for constructing (and iterating through) sets, with a notation that is flexible and close to usual mathematical usage, and in particular the benefits this yields in combinatorics.

We begin by constructing the finite set $\{i^2 \mid i \in \{1, 3, 7\}\}$:

```
sage: [ i^2 for i in [1, 3, 7] ]
[1, 9, 49]
```

and then the same set, but with i running from 1 to 9:

```
sage: [ i^2 for i in range(1,10) ]
[1, 4, 9, 16, 25, 36, 49, 64, 81]
```

A construction of this form in Python is called *set comprehension*. A clause can be added to keep only those elements with i prime:

```
sage: [ i^2 for i in range(1,10) if is_prime(i) ]
[4, 9, 25, 49]
```

Combining more than one set comprehension, it is possible to construct the set $\{(i, j) \mid 1 \leq j < i < 5\}$:

```
sage: [ (i,j) for i in range(1,6) for j in range(1,i) ]
[(2, 1), (3, 1), (3, 2), (4, 1), (4, 2), (4, 3),
 (5, 1), (5, 2), (5, 3), (5, 4)]
```

or to produce Pascal's triangle:

```
sage: [[binomial(n,i) for i in range(n+1)] for n in range(10)]
[[1],
 [1, 1],
 [1, 2, 1],
 [1, 3, 3, 1],
 [1, 4, 6, 4, 1],
 [1, 5, 10, 10, 5, 1],
 [1, 6, 15, 20, 15, 6, 1],
 [1, 7, 21, 35, 35, 21, 7, 1],
 [1, 8, 28, 56, 70, 56, 28, 8, 1],
 [1, 9, 36, 84, 126, 126, 84, 36, 9, 1]]
```

The execution of a set comprehension is accomplished in two steps; first an *iterator* is constructed, and then a list is filled with the elements successively produced by the iterator. Technically, an *iterator* is an object with a method `next` which returns a new value each time it is called, until it is exhausted. For example, the following iterator `it`:

```
sage: it = (binomial(3, i) for i in range(4))
```

returns successively the binomial coefficients $\binom{3}{i}$ with $i = 0, 1, 2, 3$:

```
sage: next(it)
1
sage: next(it)
3
sage: next(it)
3
sage: next(it)
1
```

When the iterator is finally exhausted, an exception is raised:

```
sage: next(it)
Traceback (most recent call last):
...
StopIteration
```

More generally, an *iterable* is a Python object L (a list, a set, ...) over whose elements it is possible to iterate. Technically, the iterator is constructed by `iter(L)`. In practice, the commands `iter` and `next` are used very rarely, since `for` loops and list comprehensions provide a much pleasanter syntax:

```
sage: for s in Subsets(3):
....:     print(s)
{}
{1}
{2}
{3}
{1, 2}
{1, 3}
{2, 3}
{1, 2, 3}
```

```
sage: [ s.cardinality() for s in Subsets(3) ]
[0, 1, 1, 1, 2, 2, 2, 3]
```

What is the point of an iterator? Consider the following example:

```
sage: sum( [ binomial(8, i) for i in range(9) ] )
256
```

When it is executed, a list of 9 elements is constructed, and then it is passed as an argument to `sum` to add them up. If, on the other hand, the iterator is passed directly to `sum` (note the absence of square brackets):

```
sage: sum( binomial(8, i) for i in range(9) )
256
```

the function `sum` receives the iterator directly, and can short-circuit the construction of the intermediate list. If there are a large number of elements, this avoids allocating a large quantity of memory to fill a list which will be immediately destroyed².

Most functions that take a list of elements as input will also accept an iterator (or an iterable) instead. To begin with, one can obtain the list (or the tuple) of elements of an iterator as follows:

```
sage: list(binomial(8, i) for i in range(9))
[1, 8, 28, 56, 70, 56, 28, 8, 1]
sage: tuple(binomial(8, i) for i in range(9))
(1, 8, 28, 56, 70, 56, 28, 8, 1)
```

We now consider the functions `all` and `any` which denote respectively the n -ary *and* and *or*:

```
sage: all([True, True, True, True])
True
sage: all([True, False, True, True])
False
sage: any([False, False, False, False])
```

² Technical detail: `range` returns an iterator on $\{0, \dots, 8\}$ while `range` returns the corresponding list. Starting in Python 3.0, `range` will behave like `range`, and `range` will no longer be needed.

```
False
sage: any([False, False, True, False])
True
```

The following example verifies that all primes from 3 to 99 are odd:

```
sage: all( is_odd(p) for p in range(3,100) if is_prime(p) )
True
```

A *Mersenne prime* is a prime of the form $2^p - 1$. We verify that, for $p < 1000$, if $2^p - 1$ is prime, then p is also prime:

```
sage: def mersenne(p): return 2^p - 1
sage: [ is_prime(p)
.....:   for p in range(1000) if is_prime(mersenne(p)) ]
[True, True, True, True, True, True, True, True, True,
 True, True, True, True]
```

Is the converse true?

Exercise

Try the two following commands and explain the considerable difference in the length of the calculations:

```
sage: all( is_prime(mersenne(p))
.....:   for p in range(1000) if is_prime(p) )
False
sage: all( [ is_prime(mersenne(p))
.....:   for p in range(1000) if is_prime(p)] )
False
```

We now try to find the smallest counter-example. In order to do this, we use the Sage function `exists`:

```
sage: exists( (p for p in range(1000) if is_prime(p)),
.....:   lambda p: not is_prime(mersenne(p)) )
(True, 11)
```

Alternatively, we could construct an iterator on the counter-examples:

```
sage: counter_examples = \
.....:   (p for p in range(1000)
.....:     if is_prime(p) and not is_prime(mersenne(p)))
sage: next(counter_examples)
11
sage: next(counter_examples)
23
```

Exercise

What do the following commands do?

```
sage: cubes = [t**3 for t in range(-999,1000)]
sage: exists([(x,y) for x in cubes for y in cubes], # long time (3s, 2012)
.....:   lambda x,y: x_y[0] + x_y[1] == 218)
(True, (-125, 343))
sage: exists((x,y) for x in cubes for y in cubes), # long time (2s, 2012)
.....:   lambda x,y: x_y[0] + x_y[1] == 218)
(True, (-125, 343))
```

Which of the last two is more economical in terms of time? In terms of memory? By how much?

Exercise

Try each of the following commands, and explain its result. If possible, hide the result first and try to guess it before launching the command.

Todo

hide the results by default

Warning: it will be necessary to interrupt the execution of some of the commands

```
sage: x = var('x')
sage: sum( x^len(s) for s in Subsets(8) )
x^8 + 8*x^7 + 28*x^6 + 56*x^5 + 70*x^4 + 56*x^3 + 28*x^2 + 8*x + 1
```

```
sage: sum( x^p.length() for p in Permutations(3) )
x^3 + 2*x^2 + 2*x + 1
```

```
sage: factor(sum( x^p.length() for p in Permutations(3) ))
(x^2 + x + 1)*(x + 1)
```

```
sage: P = Permutations(5)
sage: all( p in P for p in P )
True
```

```
sage: for p in GL(2, 2): print(p); print("")
[1 0]
[0 1]

[0 1]
[1 0]

[0 1]
[1 1]

[1 1]
[0 1]

[1 1]
[1 0]

[1 0]
[1 1]
```

```
sage: for p in Partitions(3): print(p)      # not tested
[3]
[2, 1]
[1, 1, 1]
...
```

```
sage: for p in Partitions(): print(p)      # not tested
[]
[1]
[2]
[1, 1]
[3]
...
```

```
sage: for p in Primes(): print(p)         # not tested
2
3
5
7
...
```

```
sage: exists( Primes(), lambda p: not is_prime(mersenne(p)) )
(True, 11)
```

```
sage: counter_examples = (p for p in Primes()
.....:                    if not is_prime(mersenne(p)))
sage: for p in counter_examples: print(p)  # not tested
11
23
29
37
41
43
47
...
```

Operations on iterators

Python provides numerous tools for manipulating iterators; most of them are in the `itertools` library, which can be imported by:

```
sage: import itertools
```

The behaviour of this library has changed a lot between Python 2 and Python 3. What follows is mostly written for Python 2.

We will demonstrate some applications, taking as a starting point the permutations of 3:

```
sage: list(Permutations(3))
[[1, 2, 3], [1, 3, 2], [2, 1, 3],
 [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

We can list the elements of a set by numbering them:

```
sage: list(enumerate(Permutations(3)))
[(0, [1, 2, 3]), (1, [1, 3, 2]), (2, [2, 1, 3]),
 (3, [2, 3, 1]), (4, [3, 1, 2]), (5, [3, 2, 1])]
```

or select only the elements in positions 2, 3, and 4 (analogue of `l[1:4]`):

```
sage: import itertools
sage: list(itertools.islice(Permutations(3), 1, 4))
[[1, 3, 2], [2, 1, 3], [2, 3, 1]]
```

The `itertools` methods `imap` and `ifilter` have been renamed to `map` and `filter` in Python 3. You can get them also in Python 2 using:

```
sage: from builtins import map, filter
```

To apply a function to all the elements, one can do:

```
sage: from builtins import map
sage: list(map(lambda z: z.cycle_type(), Permutations(3)))
[[1, 1, 1], [2, 1], [2, 1], [3], [3], [2, 1]]
```

and similarly to select the elements satisfying a certain condition:

```
sage: from builtins import filter
sage: list(filter(lambda z: z.has_pattern([1,2]), Permutations(3)))
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2]]
```

In all these situations, `attrcall` can be an advantageous alternative to creating an anonymous function:

```
sage: from builtins import map
sage: list(map(lambda z: z.cycle_type(), Permutations(3)))
[[1, 1, 1], [2, 1], [2, 1], [3], [3], [2, 1]]
sage: list(map(attrcall("cycle_type"), Permutations(3)))
[[1, 1, 1], [2, 1], [2, 1], [3], [3], [2, 1]]
```

Implementation of new iterators

It is easy to construct new iterators, using the keyword `yield` instead of `return` in a function:

```
sage: def f(n):
....:     for i in range(n):
....:         yield i
```

After the `yield`, execution is not halted, but only suspended, ready to be continued from the same point. The result of the function is therefore an iterator over the successive values returned by `yield`:

```
sage: g = f(4)
sage: next(g)
0
sage: next(g)
1
sage: next(g)
2
sage: next(g)
3
```

```
sage: next(g)
Traceback (most recent call last):
...
StopIteration
```

The function could be used as follows:

```
sage: [ x for x in f(5) ]
[0, 1, 2, 3, 4]
```

This model of computation, called *continuation*, is very useful in combinatorics, especially when combined with recursion. Here is how to generate all words of a given length on a given alphabet:

```
sage: def words(alphabet,l):
....:     if l == 0:
....:         yield []
....:     else:
....:         for word in words(alphabet, l-1):
....:             for l in alphabet:
....:                 yield word + [l]
sage: [ w for w in words(['a','b'], 3) ]
[['a', 'a', 'a'], ['a', 'a', 'b'], ['a', 'b', 'a'],
 ['a', 'b', 'b'], ['b', 'a', 'a'], ['b', 'a', 'b'],
 ['b', 'b', 'a'], ['b', 'b', 'b']]
```

These words can then be counted by:

```
sage: sum(1 for w in words(['a','b','c','d'], 10))
1048576
```

Counting the words one by one is clearly not an efficient method in this case, since the formula n^ℓ is also available; note, though, that this is not the stupidest possible approach - it does, at least, avoid constructing the entire list in memory.

We now consider Dyck words, which are well-parenthesized words in the letters “(” and “)”. The function below generates all the Dyck words of a given length (where the length is the number of pairs of parentheses), using the recursive definition which says that a Dyck word is either empty or of the form $(w_1)w_2$ where w_1 and w_2 are Dyck words:

```
sage: def dyck_words(l):
....:     if l==0:
....:         yield ''
....:     else:
....:         for k in range(l):
....:             for w1 in dyck_words(k):
....:                 for w2 in dyck_words(l-k-1):
....:                     yield '('+w1+')'+w2
```

Here are all the Dyck words of length 4:

```
sage: list(dyck_words(4))
['()()()', '()()()', '()()()', '()()()', '()()()',
 '()()()', '()()()', '()()()', '()()()', '()()()',
 '()()()', '()()()', '()()()', '()()()', '()()()']
```

Counting them, we recover a well-known sequence:

```
sage: [ sum(1 for w in dyck_words(l)) for l in range(10) ]
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
```

Exercise: complete binary tree iterator

Construct an iterator on the set C_n of complete binary trees with n leaves (see *Enumeration of trees using generating functions*).

Hint: Sage 4.8.2 does not yet have a native data structure to represent complete binary trees. One simple way to represent them is to define a formal variable `Leaf` for the leaves and a formal 2-ary function `Node`:

```
sage: var('Leaf')
Leaf
sage: function('Node', nargs=2)
Node
```

The second tree in *Figure: The five complete binary trees with four leaves* can be represented by the expression:

```
sage: tr = Node(Node(Leaf, Node(Leaf, Leaf)), Leaf)
```

Constructions

We will now see how to construct new sets starting from these building blocks. In fact, we have already begun to do this with the construction of $\mathcal{P}(\mathcal{P}(\{1, 2, 3, 4\}))$ in the previous section, and to construct the example of sets of cards in *Initial examples*.

Consider a large Cartesian product:

```
sage: C = cartesian_product([Compositions(8), Permutations(20)]); C
The Cartesian product of (Compositions of 8, Standard permutations of 20)
sage: C.cardinality()
311411457046609920000
```

Clearly, it is impractical to construct the list of all the elements of this Cartesian product! And, in the following example, H is equipped with the usual combinatorial operations and also its structure as a product group:

```
sage: G = DihedralGroup(4)
sage: H = cartesian_product([G, G])
sage: H in Groups()
True
sage: t = H.an_element()
sage: t
((1, 2, 3, 4), (1, 2, 3, 4))
sage: t*t
((1, 3) (2, 4), (1, 3) (2, 4))
```

We now construct the union of two existing disjoint sets:

```
sage: C = DisjointUnionEnumeratedSets(
....:     [ Compositions(4), Permutations(3)] )
sage: C
Disjoint union of Family (Compositions of 4,
Standard permutations of 3)
sage: C.cardinality()
14
sage: C.list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2],
[3, 1], [4], [1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1],
[3, 1, 2], [3, 2, 1]]
```

It is also possible to take the union of more than two disjoint sets, or even an infinite number of them. We will now construct the set of all permutations, viewed as the union of the sets P_n of permutations of size n . We begin by constructing the infinite family $F = (P_n)_{n \in \mathbb{N}}$:

```
sage: F = Family(NonNegativeIntegers(), Permutations); F
Lazy family (<class 'sage.combinat.permutation.Permutations'>(i))_{i in Non negative_
↳integers}
sage: F.keys()
Non negative integers
sage: F[1000]
Standard permutations of 1000
```

Now we can construct the disjoint union $\bigcup_{n \in \mathbb{N}} P_n$:

```
sage: U = DisjointUnionEnumeratedSets(F); U
Disjoint union of
Lazy family (<class 'sage.combinat.permutation.Permutations'>(i))_{i in Non negative_
↳integers}
```

It is an infinite set:

```
sage: U.cardinality()
+Infinity
```

which doesn't prohibit iteration through its elements, though it will be necessary to interrupt it at some point:

```
sage: for p in U:                                # not tested
....:     print(p)
[]
[1]
[1, 2]
[2, 1]
[1, 2, 3]
[1, 3, 2]
[2, 1, 3]
[2, 3, 1]
[3, 1, 2]
...
```

Note: the above set could also have been constructed directly with:

```
sage: U = Permutations(); U
Standard permutations
```

Summary

Sage provides a library of common enumerated sets, which can be combined by standard constructions, giving a toolbox that is flexible (but which could still be expanded). It is also possible to add new building blocks to Sage with a few lines (see the code in `FiniteEnumeratedSets().example()`). This is made possible by the uniformity of the interfaces and the fact that Sage is based on an object-oriented language. Also, very large or even infinite sets can be manipulated thanks to lazy evaluation strategies (iterators, etc.).

There is no magic to any of this: under the hood, Sage applies the usual rules (for example, that the cardinality of $E \times E$ is $|E|^2$); the added value comes from the capacity to manipulate complicated constructions. The situation is comparable to Sage's implementation of differential calculus: Sage applies the usual rules for differentiation of functions and their compositions, where the added value comes from the possibility of manipulating complicated formulas. In this sense, Sage implements a *calculus* of finite enumerated sets.

Generic algorithms

Lexicographic generation of lists of integers

Among the classic enumerated sets, especially in algebraic combinatorics, a certain number are composed of lists of integers of fixed sum, such as partitions, compositions, or integer vectors. These examples can also have supplementary constraints added to them. Here are some examples. We start with the integer vectors with sum 10 and length 3, with parts bounded below by 2, 4 and 2 respectively:

```
sage: IntegerVectors(10, 3, min_part=2, max_part=5,
....:               inner=[2, 4, 2]).list()
[[4, 4, 2], [3, 5, 2], [3, 4, 3], [2, 5, 3], [2, 4, 4]]
```

The compositions of 5 with each part at most 3, and with length 2 or 3:

```
sage: Compositions(5, max_part=3,
....:               min_length=2, max_length=3).list()
[[3, 2], [3, 1, 1], [2, 3], [2, 2, 1], [2, 1, 2], [1, 3, 1],
 [1, 2, 2], [1, 1, 3]]
```

The strictly decreasing partitions of 5:

```
sage: Partitions(5, max_slope=-1).list()
[[5], [4, 1], [3, 2]]
```

These sets share the same underlying algorithmic structure, implemented in the more general (and slightly more cumbersome) class `IntegerListsLex`. This class models sets of vectors $(\ell_0, \dots, \ell_k)$ of non-negative integers, with constraints on the sum and the length, and bounds on the parts and on the consecutive differences between the parts. Here are some more examples:

```
sage: IntegerListsLex(10, length=3,
....:               min_part=2, max_part=5,
....:               floor=[2, 4, 2]).list()
[[4, 4, 2], [3, 5, 2], [3, 4, 3], [2, 5, 3], [2, 4, 4]]

sage: IntegerListsLex(5, min_part=1, max_part=3,
....:               min_length=2, max_length=3).list()
[[3, 2], [3, 1, 1], [2, 3], [2, 2, 1], [2, 1, 2],
 [1, 3, 1], [1, 2, 2], [1, 1, 3]]

sage: IntegerListsLex(5, min_part=1, max_slope=-1).list()
[[5], [4, 1], [3, 2]]

sage: list(Compositions(5, max_length=2))
[[5], [4, 1], [3, 2], [2, 3], [1, 4]]

sage: list(IntegerListsLex(5, max_length=2, min_part=1))
[[5], [4, 1], [3, 2], [2, 3], [1, 4]]
```

The point of the model of `IntegerListsLex` is in the compromise between generality and efficiency. The main algorithm permits iteration through the elements of such a set S in reverse lexicographic order with a good complexity in most practical use cases. Roughly speaking, the time needed to iterate through all the elements of S is proportional to the number of elements, where the proportion factor is controlled by the length l of the longest element of S . In addition, the memory usage is also controlled by l , which is to say negligible in practice.

This algorithm is based on a very general principle for traversing a decision tree, called *branch and bound*: at the top level, we run through all the possible choices for ℓ_0 ; for each of these choices, we run through all the possible choices

for ℓ_1 , and so on. Mathematically speaking, we have put the structure of a prefix tree on the elements of S : a node of the tree at depth k corresponds to a prefix $\ell_0, \dots, \ell_k$ of one (or more) elements of S (see [Figure: The prefix tree of the partitions of 5](#)).

Fig. 5.2: Figure: The prefix tree of the partitions of 5.

The usual problem with this type of approach is to avoid bad decisions which lead to leaving the prefix tree and exploring dead branches; this is particularly problematic because the growth of the number of elements is usually exponential in the depth. It turns out that the constraints listed above are simple enough to be able to reasonably predict when a sequence $\ell_0, \dots, \ell_k$ is a prefix of some element S . Hence, most dead branches can be pruned.

Integer points in polytopes

Although the algorithm for iteration in `IntegerListsLex` is efficient, its counting algorithm is naive: it just iterates over all the elements.

There is an alternative approach to treating this problem: modelling the desired lists of integers as the set of integer points of a polytope, that is to say, the set of solutions with integer coordinates of a system of linear inequalities. This is a very general context in which there exist advanced counting algorithms (e.g. Barvinok), which are implemented in libraries like `LattE`. Iteration does not pose a hard problem in principle. However, there are two limitations that justify the existence of `IntegerListsLex`. The first is theoretical: lattice points in a polytope only allow modelling of problems of a fixed dimension (length). The second is practical: at the moment only the library `PALP`

has a Sage interface, and though it offers multiple capabilities for the study of polytopes, in the present application it only produces a list of lattice points, without providing either an iterator or non-naive counting:

```
sage: A = random_matrix(ZZ, 6, 3, x=7)
sage: L = LatticePolytope(A.rows())
sage: L.points()                                     # random
M(4, 1, 0),
M(0, 3, 5),
M(2, 2, 3),
M(6, 1, 3),
M(1, 3, 6),
M(6, 2, 3),
M(3, 2, 4),
M(3, 2, 3),
M(4, 2, 4),
M(4, 2, 3),
M(5, 2, 3)
in 3-d lattice M
sage: L.npoints()                                   # random
11
```

This polytope can be visualized in 3D with `L.plot3d()` (see *Figure: The polytope and its integer points, in cross-eyed stereographic perspective.*).

Fig. 5.3: Figure: The polytope L and its integer points, in cross-eyed stereographic perspective.

Species, decomposable combinatorial classes

In *Enumeration of trees using generating functions*, we showed how to use the recursive definition of binary trees to count them efficiently using generating functions. The techniques we used there are very general, and apply whenever the sets involved can be defined recursively (depending on who you ask, such a set is called a *decomposable combinatorial class* or, roughly speaking, a *combinatorial species*). This includes all the types of trees, but also permutations, compositions, functional graphs, etc.

Here, we illustrate just a few examples using the Sage library on combinatorial species:

```
sage: from sage.combinat.species.library import *
sage: o = var('o')
```

We begin by redefining the complete binary trees; to do so, we stipulate the recurrence relation directly on the sets:

```
sage: BT = CombinatorialSpecies()
sage: Leaf = SingletonSpecies()
sage: BT.define( Leaf + (BT*BT) )
```

Now we can construct the set of trees with five nodes, list them, count them...:

```
sage: BT5 = BT.isotypes([o]*5)
sage: BT5.cardinality()
14
sage: BT5.list()
[o*(o*(o*(o*(o))))], o*(o*((o*(o))*o)), o*((o*(o))*(o*(o))),
o*((o*(o*(o))*o), o*((o*(o))*o)*o), (o*(o))*(o*(o*(o))),
(o*(o))*((o*(o))*o), (o*(o*(o)))*(o*(o)), ((o*(o))*o)*(o*(o)),
(o*(o*(o*(o))))*o, o*((o*(o))*o)*o, ((o*(o))*(o*(o)))*o,
((o*(o*(o))*o)*o, ((o*(o))*o)*o)*o]
```

The trees are constructed using a generic recursive structure; the display is therefore not wonderful. To do better, it would be necessary to provide Sage with a more specialized data structure with the desired display capabilities.

We recover the generating function for the Catalan numbers:

```
sage: g = BT.isotype_generating_series(); g
x + x^2 + 2*x^3 + 5*x^4 + 14*x^5 + O(x^6)
```

which is returned in the form of a lazy power series:

```
sage: g[100]
227508830794229349661819540395688853956041682601541047340
```

We finish with the Fibonacci words, which are binary words without two consecutive “1”s. They admit a natural recursive definition:

```
sage: Eps = EmptySetSpecies()
sage: Z0 = SingletonSpecies()
sage: Z1 = Eps*SingletonSpecies()
sage: FW = CombinatorialSpecies()
sage: FW.define(Eps + Z0*FW + Z1*Eps + Z1*Z0*FW)
```

The Fibonacci sequence is easily recognized here, hence the name:

```
sage: L = FW.isotype_generating_series().coefficients(15); L
[1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987]
```

```
sage: oeis(L)                                     # optional -- internet
0: A000045: Fibonacci numbers: F(n) = F(n-1) + F(n-2) with F(0) = 0 and F(1) = 1.
1: A212804: Expansion of (1-x)/(1-x-x^2).
2: A132636: Fib(n) mod n^3.
```

This is an immediate consequence of the recurrence relation. One can also generate immediately all the Fibonacci words of a given length, with the same limitations resulting from the generic display.

```
sage: FW3 = FW.isotypes([0]*3)
sage: FW3.list()
[0*(0*(0*{})), 0*(0*({}*{})), 0*(({}*{})*{}),
 ({}*{})*0, ({}*{})*0, ({}*{})*0]
```

Graphs up to isomorphism

We saw in *Some other finite enumerated sets* that Sage could generate graphs and partial orders up to isomorphism. We will now describe the underlying algorithm, which is the same in both cases, and covers a substantially wider class of problems.

We begin by recalling some notions. A graph $G = (V, E)$ is a set V of vertices and a set E of edges connecting these vertices; an edge is described by a pair $\{u, v\}$ of distinct vertices of V . Such a graph is called labelled; its vertices are typically numbered by considering $V = \{1, 2, 3, 4, 5\}$.

In many problems, the labels on the vertices play no role. Typically a chemist wants to study all the possible molecules with a given composition, for example the alkanes with $n = 8$ atoms of carbon and $2n + 2 = 18$ atoms of hydrogen. He therefore wants to find all the graphs consisting of 8 vertices with 4 neighbours, and 18 vertices with a single neighbour. The different carbon atoms, however, are all considered to be identical, and the same for the hydrogen atoms. The problem of our chemist is not imaginary; this type of application is actually at the origin of an important part of the research in graph theory on isomorphism problems.

Working by hand on a small graph it is possible, as in the example of *Some other finite enumerated sets*, to make a drawing, erase the labels, and “forget” the geometrical information about the location of the vertices in the plane. However, to represent a graph in a computer program, it is necessary to introduce labels on the vertices so as to be able to describe how the edges connect them together. To compensate for the extra information which we have introduced, we then say that two labelled graphs g_1 and g_2 are *isomorphic* if there is a bijection from the vertices of g_1 to those of g_2 , which maps bijectively the edges of g_1 to those of g_2 ; an *unlabelled graph* is then an equivalence class of labelled graphs.

In general, testing if two labelled graphs are isomorphic is expensive. However, the number of graphs, even unlabelled, grows very rapidly. Nonetheless, it is possible to list unlabelled graphs very efficiently considering their number. For example, the program Nauty can list the 12005168 simple graphs with 10 vertices in 20 seconds.

As in *Lexicographic generation of lists of integers*, the general principle of the algorithm is to organize the objects to be enumerated into a tree that one traverses.

For this, in each equivalence class of labelled graphs (that is to say, for each unlabelled graph) one fixes a convenient canonical representative. The following are the fundamental operations:

- Testing whether a labelled graph is canonical
- Calculating the canonical representative of a labelled graph

These unavoidable operations remain expensive; one therefore tries to minimize the number of calls to them.

The canonical representatives are chosen in such a way that, for each canonical labelled graph G , there is a canonical choice of an edge whose removal produces a canonical graph again, which is called the father of G . This property implies that it is possible to organize the set of canonical representatives as a tree: at the root, the graph with no edges; below it, its unique child, the graph with one edge; then the graphs with two edges, and so on. The set of children of a graph G can be constructed by *augmentation*, adding an edge in all the possible ways to G , and then selecting, from among those graphs, the ones that are still canonical³. Recursively, one obtains all the canonical graphs.

In what sense is this algorithm generic? Consider for example planar graphs (graphs which can be drawn in the plane without edges crossing): by removing an edge from a planar graph, one obtains another planar graph; so planar graphs

³ In practice, an efficient implementation would exploit the symmetries of G , i.e., its automorphism group, to reduce the number of children to explore, and to reduce the cost of each test of canonicity.

Fig. 5.4: Figure: The generation tree of simple graphs with 4 vertices.

form a subtree of the previous tree. To generate them, exactly the same algorithm can be used, selecting only the children which are planar:

```
sage: [len(list(graphs(n, property = lambda G: G.is_planar()))
....: for n in range(7)]
[1, 1, 2, 4, 11, 33, 142]
```

In a similar fashion, one can generate any family of graphs closed under deletion of an edge, and in particular any family characterized by a forbidden subgraph. This includes for example forests (graphs without cycles), bipartite graphs (graphs without odd cycles), etc. This can be applied to generate:

- partial orders, via the bijection with Hasse diagrams which are oriented graphs without cycles and without edges implied by the transitivity of the order relation;
- lattices (not implemented in Sage), via the bijection with the meet semi-lattice obtained by deleting the maximal vertex; in this case an augmentation by vertices rather than by edges is used.

REFERENCES:

5.1.330 Vector Partitions

AUTHORS:

- Amritanshu Prasad (2013): Initial version

sage.combinat.vector_partition.**IntegerVectorsIterator** (*vect*, *min=None*)

Return an iterator over the list of integer vectors which are componentwise less than or equal to *vect*, and lexicographically greater than or equal to *min*.

INPUT:

- *vect* – A list of non-negative integers
- *min* – A list of non-negative integers dominated elementwise by *vect*

OUTPUT:

A list in lexicographic order of all integer vectors (as lists) which are dominated elementwise by *vect* and are greater than or equal to *min* in lexicographic order.

EXAMPLES:

```
sage: from sage.combinat.vector_partition import IntegerVectorsIterator
sage: list(IntegerVectorsIterator([1, 1]))
[[0, 0], [0, 1], [1, 0], [1, 1]]

sage: list(IntegerVectorsIterator([1, 1], min = [1, 0]))
[[1, 0], [1, 1]]
```

class sage.combinat.vector_partition.**VectorPartition** (*parent*, *vecpar*)

Bases: *sage.combinat.combinat.CombinatorialElement*

A vector partition is a multiset of integer vectors.

partition_at_vertex (*i*)

Return the partition obtained by sorting the *i*-th elements of the vectors in the vector partition.

EXAMPLES:

```
sage: V = VectorPartition([[1, 2, 1], [2, 4, 1]])
sage: V.partition_at_vertex(1)
[4, 2]
```

sum()

Return the sum vector as a list.

EXAMPLES:

```
sage: V = VectorPartition([[3, 2, 1], [2, 2, 1]])
sage: V.sum()
[5, 4, 2]
```

class sage.combinat.vector_partition.**VectorPartitions**(*vec*, *min*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Class of all vector partitions of *vec* with all parts greater than or equal to *min* in lexicographic order.

A vector partition of *vec* is a list of vectors with non-negative integer entries whose sum is *vec*.

INPUT:

- vec* – a list of non-negative integers.

EXAMPLES:

If *min* is not specified, then the class of all vector partitions of *vec* is created:

```
sage: VP = VectorPartitions([2, 2])
sage: for vecpar in VP:
....:     print(vecpar)
[[0, 1], [0, 1], [1, 0], [1, 0]]
[[0, 1], [0, 1], [2, 0]]
[[0, 1], [1, 0], [1, 1]]
[[0, 1], [2, 1]]
[[0, 2], [1, 0], [1, 0]]
[[0, 2], [2, 0]]
[[1, 0], [1, 2]]
[[1, 1], [1, 1]]
[[2, 2]]
```

If *min* is specified, then the class consists of only those vector partitions whose parts are all greater than or equal to *min* in lexicographic order:

```
sage: VP = VectorPartitions([2, 2], min = [1, 0])
sage: for vecpar in VP:
....:     print(vecpar)
[[1, 0], [1, 2]]
[[1, 1], [1, 1]]
[[2, 2]]
```

Element

alias of *VectorPartition*

sage.combinat.vector_partition.**find_min**(*vect*)

Return a string of 0's with one 1 at the location where the list *vect* has its last entry which is not equal to 0.

INPUT:

- vec* – A list of integers

OUTPUT:

A list of the same length with 0's everywhere, except for a 1 at the last position where `vec` has an entry not equal to 0.

EXAMPLES:

```
sage: from sage.combinat.vector_partition import find_min
sage: find_min([2, 1])
[0, 1]
sage: find_min([2, 1, 0])
[0, 1, 0]
```

5.1.331 Combinatorics on Words

Main modules and their methods:

- *Abstract word (finite or infinite)*
- *Finite word*
- *Infinite word*
- *Alphabet*
- *Set of words*
- *Word paths*
- *Word morphisms/substitutions*
- *Shuffle product of words*
- *Suffix Tries and Suffix Trees*

Main classes and functions meant to be used by the user:

```
Word(), FiniteWords, InfiniteWords, Words(), Alphabet(), WordMorphism,
WordPaths.
```

A list of common words can be accessed through `words.<tab>` and are listed in the *words catalog*.

Internal representation of words:

- *Word classes*
- *Fast word datatype using an array of unsigned char*
- *Datatypes for finite words*
- *Datatypes for words defined by iterators and callables*

Options:

- *User-customizable options for words*

See `WordOptions()`.

5.1.332 Abstract word (finite or infinite)

This module gathers functions that works for both finite and infinite words.

AUTHORS:

- Sebastien Labbe
- Franco Saliola

EXAMPLES:

```
sage: a = 0.618
sage: g = words.CodingOfRotationWord(alpha=a, beta=1-a, x=a)
sage: f = words.FibonacciWord()
sage: p = f.longest_common_prefix(g, length='finite')
sage: p
word: 010010100100101001010010010010010010010...
sage: p.length()
231
```

class sage.combinat.words.abstract_word.**Word_class**

Bases: sage.structure.sage_object.SageObject

apply_morphism (*morphism*)

Returns the word obtained by applying the morphism to self.

INPUT:

- *morphism* - Can be an instance of WordMorphism, or anything that can be used to construct one.

EXAMPLES:

```
sage: w = Word("ab")
sage: d = {'a': 'ab', 'b': 'ba'}
sage: w.apply_morphism(d)
word: abba
sage: w.apply_morphism(WordMorphism(d))
word: abba
```

```
sage: w = Word('ababa')
sage: d = dict(a='ab', b='ba')
sage: d
{'a': 'ab', 'b': 'ba'}
sage: w.apply_morphism(d)
word: abbaabbaab
```

For infinite words:

```
sage: t = words.ThueMorseWord([0,1]); t
word: 0110100110010110100101100110100110010110...
sage: t.apply_morphism({0:8,1:9})
word: 8998988998898998988988988998988998898899898...
```

complete_return_words_iterator (*fact*)

Returns an iterator over all the complete return words of *fact* in self (without unicity).

A complete return words *u* of a factor *v* is a factor starting by the given factor *v* and ending just after the next occurrence of this factor *v*. See for instance [1].

INPUT:

- fact - a non empty finite word

OUTPUT:

iterator

EXAMPLES:

```
sage: TM = words.ThueMorseWord()
sage: fact = Word([0,1,1,0,1])
sage: it = TM.complete_return_words_iterator(fact)
sage: next(it)
word: 01101001100101101
sage: next(it)
word: 01101001011001101
sage: next(it)
word: 011010011001011001101
sage: next(it)
word: 0110100101101
sage: next(it)
word: 01101001100101101
sage: next(it)
word: 01101001011001101
```

REFERENCES:

- [1] J. Justin, L. Vuillon, Return words in Sturmian and episturmian words, Theor. Inform. Appl. 34 (2000) 343–356.

delta()

Returns the image of self under the delta morphism. This is the word composed of the length of consecutive runs of the same letter in a given word.

OUTPUT:

Word over integers

EXAMPLES:

For finite words:

```
sage: W = Words('0123456789')
sage: W('22112122').delta()
word: 22112
sage: W('555008').delta()
word: 321
sage: W().delta()
word:
sage: Word('aabbabaa').delta()
word: 22112
```

For infinite words:

```
sage: t = words.ThueMorseWord()
sage: t.delta()
word: 1211222112112112221122211222112112112221...
```

factor_occurrences_iterator (fact)

Returns an iterator over all occurrences (including overlapping ones) of fact in self in their order of appearance.

INPUT:

- fact - a non empty finite word

OUTPUT:

iterator

EXAMPLES:

```
sage: TM = words.ThueMorseWord()
sage: fact = Word([0,1,1,0,1])
sage: it = TM.factor_occurrences_iterator(fact)
sage: next(it)
0
sage: next(it)
12
sage: next(it)
24
```

finite_differences (*mod=None*)

Returns the word obtained by the diffences of consecutive letters of self.

INPUT:

- self - A word over the integers.
- mod - (default: None) It can be one of the following:
 - None or 0 : result is over the integers
 - integer : result is over the integers modulo mod.

EXAMPLES:

```
sage: w = Word([x^2 for x in range(10)])
sage: w.finite_differences()
word: 1,3,5,7,9,11,13,15,17
sage: w.finite_differences(mod=4)
word: 131313131
sage: w.finite_differences(mod=0)
word: 1,3,5,7,9,11,13,15,17
```

is_empty()

Returns True if the length of self is zero, and False otherwise.

EXAMPLES:

```
sage: it = iter([])
sage: Word(it).is_empty()
True
sage: it = iter([1,2,3])
sage: Word(it).is_empty()
False
sage: from itertools import count
sage: Word(count()).is_empty()
False
```

is_finite()

Returns whether this word is known to be finite.

Warning: A word defined by an iterator such that its end has never been reached will returns False.

EXAMPLES:

```
sage: Word([]).is_finite()
True
sage: Word('a').is_finite()
True
sage: TM = words.ThueMorseWord()
sage: TM.is_finite()
False
```

```
sage: w = Word(iter('a'*100))
sage: w.is_finite()
False
```

iterated_right_palindromic_closure ($f=None$, $algorithm='recursive'$)

Returns the iterated (f -)palindromic closure of self.

INPUT:

- f - involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. WordMorphism).
- $algorithm$ - string (default: 'recursive') specifying which algorithm to be used when computing the iterated palindromic closure. It must be one of the two following values:
 - 'definition' - computed using the definition
 - 'recursive' - computation based on an efficient formula that recursively computes the iterated right palindromic closure without having to recompute the longest f -palindromic suffix at each iteration [2].

OUTPUT:

word – the iterated (f -)palindromic closure of self

EXAMPLES:

```
sage: Word('123').iterated_right_palindromic_closure()
word: 1213121
```

```
sage: w = Word('abc')
sage: w.iterated_right_palindromic_closure()
word: abacaba
```

```
sage: w = Word('aaa')
sage: w.iterated_right_palindromic_closure()
word: aaa
```

```
sage: w = Word('abbab')
sage: w.iterated_right_palindromic_closure()
word: ababaabababaababa
```

A right f -palindromic closure:

```
sage: f = WordMorphism('a->b,b->a')
sage: w = Word('abbab')
sage: w.iterated_right_palindromic_closure(f=f)
word: abbaabbaababbaabbaabbaabbaabbaab
```

An infinite word:

```
sage: t = words.ThueMorseWord('ab')  
sage: t.iterated_right_palindromic_closure()  
word: ababaabababaababaabababaababaabababaabab...
```

There are two implementations computing the iterated right f -palindromic closure, the latter being much more efficient:

```
sage: w = Word('abaab')
sage: u = w.iterated_right_palindromic_closure(algorithm='definition')
sage: v = w.iterated_right_palindromic_closure(algorithm='recursive')
sage: u
word: abaabaababaabaaba
sage: u == v
True
sage: w = words.RandomWord(8)
sage: u = w.iterated_right_palindromic_closure(algorithm='definition')
sage: v = w.iterated_right_palindromic_closure(algorithm='recursive')
sage: u == v
True
```

- [2] J. Justin, Episturmian morphisms and a Galois theorem on continued fractions, *RAIRO Theoret. Informatics Appl.* 39 (2005) 207–215.

```
length()
```

Returns the length of self.

lex_greater (*other*)

Returns True if self is lexicographically greater than other.

EXAMPLES:

```
sage: w = Word([1,2,3])
sage: u = Word([1,3,2])
sage: v = Word([3,2,1])
sage: w.lex_greater(u)
False
sage: v.lex_greater(w)
True
sage: a = Word("abba")
sage: b = Word("abbb")
sage: a.lex_greater(b)
False
sage: b.lex_greater(a)
True
```

For infinite words:

```
sage: t = words.ThueMorseWord()
sage: t[:10].lex_greater(t)
False
sage: t.lex_greater(t[:10])
True
```

lex_less (*other*)

Returns True if self is lexicographically less than other.

EXAMPLES:

```
sage: w = Word([1,2,3])
sage: u = Word([1,3,2])
sage: v = Word([3,2,1])
sage: w.lex_less(u)
True
sage: v.lex_less(w)
False
sage: a = Word("abba")
sage: b = Word("abbb")
sage: a.lex_less(b)
True
sage: b.lex_less(a)
False
```

For infinite words:

```
sage: t = words.ThueMorseWord()
sage: t.lex_less(t[:10])
False
sage: t[:10].lex_less(t)
True
```

longest_common_prefix (*other*, *length='unknown'*)

Returns the longest common prefix of self and other.

INPUT:

- *other* - word
- *length* - string (optional, default: 'unknown') the length type of the resulting word if known. It may be one of the following:
 - 'unknown'
 - 'finite'
 - 'infinite'

EXAMPLES:

```
sage: f = lambda n : add(Integer(n).digits(2)) % 2
sage: t = Word(f)
sage: u = t[:10]
sage: t.longest_common_prefix(u)
word: 0110100110
```

The longest common prefix of two equal infinite words:

```
sage: t1 = Word(f)
sage: t2 = Word(f)
sage: t1.longest_common_prefix(t2)
word: 01101001100101101001011001101001100110010110...
```

Useful to study the approximation of an infinite word:

```

sage: a = 0.618
sage: g = words.CodingOfRotationWord(alpha=a, beta=1-a, x=a)
sage: f = words.FibonacciWord()
sage: p = f.longest_common_prefix(g, length='finite')
sage: p.length()
231

```

longest_periodic_prefix (*period=1*)

Returns the longest prefix of self having the given period.

INPUT:

- *period* - positive integer (optional, default 1)

OUTPUT:

word

EXAMPLES:

```

sage: Word([]).longest_periodic_prefix()
word:
sage: Word([1]).longest_periodic_prefix()
word: 1
sage: Word([1,2]).longest_periodic_prefix()
word: 1
sage: Word([1,1,2]).longest_periodic_prefix()
word: 11
sage: Word([1,2,1,2,1,3]).longest_periodic_prefix(2)
word: 12121
sage: type(_)
<class 'sage.combinat.words.word.FiniteWord_iter_with_caching'>
sage: Word(lambda n:0).longest_periodic_prefix()
word: 0000000000000000000000000000000000000000...

```

palindrome_prefixes_iterator (*max_length=None*)

Returns an iterator over the palindrome prefixes of self.

INPUT:

- *max_length* - non negative integer or None (optional, default: None) the maximum length of the prefixes

OUTPUT:

iterator

EXAMPLES:

```

sage: w = Word('abaaba')
sage: for pp in w.palindrome_prefixes_iterator(): pp
word:
word: a
word: aba
word: abaaba
sage: for pp in w.palindrome_prefixes_iterator(max_length=4): pp
word:
word: a
word: aba

```

You can iterate over the palindrome prefixes of an infinite word:

```

sage: f = words.FibonacciWord()
sage: for pp in f.palindrome_prefixes_iterator(max_length=20): pp
word:
word: 0
word: 010
word: 010010
word: 01001010010
word: 0100101001001010010

```

parent ()

Returns the parent of self.

partial_sums (*start, mod=None*)

Returns the word defined by the partial sums of its prefixes.

INPUT:

- **self** - A word over the integers.
- **start** - integer, the first letter of the resulting word.
- **mod** - (default: None) It can be one of the following:
 - None or 0 : result is over the integers
 - integer : result is over the integers modulo mod.

EXAMPLES:

```

sage: w = Word(range(10))
sage: w.partial_sums(0)
word: 0, 0, 1, 3, 6, 10, 15, 21, 28, 36, 45
sage: w.partial_sums(1)
word: 1, 1, 2, 4, 7, 11, 16, 22, 29, 37, 46

```

```

sage: w = Word([1, 2, 3, 1, 2, 3, 2, 2, 2, 2])
sage: w.partial_sums(0, mod=None)
word: 0, 1, 3, 6, 7, 9, 12, 14, 16, 18, 20
sage: w.partial_sums(0, mod=0)
word: 0, 1, 3, 6, 7, 9, 12, 14, 16, 18, 20
sage: w.partial_sums(0, mod=8)
word: 01367146024
sage: w.partial_sums(0, mod=4)
word: 01323102020
sage: w.partial_sums(0, mod=2)
word: 01101100000
sage: w.partial_sums(0, mod=1)
word: 00000000000

```

prefixes_iterator (*max_length=None*)

Returns an iterator over the prefixes of self.

INPUT:

- **max_length** - non negative integer or None (optional, default: None) the maximum length of the prefixes

OUTPUT:

iterator

EXAMPLES:

```

sage: w = Word('abaaba')
sage: for p in w.prefixes_iterator(): p
word:
word: a
word: ab
word: aba
word: abaa
word: abaab
word: abaaba
sage: for p in w.prefixes_iterator(max_length=3): p
word:
word: a
word: ab
word: aba

```

You can iterate over the prefixes of an infinite word:

```

sage: f = words.FibonacciWord()
sage: for p in f.prefixes_iterator(max_length=8): p
word:
word: 0
word: 01
word: 010
word: 0100
word: 01001
word: 010010
word: 0100101
word: 01001010

```

return_words_iterator (*fact*)

Returns an iterator over all the return words of fact in self (without unicity).

INPUT:

- fact - a non empty finite word

OUTPUT:

iterator

EXAMPLES:

```

sage: w = Word('baccabccbacbca')
sage: b = Word('b')
sage: list(w.return_words_iterator(b))
[word: bacca, word: bcc, word: bac]

```

```

sage: TM = words.ThueMorseWord()
sage: fact = Word([0,1,1,0,1])
sage: it = TM.return_words_iterator(fact)
sage: next(it)
word: 011010011001
sage: next(it)
word: 011010010110
sage: next(it)
word: 0110100110010110
sage: next(it)
word: 01101001
sage: next(it)

```

```
word: 011010011001
sage: next(it)
word: 011010010110
```

string_rep()

Returns the (truncated) raw sequence of letters as a string.

EXAMPLES:

```
sage: Word('abbabaab').string_rep()
'abbabaab'
sage: Word([0, 1, 0, 0, 1]).string_rep()
'01001'
sage: Word([0,1,10,101]).string_rep()
'0,1,10,101'
sage: WordOptions(letter_separator='-').string_rep()
'0-1-10-101'
sage: WordOptions(letter_separator=',').string_rep()
'0,1,10,101'
```

sum_digits (base=2, mod=None)

Return the sequence of the sum modulo mod of the digits written in base base of self.

INPUT:

- self - word over natural numbers
- base - integer (default : 2), greater or equal to 2
- mod - modulo (default: None), can take the following values:
 - integer - the modulo
 - None - the value base is considered for the modulo.

EXAMPLES:

The Thue-Morse word:

```
sage: from itertools import count
sage: Word(count()).sum_digits()
word: 0110100110010110100101100110100110010110...
```

Sum of digits modulo 2 of the prime numbers written in base 2:

```
sage: Word(primes(1000)).sum_digits()
word: 1001110100111010111011001011101110011011...
```

Sum of digits modulo 3 of the prime numbers written in base 3:

```
sage: Word(primes(1000)).sum_digits(base=3)
word: 2100002020002221222121022221022122111022...
sage: Word(primes(1000)).sum_digits(base=3, mod=3)
word: 2100002020002221222121022221022122111022...
```

Sum of digits modulo 2 of the prime numbers written in base 3:

```
sage: Word(primes(1000)).sum_digits(base=3, mod=2)
word: 0111111111111111111111111111111111111111...
```

Sum of digits modulo 7 of the prime numbers written in base 10:

```
sage: Word(primes(1000)).sum_digits(base=10, mod=7)
word: 2350241354435041006132432241353546006304...
```

Negative entries:

```
sage: w = Word([-1,0,1,2,3,4,5])
sage: w.sum_digits()
Traceback (most recent call last):
...
NotImplementedError: nth digit of Thue-Morse word is not implemented for
↳negative value of n
```

```
sage: type(Word(range(10)).sum_digits())
<class 'sage.combinat.words.word.FiniteWord_iter_with_caching'>
```

`to_integer_word()`

Returns a word over the integers whose letters are those output by `self._to_integer_iterator()`

EXAMPLES:

```
sage: from itertools import count
sage: w = Word(count()); w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,
↳27,28,29,30,31,32,33,34,35,36,37,38,39,...
sage: w.to_integer_word()
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,
↳27,28,29,30,31,32,33,34,35,36,37,38,39,...
sage: w = Word(iter("abbacabba"), length="finite"); w
word: abbacabba
sage: w.to_integer_word()
word: 011020110
sage: w = Word(iter("abbacabba"), length="unknown"); w
word: abbacabba
sage: w.to_integer_word()
word: 011020110
```

5.1.333 Word features that are imported by default in the interpreter namespace

5.1.334 Alphabet

AUTHORS:

- Franco Saliola (2008-12-17) : merged into sage
- Vincent Delecroix and Stepan Starosta (2012): remove classes for alphabet and use other Sage classes otherwise (TotallyOrderFiniteSet, FiniteEnumeratedSet, ...). More shortcut to standard alphabets.

EXAMPLES:

```
sage: build_alphabet("ab")
{'a', 'b'}
sage: build_alphabet([0,1,2])
{0, 1, 2}
sage: build_alphabet(name="PP")
Positive integers
sage: build_alphabet(name="NN")
Non negative integers
```

```
sage: build_alphabet(name="lower")
{'a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm', 'n', 'o', 'p', 'q',
→ 'r', 's', 't', 'u', 'v', 'w', 'x', 'y', 'z'}
```

sage.combinat.words.alphabet.**Alphabet** (data=None, names=None, name=None)

Return an object representing an ordered alphabet.

INPUT:

- data – the letters of the alphabet; it can be:
 - a list/tuple/iterable of letters; the iterable may be infinite
 - an integer n to represent $\{1, \dots, n\}$, or infinity to represent $\mathbb{N}$
- names – (optional) a list for the letters (i.e. variable names) or a string for prefix for all letters; if given a list, it must have the same cardinality as the set represented by data
- name – (optional) if given, then return a named set and can be equal to: 'lower', 'upper', 'space', 'underscore', 'punctuation', 'printable', 'binary', 'octal', 'decimal', 'hexadecimal', 'radix64'.

You can use many of them at once, separated by spaces: 'lower punctuation' represents the union of the two alphabets 'lower' and 'punctuation'.

Alternatively, name can be set to "positive integers" (or "PP") or "natural numbers" (or "NN").

name cannot be combined with data.

EXAMPLES:

If the argument is a Set, it just returns it:

```
sage: build_alphabet(ZZ) is ZZ
True
sage: F = FiniteEnumeratedSet('abc')
sage: build_alphabet(F) is F
True
```

If a list, tuple or string is provided, then it builds a proper Sage class (TotallyOrderedFiniteSet):

```
sage: build_alphabet([0,1,2])
{0, 1, 2}
sage: F = build_alphabet('abc'); F
{'a', 'b', 'c'}
sage: print(type(F).__name__)
TotallyOrderedFiniteSet_with_category
```

If an integer and a set is given, then it constructs a TotallyOrderedFiniteSet:

```
sage: build_alphabet(3, ['a', 'b', 'c'])
{'a', 'b', 'c'}
```

If an integer and a string is given, then it considers that string as a prefix:

```
sage: build_alphabet(3, 'x')
{'x0', 'x1', 'x2'}
```

If no data is provided, name may be a string which describe an alphabet. The available names decompose into two families. The first one are ‘positive integers’, ‘PP’, ‘natural numbers’ or ‘NN’ which refer to standard set of numbers:

```
sage: build_alphabet(name="positive integers")
Positive integers
sage: build_alphabet(name="PP")
Positive integers
sage: build_alphabet(name="natural numbers")
Non negative integers
sage: build_alphabet(name="NN")
Non negative integers
```

The other families for the option name are among ‘lower’, ‘upper’, ‘space’, ‘underscore’, ‘punctuation’, ‘printable’, ‘binary’, ‘octal’, ‘decimal’, ‘hexadecimal’, ‘radix64’ which refer to standard set of charaters. Theses names may be combined by separating them by a space:

```
sage: build_alphabet(name="lower")
{'a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm', 'n', 'o', 'p',
↪ 'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y', 'z'}
sage: build_alphabet(name="hexadecimal")
{'0', '1', '2', '3', '4', '5', '6', '7', '8', '9', 'a', 'b', 'c', 'd', 'e', 'f'}
sage: build_alphabet(name="decimal punctuation")
{'0', '1', '2', '3', '4', '5', '6', '7', '8', '9', ' ', ',', '.', ';', ':', '!',
↪ '?'}

```

In the case the alphabet is built from a list or a tuple, the order on the alphabet is given by the elements themselves:

```
sage: A = build_alphabet([0,2,1])
sage: A(0) < A(2)
True
sage: A(2) < A(1)
False
```

If a different order is needed, you may use `TotallyOrderedFiniteSet` and set the option `facade` to `False`. That way, the comparison fits the order of the input:

```
sage: A = TotallyOrderedFiniteSet([4,2,6,1], facade=False)
sage: A(4) < A(2)
True
sage: A(1) < A(6)
False
```

Be careful, the element of the set in the last example are no more integers and do not compare equal with integers:

```
sage: type(A.an_element())
<class 'sage.sets.totally_ordered_finite_set.TotallyOrderedFiniteSet_with_
↪category.element_class'>
sage: A(1) == 1
False
sage: 1 == A(1)
False
```

We give an example of an infinite alphabet indexed by the positive integers and the prime numbers:

```
sage: build_alphabet(oo, 'x')
Lazy family (x(i))_{i in Non negative integers}
sage: build_alphabet(Primes(), 'y')
Lazy family (y(i))_{i in Set of all prime numbers: 2, 3, 5, 7, ...}
```

class sage.combinat.words.alphabet.**OrderedAlphabet**
 Bases: object

Warning: Not to be used! (backward compatibility)

Returns a finite or infinite ordered alphabet.

EXAMPLES:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet
sage: A = OrderedAlphabet('ab'); A
doctest:...: DeprecationWarning: OrderedAlphabet is deprecated; use Alphabet_
↳ instead.
See http://trac.sagemath.org/8920 for details.
{'a', 'b'}
sage: type(A)
<class 'sage.sets.totally_ordered_finite_set.TotallyOrderedFiniteSet_with_category'
↳ '>
```

sage.combinat.words.alphabet.**OrderedAlphabet_Finite**
 alias of *OrderedAlphabet*

class sage.combinat.words.alphabet.**OrderedAlphabet_backward_compatibility**(*elements*,
fa-
cade=True
 Bases: sage.sets.totally_ordered_finite_set.TotallyOrderedFiniteSet

Warning: Not to be used! (backward compatibility)

Version prior to [trac ticket #8920](#) uses classes `Alphabet` with an argument `._alphabet` instead of `._elements` used in `TotallyOrderedFiniteSet`. This class is dedicated to handle this problem which occurs when unpickling `OrderedAlphabet`.

sage.combinat.words.alphabet.**build_alphabet** (*data=None, names=None, name=None*)
 Return an object representing an ordered alphabet.

INPUT:

- *data* – the letters of the alphabet; it can be:
 - a list/tuple/iterable of letters; the iterable may be infinite
 - an integer n to represent $\{1, \dots, n\}$, or infinity to represent $\mathbb{N}$
- *names* – (optional) a list for the letters (i.e. variable names) or a string for prefix for all letters; if given a list, it must have the same cardinality as the set represented by *data*
- *name* – (optional) if given, then return a named set and can be equal to : 'lower', 'upper', 'space', 'underscore', 'punctuation', 'printable', 'binary', 'octal', 'decimal', 'hexadecimal', 'radix64'.

You can use many of them at once, separated by spaces: 'lower punctuation' represents the union of the two alphabets 'lower' and 'punctuation'.

Alternatively, name can be set to "positive integers" (or "PP") or "natural numbers" (or "NN").

name cannot be combined with data.

EXAMPLES:

If the argument is a Set, it just returns it:

```
sage: build_alphabet(ZZ) is ZZ
True
sage: F = FiniteEnumeratedSet('abc')
sage: build_alphabet(F) is F
True
```

If a list, tuple or string is provided, then it builds a proper Sage class (TotallyOrderedFiniteSet):

```
sage: build_alphabet([0,1,2])
{0, 1, 2}
sage: F = build_alphabet('abc'); F
{'a', 'b', 'c'}
sage: print(type(F).__name__)
TotallyOrderedFiniteSet_with_category
```

If an integer and a set is given, then it constructs a TotallyOrderedFiniteSet:

```
sage: build_alphabet(3, ['a','b','c'])
{'a', 'b', 'c'}
```

If an integer and a string is given, then it considers that string as a prefix:

```
sage: build_alphabet(3, 'x')
{'x0', 'x1', 'x2'}
```

If no data is provided, name may be a string which describe an alphabet. The available names decompose into two families. The first one are 'positive integers', 'PP', 'natural numbers' or 'NN' which refer to standard set of numbers:

```
sage: build_alphabet(name="positive integers")
Positive integers
sage: build_alphabet(name="PP")
Positive integers
sage: build_alphabet(name="natural numbers")
Non negative integers
sage: build_alphabet(name="NN")
Non negative integers
```

The other families for the option name are among 'lower', 'upper', 'space', 'underscore', 'punctuation', 'printable', 'binary', 'octal', 'decimal', 'hexadecimal', 'radix64' which refer to standard set of charaters. Theses names may be combined by separating them by a space:

```
sage: build_alphabet(name="lower")
{'a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm', 'n', 'o', 'p',
↪ 'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y', 'z'}
sage: build_alphabet(name="hexadecimal")
{'0', '1', '2', '3', '4', '5', '6', '7', '8', '9', 'a', 'b', 'c', 'd', 'e', 'f'}
```

```
sage: build_alphabet(name="decimal punctuation")
{'0', '1', '2', '3', '4', '5', '6', '7', '8', '9', ' ', ',', '.', ';', ':', '!',
↪ '?'}

```

In the case the alphabet is built from a list or a tuple, the order on the alphabet is given by the elements themselves:

```
sage: A = build_alphabet([0,2,1])
sage: A(0) < A(2)
True
sage: A(2) < A(1)
False

```

If a different order is needed, you may use `TotallyOrderedFiniteSet` and set the option `facade` to `False`. That way, the comparison fits the order of the input:

```
sage: A = TotallyOrderedFiniteSet([4,2,6,1], facade=False)
sage: A(4) < A(2)
True
sage: A(1) < A(6)
False

```

Be careful, the element of the set in the last example are no more integers and do not compare equal with integers:

```
sage: type(A.an_element())
<class 'sage.sets.totally_ordered_finite_set.TotallyOrderedFiniteSet_with_
↪category.element_class'>
sage: A(1) == 1
False
sage: 1 == A(1)
False

```

We give an example of an infinite alphabet indexed by the positive integers and the prime numbers:

```
sage: build_alphabet(oo, 'x')
Lazy family (x(i))_{i in Non negative integers}
sage: build_alphabet(Primes(), 'y')
Lazy family (y(i))_{i in Set of all prime numbers: 2, 3, 5, 7, ...}

```

5.1.335 Finite word

AUTHORS:

- Arnaud Bergeron
- Amy Glen
- Sébastien Labbé
- Franco Saliola
- Julien Leroy (March 2010): `reduced_rauzy_graph`

EXAMPLES:

Creation of a finite word

Finite words from Python strings, lists and tuples:

```
sage: Word("abbabaab")
word: abbabaab
sage: Word([0, 1, 1, 0, 1, 0, 0, 1])
word: 01101001
sage: Word( ('a', 0, 5, 7, 'b', 9, 8) )
word: a057b98
```

Finite words from functions:

```
sage: f = lambda n : n%3
sage: Word(f, length=13)
word: 0120120120120
```

Finite words from iterators:

```
sage: from itertools import count
sage: Word(count(), length=10)
word: 0123456789
```

```
sage: Word( iter('abbccdef') )
word: abbccdef
```

Finite words from words via concatenation:

```
sage: u = Word("abcccabba")
sage: v = Word([0, 4, 8, 8, 3])
sage: u * v
word: abcccabba04883
sage: v * u
word: 04883abcccabba
sage: u + v
word: abcccabba04883
sage: u^3 * v^(8/5)
word: abcccabbaabcccabbaabcccabba04883048
```

Finite words from infinite words:

```
sage: vv = v^Infinity
sage: vv[10000:10015]
word: 048830488304883
```

Finite words in a specific combinatorial class:

```
sage: W = Words("ab")
sage: W
Finite and infinite words over {'a', 'b'}
sage: W("abbabaab")
word: abbabaab
sage: W(["a", "b", "b", "a", "b", "a", "a", "b"])
word: abbabaab
sage: W( iter('ababab') )
word: ababab
```

Finite word as the image under a morphism:

```

sage: m = WordMorphism({0:[4,4,5,0],5:[0,5,5],4:[4,0,0,0]})
sage: m(0)
word: 4450
sage: m(0, order=2)
word: 400040000554450
sage: m(0, order=3)
word: 4000445044504450400044504450445044500550...

```

Note: The following two finite words have the same string representation:

```

sage: w = Word('010120')
sage: z = Word([0, 1, 0, 1, 2, 0])
sage: w
word: 010120
sage: z
word: 010120

```

but are not equal:

```

sage: w == z
False

```

Indeed, w and z are defined on different alphabets:

```

sage: w[2]
'0'
sage: z[2]
0

```

Functions and algorithms

There are more than 100 functions defined on a finite word. Here are some of them:

```

sage: w = Word('abaabbba'); w
word: abaabbba
sage: w.is_palindrome()
False
sage: w.is_lyndon()
False
sage: w.number_of_factors()
28
sage: w.critical_exponent()
3

```

```

sage: print(w.lyndon_factorization())
(ab, aabbb, a)
sage: print(w.crochemore_factorization())
(a, b, a, ab, bb, a)

```

```

sage: st = w.suffix_tree()
sage: st
Implicit Suffix Tree of the word: abaabbba
sage: st.show(word_labels=True)

```

```
sage: T = words.FibonacciWord('ab')
sage: T.longest_common_prefix(Word('abaabababbbbbbb'))
word: abaababa
```

As matrix and many other sage objects, words have a parent:

```
sage: u = Word('xyxyxyxy')
sage: u.parent()
Finite words over Set of Python objects of type 'object'
```

```
sage: v = Word('xyxyxyxy', alphabet='xy')
sage: v.parent()
Finite words over {'x', 'y'}
```

Factors and Rauzy Graphs

Enumeration of factors, the successive values returned by `next(it)` can appear in a different order depending on hardware. Therefore we mark the three first results of the test `random`. The important test is that the iteration stops properly on the fourth call:

```
sage: w = Word([4,5,6])^7
sage: it = w.factor_iterator(4)
sage: next(it) # random
word: 6456
sage: next(it) # random
word: 5645
sage: next(it) # random
word: 4564
sage: next(it)
Traceback (most recent call last):
...
StopIteration
```

The set of factors:

```
sage: sorted(w.factor_set(3))
[word: 456, word: 564, word: 645]
sage: sorted(w.factor_set(4))
[word: 4564, word: 5645, word: 6456]
sage: w.factor_set().cardinality()
61
```

Rauzy graphs:

```
sage: f = words.FibonacciWord()[:30]
sage: f.rauzy_graph(4)
Looped digraph on 5 vertices
sage: f.reduced_rauzy_graph(4)
Looped multi-digraph on 2 vertices
```

Left-special and bispecial factors:

```
sage: f.number_of_left_special_factors(7)
1
sage: f.bispecial_factors()
[word: , word: 0, word: 010, word: 010010, word: 01001010010]
```

class `sage.combinat.words.finite_word.CallableFromListOfWords`

Bases: `tuple`

A class to create a callable from a list of words. The concatenation of a list of words is obtained by creating a word from this callable.

class `sage.combinat.words.finite_word.Factorization`

Bases: `list`

A list subclass having a nicer representation for factorization of words.

class `sage.combinat.words.finite_word.FiniteWord_class`

Bases: `sage.combinat.words.abstract_word.Word_class`

BWT()

Return the Burrows-Wheeler Transform (BWT) of `self`.

The *Burrows-Wheeler transform* of a finite word w is obtained from w by first listing the conjugates of w in lexicographic order and then concatenating the final letters of the conjugates in this order. See [1].

EXAMPLES:

```
sage: Word('abaccaaba').BWT()
word: cbaabaaca
sage: Word('abaab').BWT()
word: bbaaa
sage: Word('bbabbaca').BWT()
word: cbbbbaaa
sage: Word('aabaab').BWT()
word: bbaaaa
sage: Word().BWT()
word:
sage: Word('a').BWT()
word: a
```

REFERENCES:

- [1] M. Burrows, D.J. Wheeler, “A block-sorting lossless data compression algorithm”, HP Lab Technical Report, 1994, available at <http://www.hpl.hp.com/techreports/Compaq-DEC/SRC-RR-124.html>

abelian_complexity(n)

Return the number of abelian vectors of factors of length n of `self`.

EXAMPLES:

```
sage: w = words.FibonacciWord()[100]
sage: [w.abelian_complexity(i) for i in range(20)]
[1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2]
```

```
sage: w = words.ThueMorseWord()[100]
sage: [w.abelian_complexity(i) for i in range(20)]
[1, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2, 3, 2]
```

abelian_vector(*alphabet=None*)

Return the abelian vector of `self` counting the occurrences of each letter.

The vector is defined w.r.t. the order of the alphabet of the parent. See also `evaluation_dict()`.

INPUT:

- `self` – word having a parent on a finite alphabet
- `alphabet` – *DEPRECATED*

OUTPUT:

a list

EXAMPLES:

```
sage: W = Words('ab')
sage: W('aaabbbbb').abelian_vector()
[3, 5]
sage: W('a').abelian_vector()
[1, 0]
sage: W().abelian_vector()
[0, 0]
```

The argument `alphabet` is deprecated:

```
sage: Word('aabaa').abelian_vector('abc')
doctest:...: DeprecationWarning: The argument alphabet of
methods abelian_vector and parikh_vector is deprecated and will
be removed in a future version of Sage. In order to fix this,
you must define your word on a parent with a finite alphabet.
See http://trac.sagemath.org/17058 for details.
[4, 1, 0]
```

You may fix the above deprecated use of the `alphabet` argument this way:

```
sage: W = Words('abc')
sage: W('aabaa').abelian_vector()
[4, 1, 0]
```

abelian_vectors (*n*)

Return the abelian vectors of factors of length *n* of `self`.

The vectors are defined w.r.t. the order of the alphabet of the parent.

OUTPUT:

a set of tuples

EXAMPLES:

```
sage: W = Words([0,1,2])
sage: w = W([0,1,1,0,1,2,0,2,0,2])
sage: w.abelian_vectors(3)
{(1, 0, 2), (1, 1, 1), (1, 2, 0), (2, 0, 1)}
sage: w[:5].abelian_vectors(3)
{(1, 2, 0)}
sage: w[5:].abelian_vectors(3)
{(1, 0, 2), (2, 0, 1)}
```

```
sage: w = words.FibonacciWord()[:100]
sage: sorted(w.abelian_vectors(0))
[(0, 0)]
sage: sorted(w.abelian_vectors(1))
[(0, 1), (1, 0)]
sage: sorted(w.abelian_vectors(7))
[(4, 3), (5, 2)]
```

The word must be defined with a parent on a finite alphabet:

```

sage: from itertools import count
sage: w = Word(count(), alphabet=NN)
sage: w[:2].abelian_vectors(2)
Traceback (most recent call last):
...
TypeError: The alphabet of the parent is infinite; define the
word with a parent on a finite alphabet

```

```

sage: w = Word([0,1,0], alphabet=[0,1])
sage: w.abelian_complexity(3)
1
sage: w.abelian_complexity(4)
0

```

apply_permutation_to_letters (*permutation*)

Return the word obtained by applying the permutation *permutation* of the alphabet of *self* to each letter of *self*.

EXAMPLES:

```

sage: w = Words('abcd') ('abcd')
sage: p = [2,1,4,3]
sage: w.apply_permutation_to_letters(p)
word: badc
sage: u = Words('dabc') ('abcd')
sage: u.apply_permutation_to_letters(p)
word: dcba
sage: w.apply_permutation_to_letters(Permutation(p))
word: badc
sage: w.apply_permutation_to_letters(PermutationGroupElement(p))
word: badc

```

apply_permutation_to_positions (*permutation*)

Return the word obtained by permuting the positions of the letters in *self* according to the permutation *permutation*.

EXAMPLES:

```

sage: w = Words('abcd') ('abcd')
sage: w.apply_permutation_to_positions([2,1,4,3])
word: badc
sage: u = Words('dabc') ('abcd')
sage: u.apply_permutation_to_positions([2,1,4,3])
word: badc
sage: w.apply_permutation_to_positions(Permutation([2,1,4,3]))
word: badc
sage: w.apply_permutation_to_positions(PermutationGroupElement([2,1,4,3]))
word: badc
sage: Word([1,2,3,4]).apply_permutation_to_positions([3,4,2,1])
word: 3421

```

balance ()

Return the balance of *self*.

The balance of a word is the smallest number q such that *self* is q -balanced [1].

A finite or infinite word w is said to be q -balanced if for any two factors u, v of w of the same length, the difference between the number of x 's in each of u and v is at most q for all letters x in the alphabet of w . A 1-balanced word is simply said to be balanced. See Chapter 2 of [2].

OUTPUT:

integer

EXAMPLES:

```
sage: Word('111111').balance()
0
sage: Word('001010101011').balance()
2
sage: Word('0101010101').balance()
1
```

```
sage: w = Word('11112222')
sage: w.is_balanced(2)
False
sage: w.is_balanced(3)
False
sage: w.is_balanced(4)
True
sage: w.is_balanced(5)
True
sage: w.balance()
4
```

REFERENCES:

- [2] M. Lothaire, Algebraic Combinatorics On Words, vol. 90 of Encyclopedia of Mathematics and its Applications, Cambridge University Press, U.K., 2002.

bispecial_factors ($n=None$)

Return the bispecial factors (of length n).

A factor u of a word w is *bispecial* if it is right special and left special.

INPUT:

- n – integer (optional, default: None). If None, it returns all bispecial factors.

OUTPUT:

a list of words

EXAMPLES:

```
sage: w = words.FibonacciWord()[:30]
sage: w.bispecial_factors()
[word: , word: 0, word: 010, word: 010010, word: 01001010010]
```

```
sage: w = words.ThueMorseWord()[:30]
sage: for i in range(10):
....:     print("{} {}".format(i, sorted(w.bispecial_factors(i))))
0 [word: ]
1 [word: 0, word: 1]
2 [word: 01, word: 10]
3 [word: 010, word: 101]
4 [word: 0110, word: 1001]
5 []
```

```

6 [word: 011001, word: 100110]
7 []
8 [word: 10010110]
9 []

```

bispecial_factors_iterator (*n=None*)

Return an iterator over the bispecial factors (of length *n*).

A factor *u* of a word *w* is *bispecial* if it is right special and left special.

INPUT:

- *n* – integer (optional, default: None). If None, it returns an iterator over all bispecial factors.

EXAMPLES:

```

sage: w = words.ThueMorseWord()[ :30]
sage: for i in range(10):
....:     for u in sorted(w.bispecial_factors_iterator(i)):
....:         print("{} {}".format(i,u))
0
1 0
1 1
2 01
2 10
3 010
3 101
4 0110
4 1001
6 011001
6 100110
8 10010110

```

```

sage: key = lambda u : (len(u), u)
sage: for u in sorted(w.bispecial_factors_iterator(), key=key): u
word:
word: 0
word: 1
word: 01
word: 10
word: 010
word: 101
word: 0110
word: 1001
word: 011001
word: 100110
word: 10010110

```

border ()

Return the longest word that is both a proper prefix and a proper suffix of *self*.

EXAMPLES:

```

sage: Word('121212').border()
word: 1212
sage: Word('12321').border()
word: 1
sage: Word().border() is None
True

```

charge (*check=True*)

Return the charge of `self`. This is defined as follows.

If w is a permutation of length n , (in other words, the evaluation of w is $(1, 1, \dots, 1)$), the statistic $\text{charge}(w)$ is given by $\sum_{i=1}^n c_i(w)$ where $c_1(w) = 0$ and $c_i(w)$ is defined recursively by setting p_i equal to 1 if i appears to the right of $i - 1$ in w and 0 otherwise. Then we set $c_i(w) = c_{i-1}(w) + p_i$.

EXAMPLES:

```
sage: Word([1, 2, 3]).charge()
3
sage: Word([3, 5, 1, 4, 2]).charge() == 0 + 1 + 1 + 2 + 2
True
```

If w is not a permutation, but the evaluation of w is a partition, the charge of w is defined to be the sum of its charge subwords (each of which will be a permutation). The first charge subword is found by starting at the end of w and moving left until the first 1 is found. This is marked, and we continue to move to the left until the first 2 is found, wrapping around from the beginning of the word back to the end, if necessary. We mark this 2, and continue on until we have marked the largest letter in w . The marked letters, with relative order preserved, form the first charge subword of w . This subword is removed, and the next charge subword is found in the same manner from the remaining letters. In the following example, w_1, w_2, w_3 are the charge subwords of w .

EXAMPLES:

```
sage: w = Word([5, 2, 3, 4, 4, 1, 1, 1, 2, 2, 3])
sage: w1 = Word([5, 2, 4, 1, 3])
sage: w2 = Word([3, 4, 1, 2])
sage: w3 = Word([1, 2])
sage: w.charge() == w1.charge() + w2.charge() + w3.charge()
True
```

Finally, if w does not have partition content, we apply the Lascoux-Schützenberger standardization operators s_i in such a manner as to obtain a word with partition content. (The word we obtain is independent of the choice of operators.) The charge is then defined to be the charge of this word:

```
sage: Word([3, 3, 2, 1, 1]).charge()
0
sage: Word([1, 2, 3, 1, 2]).charge()
2
```

Note that this differs from the definition of charge given in Macdonald's book. The difference amounts to a choice of reading a word from left-to-right or right-to-left. The choice in Sage was made to agree with the definition of a reading word of a tableau in Sage, and seems to be the more common convention in the literature.

cocharge ()

Return the cocharge of `self`. For a word w , this can be defined as $n_{ev} - ch(w)$, where $ch(w)$ is the charge of w and ev is the evaluation of w , and n_{ev} is $\sum_{i < j} \min(ev_i, ev_j)$.

EXAMPLES:

```
sage: Word([1,2,3]).cocharge()
0
sage: Word([3,2,1]).cocharge()
3
sage: Word([1,1,2]).cocharge()
0
sage: Word([2,1,2]).cocharge()
1
```

coerce (*other*)

Try to return a pair of words with a common parent; raise an exception if this is not possible.

This function begins by checking if both words have the same parent. If this is the case, then no work is done and both words are returned as-is.

Otherwise it will attempt to convert *other* to the domain of *self*. If that fails, it will attempt to convert *self* to the domain of *other*. If both attempts fail, it raises a `TypeError` to signal failure.

EXAMPLES:

```
sage: W1 = Words('abc'); W2 = Words('ab')
sage: w1 = W1('abc'); w2 = W2('abba'); w3 = W1('baab')
sage: w1.parent() is w2.parent()
False
sage: a, b = w1.coerce(w2)
sage: a.parent() is b.parent()
True
sage: w1.parent() is w2.parent()
False
```

colored_vector (*x=0, y=0, width='default', height=1, cmap='hsv', thickness=1, label=None*)

Return a vector (Graphics object) illustrating *self*. Each letter is represented by a coloured rectangle.

If the parent of *self* is a class of words over a finite alphabet, then each letter in the alphabet is assigned a unique colour, and this colour will be the same every time this method is called. This is especially useful when plotting and comparing words defined on the same alphabet.

If the alphabet is infinite, then the letters appearing in the word are used as the alphabet.

INPUT:

- *x* – (default: 0) bottom left x-coordinate of the vector
- *y* – (default: 0) bottom left y-coordinate of the vector
- *width* – (default: 'default') width of the vector. By default, the width is the length of *self*.
- *height* – (default: 1) height of the vector
- *thickness* – (default: 1) thickness of the contour
- *cmap* – (default: 'hsv') color map; for available color map names type: `import matplotlib.cm; list(matplotlib.cm.datad)`
- *label* – string (default: None) a label to add on the colored vector

OUTPUT:

Graphics

EXAMPLES:

```

sage: Word(range(20)).colored_vector()
Graphics object consisting of 21 graphics primitives
sage: Word(range(100)).colored_vector(0,0,10,1)
Graphics object consisting of 101 graphics primitives
sage: Words(range(100))(range(10)).colored_vector()
Graphics object consisting of 11 graphics primitives
sage: w = Word('abbabaab')
sage: w.colored_vector()
Graphics object consisting of 9 graphics primitives
sage: w.colored_vector(cmap='autumn')
Graphics object consisting of 9 graphics primitives
sage: Word(range(20)).colored_vector(label='Rainbow')
Graphics object consisting of 23 graphics primitives

```

When two words are defined under the same parent, same letters are mapped to same colors:

```

sage: W = Words(range(20))
sage: w = W(range(20))
sage: y = W(range(10,20))
sage: y.colored_vector(y=1, x=10) + w.colored_vector()
Graphics object consisting of 32 graphics primitives

```

commutes_with (*other*)

Return True if self commutes with other, and False otherwise.

EXAMPLES:

```

sage: Word('12').commutes_with(Word('12'))
True
sage: Word('12').commutes_with(Word('11'))
False
sage: Word().commutes_with(Word('21'))
True

```

complete_return_words (*fact*)

Return the set of complete return words of fact in self.

This is the set of all factors starting by the given factor and ending just after the next occurrence of this factor. See for instance [1].

INPUT:

- fact – a non-empty finite word

OUTPUT:

a Python set of finite words

EXAMPLES:

```

sage: s = Word('21331233213231').complete_return_words(Word('2'))
sage: sorted(s)
[word: 2132, word: 213312, word: 2332]
sage: Word('').complete_return_words(Word('213'))
set()
sage: Word('121212').complete_return_words(Word('1212'))
{word: 121212}

```

REFERENCES:

- [1] J. Justin, L. Vuillon, Return words in Sturmian and episturmian words, Theor. Inform. Appl. 34 (2000) 343–356.

concatenate (*other*)

Return the concatenation of `self` and `other`.

INPUT:

- `other` – a word over the same alphabet as `self`

EXAMPLES:

Concatenation may be made using `+` or `*` operations:

```
sage: w = Word('abadafd')
sage: y = Word([5, 3, 5, 8, 7])
sage: w * y
word: abadafd53587
sage: w + y
word: abadafd53587
sage: w.concatenate(y)
word: abadafd53587
```

Both words must be defined over the same alphabet:

```
sage: z = Word('12223', alphabet = '123')
sage: z + y
Traceback (most recent call last):
...
ValueError: 5 not in alphabet!
```

Eventually, it should work:

```
sage: z = Word('12223', alphabet = '123')
sage: z + y                                     #todo: not implemented
word: 1222353587
```

conjugate (*pos*)

Return the conjugate at `pos` of `self`.

`pos` can be any integer, the distance used is the modulo by the length of `self`.

EXAMPLES:

```
sage: Word('12112').conjugate(1)
word: 21121
sage: Word().conjugate(2)
word:
sage: Word('12112').conjugate(8)
word: 12121
sage: Word('12112').conjugate(-1)
word: 21211
```

conjugate_position (*other*)

Return the position where `self` is conjugate with `other`. Return `None` if there is no such position.

EXAMPLES:

```
sage: Word('12113').conjugate_position(Word('31211'))
1
sage: Word('12131').conjugate_position(Word('12113')) is None
```

```
True
sage: Word().conjugate_position(Word('123')) is None
True
```

conjugates()

Return the list of unique conjugates of `self`.

EXAMPLES:

```
sage: Word(range(6)).conjugates()
[word: 012345,
 word: 123450,
 word: 234501,
 word: 345012,
 word: 450123,
 word: 501234]
sage: Word('cbbca').conjugates()
[word: cbbca, word: bbcac, word: bcacb, word: cacbb, word: acbbc]
```

The result contains each conjugate only once:

```
sage: Word('abcabc').conjugates()
[word: abcabc, word: bcabca, word: cabcab]
```

conjugates_iterator()

Return an iterator over the conjugates of `self`.

EXAMPLES:

```
sage: it = Word(range(4)).conjugates_iterator()
sage: for w in it: w
word: 0123
word: 1230
word: 2301
word: 3012
```

content (*n=None*)

Return content of `self`.

INPUT:

- `n` – (optional) an integer specifying the maximal letter in the alphabet

OUTPUT:

- a list where the i -th entry indicates the multiplicity of the i -th letter in the alphabet in `self`

EXAMPLES:

```
sage: w = Word([1, 2, 4, 3, 2, 2, 2])
sage: w.content()
[1, 4, 1, 1]
sage: w = Word([3, 1])
sage: w.content()
[1, 1]
sage: w.content(n=3)
[1, 0, 1]
sage: w = Word([2, 4], alphabet=[1, 2, 3, 4])
sage: w.content(n=3)
[0, 1, 0]
```

```
sage: w.content()
[0, 1, 0, 1]
```

count (*letter*)

Count the number of occurrences of *letter* in *self*.

EXAMPLES:

```
sage: Word('abbabaab').count('a')
4
```

critical_exponent ()

Return the critical exponent of *self*.

The *critical exponent* of a word is the supremum of the order of all its (finite) factors. See [1].

Note: The implementation here uses the suffix tree to enumerate all the factors. It should be improved.

EXAMPLES:

```
sage: Word('aaba').critical_exponent()
2
sage: Word('aabaa').critical_exponent()
2
sage: Word('aabaaba').critical_exponent()
7/3
sage: Word('ab').critical_exponent()
1
sage: Word('aba').critical_exponent()
3/2
sage: words.ThueMorseWord()[20].critical_exponent()
2
```

REFERENCES:

crochemore_factorization ()

Return the Crochemore factorization of *self* as an ordered list of factors.

The *Crochemore factorization* of a finite word w is the unique factorization: $(x_1, x_2, \dots, x_n)$ of w with each x_i satisfying either: C1. x_i is a letter that does not appear in $u = x_1 \dots x_{i-1}$; C2. x_i is the longest prefix of $v = x_i \dots x_n$ that also has an occurrence beginning within $u = x_1 \dots x_{i-1}$. See [1].

Note: This is not a very good implementation, and should be improved.

EXAMPLES:

```
sage: x = Word('abababb')
sage: x.crochemore_factorization()
(a, b, abab, b)
sage: mul(x.crochemore_factorization()) == x
True
sage: y = Word('abaababacabba')
sage: y.crochemore_factorization()
(a, b, a, aba, ba, c, ab, ba)
sage: mul(y.crochemore_factorization()) == y
True
```

```

sage: x = Word([0,1,0,1,0,1,1])
sage: x.crochemore_factorization()
(0, 1, 0101, 1)
sage: mul(x.crochemore_factorization()) == x
True

```

defect ($f=None$)

Return the defect of `self`.

The *defect* of a finite word w is given by the difference between the maximum number of possible palindromic factors in a word of length $|w|$ and the actual number of palindromic factors contained in w . It is well known that the maximum number of palindromic factors in w is $|w| + 1$ (see [DJP01]).

An optional involution on letters f can be given. In that case, the *f-palindromic defect* (or *pseudopalindromic defect*, or *theta-palindromic defect*) of w is returned. It is a generalization of defect to f -palindromes. More precisely, the defect is $D(w) = |w| + 1 - g_f(w) - |PAL_f(w)|$, where $PAL_f(w)$ denotes the set of f -palindromic factors of w (including the empty word) and $g_f(w)$ is the number of pairs $\{a, f(a)\}$ such that a is a letter, a is not equal to $f(a)$, and a or $f(a)$ occurs in w . In the case of usual palindromes (i.e., for f not given or equal to the identity), $g_f(w) = 0$ for all w . See [BHN04] for usual palindromes and [Sta11] for f -palindromes.

INPUT:

- f – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`). The default value corresponds to usual palindromes, i.e., f equal to the identity.

OUTPUT:

an integer – If f is `None`, the palindromic defect of `self`; otherwise, the f -palindromic defect of `self`.

EXAMPLES:

```

sage: Word('ara').defect()
0
sage: Word('abcacba').defect()
1

```

It is known that Sturmian words (see [DJP01]) have zero defect:

```

sage: words.FibonacciWord()[100].defect()
0

sage: sa = WordMorphism('a->ab,b->b')
sage: sb = WordMorphism('a->a,b->ba')
sage: w = (sa*sb*sb*sa*sa*sa*sb).fixed_point('a')
sage: w[:30].defect()
0
sage: w[110:140].defect()
0

```

It is even conjectured that the defect of an aperiodic word which is a fixed point of a primitive morphism is either 0 or infinite (see [BBGL08]):

```

sage: w = words.ThueMorseWord()
sage: w[:50].defect()
12
sage: w[:100].defect()
16
sage: w[:300].defect()
52

```

For generalized defect with an involution different from the identity, there is always a letter which is not a palindrome! This is the reason for the modification of the definition:

```

sage: f = WordMorphism('a->b,b->a')
sage: Word('a').defect(f)
0
sage: Word('ab').defect(f)
0
sage: Word('aa').defect(f)
1
sage: Word('abbabaabbaababba').defect(f)
3

```

```

sage: f = WordMorphism('a->b,b->a,c->c')
sage: Word('cab').defect(f)
0
sage: Word('abcaab').defect(f)
2

```

Other examples:

```

sage: Word('00000000000').defect()
0
sage: Word('011010011001').defect()
2
sage: Word('0101001010001').defect()
0
sage: Word().defect()
0
sage: Word('abbabaabbaababba').defect()
2

```

REFERENCES:

deg_inv_lex_less (*other*, *weights=None*)

Return True if the word *self* is degree inverse lexicographically less than *other*.

EXAMPLES:

```

sage: Word([1,2,4]).deg_inv_lex_less(Word([1,3,2]))
False
sage: Word([3,2,1]).deg_inv_lex_less(Word([1,2,3]))
True

```

deg_lex_less (*other*, *weights=None*)

Return True if *self* is degree lexicographically less than *other*, and False otherwise. The weight of each letter in the ordered alphabet is given by *weights*, which defaults to [1, 2, 3, ...].

EXAMPLES:

```

sage: Word([1,2,3]).deg_lex_less(Word([1,3,2]))
True
sage: Word([3,2,1]).deg_lex_less(Word([1,2,3]))
False
sage: W = Words(range(5))
sage: W([1,2,4]).deg_lex_less(W([1,3,2]))
False
sage: Word("abba").deg_lex_less(Word("abbb"), dict(a=1,b=2))
True
sage: Word("abba").deg_lex_less(Word("baba"), dict(a=1,b=2))
True
sage: Word("abba").deg_lex_less(Word("aaba"), dict(a=1,b=2))
False
sage: Word("abba").deg_lex_less(Word("aaba"), dict(a=1,b=0))
True

```

deg_rev_lex_less (*other*, *weights=None*)

Return True if self is degree reverse lexicographically less than other.

EXAMPLES:

```

sage: Word([3,2,1]).deg_rev_lex_less(Word([1,2,3]))
False
sage: Word([1,2,4]).deg_rev_lex_less(Word([1,3,2]))
False
sage: Word([1,2,3]).deg_rev_lex_less(Word([1,2,4]))
True

```

degree (*weights=None*)

Return the weighted degree of self, where the weighted degree of each letter in the ordered alphabet is given by weights, which defaults to [1, 2, 3, ...].

INPUT:

•weights – a list or a tuple, or a dictionary keyed by the letters occurring in self.

EXAMPLES:

```

sage: Word([1,2,3]).degree()
6
sage: Word([3,2,1]).degree()
6
sage: Words("ab")("abba").degree()
6
sage: Words("ab")("abba").degree([0,2])
4
sage: Words("ab")("abba").degree([-1,-1])
-4
sage: Words("ab")("aabba").degree([1,1])
5
sage: Words([1,2,4])([1,2,4]).degree()
6
sage: Word([1,2,4]).degree()
7
sage: Word("aabba").degree({'a':1,'b':2})
7
sage: Word([0,1,0]).degree({0:17,1:0})
34

```

delta()

Return the image of `self` under the delta morphism. This is the word composed of the length of consecutive runs of the same letter in a given word.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('22112122').delta()
word: 22112
sage: W('555008').delta()
word: 321
sage: W().delta()
word:
sage: Word('aabbabaa').delta()
word: 22112
```

delta_derivate(*W=None*)

Return the derivative under delta for `self`.

EXAMPLES:

```
sage: W = Words('12')
sage: W('12211').delta_derivate()
word: 22
sage: W('1').delta_derivate(Words([1]))
word: 1
sage: W('2112').delta_derivate()
word: 2
sage: W('2211').delta_derivate()
word: 22
sage: W('112').delta_derivate()
word: 2
sage: W('11222').delta_derivate(Words([1, 2, 3]))
word: 3
```

delta_derivate_left(*W=None*)

Return the derivative under delta for `self`.

EXAMPLES:

```
sage: W = Words('12')
sage: W('12211').delta_derivate_left()
word: 22
sage: W('1').delta_derivate_left(Words([1]))
word: 1
sage: W('2112').delta_derivate_left()
word: 21
sage: W('2211').delta_derivate_left()
word: 22
sage: W('112').delta_derivate_left()
word: 21
sage: W('11222').delta_derivate_left(Words([1, 2, 3]))
word: 3
```

delta_derivate_right(*W=None*)

Return the right derivative under delta for `self`.

EXAMPLES:

```

sage: W = Words('12')
sage: W('12211').delta_derivate_right()
word: 122
sage: W('1').delta_derivate_right(Words([1]))
word: 1
sage: W('2112').delta_derivate_right()
word: 12
sage: W('2211').delta_derivate_right()
word: 22
sage: W('112').delta_derivate_right()
word: 2
sage: W('11222').delta_derivate_right(Words([1, 2, 3]))
word: 23

```

delta_inv (*W=None, s=None*)

Lift self via the delta operator to obtain a word containing the letters in alphabet (default is `[0, 1]`). The letters used in the construction start with `s` (default is `alphabet[0]`) and cycle through alphabet.

INPUT:

- `alphabet` – an iterable
- `s` – an object in the iterable

EXAMPLES:

```

sage: W = Words([1, 2])
sage: W([2, 2, 1, 1]).delta_inv()
word: 112212
sage: W([1, 1, 1, 1]).delta_inv(Words('123'))
word: 1231
sage: W([2, 2, 1, 1, 2]).delta_inv(s=2)
word: 22112122

```

evaluation (*alphabet=None*)

Return the abelian vector of self counting the occurrences of each letter.

The vector is defined w.r.t. the order of the alphabet of the parent. See also `evaluation_dict()`.

INPUT:

- `self` – word having a parent on a finite alphabet
- `alphabet` – *DEPRECATED*

OUTPUT:

a list

EXAMPLES:

```

sage: W = Words('ab')
sage: W('aaabbbbb').abelian_vector()
[3, 5]
sage: W('a').abelian_vector()
[1, 0]
sage: W().abelian_vector()
[0, 0]

```

The argument `alphabet` is deprecated:

```
sage: Word('aabaa').abelian_vector('abc')
doctest:...: DeprecationWarning: The argument alphabet of
methods abelian_vector and parikh_vector is deprecated and will
be removed in a future version of Sage. In order to fix this,
you must define your word on a parent with a finite alphabet.
See http://trac.sagemath.org/17058 for details.
[4, 1, 0]
```

You may fix the above deprecated use of the alphabet argument this way:

```
sage: W = Words('abc')
sage: W('aabaa').abelian_vector()
[4, 1, 0]
```

evaluation_dict()

Return a dictionary keyed by the letters occurring in `self` with values the number of occurrences of the letter.

EXAMPLES:

```
sage: Word([2,1,4,2,3,4,2]).evaluation_dict()
{1: 1, 2: 3, 3: 1, 4: 2}
sage: Word('badbcdab').evaluation_dict()
{'a': 1, 'b': 3, 'c': 1, 'd': 2}
sage: Word().evaluation_dict()
{}
```

```
sage: f = Word('1213121').evaluation_dict() # keys appear in random order
{'1': 4, '2': 2, '3': 1}
```

evaluation_partition()

Return the evaluation of the word `w` as a partition.

EXAMPLES:

```
sage: Word("acdabda").evaluation_partition()
[3, 2, 1, 1]
sage: Word([2,1,4,2,3,4,2]).evaluation_partition()
[3, 2, 1, 1]
```

evaluation_sparse()

Return a list representing the evaluation of `self`. The entries of the list are two-element lists `[a, n]`, where `a` is a letter occurring in `self` and `n` is the number of occurrences of `a` in `self`.

EXAMPLES:

```
sage: Word([4,4,2,5,2,1,4,1]).evaluation_sparse()
[(1, 2), (2, 2), (4, 3), (5, 1)]
sage: Word("abcaccab").evaluation_sparse()
[('a', 3), ('c', 3), ('b', 2)]
```

exponent()

Return the exponent of `self`.

OUTPUT:

integer – the exponent

EXAMPLES:

```

sage: Word('1231').exponent()
1
sage: Word('121212').exponent()
3
sage: Word().exponent()
0

```

factor_iterator (*n=None*)

Generate distinct factors of self.

INPUT:

- *n* – an integer, or None.

OUTPUT:

If *n* is an integer, returns an iterator over all distinct factors of length *n*. If *n* is None, returns an iterator generating all distinct factors.

EXAMPLES:

```

sage: w = Word('1213121')
sage: sorted( w.factor_iterator(0) )
[word: ]
sage: sorted( w.factor_iterator(10) )
[]
sage: sorted( w.factor_iterator(1) )
[word: 1, word: 2, word: 3]
sage: sorted( w.factor_iterator(4) )
[word: 1213, word: 1312, word: 2131, word: 3121]
sage: sorted( w.factor_iterator() )
[word: , word: 1, word: 12, word: 121, word: 1213, word: 12131, word: 121312, ↵
↵word: 1213121, word: 13, word: 131, word: 1312, word: 13121, word: 2, word: ↵
↵21, word: 213, word: 2131, word: 21312, word: 213121, word: 3, word: 31, ↵
↵word: 312, word: 3121]

```

```

sage: u = Word([1,2,1,2,3])
sage: sorted( u.factor_iterator(0) )
[word: ]
sage: sorted( u.factor_iterator(10) )
[]
sage: sorted( u.factor_iterator(1) )
[word: 1, word: 2, word: 3]
sage: sorted( u.factor_iterator(5) )
[word: 12123]
sage: sorted( u.factor_iterator() )
[word: , word: 1, word: 12, word: 121, word: 1212, word: 12123, word: 123, ↵
↵word: 2, word: 21, word: 212, word: 2123, word: 23, word: 3]

```

```

sage: xxx = Word("xxx")
sage: sorted( xxx.factor_iterator(0) )
[word: ]
sage: sorted( xxx.factor_iterator(4) )
[]
sage: sorted( xxx.factor_iterator(2) )
[word: xx]
sage: sorted( xxx.factor_iterator() )
[word: , word: x, word: xx, word: xxx]

```

```

sage: e = Word()
sage: sorted( e.factor_iterator(0) )
[word: ]
sage: sorted( e.factor_iterator(17) )
[]
sage: sorted( e.factor_iterator() )
[word: ]

```

factor_occurrences_in (*other*)

Return an iterator over all occurrences (including overlapping ones) of *self* in *other* in their order of appearance.

EXAMPLES:

```

sage: u = Word('121')
sage: w = Word('121213211213')
sage: list(u.factor_occurrences_in(w))
[0, 2, 8]

```

factor_set (*n=None*, *algorithm='suffix tree'*)

Return the set of factors (of length *n*) of *self*.

INPUT:

- *n* – an integer or None (default: None).
- *algorithm* – string (default: 'suffix tree'), takes the following values:
 - 'suffix tree' – construct and use the suffix tree of the word
 - 'naive' – algorithm uses a sliding window

OUTPUT:

If *n* is an integer, returns the set of all distinct factors of length *n*. If *n* is None, returns the set of all distinct factors.

EXAMPLES:

```

sage: w = Word('121')
sage: sorted(w.factor_set())
[word: , word: 1, word: 12, word: 121, word: 2, word: 21]
sage: sorted(w.factor_set(algorithm='naive'))
[word: , word: 1, word: 12, word: 121, word: 2, word: 21]

```

```

sage: w = Word('1213121')
sage: for i in range(w.length()): sorted(w.factor_set(i))
[word: ]
[word: 1, word: 2, word: 3]
[word: 12, word: 13, word: 21, word: 31]
[word: 121, word: 131, word: 213, word: 312]
[word: 1213, word: 1312, word: 2131, word: 3121]
[word: 12131, word: 13121, word: 21312]
[word: 121312, word: 213121]

```

```

sage: w = Word([1,2,1,2,3])
sage: s = w.factor_set()
sage: sorted(s)
[word: , word: 1, word: 12, word: 121, word: 1212, word: 12123, word: 123,
↵word: 2, word: 21, word: 212, word: 2123, word: 23, word: 3]

```

```
sage: Set(Word().factor_set())
{word: }
```

```
sage: w = Word(range(10), alphabet=range(10))
sage: S1 = w.factor_set(3, algorithm='suffix tree')
sage: S2 = w.factor_set(3, algorithm='naive')
sage: S1 == S2
True
```

find(sub, start=0, end=None)

Return the index of the first occurrence of sub in self, such that sub is contained within self[start:end]. Return -1 on failure.

INPUT:

- sub – string, list, tuple or word to search for.
- start – non-negative integer (default: 0) specifying the position from which to start the search.
- end – non-negative integer (default: None) specifying the position at which the search must stop. If None, then the search is performed up to the end of the string.

OUTPUT:

a non-negative integer or -1

EXAMPLES:

```
sage: w = Word([0,1,0,0,1])
sage: w.find(Word([1,0]))
1
```

The sub argument can also be a tuple or a list:

```
sage: w.find([1,0])
1
sage: w.find((1,0))
1
```

Examples using start and end:

```
sage: w.find(Word([0,1]), start=1)
3
sage: w.find(Word([0,1]), start=1, end=5)
3
sage: w.find(Word([0,1]), start=1, end=4) == -1
True
sage: w.find(Word([1,1])) == -1
True
sage: w.find("aa")
-1
```

Instances of Word_str handle string inputs as well:

```
sage: w = Word('abac')
sage: w.find('a')
0
sage: w.find('ba')
1
```

first_pos_in(*other*)

Return the position of the first occurrence of *self* in *other*, or None if *self* is not a factor of *other*.

EXAMPLES:

```
sage: Word('12').first_pos_in(Word('131231'))
2
sage: Word('32').first_pos_in(Word('131231')) is None
True
```

foata_bijection()

Return word *self* under the Foata bijection.

The Foata bijection ϕ is a bijection on the set of words of given content (by a slight generalization of Section 2 in [FoSc78]). It can be defined by induction on the size of the word: Given a word $w_1 w_2 \cdots w_n$, start with $\phi(w_1) = w_1$. At the i -th step, if $\phi(w_1 w_2 \cdots w_i) = v_1 v_2 \cdots v_i$, we define $\phi(w_1 w_2 \cdots w_i w_{i+1})$ by placing w_{i+1} on the end of the word $v_1 v_2 \cdots v_i$ and breaking the word up into blocks as follows. If $w_{i+1} \geq v_i$, place a vertical line to the right of each v_k for which $w_{i+1} \geq v_k$. Otherwise, if $w_{i+1} < v_i$, place a vertical line to the right of each v_k for which $w_{i+1} < v_k$. In either case, place a vertical line at the start of the word as well. Now, within each block between vertical lines, cyclically shift the entries one place to the right.

For instance, to compute $\phi([4, 1, 5, 4, 2, 2, 3])$, the sequence of words is

- 4,
- 4|1 $\rightarrow$ 41,
- 4|1|5 $\rightarrow$ 415,
- 415|4 $\rightarrow$ 5414,
- 5|4|14|2 $\rightarrow$ 54412,
- 5441|2|2 $\rightarrow$ 154422,
- 1|5442|2|3 $\rightarrow$ 1254423.

So $\phi([4, 1, 5, 4, 2, 2, 3]) = [1, 2, 5, 4, 4, 2, 3]$.

See also:

Foata bijection on Permutations.

EXAMPLES:

```
sage: w = Word([2, 2, 2, 1, 1, 1])
sage: w.foata_bijection()
word: 112221
sage: w = Word([2, 2, 1, 2, 2, 2, 1, 1, 2, 1])
sage: w.foata_bijection()
word: 2122212211
sage: w = Word([4, 1, 5, 4, 2, 2, 3])
sage: w.foata_bijection()
word: 1254423
```

good_suffix_table()

Return a table of the maximum skip you can do in order not to miss a possible occurrence of *self* in a word.

This is a part of the Boyer-Moore algorithm to find factors. See [1].

EXAMPLES:

```
sage: Word('121321').good_suffix_table()
[5, 5, 5, 5, 3, 3, 1]
sage: Word('12412').good_suffix_table()
[3, 3, 3, 3, 3, 1]
```

REFERENCES:

- [1] R.S. Boyer, J.S. Moore, A fast string searching algorithm, Communications of the ACM 20 (1977) 762–772.

has_period(*p*)

Return True if self has the period *p*, False otherwise.

Note: By convention, integers greater than the length of *self* are periods of *self*.

INPUT:

- p* – an integer to check if it is a period of *self*.

EXAMPLES:

```
sage: w = Word('ababa')
sage: w.has_period(2)
True
sage: w.has_period(3)
False
sage: w.has_period(4)
True
sage: w.has_period(-1)
False
sage: w.has_period(5)
True
sage: w.has_period(6)
True
```

has_prefix(*other*)

Test whether *self* has *other* as a prefix.

INPUT:

- other* – a word, or data describing a word

OUTPUT:

boolean

EXAMPLES:

```
sage: w = Word("abbabaabababa")
sage: u = Word("abbab")
sage: w.has_prefix(u)
True
sage: u.has_prefix(w)
False
sage: u.has_prefix("abbab")
True
```

```
sage: w = Word([0,1,1,0,1,0,0,1,0,1,0,1,0])
sage: u = Word([0,1,1,0,1])
```

```

sage: w.has_prefix(u)
True
sage: u.has_prefix(w)
False
sage: u.has_prefix([0,1,1,0,1])
True

```

has_suffix(*other*)

Test whether `self` has `other` as a suffix.

Note: Some word datatype classes, like `WordDatatype_str`, override this method.

INPUT:

- `other` – a word, or data describing a word

OUTPUT:

boolean

EXAMPLES:

```

sage: w = Word("abbabaabababa")
sage: u = Word("ababa")
sage: w.has_suffix(u)
True
sage: u.has_suffix(w)
False
sage: u.has_suffix("ababa")
True

```

```

sage: w = Word([0,1,1,0,1,0,0,1,0,1,0,1,0])
sage: u = Word([0,1,0,1,0])
sage: w.has_suffix(u)
True
sage: u.has_suffix(w)
False
sage: u.has_suffix([0,1,0,1,0])
True

```

implicit_suffix_tree()

Return the implicit suffix tree of `self`.

The *suffix tree* of a word w is a compactification of the suffix trie for w . The compactification removes all nodes that have exactly one incoming edge and exactly one outgoing edge. It consists of two components: a tree and a word. Thus, instead of labelling the edges by factors of w , we can label them by indices of the occurrence of the factors in w .

Type `sage.combinat.words.suffix_trees.ImplicitSuffixTree?` for more information.

EXAMPLES:

```

sage: w = Word("cacao")
sage: w.implicit_suffix_tree()
Implicit Suffix Tree of the word: cacao

```

```
sage: w = Word([0,1,0,1,1])
sage: w.implicit_suffix_tree()
Implicit Suffix Tree of the word: 01011
```

inv_lex_less (*other*)

Return True if self is inverse lexicographically less than other.

EXAMPLES:

```
sage: Word([1,2,4]).inv_lex_less(Word([1,3,2]))
False
sage: Word([3,2,1]).inv_lex_less(Word([1,2,3]))
True
```

inversions ()

Return a list of the inversions of self. An inversion is a pair (i, j) of non-negative integers $i < j$ such that $\text{self}[i] > \text{self}[j]$.

EXAMPLES:

```
sage: Word([1,2,3,2,2,1]).inversions()
[[1, 5], [2, 3], [2, 4], [2, 5], [3, 5], [4, 5]]
sage: Words([3,2,1])([1,2,3,2,2,1]).inversions()
[[0, 1], [0, 2], [0, 3], [0, 4], [1, 2]]
sage: Word('abbaba').inversions()
[[1, 3], [1, 5], [2, 3], [2, 5], [4, 5]]
sage: Words('ba')('abbaba').inversions()
[[0, 1], [0, 2], [0, 4], [3, 4]]
```

is_balanced ($q=1$)

Return True if self is q -balanced, and False otherwise.

A finite or infinite word w is said to be q -balanced if for any two factors u, v of w of the same length, the difference between the number of x 's in each of u and v is at most q for all letters x in the alphabet of w . A 1-balanced word is simply said to be balanced. See for instance [1] and Chapter 2 of [2].

INPUT:

- q – integer (default: 1), the balance level

OUTPUT:

boolean – the result

EXAMPLES:

```
sage: Word('1213121').is_balanced()
True
sage: Word('1122').is_balanced()
False
sage: Word('121333121').is_balanced()
False
sage: Word('121333121').is_balanced(2)
False
sage: Word('121333121').is_balanced(3)
True
sage: Word('121122121').is_balanced()
False
sage: Word('121122121').is_balanced(2)
True
```

REFERENCES:

- [2] M. Lothaire, *Algebraic Combinatorics On Words*, vol. 90 of *Encyclopedia of Mathematics and its Applications*, Cambridge University Press, U.K., 2002.

is_cadence (*seq*)

Return `True` if *seq* is a cadence of *self*, and `False` otherwise.

A *cadence* is an increasing sequence of indexes that all map to the same letter.

EXAMPLES:

```
sage: Word('121132123').is_cadence([0, 2, 6])
True
sage: Word('121132123').is_cadence([0, 1, 2])
False
sage: Word('121132123').is_cadence([])
True
```

is_christoffel ()

Return `True` if *self* is a Christoffel word, and `False` otherwise.

The *Christoffel word* of slope p/q is obtained from the Cayley graph of $\mathbf{Z}/(p+q)\mathbf{Z}$ with generator q as follows. If $u \rightarrow v$ is an edge in the Cayley graph, then, $v = u + p \pmod{p+q}$. Let a, b be the alphabet of w . Label the edge $u \rightarrow v$ by a if $u < v$ and b otherwise. The Christoffel word is the word obtained by reading the edge labels along the cycle beginning from 0.

Equivalently, w is a Christoffel word iff w is a symmetric non-empty word and $w[1 : n-1]$ is a palindrome.

See for instance¹ and².

INPUT:

- self* – word

OUTPUT:

boolean – `True` if *self* is a Christoffel word, `False` otherwise.

EXAMPLES:

```
sage: Word('00100101').is_christoffel()
True
sage: Word('aab').is_christoffel()
True
sage: Word().is_christoffel()
False
sage: Word('123123123').is_christoffel()
False
sage: Word('00100').is_christoffel()
False
sage: Word('0').is_christoffel()
True
```

is_conjugate_with(*other*)

Return True if self is a conjugate of other, and False otherwise.

INPUT:

- other – a finite word

OUTPUT:

bool

EXAMPLES:

```

sage: w = Word([0..20])
sage: z = Word([7..20] + [0..6])
sage: w
word: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20
sage: z
word: 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 0, 1, 2, 3, 4, 5, 6
sage: w.is_conjugate_with(z)
True
sage: z.is_conjugate_with(w)
True
sage: u = Word([4]*21)
sage: u.is_conjugate_with(w)
False
sage: u.is_conjugate_with(z)
False

```

Both words must be finite:

```

sage: w = Word(iter([2]*100), length='unknown')
sage: z = Word([2]*100)
sage: z.is_conjugate_with(w) #TODO: Not implemented for word of unknown length
True
sage: wf = Word(iter([2]*100), length='finite')
sage: z.is_conjugate_with(wf)
True
sage: wf.is_conjugate_with(z)
True

```

is_cube()

Return True if self is a cube, and False otherwise.

EXAMPLES:

```

sage: Word('012012012').is_cube()
True
sage: Word('01010101').is_cube()
False
sage: Word().is_cube()
True
sage: Word('012012').is_cube()
False

```

is_cube_free()

Return True if self does not contain cubes, and False otherwise.

EXAMPLES:

```
sage: Word('12312').is_cube_free()
True
sage: Word('32221').is_cube_free()
False
sage: Word().is_cube_free()
True
```

is_empty()

Return True if the length of `self` is zero, and False otherwise.

EXAMPLES:

```
sage: Word().is_empty()
True
sage: Word('a').is_empty()
False
```

is_factor(*other*)

Return True if `self` is a factor of `other`, and False otherwise.

EXAMPLES:

```
sage: u = Word('2113')
sage: w = Word('123121332131233121132123')
sage: u.is_factor(w)
True
sage: u = Word('321')
sage: w = Word('1231241231312312312')
sage: u.is_factor(w)
False
```

The empty word is factor of another word:

```
sage: Word().is_factor(Word())
True
sage: Word().is_factor(Word('a'))
True
sage: Word().is_factor(Word([1,2,3]))
True
sage: Word().is_factor(Word(lambda n:n, length=5))
True
```

is_finite()

Return True.

EXAMPLES:

```
sage: Word().is_finite()
True
sage: Word('a').is_finite()
True
```

is_full(*f=None*)

Return True if `self` has defect 0, and False otherwise.

A word is *full* (or *rich*) if its defect is zero (see [1]). If `f` is given, then the `f`-palindromic defect is used (see [2]).

INPUT:

- `f` – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

boolean – If `f` is `None`, whether `self` is full; otherwise, whether `self` is full of `f`-palindromes.

EXAMPLES:

```
sage: words.ThueMorseWord()[100].is_full()
False
sage: words.FibonacciWord()[100].is_full()
True
sage: Word('000000000000000').is_full()
True
sage: Word('011010011001').is_full()
False
sage: Word('2194').is_full()
True
sage: Word().is_full()
True
```

```
sage: f = WordMorphism('a->b,b->a')
sage: Word().is_full(f)
True
sage: w = Word('ab')
sage: w.is_full()
True
sage: w.is_full(f)
True
```

```
sage: f = WordMorphism('a->b,b->a')
sage: Word('abab').is_full(f)
True
sage: Word('abba').is_full(f)
False
```

A simple example of an infinite word full of `f`-palindromes:

```
sage: p = WordMorphism({0:'abc',1:'ab'})
sage: f = WordMorphism('a->b,b->a,c->c')
sage: p(words.FibonacciWord()[50]).is_full(f)
True
sage: p(words.FibonacciWord()[150]).is_full(f)
True
```

`is_lyndon()`

Return `True` if `self` is a Lyndon word, and `False` otherwise.

A *Lyndon word* is a non-empty word that is lexicographically smaller than each of its proper suffixes (for the given order on its alphabet). That is, w is a Lyndon word if w is non-empty and for each factorization $w = uv$ (with u, v both non-empty), we have $w < v$.

Equivalently, w is a Lyndon word iff w is a non-empty word that is lexicographically smaller than each of its proper conjugates for the given order on its alphabet.

See for instance [1].

EXAMPLES:

```
sage: Word('123132133').is_lyndon()
True
sage: Word().is_lyndon()
False
sage: Word('122112').is_lyndon()
False
```

REFERENCES:

- [1] M. Lothaire, *Combinatorics On Words*, vol. 17 of *Encyclopedia of Mathematics and its Applications*, Addison-Wesley, Reading, Massachusetts, 1983.

is_overlap()

Return True if self is an overlap, and False otherwise.

EXAMPLES:

```
sage: Word('12121').is_overlap()
True
sage: Word('123').is_overlap()
False
sage: Word('1231').is_overlap()
False
sage: Word('123123').is_overlap()
False
sage: Word('1231231').is_overlap()
True
sage: Word().is_overlap()
False
```

is_palindrome(f=None)

Return True if self is a palindrome (or a f -palindrome), and False otherwise.

Let $f : \Sigma \rightarrow \Sigma$ be an involution that extends to a morphism on Σ^* . We say that $w \in \Sigma^*$ is a ' f -palindrome' if $w = f(\tilde{w})$ [1]. Also called ' f -pseudo-palindrome' [2].

INPUT:

- f – involution (default: None) on the alphabet of self. It must be callable on letters as well as words (e.g. *WordMorphism*). The default value corresponds to usual palindromes, i.e., f equal to the identity.

EXAMPLES:

```
sage: Word('esope reste ici et se repose').is_palindrome()
False
sage: Word('esoperesteicietseresepose').is_palindrome()
True
sage: Word('I saw I was I').is_palindrome()
True
```

```
sage: Word('abbcbbba').is_palindrome()
True
sage: Word('abcbdbba').is_palindrome()
False
```

Some f -palindromes:

```
sage: f = WordMorphism('a->b,b->a')
sage: Word('aababb').is_palindrome(f)
True
```

```
sage: f = WordMorphism('a->b,b->a,c->c')
sage: Word('abacbacbab').is_palindrome(f)
True
```

```
sage: f = WordMorphism({'a':'b','b':'a'})
sage: Word('aababb').is_palindrome(f)
True
```

```
sage: f = WordMorphism({0:[1],1:[0]})
sage: w = words.ThueMorseWord()[8]; w
word: 01101001
sage: w.is_palindrome(f)
True
```

The word must be in the domain of the involution:

```
sage: f = WordMorphism('a->a')
sage: Word('aababb').is_palindrome(f)
Traceback (most recent call last):
...
KeyError: 'b'
```

```
sage: Y = Word
sage: Y().is_palindrome()
True
sage: Y('a').is_palindrome()
True
sage: Y('ab').is_palindrome()
False
sage: Y('aba').is_palindrome()
True
sage: Y('aa').is_palindrome()
True
sage: E = WordMorphism('a->b,b->a')
sage: Y().is_palindrome(E)
True
sage: Y('a').is_palindrome(E)
False
sage: Y('ab').is_palindrome(E)
True
sage: Y('aa').is_palindrome(E)
False
sage: Y('aba').is_palindrome(E)
False
sage: Y('abab').is_palindrome(E)
```

```
True
```

REFERENCES:

- [2] V. Anne, L.Q. Zamboni, I. Zorca, Palindromes and Pseudo- Palindromes in Episturmian and Pseudo-Palindromic Infinite Words, in : S. Brlek, C. Reutenauer (Eds.), Words 2005, Publications du LaCIM, Vol. 36 (2005) 91–100.

is_prefix (*other*)

Return True if self is a prefix of other, and False otherwise.

EXAMPLES:

```
sage: w = Word('0123456789')
sage: y = Word('012345')
sage: y.is_prefix(w)
True
sage: w.is_prefix(y)
False
sage: w.is_prefix(Word())
False
sage: Word().is_prefix(w)
True
sage: Word().is_prefix(Word())
True
```

is_primitive ()

Return True if self is primitive, and False otherwise.

A finite word w is *primitive* if it is not a positive integer power of a shorter word.

EXAMPLES:

```
sage: Word('1231').is_primitive()
True
sage: Word('111').is_primitive()
False
```

is_proper_prefix (*other*)

Return True if self is a proper prefix of other, and False otherwise.

EXAMPLES:

```
sage: Word('12').is_proper_prefix(Word('123'))
True
sage: Word('12').is_proper_prefix(Word('12'))
False
sage: Word().is_proper_prefix(Word('123'))
True
sage: Word('123').is_proper_prefix(Word('12'))
False
sage: Word().is_proper_prefix(Word())
False
```

is_proper_suffix (*other*)

Return True if self is a proper suffix of other, and False otherwise.

EXAMPLES:

```
sage: Word('23').is_proper_suffix(Word('123'))
True
sage: Word('12').is_proper_suffix(Word('12'))
False
sage: Word().is_proper_suffix(Word('123'))
True
sage: Word('123').is_proper_suffix(Word('12'))
False
```

is_quasiperiodic()

Return True if `self` is quasiperiodic, and False otherwise.

A finite or infinite word w is *quasiperiodic* if it can be constructed by concatenations and superpositions of one of its proper factors u , which is called a *quasiperiod* of w . See for instance [1], [2], and [3].

EXAMPLES:

```
sage: Word('abaababaabaababaaba').is_quasiperiodic()
True
sage: Word('abacaba').is_quasiperiodic()
False
sage: Word('a').is_quasiperiodic()
False
sage: Word().is_quasiperiodic()
False
sage: Word('abaaba').is_quasiperiodic()
True
```

REFERENCES:

is_rich(f=None)

Return True if `self` has defect 0, and False otherwise.

A word is *full* (or *rich*) if its defect is zero (see [1]). If f is given, then the f -palindromic defect is used (see [2]).

INPUT:

- f – involution (default: None) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

boolean – If f is None, whether `self` is full; otherwise, whether `self` is full of f -palindromes.

EXAMPLES:

```
sage: words.ThueMorseWord()[100].is_full()
False
sage: words.FibonacciWord()[100].is_full()
True
```

```
sage: Word('000000000000000').is_full()
True
sage: Word('011010011001').is_full()
False
sage: Word('2194').is_full()
True
sage: Word().is_full()
True
```

```
sage: f = WordMorphism('a->b,b->a')
sage: Word().is_full(f)
True
sage: w = Word('ab')
sage: w.is_full()
True
sage: w.is_full(f)
True
```

```
sage: f = WordMorphism('a->b,b->a')
sage: Word('abab').is_full(f)
True
sage: Word('abba').is_full(f)
False
```

A simple example of an infinite word full of f-palindromes:

```
sage: p = WordMorphism({0:'abc',1:'ab'})
sage: f = WordMorphism('a->b,b->a,c->c')
sage: p(words.FibonacciWord()[:50]).is_full(f)
True
sage: p(words.FibonacciWord()[:150]).is_full(f)
True
```

REFERENCES:

- [1] S. Brlek, S. Hamel, M. Nivat, C. Reutenauer, On the Palindromic Complexity of Infinite Words, in J. Berstel, J. Karhumäki, D. Perrin, Eds, Combinatorics on Words with Applications, International Journal of Foundation of Computer Science, Vol. 15, No. 2 (2004) 293–306.

`is_smooth_prefix()`

Return `True` if `self` is the prefix of a smooth word, and `False` otherwise.

Let $A_k = \{1, \dots, k\}$, $k \geq 2$. An infinite word w in A_k^ω is said to be *smooth* if and only if for all positive integers m , $\Delta^m(w)$ is in A_k^ω , where $\Delta(w)$ is the word obtained from w by composing the length of consecutive runs of the same letter in w . See for instance [1] and [2].

INPUT:

- `self` – must be a word over the integers to get something other than `False`

OUTPUT:

boolean – whether `self` is a smooth prefix or not

EXAMPLES:

```

sage: W = Words([1, 2])
sage: W([1, 1, 2, 2, 1, 2, 1, 1]).is_smooth_prefix()
True
sage: W([1, 2, 1, 2, 1, 2]).is_smooth_prefix()
False

```

REFERENCES:

is_square()

Return True if `self` is a square, and False otherwise.

EXAMPLES:

```

sage: Word([1,0,0,1]).is_square()
False
sage: Word('1212').is_square()
True
sage: Word('1213').is_square()
False
sage: Word('12123').is_square()
False
sage: Word().is_square()
True

```

is_square_free()

Return True if `self` does not contain squares, and False otherwise.

EXAMPLES:

```

sage: Word('12312').is_square_free()
True
sage: Word('31212').is_square_free()
False
sage: Word().is_square_free()
True

```

is_sturmian_factor()

Tell whether `self` is a factor of a Sturmian word.

The finite word `self` must be defined on a two-letter alphabet.

Equivalently, tells whether `self` is balanced. The advantage over the `is_balanced` method is that this one runs in linear time whereas `is_balanced` runs in quadratic time.

OUTPUT:

boolean – the result

EXAMPLES:

```

sage: w = Word('0111011011011101101', alphabet='01')
sage: w.is_sturmian_factor()
True

```

```

sage: words.LowerMechanicalWord(random(), alphabet='01')[:100].is_sturmian_
↪factor()
True
sage: words.CharacteristicSturmianWord(random())[:100].is_sturmian_factor()
True

```

```

sage: w = Word('aabb', alphabet='ab')
sage: w.is_sturmian_factor()
False

sage: s1 = WordMorphism('a->ab,b->b')
sage: s2 = WordMorphism('a->ba,b->b')
sage: s3 = WordMorphism('a->a,b->ba')
sage: s4 = WordMorphism('a->a,b->ab')
sage: W = Words('ab')
sage: w = W('ab')
sage: for i in range(8): w = choice([s1,s2,s3,s4])(w)
sage: w
word: abaaabaaabaabaabaabaabaabaabaabaabaaba...
sage: w.is_sturmian_factor()
True

```

Famous words:

```

sage: words.FibonacciWord()[:100].is_sturmian_factor()
True
sage: words.ThueMorseWord()[:1000].is_sturmian_factor()
False
sage: words.KolakoskiWord()[:1000].is_sturmian_factor()
False

```

REFERENCES:

AUTHOR:

•Thierry Monteil

is_subword_of(*other*)

Return True if self is a subword of other, and False otherwise.

EXAMPLES:

```

sage: Word().is_subword_of(Word('123'))
True
sage: Word('123').is_subword_of(Word('3211333213233321'))
True
sage: Word('321').is_subword_of(Word('11122212112122133111222332'))
False

```

See also:

longest_common_subword()

is_suffix(*other*)

Return True if self is a suffix of other, and False otherwise.

EXAMPLES:

```

sage: w = Word('0123456789')
sage: y = Word('56789')

```

```

sage: y.is_suffix(w)
True
sage: w.is_suffix(y)
False
sage: Word('579').is_suffix(w)
False
sage: Word().is_suffix(y)
True
sage: w.is_suffix(Word())
False
sage: Word().is_suffix(Word())
True

```

is_symmetric (*f=None*)

Return True if *self* is symmetric (or *f*-symmetric), and False otherwise.

A word is *symmetric* (resp. *f*-*symmetric*) if it is the product of two palindromes (resp. *f*-palindromes). See [1] and [2].

INPUT:

- *f* – involution (default: None) on the alphabet of *self*. It must be callable on letters as well as words (e.g. WordMorphism).

EXAMPLES:

```

sage: Word('abbabab').is_symmetric()
True
sage: Word('ababa').is_symmetric()
True
sage: Word('aababaabba').is_symmetric()
False
sage: Word('aabbbbaababba').is_symmetric()
False
sage: f = WordMorphism('a->b,b->a')
sage: Word('aabbbbaababba').is_symmetric(f)
True

```

- [2] A. de Luca, A. De Luca, Pseudopalindrome closure operators in free monoids, Theoret. Comput. Sci. 362 (2006) 282–300.

is_tangent ()

Tell whether *self* is a tangent word.

The finite word *self* must be defined on a two-letter alphabet.

A binary word is said to be *tangent* if it can appear in infinitely many cutting sequences of a smooth curve, where each cutting sequence is observed on a progressively smaller grid.

This class of words strictly contains the class of 1-balanced words, and is strictly contained in the class of 2-balanced words.

This method runs in linear time.

OUTPUT:

boolean – the result

EXAMPLES:

```
sage: w = Word('01110110110111011101', alphabet='01')
sage: w.is_tangent()
True
```

Some tangent words may not be balanced:

```
sage: Word('aabb', alphabet='ab').is_balanced()
False
sage: Word('aabb', alphabet='ab').is_tangent()
True
```

Some 2-balanced words may not be tangent:

```
sage: Word('aaabb', alphabet='ab').is_tangent()
False
sage: Word('aaabb', alphabet='ab').is_balanced(2)
True
```

Famous words:

```
sage: words.FibonacciWord()[100].is_tangent()
True
sage: words.ThueMorseWord()[1000].is_tangent()
True
sage: words.KolakoskiWord()[1000].is_tangent()
False
```

REFERENCES:

AUTHOR:

- Thierry Monteil

is_yamanouchi ($n=None$)

Return whether `self` is Yamanouchi.

A word w is Yamanouchi if, when read from right to left, it always has weakly more i 's than $i + 1$'s for all i that appear in w .

INPUT:

- n – (optional) an integer specifying the maximal letter in the alphabet

EXAMPLES:

```
sage: w = Word([1, 2, 4, 3, 2, 2, 2])
sage: w.is_yamanouchi()
False
sage: w = Word([2, 3, 4, 3, 1, 2, 1, 1, 2, 1])
sage: w.is_yamanouchi()
True
sage: w = Word([3, 1])
sage: w.is_yamanouchi(n=3)
False
sage: w.is_yamanouchi()
True
sage: w = Word([3, 1], alphabet=[1, 2, 3])
```

```

sage: w.is_yamanouchi()
False
sage: w = Word([2,1,1,2])
sage: w.is_yamanouchi()
False

```

iterated_left_palindromic_closure ($f=None$)

Return the iterated left (f -)palindromic closure of `self`.

INPUT:

- f – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

word – the left iterated f -palindromic closure of `self`.

EXAMPLES:

```

sage: Word('123').iterated_left_palindromic_closure()
word: 3231323
sage: f = WordMorphism('a->b,b->a')
sage: Word('ab').iterated_left_palindromic_closure(f=f)
word: abbaab
sage: Word('aab').iterated_left_palindromic_closure(f=f)
word: abbaabbaab

```

REFERENCES:

- A. de Luca, A. De Luca, Pseudopalindrome closure operators in free monoids, *Theoret. Comput. Sci.* 362 (2006) 282–300.

lacunas ($f=None$)

Return the list of all the lacunas of `self`.

A *lacuna* is a position in a word where the longest (f -)palindromic suffix is not unioccurrent (see [1]).

INPUT:

- f – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`). The default value corresponds to usual palindromes, i.e., f equal to the identity.

OUTPUT:

a list – list of all the lacunas of `self`

EXAMPLES:

```

sage: w = Word([0,1,1,2,3,4,5,1,13,3])
sage: w.lacunas()
[7, 9]
sage: words.ThueMorseWord()[100].lacunas()
[8, 9, 24, 25, 32, 33, 34, 35, 36, 37, 38, 39, 96, 97, 98, 99]
sage: f = WordMorphism({0:[1],1:[0]})
sage: words.ThueMorseWord()[50].lacunas(f)
[0, 2, 4, 12, 16, 17, 18, 19, 48, 49]

```

REFERENCES:

- [1] A. Blondin-Massé, S. Brlek, S. Labbé, Palindromic lacunas of the Thue-Morse word, Proc. GAS-COM 2008 (June 16-20 2008, Bibbiena, Arezzo-Italia), 53–67.

last_position_dict()

Return a dictionary that contains the last position of each letter in `self`.

EXAMPLES:

```
sage: Word('1231232').last_position_dict()
{'1': 3, '2': 6, '3': 5}
```

left_special_factors ($n=None$)

Return the left special factors (of length n).

A factor u of a word w is *left special* if there are two distinct letters a and b such that au and bu are factors of w .

INPUT:

- n – integer (optional, default: `None`). If `None`, it returns all left special factors.

OUTPUT:

a list of words

EXAMPLES:

```
sage: alpha, beta, x = 0.54, 0.294, 0.1415
sage: w = words.CodingOfRotationWord(alpha, beta, x)[:40]
sage: for i in range(5):
....:     print("{} {}".format(i, sorted(w.left_special_factors(i))))
0 [word: ]
1 [word: 0]
2 [word: 00, word: 01]
3 [word: 000, word: 010]
4 [word: 0000, word: 0101]
```

left_special_factors_iterator ($n=None$)

Return an iterator over the left special factors (of length n).

A factor u of a word w is *left special* if there are two distinct letters a and b such that au and bu are factors of w .

INPUT:

- n – integer (optional, default: `None`). If `None`, it returns an iterator over all left special factors.

EXAMPLES:

```
sage: alpha, beta, x = 0.54, 0.294, 0.1415
sage: w = words.CodingOfRotationWord(alpha, beta, x)[:40]
sage: sorted(w.left_special_factors_iterator(3))
[word: 000, word: 010]
sage: sorted(w.left_special_factors_iterator(4))
[word: 0000, word: 0101]
sage: sorted(w.left_special_factors_iterator(5))
[word: 00000, word: 01010]
```

length()

Return the length of `self`.

length_border()

Return the length of the border of `self`.

The *border* of a word is the longest word that is both a proper prefix and a proper suffix of `self`.

EXAMPLES:

```
sage: Word('121').length_border()
1
sage: Word('1').length_border()
0
sage: Word('1212').length_border()
2
sage: Word('111').length_border()
2
sage: Word().length_border() is None
True
```

length_maximal_palindrome (*j*, *m=None*, *f=None*)

Return the length of the longest palindrome centered at position *j*.

INPUT:

- *j* – rational, position of the symmetry axis of the palindrome. Must return an integer when doubled. It is an integer when the center of the palindrome is a letter.
- *m* – integer (default: `None`), minimal length of palindrome, if known. The parity of *m* can't be the same as the parity of $2j$.
- *f* – involution (default: `None`), on the alphabet. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

length of the longest *f*-palindrome centered at position *j*

EXAMPLES:

```
sage: Word('01001010').length_maximal_palindrome(3/2)
0
sage: Word('01101001').length_maximal_palindrome(3/2)
4
sage: Word('01010').length_maximal_palindrome(j=3, f='0->1,1->0')
0
sage: Word('01010').length_maximal_palindrome(j=2.5, f='0->1,1->0')
4
sage: Word('0222220').length_maximal_palindrome(3, f='0->1,1->0,2->2')
5
```

```
sage: w = Word('abcdcbaxyzzyx')
sage: w.length_maximal_palindrome(3)
7
sage: w.length_maximal_palindrome(3, 3)
7
sage: w.length_maximal_palindrome(3.5)
0
sage: w.length_maximal_palindrome(9.5)
6
sage: w.length_maximal_palindrome(9.5, 2)
6
```

lengths_lps (*f=None*)

Return the list of the length of the longest palindromic suffix (lps) for each non-empty prefix of `self`.

It corresponds to the function G_w defined in [1].

INPUT:

- f – involution (default: None) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

a list – list of the length of the longest palindromic suffix (lps) for each non-empty prefix of `self`

EXAMPLES:

```
sage: Word().lengths_lps()
[]
sage: Word('a').lengths_lps()
[1]
sage: Word('aaa').lengths_lps()
[1, 2, 3]
sage: Word('abbabaabbaab').lengths_lps()
[1, 1, 2, 4, 3, 3, 2, 4, 2, 4, 6, 8]
```

```
sage: f = WordMorphism('a->b,b->a')
sage: Word('abbabaabbaab').lengths_lps(f)
[0, 2, 0, 2, 2, 4, 6, 8, 4, 6, 4, 6]
```

```
sage: f = WordMorphism({5:[8],8:[5]})
sage: Word([5,8,5,5,8,8,5,5,8,8,5,8,5]).lengths_lps(f)
[0, 2, 2, 0, 2, 4, 6, 4, 6, 8, 10, 12, 4]
```

REFERENCES:

- [1] A. Blondin-Massé, S. Brlek, A. Frosini, S. Labbé, S. Rinaldi, Reconstructing words from a fixed palindromic length sequence, Proc. TCS 2008, 5th IFIP International Conference on Theoretical Computer Science (September 8-10 2008, Milano, Italia), accepted.

lengths_maximal_palindromes ($f=None$)

Return the length of maximal palindromes centered at each position.

INPUT:

- f – involution (default: None) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

a list – The length of the maximal palindrome (or f -palindrome) with a given symmetry axis (letter or space between two letters).

EXAMPLES:

```
sage: Word('01101001').lengths_maximal_palindromes()
[0, 1, 0, 1, 4, 1, 0, 3, 0, 3, 0, 1, 4, 1, 0, 1, 0]
sage: Word('00000').lengths_maximal_palindromes()
[0, 1, 2, 3, 4, 5, 4, 3, 2, 1, 0]
sage: Word('0').lengths_maximal_palindromes()
[0, 1, 0]
sage: Word('').lengths_maximal_palindromes()
[0]
sage: Word().lengths_maximal_palindromes()
[0]
sage: f = WordMorphism('a->b,b->a')
```

```
sage: Word('abbabaab').lengths_maximal_palindromes(f)
[0, 0, 2, 0, 0, 0, 2, 0, 8, 0, 2, 0, 0, 0, 2, 0, 0]
```

lengths_unioccurent_lps (*f=None*)

Return the list of the lengths of the unioccurent longest (*f*)-palindromic suffixes (lps) for each non-empty prefix of *self*. No unioccurent lps are indicated by *None*.

It corresponds to the function H_w defined in [1] and [2].

INPUT:

- *f* – involution (default: *None*) on the alphabet of *self*. It must be callable on letters as well as words (e.g. *WordMorphism*). The default value corresponds to usual palindromes, i.e., *f* equal to the identity.

OUTPUT:

a list – list of the length of the unioccurent longest palindromic suffix (lps) for each non-empty prefix of *self*. No unioccurent lps are indicated by *None*.

EXAMPLES:

```
sage: w = Word([0,1,1,2,3,4,5,1,13,3])
sage: w.lengths_unioccurent_lps()
[1, 1, 2, 1, 1, 1, 1, None, 1, None]
sage: f = words.FibonacciWord()[0:20]
sage: f.lengths_unioccurent_lps() == f.lengths_lps()
True
sage: t = words.ThueMorseWord()
sage: t[0:20].lengths_unioccurent_lps()
[1, 1, 2, 4, 3, 3, 2, 4, None, None, 6, 8, 10, 12, 14, 16, 6, 8, 10, 12]
sage: f = WordMorphism({1:[0],0:[1]})
sage: t[0:15].lengths_unioccurent_lps(f)
[None, 2, None, 2, None, 4, 6, 8, 4, 6, 4, 6, None, 4, 6]
```

REFERENCES:

- [1] A. Blondin-Massé, S. Brlek, S. Labbé, Palindromic lacunas of the Thue-Morse word, Proc. GAS-COM 2008 (June 16-20 2008, Bibbiena, Arezzo-Italia), 53–67.
- [2] A. Blondin-Massé, S. Brlek, A. Frosini, S. Labbé, S. Rinaldi, Reconstructing words from a fixed palindromic length sequence, Proc. TCS 2008, 5th IFIP International Conference on Theoretical Computer Science (September 8-10 2008, Milano, Italia), accepted.

letters ()

Return the list of letters that appear in this word, listed in the order of first appearance.

EXAMPLES:

```
sage: Word([0,1,1,0,1,0,0,1]).letters()
[0, 1]
sage: Word("cacao").letters()
['c', 'a', 'o']
```

longest_common_subword (*other*)

Return a longest subword of *self* and *other*.

A subword of a word is a subset of the word's letters, read in the order in which they appear in the word.

For more information, see [Wikipedia article Longest_common_subsequence_problem](#).

INPUT:

EXAMPLES:

```

sage: Word('0111').lps()
word: 111
sage: Word('011101').lps()
word: 101
sage: Word('6667').lps()
word: 7
sage: Word('abbabaab').lps()
word: baab
sage: Word().lps()
word:
sage: f = WordMorphism('a->b,b->a')
sage: Word('abbabaab').lps(f=f)
word: abbabaab
sage: w = Word('33412321')
sage: w.lps(l=3)
word: 12321
sage: Y = Word
sage: w = Y('01101001')
sage: w.lps(l=2)
word: 1001
sage: w.lps()
word: 1001
sage: w.lps(l=None)
word: 1001
sage: Y().lps(l=2)
Traceback (most recent call last):
...
IndexError: list index out of range
sage: v = Word('abbabaab')
sage: pal = v[:0]
sage: for i in range(1, v.length()+1):
....:     pal = v[:i].lps(l=pal.length())
....:     pal
word: a
word: b
word: bb
word: abba
word: bab
word: aba
word: aa
word: baab
sage: f = WordMorphism('a->b,b->a')
sage: v = Word('abbabaab')
sage: pal = v[:0]
sage: for i in range(1, v.length()+1):
....:     pal = v[:i].lps(f=f, l=pal.length())
....:     pal
word:
word: ab
word:
word: ba
word: ab
word: baba
word: bbabaa
word: abbabaab

```

lps_lengths (*f=None*)

Return the length of the longest palindromic suffix of each prefix.

INPUT:

- `f` – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

a list – The length of the longest palindromic (or `f`-palindromic) suffix of each prefix of `self`.

EXAMPLES:

```
sage: Word('01101001').lps_lengths()
[0, 1, 1, 2, 4, 3, 3, 2, 4]
sage: Word('00000').lps_lengths()
[0, 1, 2, 3, 4, 5]
sage: Word('0').lps_lengths()
[0, 1]
sage: Word('').lps_lengths()
[0]
sage: Word().lps_lengths()
[0]
sage: f = WordMorphism('a->b,b->a')
sage: Word('abbabaab').lps_lengths(f)
[0, 0, 2, 0, 2, 2, 4, 6, 8]
```

lyndon_factorization()

Return the Lyndon factorization of `self`.

The *Lyndon factorization* of a finite word w is the unique factorization of w as a non-increasing product of Lyndon words, i.e., $w = l_1 \cdots l_n$ where each l_i is a Lyndon word and $l_1 \geq \cdots \geq l_n$. See for instance [1].

OUTPUT:

the list $[l_1, \dots, l_n]$ of factors obtained

EXAMPLES:

```
sage: Word('010010010001000').lyndon_factorization()
(01, 001, 001, 0001, 0, 0, 0)
sage: Words('10')('010010010001000').lyndon_factorization()
(0, 10010010001000)
sage: Word('abbababbaababba').lyndon_factorization()
(abb, ababb, aababb, a)
sage: Words('ba')('abbababbaababba').lyndon_factorization()
(a, bbababbaaba, bba)
sage: Word([1,2,1,3,1,2,1]).lyndon_factorization()
(1213, 12, 1)
```

- [2] G. Melancon, Factorizing infinite words using Maple, MapleTech journal, vol. 4, no. 1, 1997, pp. 34-42.

major_index (*final_descent=False*)

Return the major index of `self`.

The major index of a word w is the sum of the descents of w .

With the `final_descent` option, the last position of a non-empty word is also considered as a descent.

See also:

major index on Permutations.

EXAMPLES:

```
sage: w = Word([2,1,3,3,2])
sage: w.major_index()
5
sage: w = Word([2,1,3,3,2])
sage: w.major_index(final_descent=True)
10
```

minimal_period()

Return the period of self.

Let A be an alphabet. An integer $p \geq 1$ is a *period* of a word $w = a_1a_2 \cdots a_n$ where $a_i \in A$ if $a_i = a_{i+p}$ for $i = 1, \dots, n - p$. The smallest period of w is called *the* period of w . See Chapter 1 of [1].

EXAMPLES:

```
sage: Word('aba').minimal_period()
2
sage: Word('abab').minimal_period()
2
sage: Word('ababa').minimal_period()
2
sage: Word('ababaa').minimal_period()
5
sage: Word('ababac').minimal_period()
6
sage: Word('aaaaaa').minimal_period()
1
sage: Word('a').minimal_period()
1
sage: Word().minimal_period()
1
```

REFERENCES:

- [1] M. Lothaire, Algebraic Combinatorics On Words, vol. 90 of Encyclopedia of Mathematics and its Applications, Cambridge University Press, U.K., 2002.

nb_factor_occurrences_in(other)

Return the number of times self appears as a factor in other.

EXAMPLES:

```
sage: Word().nb_factor_occurrences_in(Word('123'))
Traceback (most recent call last):
...
NotImplementedError: The factor must be non empty
sage: Word('123').nb_factor_occurrences_in(Word('112332312313112332121123'))
4
sage: Word('321').nb_factor_occurrences_in(Word('11233231231311233221123'))
0
```

nb_subword_occurrences_in(other)

Return the number of times self appears in other as a subword.

This corresponds to the notion of *binomialcoefficient* of two finite words whose properties are presented in the chapter of Lothaire's book written by Sakarovitch and Simon [1].

INPUT:

- other – finite word

EXAMPLES:

```
sage: tm = words.ThueMorseWord()

sage: u = Word([0,1,0,1])
sage: u.nb_subword_occurrences_in(tm[:1000])
2604124996

sage: u = Word([0,1,0,1,1,0])
sage: u.nb_subword_occurrences_in(tm[:100])
20370432
```

Note: This code, based on [2], actually compute the number of occurrences of all prefixes of `self` as subwords in all prefixes of `other`. In particular, its complexity is bounded by `len(self) * len(other)`.

REFERENCES:

- [1] M. Lothaire, Combinatorics on Words, Cambridge University Press, (1997).

number_of_factors (*n=None, algorithm='suffix tree'*)

Count the number of distinct factors of `self`.

INPUT:

- n – an integer, or None.
- algorithm – string (default: 'suffix tree'), takes the following values:
 - 'suffix tree' – construct and use the suffix tree of the word
 - 'naive' – algorithm uses a sliding window

OUTPUT:

If `n` is an integer, returns the number of distinct factors of length `n`. If `n` is None, returns the total number of distinct factors.

EXAMPLES:

```
sage: w = Word([1,2,1,2,3])
sage: w.number_of_factors()
13
sage: [w.number_of_factors(i) for i in range(6)]
[1, 3, 3, 3, 2, 1]
```

```
sage: w = words.ThueMorseWord()[:100]
sage: [w.number_of_factors(i) for i in range(10)]
[1, 2, 4, 6, 10, 12, 16, 20, 22, 24]
```

```
sage: Word('1213121').number_of_factors()
22
sage: Word('1213121').number_of_factors(1)
3
```

```
sage: Word('a'*100).number_of_factors()
101
sage: Word('a'*100).number_of_factors(77)
1
```

```
sage: Word().number_of_factors()
1
sage: Word().number_of_factors(17)
0
```

```
sage: blueberry = Word("blueberry")
sage: blueberry.number_of_factors()
43
sage: [blueberry.number_of_factors(i) for i in range(10)]
[1, 6, 8, 7, 6, 5, 4, 3, 2, 1]
```

number_of_inversions()

Return the number of inversions in `self`.

An inversion of a word $w = w_1 \dots w_n$ is a pair of indices (i, j) with $i < j$ and $w_i > w_j$.

See also:

number of inversions on Permutations.

EXAMPLES:

```
sage: w = Word([2,1,3,3,2])
sage: w.number_of_inversions()
3
```

number_of_left_special_factors(n)

Return the number of left special factors of length `n`.

A factor u of a word w is *left special* if there are two distinct letters a and b such that au and bu are factors of w .

INPUT:

• `n` – integer

OUTPUT:

a non-negative integer

EXAMPLES:

```
sage: w = words.FibonacciWord()[:100]
sage: [w.number_of_left_special_factors(i) for i in range(10)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
```

```
sage: w = words.ThueMorseWord()[:100]
sage: [w.number_of_left_special_factors(i) for i in range(10)]
[1, 2, 2, 4, 2, 4, 4, 2, 2, 4]
```

number_of_right_special_factors(*n*)

Return the number of right special factors of length *n*.

A factor *u* of a word *w* is *right special* if there are two distinct letters *a* and *b* such that *ua* and *ub* are factors of *w*.

INPUT:

• *n* – integer

OUTPUT:

a non-negative integer

EXAMPLES:

```
sage: w = words.FibonacciWord()[:100]
sage: [w.number_of_right_special_factors(i) for i in range(10)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
```

```
sage: w = words.ThueMorseWord()[:100]
sage: [w.number_of_right_special_factors(i) for i in range(10)]
[1, 2, 2, 4, 2, 4, 4, 2, 2, 4]
```

order()

Return the order of *self*.

Let $p(w)$ be the period of a word *w*. The positive rational number $|w|/p(w)$ is the *order* of *w*. See Chapter 8 of [1].

OUTPUT:

rational – the order

EXAMPLES:

```
sage: Word('abaaba').order()
2
sage: Word('ababaaba').order()
8/5
sage: Word('a').order()
1
sage: Word('aa').order()
2
sage: Word().order()
0
```

REFERENCES:

- [1] M. Lothaire, Algebraic Combinatorics On Words, vol. 90 of Encyclopedia of Mathematics and its Applications, Cambridge University Press, U.K., 2002.

overlap_partition(*other*, *delay=0*, *p=None*, *involution=None*)

Return the partition of the alphabet induced by the overlap of *self* and *other* with the given *delay*.

The partition of the alphabet is given by the equivalence relation obtained from the symmetric, reflexive and transitive closure of the set of pairs of letters $R_{u,v,d} = \{(u_k, v_{k-d}) : 0 \leq k < n, 0 \leq k-d < m\}$ where $u = u_0u_1 \cdots u_{n-1}$, $v = v_0v_1 \cdots v_{m-1}$ are two words on the alphabet *A* and *d* is an integer.

The equivalence relation defined by *R* is inspired from [1].

INPUT:

- other – word on the same alphabet as self
- delay – integer (default: 0)
- p – disjoint sets data structure (optional, default: None), a partition of the alphabet into disjoint sets to start with. If None, each letter start in distinct equivalence classes.
- involution – callable (optional, default: None), an involution on the alphabet. If involution is not None, the relation $R_{u,v,d} \cup R_{\text{involution}(u),\text{involution}(v),d}$ is considered.

OUTPUT:

a disjoint set data structure

EXAMPLES:

```
sage: W = Words(list('abc') + list(range(6)))
sage: u = W('abc')
sage: v = W(range(5))
sage: u.overlap_partition(v)
{{0, 'a'}, {1, 'b'}, {2, 'c'}, {3}, {4}, {5}}
sage: u.overlap_partition(v, 2)
{{'a'}, {'b'}, {0, 'c'}, {1}, {2}, {3}, {4}, {5}}
sage: u.overlap_partition(v, -1)
{{0}, {1, 'a'}, {2, 'b'}, {3, 'c'}, {4}, {5}}
```

You can re-use the same disjoint set and do more than one overlap:

```
sage: p = u.overlap_partition(v, 2)
sage: p
{{'a'}, {'b'}, {0, 'c'}, {1}, {2}, {3}, {4}, {5}}
sage: u.overlap_partition(v, 1, p)
{{'a'}, {0, 1, 'b', 'c'}, {2}, {3}, {4}, {5}}
```

The function `overlap_partition` can be used to study equations on words. For example, if a word w overlaps itself with delay d , then d is a period of w :

```
sage: W = Words(range(20))
sage: w = W(range(14)); w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13
sage: d = 5
sage: p = w.overlap_partition(w, d)
sage: m = WordMorphism(p.element_to_root_dict())
sage: w2 = m(w); w2
word: 56789567895678
sage: w2.minimal_period() == d
True
```

If a word is equal to its reversal, then it is a palindrome:

```
sage: W = Words(range(20))
sage: w = W(range(17)); w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16
sage: p = w.overlap_partition(w.reversal(), 0)
sage: m = WordMorphism(p.element_to_root_dict())
sage: w2 = m(w); w2
word: 01234567876543210
sage: w2.parent()
Finite words over {0, 1, 2, 3, 4, 5, 6, 7, 8, 17, 18, 19}
sage: w2.is_palindrome()
True
```

If the reversal of a word w is factor of its square w^2 , then w is symmetric, i.e. the product of two palindromes:

```
sage: W = Words(range(10))
sage: w = W(range(10)); w
word: 0123456789
sage: p = (w*w).overlap_partition(w.reversal(), 4)
sage: m = WordMorphism(p.element_to_root_dict())
sage: w2 = m(w); w2
word: 0110456654
sage: w2.is_symmetric()
True
```

If the image of the reversal of a word w under an involution f is factor of its square w^2 , then w is f -symmetric:

```
sage: W = Words([-11,-9,...,11])
sage: w = W([1,3,...,11])
sage: w
word: 1,3,5,7,9,11
sage: inv = lambda x:-x
sage: f = WordMorphism(dict((a, inv(a)) for a in W.alphabet()))
sage: p = (w*w).overlap_partition(f(w).reversal(), 2, involution=f)
sage: m = WordMorphism(p.element_to_root_dict())
sage: m(w)
word: 1,-1,5,7,-7,-5
sage: m(w).is_symmetric(f)
True
```

```
sage: W = Words(range(2))
sage: w = W([0,1,0,1,0,1]); w
word: 010101
sage: w.overlap_partition(w, 0)
{{0}, {1}}
sage: w.overlap_partition(w, 1)
{{0, 1}}
```

```
sage: empty = Word()
sage: empty.overlap_partition(empty, 'yo')
Traceback (most recent call last):
...
TypeError: delay (=yo) must be an integer
sage: empty.overlap_partition(empty, 2, 'yo')
Traceback (most recent call last):
...
TypeError: p(=yo) is not a DisjointSet
```

The involution input can be any callable:

```
sage: w = Words([-5,...,5])([-5..5])
sage: inv = lambda x:-x
sage: w.overlap_partition(w, 2, involution=inv)
{{-4, -2, 0, 2, 4}, {-5, -3, -1, 1, 3, 5}}
```

REFERENCES:

- [1] S. Labbé, Propriétés combinatoires des f -palindromes, Mémoire de maîtrise en Mathématiques, Montréal, UQAM, 2008, 109 pages.

palindrome_prefixes()

Return a list of all palindrome prefixes of `self`.

OUTPUT:

a list – A list of all palindrome prefixes of `self`.

EXAMPLES:

```
sage: w = Word('abaaba')
sage: w.palindrome_prefixes()
[word: , word: a, word: aba, word: abaaba]
sage: w = Word('abbbbbbbbb')
sage: w.palindrome_prefixes()
[word: , word: a]
```

palindromes($f=None$)

Return the set of all palindromic (or f -palindromic) factors of `self`.

INPUT:

- f – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

a set – If f is `None`, the set of all palindromic factors of `self`; otherwise, the set of all f -palindromic factors of `self`.

EXAMPLES:

```
sage: sorted(Word('01101001').palindromes())
[word: , word: 0, word: 00, word: 010, word: 0110, word: 1, word: 1001, word:
↪101, word: 11]
sage: sorted(Word('00000').palindromes())
[word: , word: 0, word: 00, word: 000, word: 0000, word: 00000]
sage: sorted(Word('0').palindromes())
[word: , word: 0]
sage: sorted(Word('').palindromes())
[word: ]
sage: sorted(Word().palindromes())
[word: ]
sage: f = WordMorphism('a->b,b->a')
sage: sorted(Word('abbabaab').palindromes(f))
[word: , word: ab, word: abbabaab, word: ba, word: baba, word: bbabaa]
```

palindromic_closure($side='right', f=None$)

Return the shortest palindrome having `self` as a prefix (or as a suffix if `side` is `'left'`).

See [1].

INPUT:

- `side` – `'right'` or `'left'` (default: `'right'`) the direction of the closure
- f – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

OUTPUT:

a word – If f is `None`, the right palindromic closure of `self`; otherwise, the right f -palindromic closure of `self`. If `side` is `'left'`, the left palindromic closure.

EXAMPLES:

```
sage: Word('1233').palindromic_closure()
word: 123321
sage: Word('12332').palindromic_closure()
word: 123321
sage: Word('0110343').palindromic_closure()
word: 01103430110
sage: Word('0110343').palindromic_closure(side='left')
word: 3430110343
sage: Word('01105678').palindromic_closure(side='left')
word: 876501105678
sage: w = Word('abbaba')
sage: w.palindromic_closure()
word: abbababba
```

```
sage: f = WordMorphism('a->b,b->a')
sage: w.palindromic_closure(f=f)
word: abbabaab
sage: w.palindromic_closure(f=f, side='left')
word: babaabbaba
```

REFERENCES:

- [1] A. de Luca, A. De Luca, Pseudopalindrome closure operators in free monoids, Theoret. Comput. Sci. 362 (2006) 282–300.

palindromic_lacunas_study ($f=$ `None`)

Return interesting statistics about longest (f)-palindromic suffixes and lacunas of `self` (see [1] and [2]).

Note that a word w has at most $|w| + 1$ different palindromic factors (see [3]). For f -palindromes (or pseudopalindromes or theta-palindromes), the maximum number of f -palindromic factors is $|w| + 1 - g_f(w)$, where $g_f(w)$ is the number of pairs $\{a, f(a)\}$ such that a is a letter, a is not equal to $f(a)$, and a or $f(a)$ occurs in w , see [4].

INPUT:

- f – involution (default: `None`) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`). The default value corresponds to usual palindromes, i.e., f equal to the identity.

OUTPUT:

- `list` – list of the length of the longest palindromic suffix (lps) for each non-empty prefix of `self`
- `list` – list of all the lacunas, i.e. positions where there is no unioccurrent lps
- `set` – set of palindromic factors of `self`

EXAMPLES:

```
sage: a,b,c = Word('abbabaabbaab').palindromic_lacunas_study()
sage: a
[1, 1, 2, 4, 3, 3, 2, 4, 2, 4, 6, 8]
sage: b
[8, 9]
sage: c          # random order
set([word: , word: b, word: bab, word: abba, word: bb, word: aa, word: _
↳baabbaab, word: baab, word: aba, word: aabbaa, word: a])
```

```

sage: f = WordMorphism('a->b,b->a')
sage: a,b,c = Word('abbabaab').palindromic_lacunae_study(f=f)
sage: a
[0, 2, 0, 2, 2, 4, 6, 8]
sage: b
[0, 2, 4]
sage: c          # random order
set([word: , word: ba, word: baba, word: ab, word: bbabaa, word: abbabaab])
sage: c == set([Word(), Word('ba'), Word('baba'), Word('ab'), Word('bbabaa'),
↪ Word('abbabaab')])
True

```

parikh_vector (*args, **kws)

Deprecated: Use `abelian_vector()` instead. See [trac ticket #17058](#) for details.

periods (divide_length=False)

Return a list containing the periods of `self` between 1 and $n - 1$, where n is the length of `self`.

INPUT:

- `divide_length` – boolean (default: False). When set to True, then only periods that divide the length of `self` are considered.

OUTPUT:

a list of positive integers

EXAMPLES:

```

sage: w = Word('ababab')
sage: w.periods()
[2, 4]
sage: w.periods(divide_length=True)
[2]
sage: w = Word('ababa')
sage: w.periods()
[2, 4]
sage: w.periods(divide_length=True)
[]

```

phi ()

Apply the phi function to `self` and return the result. This is the word obtained by taking the first letter of the words obtained by iterating delta on `self`.

OUTPUT:

a word – the result of the phi function

EXAMPLES:

```

sage: W = Words([1, 2])
sage: W([2, 2, 1, 1, 2, 1, 2, 2, 1, 2, 2, 1, 1, 2]).phi()
word: 222222
sage: W([2, 1, 2, 2, 1, 2, 2, 1, 2, 1]).phi()
word: 212113
sage: W().phi()
word:
sage: Word([2, 1, 2, 2, 1, 2, 2, 1, 2, 1]).phi()
word: 212113
sage: Word([2, 3, 1, 1, 2, 1, 2, 3, 1, 2, 2, 3, 1, 2]).phi()
word: 21215
sage: Word("aabbabaabaabba").phi()
word: a22222
sage: w = Word([2, 3, 1, 1, 2, 1, 2, 3, 1, 2, 2, 3, 1, 2])

```

REFERENCES:

phi_inv (*W=None*)

Apply the inverse of the phi function to *self*.

INPUT:

- self* – a word over the integers
- W* – a parent object of words defined over integers

OUTPUT:

a word – the inverse of the phi function

EXAMPLES:

```

sage: W = Words([1, 2])
sage: W([2, 2, 2, 2, 1, 2]).phi_inv()
word: 22112122
sage: W([2, 2, 2]).phi_inv(Words([2, 3]))
word: 2233

```

prefix_function_table ()

Return a vector containing the length of the proper prefix-suffixes for all the non-empty prefixes of *self*.

EXAMPLES:

```

sage: Word('121321').prefix_function_table()
[0, 0, 1, 0, 0, 1]
sage: Word('1241245').prefix_function_table()
[0, 0, 0, 1, 2, 3, 0]
sage: Word().prefix_function_table()
[]

```

primitive ()

Return the primitive of *self*.

EXAMPLES:

```
sage: Word('12312').primitive()
word: 12312
sage: Word('121212').primitive()
word: 12
```

primitive_length()

Return the length of the primitive of `self`.

EXAMPLES:

```
sage: Word('1231').primitive_length()
4
sage: Word('121212').primitive_length()
2
```

quasiperiods()

Return the quasiperiods of `self` as a list ordered from shortest to longest.

Let w be a finite or infinite word. A *quasiperiod* of w is a proper factor u of w such that the occurrences of u in w entirely cover w , i.e., every position of w falls within some occurrence of u in w . See for instance [1], [2], and [3].

EXAMPLES:

```
sage: Word('abaababaabaabaaba').quasiperiods()
[word: aba, word: abaaba, word: abaababaaba]
sage: Word('abaaba').quasiperiods()
[word: aba]
sage: Word('abacaba').quasiperiods()
[]
```

REFERENCES:

- [1] A. Apostolico, A. Ehrenfeucht, Efficient detection of quasiperiodicities in strings, Theoret. Comput. Sci. 119 (1993) 247–265.
- [2] S. Marcus, Quasiperiodic infinite words, Bull. Eur. Assoc. Theor. Comput. Sci. 82 (2004) 170-174.
- [3] A. Glen, F. Levé, G. Richomme, Quasiperiodic and Lyndon episturmian words, Preprint, 2008, arXiv:0805.0730.

rauzy_graph(n)

Return the Rauzy graph of the factors of length n of `self`.

The vertices are the factors of length n and there is an edge from u to v if $ua = bv$ is a factor of length $n + 1$ for some letters a and b .

INPUT:

- n – integer

EXAMPLES:

```
sage: w = Word(range(10)); w
word: 0123456789
sage: g = w.rauzy_graph(3); g
Looped digraph on 8 vertices
sage: WordOptions(identifier='')
sage: g.vertices()
[012, 123, 234, 345, 456, 567, 678, 789]
```

```

sage: g.edges()
[(012, 123, 3),
 (123, 234, 4),
 (234, 345, 5),
 (345, 456, 6),
 (456, 567, 7),
 (567, 678, 8),
 (678, 789, 9)]
sage: WordOptions(identifier='word: ')

```

```

sage: f = words.FibonacciWord()[:100]
sage: f.rauzy_graph(8)
Looped digraph on 9 vertices

```

```

sage: w = Word('1111111')
sage: g = w.rauzy_graph(3)
sage: g.edges()
[(word: 111, word: 111, word: 1)]

```

```

sage: w = Word('111')
sage: for i in range(5) : w.rauzy_graph(i)
Looped multi-digraph on 1 vertex
Looped digraph on 1 vertex
Looped digraph on 1 vertex
Looped digraph on 1 vertex
Looped digraph on 0 vertices

```

Multi-edges are allowed for the empty word:

```

sage: W = Words('abcde')
sage: w = W('abc')
sage: w.rauzy_graph(0)
Looped multi-digraph on 1 vertex
sage: _.edges()
[(word: , word: , word: a),
 (word: , word: , word: b),
 (word: , word: , word: c)]

```

reduced_rauzy_graph(*n*)

Return the reduced Rauzy graph of order *n* of *self*.

INPUT:

- *n* – a non-negative integer. Every vertex of a reduced Rauzy graph of order *n* is a factor of length *n* of *self*.

OUTPUT:

a looped multi-digraph

DEFINITION:

For infinite periodic words (resp. for finite words of type $u^i u[0 : j]$), the reduced Rauzy graph of order *n* (resp. for *n* smaller or equal to $(i - 1)|u| + j$) is the directed graph whose unique vertex is the prefix *p* of length *n* of *self* and which has an only edge which is a loop on *p* labelled by $w[n + 1 : |w|]p$ where *w* is the unique return word to *p*.

In other cases, it is the directed graph defined as followed. Let G_n be the Rauzy graph of order *n* of *self*. The vertices are the vertices of G_n that are either special or not prolongable to the right or to the left. For

each couple (u, v) of such vertices and each directed path in G_n from u to v that contains no other vertices that are special, there is an edge from u to v in the reduced Rauzy graph of order n whose label is the label of the path in G_n .

Note: In the case of infinite recurrent non-periodic words, this definition corresponds to the following one that can be found in [1] and [2] where a simple path is a path that begins with a special factor, ends with a special factor and contains no other vertices that are special:

The reduced Rauzy graph of factors of length n is obtained from G_n by replacing each simple path $P = v_1v_2\dots v_\ell$ with an edge v_1v_ℓ whose label is the concatenation of the labels of the edges of P .

EXAMPLES:

```
sage: w = Word(range(10)); w
word: 0123456789
sage: g = w.reduced_rauzy_graph(3); g
Looped multi-digraph on 2 vertices
sage: g.vertices()
[word: 012, word: 789]
sage: g.edges()
[(word: 012, word: 789, word: 3456789)]
```

For the Fibonacci word:

```
sage: f = words.FibonacciWord()[:100]
sage: g = f.reduced_rauzy_graph(8); g
Looped multi-digraph on 2 vertices
sage: g.vertices()
[word: 01001010, word: 01010010]
sage: g.edges()
[(word: 01001010, word: 01010010, word: 010), (word: 01010010, word: 01001010,
↪ word: 01010), (word: 01010010, word: 01001010, word: 10)]
```

For periodic words:

```
sage: from itertools import cycle
sage: w = Word(cycle('abcd'))[:100]
sage: g = w.reduced_rauzy_graph(3)
sage: g.edges()
[(word: abc, word: abc, word: dabc)]
```

```
sage: w = Word('111')
sage: for i in range(5) : w.reduced_rauzy_graph(i)
Looped digraph on 1 vertex
Looped digraph on 1 vertex
Looped digraph on 1 vertex
Looped multi-digraph on 1 vertex
Looped multi-digraph on 0 vertices
```

For ultimately periodic words:

```
sage: sigma = WordMorphism('a->abcd,b->cd,c->cd,d->cd')
sage: w = sigma.fixed_point('a')[:100]; w
word: abcdcdcdcdcdcdcdcdcdcdcdcdcdcdcdcdcdcdcdcd...
sage: g = w.reduced_rauzy_graph(5)
sage: g.vertices()
[word: abcdc, word: cdcdc]
```

```
sage: g.edges()
[(word: abcdc, word: cdcdc, word: dc), (word: cdcdc, word: cdcdc, word: dc)]
```

return_words (*fact*)

Return the set of return words of *fact* in self.

This is the set of all factors starting by the given factor and ending just before the next occurrence of this factor. See [1] and [2].

INPUT:

- fact* – a non-empty finite word

OUTPUT:

a Python set of finite words

EXAMPLES:

```
sage: Word('21331233213231').return_words(Word('2'))
{word: 213, word: 21331, word: 233}
sage: Word().return_words(Word('213'))
set()
sage: Word('121212').return_words(Word('1212'))
{word: 12}
```

```
sage: TM = words.ThueMorseWord()[:1000]
sage: sorted(TM.return_words(Word([0])))
[word: 0, word: 01, word: 011]
```

REFERENCES:

- [1] F. Durand, A characterization of substitutive sequences using return words, *Discrete Math.* 179 (1998) 89-101.
- [2] C. Holton, L.Q. Zamboni, Descendants of primitive substitutions, *Theory Comput. Syst.* 32 (1999) 133-157.

return_words_derivate (*fact*)

Return the word generated by mapping a letter to each occurrence of the return words for the given factor dropping any dangling prefix and suffix. See for instance [1].

EXAMPLES:

```
sage: Word('12131221312313122').return_words_derivate(Word('1'))
word: 123242
```

REFERENCES:

- [1] F. Durand, A characterization of substitutive sequences using return words, *Discrete Math.* 179 (1998) 89-101.

rev_lex_less (*other*)

Return True if the word `self` is reverse lexicographically less than `other`.

EXAMPLES:

```
sage: Word([1,2,4]).rev_lex_less(Word([1,3,2]))
True
sage: Word([3,2,1]).rev_lex_less(Word([1,2,3]))
False
```

reversal ()

Return the reversal of `self`.

EXAMPLES:

```
sage: Word('124563').reversal()
word: 365421
```

rfind (*sub*, *start*=0, *end*=None)

Return the index of the last occurrence of `sub` in `self`, such that `sub` is contained within `self[start:end]`. Return -1 on failure.

INPUT:

- `sub` – string, list, tuple or word to search for.
- `start` – non-negative integer (default: 0) specifying the position at which the search must stop.
- `end` – non-negative integer (default: None) specifying the position from which to start the search. If None, then the search is performed up to the end of the string.

OUTPUT:

a non-negative integer or -1

EXAMPLES:

```
sage: w = Word([0,1,0,0,1])
sage: w.rfind(Word([0,1]))
3
```

The `sub` parameter can also be a list or a tuple:

```
sage: w.rfind([0,1])
3
sage: w.rfind((0,1))
3
```

Examples using the argument `start` and `end`:

```
sage: w.rfind(Word([0,1]), end=4)
0
sage: w.rfind(Word([0,1]), end=5)
3
sage: w.rfind(Word([0,0]), start=2, end=5)
2
sage: w.rfind(Word([0,0]), start=3, end=5)
-1
```

Instances of `Word_str` handle string inputs as well:

```

sage: w = Word('abac')
sage: w.rfind('a')
2
sage: w.rfind(Word('a'))
2
sage: w.rfind([0,1])
-1

```

right_special_factors (*n=None*)

Return the right special factors (of length *n*).

A factor *u* of a word *w* is *right special* if there are two distinct letters *a* and *b* such that *ua* and *ub* are factors of *w*.

INPUT:

- *n* – integer (optional, default: None). If None, it returns all right special factors.

OUTPUT:

a list of words

EXAMPLES:

```

sage: w = words.ThueMorseWord()[:30]
sage: for i in range(5):
....:     print("{} {}".format(i, sorted(w.right_special_factors(i))))
0 [word: ]
1 [word: 0, word: 1]
2 [word: 01, word: 10]
3 [word: 001, word: 010, word: 101, word: 110]
4 [word: 0110, word: 1001]

```

right_special_factors_iterator (*n=None*)

Return an iterator over the right special factors (of length *n*).

A factor *u* of a word *w* is *right special* if there are two distinct letters *a* and *b* such that *ua* and *ub* are factors of *w*.

INPUT:

- *n* – integer (optional, default: None). If None, it returns an iterator over all right special factors.

EXAMPLES:

```

sage: alpha, beta, x = 0.61, 0.54, 0.3
sage: w = words.CodingOfRotationWord(alpha, beta, x)[:40]
sage: sorted(w.right_special_factors_iterator(3))
[word: 010, word: 101]
sage: sorted(w.right_special_factors_iterator(4))
[word: 0101, word: 1010]
sage: sorted(w.right_special_factors_iterator(5))
[word: 00101, word: 11010]

```

robinson_schensted()

Return the semistandard tableau and standard tableau pair obtained by running the Robinson-Schensted algorithm on *self*.

This can also be done by running *RSK()* on *self*.

EXAMPLES:

```
sage: Word([1,1,3,1,2,3,1]).robinson_schensted()
[[[1, 1, 1, 1, 3], [2], [3]], [[1, 2, 3, 5, 6], [4], [7]]]
```

schuetzenberger_involution (*n=None*)

Return the Schützenberger involution of the word `self`, which is obtained by reverting the word and then complementing all letters within the underlying ordered alphabet. If `n` is specified, the underlying alphabet is assumed to be $[1, 2, \dots, n]$. If no alphabet is specified, `n` is the maximal letter appearing in `self`.

INPUT:

- `self` – a word
- `n` – an integer specifying the maximal letter in the alphabet (optional)

OUTPUT:

a word, the Schützenberger involution of `self`

EXAMPLES:

```
sage: w = Word([9,7,4,1,6,2,3])
sage: v = w.schuetzenberger_involution(); v
word: 7849631
sage: v.parent()
Finite words over Set of Python objects of type 'object'

sage: w = Word([1,2,3], alphabet=[1,2,3,4,5])
sage: v = w.schuetzenberger_involution(); v
word: 345
sage: v.parent()
Finite words over {1, 2, 3, 4, 5}

sage: w = Word([1,2,3])
sage: v = w.schuetzenberger_involution(n=5); v
word: 345
sage: v.parent()
Finite words over Set of Python objects of type 'object'

sage: w = Word([11,32,69,2,53,1,2,3,18,41])
sage: w.schuetzenberger_involution()
word: 29,52,67,68,69,17,68,1,38,59

sage: w = Word([], alphabet=[1,2,3,4,5])
sage: w.schuetzenberger_involution()
word:

sage: w = Word([])
sage: w.schuetzenberger_involution()
word:
```

shifted_shuffle (*other, shift=None*)

Return the combinatorial class representing the shifted shuffle product between words `self` and `other`. This is the same as the shuffle product of `self` with the word obtained from `other` by incrementing its values (i.e. its letters) by the given `shift`.

INPUT:

- `other` – finite word over the integers
- `shift` – integer or `None` (default: `None`) added to each letter of `other`. When `shift` is `None`, it is replaced by `self.length()`

OUTPUT:

combinatorial class of shifted shuffle products of self and other

EXAMPLES:

```
sage: w = Word([0,1,1])
sage: sp = w.shifted_shuffle(w); sp
Shuffle product of word: 011 and word: 344
sage: sp = w.shifted_shuffle(w, 2); sp
Shuffle product of word: 011 and word: 233
sage: sp.cardinality()
20
sage: WordOptions(identifier='')
sage: sp.list()
[011233, 012133, 012313, 012331, 021133, 021313, 021331, 023113, 023131,
↪023311, 201133, 201313, 201331, 203113, 203131, 203311, 230113, 230131,
↪230311, 233011]
sage: WordOptions(identifier='word: ')
sage: y = Word('aba')
sage: y.shifted_shuffle(w,2)
Traceback (most recent call last):
...
ValueError: for shifted shuffle, words must only contain integers as letters
```

shuffle (*other*, *overlap=0*)

Return the combinatorial class representing the shuffle product between words self and other. This consists of all words of length `self.length()+other.length()` that have both self and other as subwords.

If `overlap` is non-zero, then the combinatorial class representing the shuffle product with overlaps is returned. The calculation of the shift in each overlap is done relative to the order of the alphabet. For example, *a* shifted by *a* is *b* in the alphabet $[a, b, c]$ and 0 shifted by 1 in $[0, 1, 2, 3]$ is 2.

INPUT:

- `other` – finite word
- `overlap` – (default: 0) integer or True

OUTPUT:

combinatorial class of shuffle product of self and other

EXAMPLES:

```
sage: ab = Word("ab")
sage: cd = Word("cd")
sage: sp = ab.shuffle(cd); sp
Shuffle product of word: ab and word: cd
sage: sp.cardinality()
6
sage: sp.list()
[word: abcd, word: acbd, word: acdb, word: cabd, word: cadb, word: cdab]
sage: w = Word([0,1])
sage: u = Word([2,3])
sage: w.shuffle(w)
Shuffle product of word: 01 and word: 01
sage: u.shuffle(u)
Shuffle product of word: 23 and word: 23
sage: w.shuffle(u)
```

```

Shuffle product of word: 01 and word: 23
sage: w.shuffle(u,2)
Overlapping shuffle product of word: 01 and word: 23 with 2 overlaps

```

standard_factorization()

Return the standard factorization of `self`.

The *standard factorization* of a word w of length greater than 1 is the factorization $w = uv$ where v is the longest proper suffix of w that is a Lyndon word.

Note that if w is a Lyndon word of length greater than 1 with standard factorization $w = uv$, then u and v are also Lyndon words and $u < v$.

See for instance [1], [2] and [3].

INPUT:

- `self` – finite word of length greater than 1

OUTPUT:

2-tuple (u, v)

EXAMPLES:

```

sage: Words('01')('0010110011').standard_factorization()
(word: 001011, word: 0011)
sage: Words('123')('1223312').standard_factorization()
(word: 12233, word: 12)
sage: Word([3,2,1]).standard_factorization()
(word: 32, word: 1)

```

```

sage: w = Word('0010110011', alphabet='01')
sage: w.standard_factorization()
(word: 001011, word: 0011)
sage: w = Word('0010110011', alphabet='10')
sage: w.standard_factorization()
(word: 001011001, word: 1)
sage: w = Word('1223312', alphabet='123')
sage: w.standard_factorization()
(word: 12233, word: 12)

```

standard_permutation()

Return the standard permutation of the word `self` on the ordered alphabet. It is defined as the permutation with exactly the same number of inversions as w . Equivalently, it is the permutation of minimal length whose inverse sorts `self`.

EXAMPLES:

```

sage: w = Word([1,2,3,2,2,1]); w
word: 123221

```

```

sage: p = w.standard_permutation(); p
[1, 3, 6, 4, 5, 2]
sage: v = Word(p.inverse().action(w)); v
word: 112223
sage: filter(lambda q: q.length() <= p.length() and \
....:         q.inverse().action(w) == list(v), \
....:         Permutations(w.length()) )
[[1, 3, 6, 4, 5, 2]]

```

```

sage: w = Words([1,2,3])([1,2,3,2,2,1,2,1]); w
word: 12322121
sage: p = w.standard_permutation(); p
[1, 4, 8, 5, 6, 2, 7, 3]
sage: Word(p.inverse().action(w))
word: 11122223

```

```

sage: w = Words([3,2,1])([1,2,3,2,2,1,2,1]); w
word: 12322121
sage: p = w.standard_permutation(); p
[6, 2, 1, 3, 4, 7, 5, 8]
sage: Word(p.inverse().action(w))
word: 32222111

```

```

sage: w = Words('ab')('abbaba'); w
word: abbaba
sage: p = w.standard_permutation(); p
[1, 4, 5, 2, 6, 3]
sage: Word(p.inverse().action(w))
word: aaabbb

```

```

sage: w = Words('ba')('abbaba'); w
word: abbaba
sage: p = w.standard_permutation(); p
[4, 1, 2, 5, 3, 6]
sage: Word(p.inverse().action(w))
word: bbbaaa

```

sturmian_desubstitute_as_possible()

Sturmian-desubstitute the word `self` as much as possible.

The finite word `self` must be defined on a two-letter alphabet or use at most two letters.

It can be Sturmian desubstituted if one letter appears isolated: the Sturmian desubstitution consists in removing one letter per run of the non-isolated letter. The accelerated Sturmian desubstitution consists in removing a run equal to the length of the shortest inner run from any run of the non-isolated letter (including possible leading and trailing runs even if they have shorter length). The (accelerated) Sturmian desubstitution is done as much as possible. A word is a factor of a Sturmian word if, and only if, the result is the empty word.

OUTPUT:

a finite word defined on a two-letter alphabet

EXAMPLES:

```

sage: u = Word('10111101101110111', alphabet='01') ; u
word: 10111101101110111
sage: v = u.sturmian_desubstitute_as_possible() ; v

```

```

word: 01100101
sage: v == v.sturmian_desubstitute_as_possible()
True

sage: Word('azaazaaazaaazaaaz', alphabet='az').sturmian_desubstitute_as_
↳ possible()
word:

```

AUTHOR:

•Thierry Monteil

suffix_tree()

Alias for `implicit_suffix_tree()`.

EXAMPLES:

```

sage: Word('abbabaab').suffix_tree()
Implicit Suffix Tree of the word: abbabaab

```

suffix_trie()

Return the suffix trie of `self`.

The *suffix trie* of a finite word w is a data structure representing the factors of w . It is a tree whose edges are labelled with letters of w , and whose leafs correspond to suffixes of w .

Type `sage.combinat.words.suffix_trees.SuffixTrie?` for more information.

EXAMPLES:

```

sage: w = Word("cacao")
sage: w.suffix_trie()
Suffix Trie of the word: cacao

```

```

sage: w = Word([0,1,0,1,1])
sage: w.suffix_trie()
Suffix Trie of the word: 01011

```

swap(*i*, *j*=None)

Return the word w with entries at positions i and j swapped. By default, $j = i+1$.

EXAMPLES:

```

sage: Word([1,2,3]).swap(0,2)
word: 321
sage: Word([1,2,3]).swap(1)
word: 132
sage: Word("abba").swap(1,-1)
word: aabb

```

swap_decrease(*i*)

Return the word with positions i and $i+1$ exchanged if `self[i] < self[i+1]`. Otherwise, it returns `self`.

EXAMPLES:

```

sage: w = Word([1,3,2])
sage: w.swap_decrease(0)
word: 312
sage: w.swap_decrease(1)

```

```

word: 132
sage: w.swap_decrease(1) is w
True
sage: Words("ab")("abba").swap_decrease(0)
word: baba
sage: Words("ba")("abba").swap_decrease(0)
word: abba

```

swap_increase(*i*)

Return the word with positions *i* and *i*+1 exchanged if `self[i] > self[i+1]`. Otherwise, it returns `self`.

EXAMPLES:

```

sage: w = Word([1,3,2])
sage: w.swap_increase(1)
word: 123
sage: w.swap_increase(0)
word: 132
sage: w.swap_increase(0) is w
True
sage: Words("ab")("abba").swap_increase(0)
word: abba
sage: Words("ba")("abba").swap_increase(0)
word: baba

```

to_integer_list()

Return a list of integers from `[0, 1, ..., self.length()-1]` in the same relative order as the letters in `self` in the parent.

EXAMPLES:

```

sage: from itertools import count
sage: w = Word('abbabaaab')
sage: w.to_integer_list()
[0, 1, 1, 0, 1, 0, 0, 1]
sage: w = Word(iter("cacao"), length="finite")
sage: w.to_integer_list()
[1, 0, 1, 0, 2]
sage: w = Words([3,2,1])([2,3,3,1])
sage: w.to_integer_list()
[1, 0, 0, 2]

```

to_integer_word()

Return a word defined over the integers `[0, 1, ..., self.length()-1]` whose letters are in the same relative order in the parent.

EXAMPLES:

```

sage: from itertools import count
sage: w = Word('abbabaaab')
sage: w.to_integer_word()
word: 01101001
sage: w = Word(iter("cacao"), length="finite")
sage: w.to_integer_word()
word: 10102

sage: w = Words([3,2,1])([2,3,3,1])

```

```
sage: w.to_integer_word()
word: 1002
```

to_monoid_element()

Return self as an element of the free monoid with the same alphabet as self.

EXAMPLES:

```
sage: w = Word('aabb')
sage: w.to_monoid_element()
a^2*b^2
sage: W = Words('abc')
sage: w = W(w)
sage: w.to_monoid_element()
a^2*b^2
```

topological_entropy(n)

Return the topological entropy for the factors of length n.

The topological entropy of a sequence u is defined as the exponential growth rate of the complexity of u as the length increases: $H_{top}(u) = \lim_{n \rightarrow \infty} \frac{\log_d(p_u(n))}{n}$ where d denotes the cardinality of the alphabet and $p_u(n)$ is the complexity function, i.e. the number of factors of length n in the sequence u [1].

INPUT:

- self – a word defined over a finite alphabet
- n – positive integer

OUTPUT:

real number (a symbolic expression)

EXAMPLES:

```
sage: W = Words([0, 1])
sage: w = W([0, 1, 0, 0, 0, 1, 1, 0, 0, 1, 0, 1])
sage: t = w.topological_entropy(3); t
1/3*log(7)/log(2)
sage: n(t)
0.935784974019201
```

```
sage: w = words.ThueMorseWord()[:100]
sage: topo = w.topological_entropy
sage: for i in range(0, 41, 5):
....:     print("{} {}".format(i, n(topo(i), digits=5)))
0 1.0000
5 0.71699
10 0.48074
15 0.36396
20 0.28774
25 0.23628
30 0.20075
35 0.17270
40 0.14827
```

If no alphabet is specified, an error is raised:

```
sage: w = Word(range(20))
sage: w.topological_entropy(3)
```

```
Traceback (most recent call last):
...
TypeError: The word must be defined over a finite alphabet
```

The following is ok:

```
sage: W = Words(range(20))
sage: w = W(range(20))
sage: w.topological_entropy(3)
1/3*log(18)/log(20)
```

[1] N. Pytheas Fogg, Substitutions in Dynamics, Arithmetics, and Combinatorics, Lecture Notes in Mathematics 1794, Springer Verlag. V. Berthe, S. Ferenczi, C. Mauduit and A. Siegel, Eds. (2002).

`sage.combinat.words.finite_word.evaluation_dict(w)`

Return a dictionary keyed by the letters occurring in `w` with values the number of occurrences of the letter.

INPUT:

• `w` – a word

```
sage: evaluation_dict('1213121') # keys appear in random order
{'1': 4, '2': 2, '3': 1}
```

5.1.336 Infinite word

AUTHORS:

- Sebastien Labbe
- Franco Saliola

EXAMPLES:

Creation of an infinite word

Periodic infinite words:

```
sage: v = Word([0, 4, 8, 8, 3])
sage: vv = v^Infinity
sage: vv
word: 048830488304883048830488304883048830488304883...
```

Infinite words from a function $f : \mathbb{N} \rightarrow A$ over an alphabet A :

```
sage: Word(lambda n: n%3)
word: 0120120120120120120120120120120120...
```

```
sage: def t(n):
....:     return add(Integer(n).digits(base=2)) % 2
sage: Word(t, alphabet = [0, 1])
word: 0110100110010110100101100110100110010110...
```

or as a one-liner:

```
sage: Word(lambda n : add(Integer(n).digits(base=2)) % 2, alphabet = [0, 1])
word: 0110100110010110100101100110100110010110...
```

Infinite words from iterators:

```
sage: from itertools import count, repeat
sage: Word( repeat(4) )
word: 444444444444444444444444444444444444...
sage: Word( count() )
word: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29,
↳ 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, ...
```

Infinite words from morphism

For example, let $A = \{a, b\}$ and $\mu : A^* \rightarrow A^*$ be the morphism defined by $a \mapsto ab, b \mapsto ba$:

```
sage: mu = WordMorphism('a->ab,b->ba'); mu
WordMorphism: a->ab, b->ba
sage: mu.fixed_point('a')
word: abbabaabbaababbabaababbaabbabaabbaababba...
```

Infinite words in a specific combinatorial class:

```
sage: W = InfiniteWords("ab"); W  
Infinite words over {'a', 'b'}  
sage: f = lambda n : 'a' if n % 2 == 1 else 'b'  
sage: W(f)  
word: bababababababababababababababababababa...
```

```
class sage.combinat.words.infinite_word.InfiniteWord_class
```

Bases: `sage.combinat.words.abstract_word.Word_class`

length()

Returns the length of self.

EXAMPLES:

```
sage: f = lambda n : n % 6
sage: w = Word(f); w
word: 0123450123450123450123450123450123...
sage: w.length()
+Infinity
```

5.1.337 Word morphisms/substitutions

This modules implements morphisms over finite and infinite words.

AUTHORS:

- Sebastien Labbe (2007-06-01): initial version
- Sebastien Labbe (2008-07-01): merged into sage-words
- Sebastien Labbe (2008-12-17): merged into sage
- Sebastien Labbe (2009-02-03): words next generation
- Sebastien Labbe (2009-11-20): allowing the choice of the datatype of the image. Doc improvements.
- Stepan Starosta (2012-11-09): growing letters

EXAMPLES:

Creation of a morphism from a dictionary or a string:

```
sage: n = WordMorphism({0:[0,2,2,1],1:[0,2],2:[2,2,1]})
```

```
sage: m = WordMorphism('x->xyxsxss,s->xyss,y->ys')
```

```
sage: n
WordMorphism: 0->0221, 1->02, 2->221
sage: m
WordMorphism: s->xyss, x->xyxsxss, y->ys
```

The codomain may be specified:

```
sage: WordMorphism({0:[0,2,2,1],1:[0,2],2:[2,2,1]}, codomain=Words([0,1,2,3,4]))
WordMorphism: 0->0221, 1->02, 2->221
```

Power of a morphism:

```
sage: n^2
WordMorphism: 0->022122122102, 1->0221221, 2->22122102
```

Image under a morphism:

```
sage: m('y')
word: ys
sage: m('xxsxy')
word: xyxsxssxyxsxssxyxsxssxyssys
```

Iterated image under a morphism:

```
sage: m('y', 3)
word: ysyssxyxsxssysxyssxyss
```

Infinite fixed point of morphism:

```
sage: fix = m.fixed_point('x')
sage: fix
word: xyxsxssysxyxsxssxyssxyxsxssxyssxyssxyss...
sage: fix.length()
+Infinity
```

Incidence matrix:

```
sage: matrix(m)
[2 3 1]
[1 3 0]
[1 1 1]
```

Many other functionalities...:

```
sage: m.is_identity()
False
sage: m.is_endomorphism()
True
```

class `sage.combinat.words.morphism.PeriodicPointIterator(m, cycle)`

Bases: `object`

(Lazy) constructor of the periodic points of a word morphism.

This class is mainly used in `WordMorphism.periodic_point` and `WordMorphism.periodic_points`.

EXAMPLES:

```
sage: from sage.combinat.words.morphism import PeriodicPointIterator
sage: s = WordMorphism('a->bacca,b->cba,c->aab')
sage: p = PeriodicPointIterator(s, ['a','b','c'])
sage: p._cache[0]
lazy list ['a', 'a', 'b', ...]
sage: p._cache[1]
lazy list ['b', 'a', 'c', ...]
sage: p._cache[2]
lazy list ['c', 'b', 'a', ...]
```

get_iterator(i)

Internal method.

EXAMPLES:

```
sage: from sage.combinat.words.morphism import PeriodicPointIterator
sage: s = WordMorphism('a->bacca,b->cba,c->aab')
sage: p = PeriodicPointIterator(s, ['a','b','c'])
sage: p.get_iterator(0)
<generator object get_iterator at ...>
```

class `sage.combinat.words.morphism.WordMorphism(data, domain=None, codomain=None)`

Bases: `sage.structure.sage_object.SageObject`

WordMorphism class

EXAMPLES:

```
sage: n = WordMorphism({0:[0,2,2,1],1:[0,2],2:[2,2,1]})
sage: m = WordMorphism('x->xyxsxss,s->xyss,y->ys')
```

Power of a morphism:

```
sage: n^2
WordMorphism: 0->022122122102, 1->0221221, 2->22122102
```

Image under a morphism:

```
sage: m('y')
word: ys
sage: m('xxsxy')
word: xysxsxssxysxsxssxysxssxys
```

Iterated image under a morphism:

```
sage: m('y', 3)
word: yxsxysxysxsxssxysxysxys
```

See more examples in the documentation of the call method (`m.__call__?`).

Infinite fixed point of morphism:

```

sage: fix = m.fixed_point('x')
sage: fix
word: xyxsxssysxyxsxssxyssxyxsxssxyssxyssysxys...
sage: fix.length()
+Infinity

```

Incidence matrix:

```

sage: matrix(m)
[2 3 1]
[1 3 0]
[1 1 1]

```

Many other functionalities...:

```

sage: m.is_identity()
False
sage: m.is_endomorphism()
True

```

abelian_rotation_subspace()

Returns the subspace on which the incidence matrix of `self` acts by roots of unity.

EXAMPLES:

```

sage: WordMorphism('0->1,1->0').abelian_rotation_subspace()
Vector space of degree 2 and dimension 2 over Rational Field
Basis matrix:
[1 0]
[0 1]
sage: WordMorphism('0->01,1->10').abelian_rotation_subspace()
Vector space of degree 2 and dimension 0 over Rational Field
Basis matrix:
[]
sage: WordMorphism('0->01,1->1').abelian_rotation_subspace()
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[0 1]
sage: WordMorphism('1->122,2->211').abelian_rotation_subspace()
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[ 1 -1]
sage: WordMorphism('0->1,1->102,2->3,3->4,4->2').abelian_rotation_subspace()
Vector space of degree 5 and dimension 3 over Rational Field
Basis matrix:
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]

```

The domain needs to be equal to the codomain:

```

sage: WordMorphism('0->1,1->', codomain=Words('01')).abelian_rotation_
↪subspace()
Vector space of degree 2 and dimension 0 over Rational Field
Basis matrix:
[]

```

codomain()

Returns the codomain of `self`.

EXAMPLES:

```
sage: WordMorphism('a->ab,b->a').codomain()
Finite words over {'a', 'b'}
sage: WordMorphism('6->ab,y->5,0->asd').codomain()
Finite words over {'5', 'a', 'b', 'd', 's'}
```

conjugate (*pos*)

Returns the morphism where the image of the letter by `self` is conjugated of parameter `pos`.

INPUT:

- `pos` - integer

EXAMPLES:

```
sage: m = WordMorphism('a->abcde')
sage: m.conjugate(0) == m
True
sage: m.conjugate(1)
WordMorphism: a->bcdea
sage: m.conjugate(3)
WordMorphism: a->deabc
sage: WordMorphism('').conjugate(4)
WordMorphism:
sage: m = WordMorphism('a->abcde,b->xyz')
sage: m.conjugate(2)
WordMorphism: a->cdeab, b->zxy
```

domain ()

Returns domain of `self`.

EXAMPLES:

```
sage: WordMorphism('a->ab,b->a').domain()
Finite words over {'a', 'b'}
sage: WordMorphism('b->ba,a->ab').domain()
Finite words over {'a', 'b'}
sage: WordMorphism('6->ab,y->5,0->asd').domain()
Finite words over {'0', '6', 'y'}
```

dual_map (*k=1*)

Return the dual map E_k^* of `self` (see [1]).

Note: It is actually implemented only for $k = 1$.

INPUT:

- `self` - unimodular endomorphism defined on integers 1, 2, \ldots, d
- `k` - integer (optional, default: 1)

OUTPUT:

an instance of `E1Star` - the dual map

EXAMPLES:

```
sage: sigma = WordMorphism({1:[2],2:[3],3:[1,2]})
sage: sigma.dual_map()
E_1^(1->2, 2->3, 3->12)
```

```
sage: sigma.dual_map(k=2)
Traceback (most recent call last):
...
NotImplementedError: The dual map E_k^* is implemented only for k = 1 (not 2)
```

REFERENCES:

- [1] Sano, Y., Arnoux, P. and Ito, S., Higher dimensional extensions of substitutions and their dual maps, Journal d'Analyse Mathématique 83 (2001), 183-206.

extend_by (*other*)

Returns self extended by other.

Let $\varphi_1 : A^* \rightarrow B^*$ and $\varphi_2 : C^* \rightarrow D^*$ be two morphisms. A morphism $\mu : (A \cup C)^* \rightarrow (B \cup D)^*$ corresponds to φ_1 *extended by* φ_2 if $\mu(a) = \varphi_1(a)$ if $a \in A$ and $\mu(a) = \varphi_2(a)$ otherwise.

INPUT:

- other - a WordMorphism.

OUTPUT:

WordMorphism

EXAMPLES:

```
sage: m = WordMorphism('a->ab,b->ba')
sage: n = WordMorphism({0:1,1:0,'a':5})
sage: m.extend_by(n)
WordMorphism: 0->1, 1->0, a->ab, b->ba
sage: n.extend_by(m)
WordMorphism: 0->1, 1->0, a->5, b->ba
sage: m.extend_by(m)
WordMorphism: a->ab, b->ba
```

```
sage: m.extend_by(4)
Traceback (most recent call last):
...
TypeError: other (=4) is not a WordMorphism
```

fixed_point (*letter*)

Returns the fixed point of self beginning by the given letter.

A fixed point of morphism φ is a word w such that $\varphi(w) = w$.

INPUT:

- self - an endomorphism, must be prolongable on letter
- letter - in the domain of self, the first letter of the fixed point.

OUTPUT:

- word - the fixed point of self beginning with letter.

EXAMPLES:

```
sage: W = FiniteWords('abc')
```

1. Infinite fixed point:

```

sage: WordMorphism('a->ab,b->ba').fixed_point(letter='a')
word: abbabaabbaababbabaababbaabbabaabbaababba...
sage: WordMorphism('a->ab,b->a').fixed_point(letter='a')
word: abaababaabaababaababaabaababaabaabaaba...
sage: WordMorphism('a->ab,b->b,c->ba', codomain=W).fixed_point(letter='a')
word: abbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbb...

```

2. Infinite fixed point of an erasing morphism:

```

sage: WordMorphism('a->ab,b->,c->ba', codomain=W).fixed_point(letter='a')
word: ab

```

3. Finite fixed point:

```

sage: WordMorphism('a->ab,b->b,c->ba', codomain=W).fixed_point(letter='b')
word: b
sage: _.parent()
Finite words over {'a', 'b', 'c'}

sage: WordMorphism('a->ab,b->cc,c->', codomain=W).fixed_point(letter='a')
word: abcc
sage: _.parent()
Finite words over {'a', 'b', 'c'}

sage: m = WordMorphism('a->abc,b->,c->')
sage: fp = m.fixed_point('a'); fp
word: abc

sage: m = WordMorphism('a->ba,b->')
sage: m('ba')
word: ba
sage: m.fixed_point('a') #todo: not implemented
word: ba

```

5. Fixed point of a power of a morphism:

```

sage: m = WordMorphism('a->ba,b->ab')
sage: (m^2).fixed_point(letter='a')
word: abbabaabbaababbabaababbaabbabaabbaababba...

```

fixed_points()

Returns the list of all fixed points of self.

EXAMPLES:

```

sage: f = WordMorphism('a->ab,b->ba')
sage: for w in f.fixed_points(): print(w)
abbabaabbaababbabaababbaabbabaabbaababba...
baababbaabbaababbabaabbaababbaabbaabaab...

sage: f = WordMorphism('a->ab,b->c,c->a')
sage: for w in f.fixed_points(): print(w)
abcaababcbcaabcaababcaababcbcaababcbabc...

sage: f = WordMorphism('a->ab,b->cab,c->bcc')

```

```
sage: for w in f.fixed_points(): print(w)
abcabbccabcbcabbbccbccabcbcabbbccab...
```

This shows that ticket [trac ticket #13668](#) has been resolved:

```
sage: d = {1:[1,2],2:[2,3],3:[4],4:[5],5:[6],6:[7],7:[8],8:[9],9:[10],10:[1]}
sage: s = WordMorphism(d)
sage: s7 = s^7
sage: s7.fixed_points()
[word: 12232342..., word: 2,3,4,5,6,7,8...]
sage: s7r = s7.reversal()
sage: s7r.periodic_point(2)
word: 2,1,1,10,9,8,7,6,5,4,3,2,1,10,9,8,7,6,5,4,3,2,10,9,8,7,6,5,4,3,2,9,8,7,
↪ 6,5,4,3,2,8,...
```

This shows that ticket [trac ticket #13668](#) has been resolved:

```
sage: s = "1->321331332133133,2->133321331332133133,3->
↪ 2133133133321331332133133"
sage: s = WordMorphism(s)
sage: (s^2).fixed_points()
[]
```

growing_letters()

Returns the list of growing letters.

See [is_growing\(\)](#) for more information.

EXAMPLES:

```
sage: WordMorphism('0->01,1->10').growing_letters()
['0', '1']
sage: WordMorphism('0->01,1->1').growing_letters()
['0']
sage: WordMorphism('0->01,1->0,2->1', codomain=Words('012')).growing_letters()
['0', '1', '2']
```

has_conjugate_in_classP(f=None)

Returns True if `self` has a conjugate in class f - P .

DEFINITION : Let A be an alphabet. We say that a primitive substitution S is in the class P if there exists a palindrome p and for each $b \in A$ a palindrome q_b such that $S(b) = pq_b$ for all $b \in A$. [1]

Let f be an involution on A . We say that a morphism φ is in class f - P if there exists an f -palindrome p and for each $\alpha \in A$ there exists an f -palindrome q_α such that $\varphi(\alpha) = pq_\alpha$. [2]

INPUT:

- f - involution (default: None) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

REFERENCES:

- [1] Hof, A., O. Knill et B. Simon, Singular continuous spectrum for palindromic Schrödinger operators, Commun. Math. Phys. 174 (1995) 149-159.
- [2] Labbe, Sebastien. Propriétés combinatoires des f -palindromes, Memoire de maitrise en Mathématiques, Montreal, UQAM, 2008, 109 pages.

EXAMPLES:

```

sage: fibo = WordMorphism('a->ab,b->a')
sage: fibo.has_conjugate_in_classP()
True
sage: (fibo^2).is_in_classP()
False
sage: (fibo^2).has_conjugate_in_classP()
True

```

has_left_conjugate()

Returns True if all the non empty images of self begins with the same letter.

EXAMPLES:

```

sage: m = WordMorphism('a->abcde,b->xyz')
sage: m.has_left_conjugate()
False
sage: WordMorphism('b->xyz').has_left_conjugate()
True
sage: WordMorphism('').has_left_conjugate()
True
sage: WordMorphism('a->,b->xyz').has_left_conjugate()
True
sage: WordMorphism('a->abbab,b->abb').has_left_conjugate()
True
sage: WordMorphism('a->abbab,b->abb,c->').has_left_conjugate()
True

```

has_right_conjugate()

Returns True if all the non empty images of self ends with the same letter.

EXAMPLES:

```

sage: m = WordMorphism('a->abcde,b->xyz')
sage: m.has_right_conjugate()
False
sage: WordMorphism('b->xyz').has_right_conjugate()
True
sage: WordMorphism('').has_right_conjugate()
True
sage: WordMorphism('a->,b->xyz').has_right_conjugate()
True
sage: WordMorphism('a->abbab,b->abb').has_right_conjugate()
True
sage: WordMorphism('a->abbab,b->abb,c->').has_right_conjugate()
True

```

image(letter)

Return the image of a letter.

INPUT:

- letter – a letter in the domain alphabet

OUTPUT:

word

Note: The letter is assumed to be in the domain alphabet (no check done). Hence, this method is faster

than the `__call__` method suitable for words input.

EXAMPLES:

```
sage: m = WordMorphism('a->ab,b->ac,c->a')
sage: m.image('b')
word: ac
```

```
sage: s = WordMorphism({('a', 1):[('a', 1), ('a', 2)], ('a', 2):[('a', 1)]})
sage: s.image(('a', 1))
word: ('a', 1), ('a', 2)
```

```
sage: s = WordMorphism({0:[1,2], 'a':(2,3,4), ():[9,8,7]})
sage: s.image(0)
word: 12
sage: s.image('a')
word: 234
sage: s.image(())
word: 987
```

images()

Returns the list of all the images of the letters of the alphabet under `self`.

EXAMPLES:

```
sage: WordMorphism('a->ab,b->a').images()
[word: ab, word: a]
sage: WordMorphism('6->ab,y->5,0->asd').images()
[word: 5, word: asd, word: ab]
```

incidence_matrix()

Returns the incidence matrix of the morphism. The order of the rows and column are given by the order defined on the alphabet of the domain and the codomain.

The matrix returned is over the integers. If a different ring is desired, use either the `change_ring` function or the `matrix` function.

EXAMPLES:

```
sage: m = WordMorphism('a->abc,b->a,c->c')
sage: m.incidence_matrix()
[1 1 0]
[1 0 0]
[1 0 1]
sage: m = WordMorphism('a->abc,b->a,c->c,d->abbcccccabca,e->abc')
sage: m.incidence_matrix()
[1 1 0 3 1]
[1 0 0 3 1]
[1 0 1 5 1]
```

is_empty()

Returns `True` if the cardinality of the domain is zero and `False` otherwise.

EXAMPLES:

```
sage: WordMorphism('').is_empty()
True
```

```
sage: WordMorphism('a->a').is_empty()
False
```

is_endomorphism()

Returns True if the codomain is a subset of the domain.

EXAMPLES:

```
sage: WordMorphism('a->ab,b->a').is_endomorphism()
True
sage: WordMorphism('6->ab,y->5,0->asd').is_endomorphism()
False
sage: WordMorphism('a->a,b->aa,c->aaa').is_endomorphism()
False
sage: Wabc = Words('abc')
sage: m = WordMorphism('a->a,b->aa,c->aaa', codomain = Wabc)
sage: m.is_endomorphism()
True
```

We check that [trac ticket #8674](#) is fixed:

```
sage: P = WordPaths('abcd')
sage: m = WordMorphism('a->adab,b->ab,c->cbcd,d->cd', domain=P, codomain=P)
sage: m.is_endomorphism()
True
```

is_erasing()

Returns True if self is an erasing morphism, i.e. the image of a letter is the empty word.

EXAMPLES:

```
sage: WordMorphism('a->ab,b->a').is_erasing()
False
sage: WordMorphism('6->ab,y->5,0->asd').is_erasing()
False
sage: WordMorphism('6->ab,y->5,0->asd,7->').is_erasing()
True
sage: WordMorphism('').is_erasing()
False
```

is_growing(letter=None)

Return True if letter is a growing letter.

A letter a is *growing* for the morphism s if the length of the iterates of $|s^n(a)|$ tend to infinity as n goes to infinity.

INPUT:

- letter – None or a letter in the domain of self

Note: If letter is None, this returns True if self is everywhere growing, i.e., all letters are growing letters (see [[CassNic10](#)]), and that self **must** be an endomorphism.

EXAMPLES:

```
sage: WordMorphism('0->01,1->1').is_growing('0')
True
sage: WordMorphism('0->01,1->1').is_growing('1')
```

```
False
sage: WordMorphism('0->01,1->10').is_growing()
True
sage: WordMorphism('0->1,1->2,2->01').is_growing()
True
sage: WordMorphism('0->01,1->1').is_growing()
False
```

The domain needs to be equal to the codomain:

```
sage: WordMorphism('0->01,1->0,2->1', codomain=Words('012')).is_growing()
True
```

Test of erasing morphisms:

```
sage: WordMorphism('0->01,1->').is_growing('0')
False
sage: m = WordMorphism('a->bc,b->bcc,c->', codomain=Words('abc'))
sage: m.is_growing('a')
False
sage: m.is_growing('b')
False
sage: m.is_growing('c')
False
```

REFERENCES:

is_identity()

Returns True if self is the identity morphism.

EXAMPLES:

```
sage: m = WordMorphism('a->a,b->b,c->c,d->e')
sage: m.is_identity()
False
sage: WordMorphism('a->a,b->b,c->c').is_identity()
True
sage: WordMorphism('a->a,b->b,c->cb').is_identity()
False
sage: m = WordMorphism('a->b,b->c,c->a')
sage: (m^2).is_identity()
False
sage: (m^3).is_identity()
True
sage: (m^4).is_identity()
False
sage: WordMorphism('').is_identity()
True
sage: WordMorphism({0:[0],1:[1]}).is_identity()
True
```

We check that [trac ticket #8618](#) is fixed:

```
sage: t = WordMorphism({'a1':['a2'], 'a2':['a1']})
sage: (t*t).is_identity()
True
```

is_in_classP ($f=None$)

Returns True if self is in class P (or $f\cdot P$).

DEFINITION : Let A be an alphabet. We say that a primitive substitution S is in the *class* P if there exists a palindrome p and for each $b \in A$ a palindrome q_b such that $S(b) = pq_b$ for all $b \in A$. [1]

Let f be an involution on A . “We say that a morphism φ is in class f - P if there exists an f -palindrome p and for each $\alpha \in A$ there exists an f -palindrome q_α such that $\varphi(\alpha) = pq_\alpha$. [2]

INPUT:

- f - involution (default: None) on the alphabet of `self`. It must be callable on letters as well as words (e.g. `WordMorphism`).

REFERENCES:

- [1] Hof, A., O. Knill et B. Simon, Singular continuous spectrum for palindromic Schrödinger operators, *Commun. Math. Phys.* 174 (1995) 149-159.
- [2] Labbe, Sebastien. Propriétés combinatoires des f -palindromes, *Memoire de maitrise en Mathématiques*, Montreal, UQAM, 2008, 109 pages.

EXAMPLES:

```
sage: WordMorphism('a->bbaba,b->bba').is_in_classP()
True
sage: tm = WordMorphism('a->ab,b->ba')
sage: tm.is_in_classP()
False
sage: f = WordMorphism('a->b,b->a')
sage: tm.is_in_classP(f=f)
True
sage: (tm^2).is_in_classP()
True
sage: (tm^2).is_in_classP(f=f)
False
sage: fibo = WordMorphism('a->ab,b->a')
sage: fibo.is_in_classP()
True
sage: fibo.is_in_classP(f=f)
False
sage: (fibo^2).is_in_classP()
False
sage: f = WordMorphism('a->b,b->a,c->c')
sage: WordMorphism('a->acbcc,b->acbab,c->acbba').is_in_classP(f)
True
```

is_involution()

Returns True if `self` is an involution, i.e. its square is the identity.

INPUT:

- `self` - an endomorphism

EXAMPLES:

```
sage: WordMorphism('a->b,b->a').is_involution()
True
sage: WordMorphism('a->b,b->ba').is_involution()
False
sage: WordMorphism({0:[1],1:[0]}).is_involution()
True
```

is_primitive()

Returns True if `self` is primitive.

A morphism φ is *primitive* if there exists a positive integer k such that for all $\alpha \in \Sigma$, $\varphi^k(\alpha)$ contains all the letters of Σ .

INPUT:

- self - an endomorphism

ALGORITHM:

Exercices 8.7.8, p.281 in [1] : (c) Let $y(M)$ be the least integer e such that M^e has all positive entries. Prove that, for all primitive matrices M , we have $y(M) \leq (d-1)^2 + 1$. (d) Prove that the bound $y(M) \leq (d-1)^2 + 1$ is best possible.

EXAMPLES:

```
sage: tm = WordMorphism('a->ab,b->ba')
sage: tm.is_primitive()
True
sage: fibo = WordMorphism('a->ab,b->a');
sage: fibo.is_primitive()
True
sage: m = WordMorphism('a->bb,b->aa')
sage: m.is_primitive()
False
sage: f = WordMorphism({0:[1],1:[0]})
sage: f.is_primitive()
False
```

```
sage: s = WordMorphism('a->b,b->c,c->ab')
sage: s.is_primitive()
True
sage: s = WordMorphism('a->b,b->c,c->d,d->e,e->f,f->g,g->h,h->ab')
sage: s.is_primitive()
True
```

REFERENCES:

- [1] Jean-Paul Allouche and Jeffrey Shallit, Automatic Sequences: Theory, Applications, Generalizations, Cambridge University Press, 2003.

is_prolongable (*letter*)

Returns True if self is prolongable on letter.

A morphism φ is prolongable on a letter a if a is a prefix of $\varphi(a)$.

INPUT:

- self - its codomain must be an instance of Words
- letter - a letter in the domain alphabet

OUTPUT:

Boolean

EXAMPLES:

```
sage: WordMorphism('a->ab,b->a').is_prolongable(letter='a')
True
sage: WordMorphism('a->ab,b->a').is_prolongable(letter='b')
False
sage: WordMorphism('a->ba,b->ab').is_prolongable(letter='b')
False
```

```

sage: (WordMorphism('a->ba,b->ab')^2).is_prolongable(letter='b')
True
sage: WordMorphism('a->ba,b->').is_prolongable(letter='b')
False
sage: WordMorphism('a->bb,b->aac').is_prolongable(letter='a')
False

```

We check that [trac ticket #8595](#) is fixed:

```

sage: s = WordMorphism({'a': 1 : [(('a', 1), ('a', 2)], ('a', 2) : [(('a', 1),
↪1)]})
sage: s.is_prolongable(('a',1))
True

```

```

sage: n0, n1 = matrix(2,[1,1,1,0]), matrix(2,[2,1,1,0])
sage: n = {'a':n0, 'b':n1}
sage: WordMorphism(n).is_prolongable(letter='a') #todo: not implemented
Traceback (most recent call last):
...
TypeError: codomain of self must be an instance of Words

```

is_uniform (*k=None*)

Returns True if self is a k -uniform morphism.

Let k be a positive integer. A morphism ϕ is called k -uniform if for every letter α , we have $|\phi(\alpha)| = k$. In other words, all images have length k . A morphism is called uniform if it is k -uniform for some positive integer k .

INPUT:

- k - a positive integer or None. If set to a positive integer, then the function return True if self is k -uniform. If set to None, then the function return True if self is uniform.

EXAMPLES:

```

sage: phi = WordMorphism('a->ab,b->a')
sage: phi.is_uniform()
False
sage: phi.is_uniform(k=1)
False
sage: tau = WordMorphism('a->ab,b->ba')
sage: tau.is_uniform()
True
sage: tau.is_uniform(k=1)
False
sage: tau.is_uniform(k=2)
True

```

latex_layout (*layout=None*)

Get or set the actual latex layout (oneliner vs array).

INPUT:

- layout - string (default: None), can take one of the following values:
 - None - Returns the actual latex layout. By default, the layout is 'array'
 - 'oneliner' - Set the layout to 'oneliner'
 - 'array' - Set the layout to 'array'

EXAMPLES:

```
sage: s = WordMorphism('a->ab,b->ba')
sage: s.latex_layout()
'array'
sage: s.latex_layout('oneliner')
sage: s.latex_layout()
'oneliner'
```

list_of_conjugates()

Returns the list of all the conjugate morphisms of `self`.

DEFINITION:

Recall from Lothaire [1] (Section 2.3.4) that φ is *right conjugate* of φ' , noted $\varphi \triangleleft \varphi'$, if there exists $u \in \Sigma^*$ such that

$$\varphi(\alpha)u = u\varphi'(\alpha),$$

for all $\alpha \in \Sigma$, or equivalently that $\varphi(x)u = u\varphi'(x)$, for all words $x \in \Sigma^*$. Clearly, this relation is not symmetric so that we say that two morphisms φ and φ' are *conjugate*, noted $\varphi \bowtie \varphi'$, if $\varphi \triangleleft \varphi'$ or $\varphi' \triangleleft \varphi$. It is easy to see that conjugacy of morphisms is an equivalence relation.

REFERENCES:

- [1] M. Lothaire, Algebraic Combinatorics on words, Cambridge University Press, 2002.

EXAMPLES:

```
sage: m = WordMorphism('a->abbab,b->abb')
sage: m.list_of_conjugates()
[WordMorphism: a->babba, b->bab,
WordMorphism: a->abbab, b->abb,
WordMorphism: a->bbaba, b->bba,
WordMorphism: a->babab, b->bab,
WordMorphism: a->ababb, b->abb,
WordMorphism: a->babba, b->bba,
WordMorphism: a->abbab, b->bab]
sage: m = WordMorphism('a->aaa,b->aa')
sage: m.list_of_conjugates()
[WordMorphism: a->aaa, b->aa]
sage: WordMorphism('').list_of_conjugates()
[WordMorphism: ]
sage: m = WordMorphism('a->aba,b->aba')
sage: m.list_of_conjugates()
[WordMorphism: a->baa, b->baa,
WordMorphism: a->aab, b->aab,
WordMorphism: a->aba, b->aba]
sage: m = WordMorphism('a->abb,b->abbab,c->')
sage: m.list_of_conjugates()
[WordMorphism: a->bab, b->babba, c->,
WordMorphism: a->abb, b->abbab, c->,
WordMorphism: a->bba, b->bbaba, c->,
WordMorphism: a->bab, b->babab, c->,
WordMorphism: a->abb, b->ababb, c->,
WordMorphism: a->bba, b->babba, c->,
WordMorphism: a->bab, b->abbab, c->]
```

partition_of_domain_alphabet()

Returns a partition of the domain alphabet.

```
....: print("{} , {}".format(len(p), p[0]))
2 , aababaaaababaabbababaaabababbabababaa...
sage: f.fixed_points()
[]
```

This shows that ticket [trac ticket #13668](#) has been resolved:

```
sage: d = {1:[1,2],2:[2,3],3:[4],4:[5],5:[6],6:[7],7:[8],8:[9],9:[10],10:[1]}
sage: s = WordMorphism(d)
sage: s7 = s^7
sage: s7r = s7.reversal()
sage: for p in s7r.periodic_points(): p
[word: 1,10,9,8,7,6,5,4,3,2,10,9,8,7,6,5,4,3,2,...,

```

`pisot_eigenvector_left()`

Returns the left eigenvector of the incidence matrix associated to the largest eigenvalue (in absolute value).

Unicity of the result is guaranteed when the multiplicity of the largest eigenvalue is one, for example when σ itself is a Pisot irreducible substitution.

A substitution is Pisot irreducible if the characteristic polynomial of its incidence matrix is irreducible over $\mathbb{Q}$ and has all roots, except one, of modulus strictly smaller than 1.

INPUT:

- `self` - a Pisot irreducible substitution.

EXAMPLES:

```
sage: m = WordMorphism('a->aaaabbc,b->aaabbc,c->aabc')
sage: matrix(m)
[4 3 2]
[2 2 1]
[1 1 1]
sage: m.pisot_eigenvector_left()
(1, 0.8392867552141611?, 0.5436890126920763?)
```

`pisot_eigenvector_right()`

Returns the right eigenvector of the incidence matrix associated to the largest eigenvalue (in absolute value).

Unicity of the result is guaranteed when the multiplicity of the largest eigenvalue is one, for example when σ itself is a Pisot irreducible substitution.

A substitution is Pisot irreducible if the characteristic polynomial of its incidence matrix is irreducible over $\mathbb{Q}$ and has all roots, except one, of modulus strictly smaller than 1.

INPUT:

- self - a Pisot irreducible substitution.

EXAMPLES:

```

sage: m = WordMorphism('a->aaaabbc,b->aaabbc,c->aabc')
sage: matrix(m)
[4 3 2]
[2 2 1]
[1 1 1]
sage: m.pisot_eigenvector_right()
(1, 0.5436890126920763?, 0.2955977425220848?)

```

rauzy_fractal_plot (*n=None*, *exchange=False*, *eig=None*, *translate=None*, *prec=53*, *colormap='hsv'*, *opacity=None*, *plot_origin=None*, *plot_basis=False*, *point_size=None*)

Returns a plot of the Rauzy fractal associated with a substitution.

The substitution does not have to be irreducible. The usual definition of a Rauzy fractal requires that its dominant eigenvalue is a Pisot number but the present method doesn't require this, allowing to plot some interesting pictures in the non-Pisot case (see the examples below).

For more details about the definition of the fractal and the projection which is used, see Section 3.1 of [1].

Plots with less than 100,000 points take a few seconds, and several millions of points can be plotted in reasonable time.

Other ways to draw Rauzy fractals (and more generally projections of paths) can be found in `sage.combinat.words.paths.FiniteWordPath_all.plot_projection()` or in `sage.combinat.e_one_star()`.

OUTPUT:

A Graphics object.

INPUT:

- *n* - integer (default: None) The number of points used to plot the fractal. Default values: 1000 for a 1D fractal, 50000 for a 2D fractal, 10000 for a 3D fractal.
- *exchange* - boolean (default: False). Plot the Rauzy fractal with domain exchange.
- *eig* - a real element of $\overline{\mathbb{Q}\mathbb{Q}}$ of degree ≥ 2 (default: None). The eigenvalue used to plot the fractal. It must be an eigenvalue of `self.incidence_matrix()`. The one used by default the maximal eigenvalue of `self.incidence_matrix()` (usually a Pisot number), but for substitutions with more than 3 letters other interesting choices are sometimes possible.
- *translate* - a list of vectors of $\mathbb{R}^{\text{size\_alphabet}}$, or a dictionary from the alphabet to lists of vectors (default: None). Plot translated copies of the fractal. This option allows to plot tilings easily. The projection used for these vectors is the same as the projection used for the canonical basis to plot the fractal. If the input is a list, all the pieces will be translated and plotted. If the input is a dictionary, each piece will be translated and plotted accordingly to the vectors associated with each letter in the dictionary. Note: by default, the Rauzy fractal placed at the origin is not plotted with the *translate* option; the vector $(0, 0, \dots, 0)$ has to be added manually.
- *prec* - integer (default: 53). The number of bits used in the floating point representations of the points of the fractal.
- *colormap* - color map or dictionary (default: 'hsv'). It can be one of the following :
 - *string* - a coloring map. For available coloring map names type: `sorted(colormaps)`
 - *dict* - a dictionary of the alphabet mapped to colors.
- *opacity* - a dictionary from the alphabet to the real interval $[0,1]$ (default: None). If none is specified, all letters are plotted with opacity 1.

- `plot_origin` - a couple (k, c) (default: `None`). If specified, mark the origin by a point of size k and color c .
- `plot_basis` - boolean (default: `False`). Plot the projection of the canonical basis with the fractal.
- `point_size` - float (default: `None`). The size of the points used to plot the fractal.

EXAMPLES:

1. The Rauzy fractal of the Tribonacci substitution:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: s.rauzy_fractal_plot()          # long time
Graphics object consisting of 3 graphics primitives
```

2. The “Hokkaido” fractal. We tweak the plot using the plotting options to get a nice reusable picture, in which we mark the origin by a black dot:

```
sage: s = WordMorphism('a->ab,b->c,c->d,d->e,e->a')
sage: G = s.rauzy_fractal_plot(n=100000, point_size=3, plot_origin=(50,
↪ "black")) # not tested
sage: G.show(figsize=10, axes=false) # not tested
```

3. Another “Hokkaido” fractal and its domain exchange:

```
sage: s = WordMorphism({1:[2], 2:[4,3], 3:[4], 4:[5,3], 5:[6], 6:[1]})
sage: s.rauzy_fractal_plot()          # not tested takes > 1
↪ second
sage: s.rauzy_fractal_plot(exchange=True) # not tested takes > 1
↪ second
```

4. A three-dimensional Rauzy fractal:

```
sage: s = WordMorphism('1->12,2->13,3->14,4->1')
sage: s.rauzy_fractal_plot()          # not tested takes > 1 second
```

5. A one-dimensional Rauzy fractal (very scattered):

```
sage: s = WordMorphism('1->2122,2->1')
sage: s.rauzy_fractal_plot().show(figsize=20) # not tested takes > 1
↪ second
```

6. A high resolution plot of a complicated fractal:

```
sage: s = WordMorphism('1->23,2->123,3->1122233')
sage: G = s.rauzy_fractal_plot(n=300000) # not tested takes > 1 second
sage: G.show(axes=false, figsize=20)    # not tested takes > 1 second
```

7. A nice colorful animation of a domain exchange:

```
sage: s = WordMorphism('1->21,2->3,3->4,4->25,5->6,6->7,7->1')
sage: L = [s.rauzy_fractal_plot(), s.rauzy_fractal_plot(exchange=True)]
↪ # not tested takes > 1 second
sage: animate(L, axes=false).show(delay=100) # not tested takes > 1
↪ second
```

8. Plotting with only one color:

```
sage: s = WordMorphism('1->12,2->31,3->1')
sage: s.rauzy_fractal_plot(colormap={'1':'black', '2':'black', '3':'black',
↪ ' '}) # not tested takes > 1 second
```

9. Different fractals can be obtained by choosing another (non-Pisot) eigenvalue:

```
sage: s = WordMorphism('1->12,2->3,3->45,4->5,5->6,6->7,7->8,8->1')
sage: E = s.incidence_matrix().eigenvalues()
sage: x = [x for x in E if -0.8 < x < -0.7][0]
sage: s.rauzy_fractal_plot() # not tested takes > 1 second
sage: s.rauzy_fractal_plot(eig=x) # not tested takes > 1 second
```

10. A Pisot reducible substitution with seemingly overlapping tiles:

```
sage: s = WordMorphism({1:[1,2], 2:[2,3], 3:[4], 4:[5], 5:[6], 6:[7],
↪ 7:[8], 8:[9], 9:[10], 10:[1]})
sage: s.rauzy_fractal_plot() # not tested takes > 1 second
```

11. A non-Pisot reducible substitution with a strange Rauzy fractal:

```
sage: s = WordMorphism({1:[3,2], 2:[3,3], 3:[4], 4:[1]})
sage: s.rauzy_fractal_plot() # not tested takes > 1 second
```

12. A substitution with overlapping tiles. We use the options `colormap` and `opacity` to study how the tiles overlap:

```
sage: s = WordMorphism('1->213,2->4,3->5,4->1,5->21')
sage: s.rauzy_fractal_plot() # not_
↪ tested takes > 1 second
sage: s.rauzy_fractal_plot(colormap={'1':'red', '4':'purple'}) # not_
↪ tested takes > 1 second
sage: s.rauzy_fractal_plot(opacity={'1':0.1,'2':1,'3':0.1,'4':0.1,'5':0.1},
↪ n=150000) # not tested takes > 1 second
```

13. Funny experiments by playing with the precision of the float numbers used to plot the fractal:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: s.rauzy_fractal_plot(prec=6) # not tested
sage: s.rauzy_fractal_plot(prec=9) # not tested
sage: s.rauzy_fractal_plot(prec=15) # not tested
sage: s.rauzy_fractal_plot(prec=19) # not tested
sage: s.rauzy_fractal_plot(prec=25) # not tested
```

14. Using the `translate` option to plot periodic tilings:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: s.rauzy_fractal_plot(n=10000, translate=[(0,0,0), (-1,0,1), (0,-1,1),
↪ (1,-1,0), (1,0,-1), (0,1,-1), (-1,1,0)]) # not tested takes > 1 second
```

```
sage: t = WordMorphism("a->aC,b->d,C->de,d->a,e->ab") # substitution_
↪ found by Julien Bernat
sage: V = [vector((0,0,1,0,-1)), vector((0,0,1,-1,0))]
sage: S = set(map(tuple, [i*V[0] + j*V[1] for i in [-1,0,1] for j in [-1,
↪ 0,1]]))
sage: t.rauzy_fractal_plot(n=10000, translate=S, exchange=true) # not_
↪ tested takes > 1 second
```

15. Using the `translate` option to plot arbitrary tilings with the fractal pieces. This can be used for example to plot the self-replicating tiling of the Rauzy fractal:

```
sage: s = WordMorphism({1:[1,2], 2:[3], 3:[4,3], 4:[5], 5:[6], 6:[1]})
sage: s.rauzy_fractal_plot() # not tested takes > 1 second
sage: D = {1:[(0,0,0,0,0,0), (0,1,0,0,0,0)], 3:[(0,0,0,0,0,0), (0,1,0,0,0,
↪0)], 6:[(0,1,0,0,0,0)]}
sage: s.rauzy_fractal_plot(n=30000, translate=D) # not tested takes > 1
↪second
```

16. Plot the projection of the canonical basis with the fractal:

```
sage: s = WordMorphism({1:[2,1], 2:[3], 3:[6,4], 4:[5,1], 5:[6], 6:[7],
↪7:[8], 8:[9], 9:[1]})
sage: s.rauzy_fractal_plot(plot_basis=True) # not tested takes > 1
↪second
```

rauzy_fractal_points (*n=None, exchange=False, eig=None, translate=None, prec=53*)

Returns a dictionary of list of points associated with the pieces of the Rauzy fractal of `self`.

INPUT:

See the method `rauzy_fractal_plot()` for a description of the options and more examples.

OUTPUT:

dictionary of list of points

EXAMPLES:

The Rauzy fractal of the Tribonacci substitution and the number of points in the piece of the fractal associated with '1', '2' and '3' are respectively:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: D = s.rauzy_fractal_points(n=100)
sage: len(D['1'])
54
sage: len(D['2'])
30
sage: len(D['3'])
16
```

AUTHOR:

Timo Jolivet (2012-06-16)

rauzy_fractal_projection (*eig=None, prec=53*)

Returns a dictionary giving the projection of the canonical basis.

See the method `rauzy_fractal_plot()` for more details about the projection.

INPUT:

- eig** - a real element of $\mathbb{Q}\bar{\mathbb{Q}}$ of degree ≥ 2 (default: None). The eigenvalue used for the projection. It must be an eigenvalue of `self.incidence_matrix()`. The one used by default is the maximal eigenvalue of `self.incidence_matrix()` (usually a Pisot number), but for substitutions with more than 3 letters other interesting choices are sometimes possible.
- prec** - integer (default: 53). The number of bits used in the floating point representations of the coordinates.

OUTPUT:

dictionary, letter -> vector, giving the projection

EXAMPLES:

The projection for the Rauzy fractal of the Tribonacci substitution is:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: s.rauzy_fractal_projection()
{'1': (1.000000000000000, 0.000000000000000),
 '2': (-1.41964337760708, -0.606290729207199),
 '3': (-0.771844506346038, 1.11514250803994)}
```

AUTHOR:

Timo Jolivet (2012-06-16)

restrict_domain (*alphabet*)

Returns a restriction of `self` to the given alphabet.

INPUT:

- alphabet** - an iterable

OUTPUT:

WordMorphism

EXAMPLES:

```
sage: m = WordMorphism('a->b,b->a')
sage: m.restrict_domain('a')
WordMorphism: a->b
sage: m.restrict_domain('')
WordMorphism:
sage: m.restrict_domain('A')
WordMorphism:
sage: m.restrict_domain('Aa')
WordMorphism: a->b
```

The input alphabet must be iterable:

```
sage: m.restrict_domain(66)
Traceback (most recent call last):
...
TypeError: 'sage.rings.integer.Integer' object is not iterable
```

reversal ()

Returns the reversal of `self`.

EXAMPLES:

```
sage: WordMorphism('6->ab,y->5,0->asd').reversal()
WordMorphism: 0->dsa, 6->ba, y->5
sage: WordMorphism('a->ab,b->a').reversal()
WordMorphism: a->ba, b->a
```

`sage.combinat.words.morphism.get_cycles(f, domain=None)`

Return the cycle of the function f on the finite set domain. It is assumed that f is an endomorphism.

INPUT:

- f - function.
- domain - set (default: None) - the domain of f . If none, then tries to use `f.domain()`.

EXAMPLES:

```
sage: from sage.combinat.words.morphism import get_cycles
sage: get_cycles(lambda i: (i+1)%3, domain=[0,1,2])
[(0, 1, 2)]
sage: get_cycles(lambda i: [0,0,0][i], domain=[0,1,2])
[(0,)]
sage: get_cycles(lambda i: [1,1,1][i], domain=[0,1,2])
[(1,)]
```

5.1.338 Word paths

This module implements word paths, which is an application of Combinatorics on Words to Discrete Geometry. A word path is the representation of a word as a discrete path in a vector space using a one-to-one correspondence between the alphabet and a set of vectors called steps. Many problems surrounding 2d lattice polygons (such as questions of self-intersection, area, inertia moment, etc.) can be solved in linear time (linear in the length of the perimeter) using theory from Combinatorics on Words.

On the square grid, the encoding of a path using a four-letter alphabet (for East, North, West and South directions) is also known as the Freeman chain code [1,2] (see [3] for further reading).

AUTHORS:

- Arnaud Bergeron (2008) : Initial version, path on the square grid
- Sebastien Labbe (2009-01-14) : New classes and hierarchy, doc and functions.

EXAMPLES:

The combinatorial class of all paths defined over three given steps:

```
sage: P = WordPaths('abc', steps=[(1,2), (-3,4), (0,-3)]); P
Word Paths over 3 steps
```

This defines a one-to-one correspondence between alphabet and steps:

```
sage: d = P.letters_to_steps()
sage: sorted(d.items())
[('a', (1, 2)), ('b', (-3, 4)), ('c', (0, -3))]
```

Creation of a path from the combinatorial class P defined above:

```
sage: p = P('abaccba'); p
Path: abaccba
```

Many functions can be used on `p`: the coordinates of its trajectory, ask whether `p` is a closed path, plot it and many other:

```
sage: list(p.points())
[(0, 0), (1, 2), (-2, 6), (-1, 8), (-1, 5), (-1, 2), (-4, 6), (-3, 8)]
sage: p.is_closed()
False
sage: p.plot()
Graphics object consisting of 3 graphics primitives
```

To obtain a list of all the available word path specific functions, use `help(p)`:

```
sage: help(p)
Help on FiniteWordPath_2d_str in module sage.combinat.words.paths object:
...
Methods inherited from FiniteWordPath_2d:
...
Methods inherited from FiniteWordPath_all:
...
```

Since `p` is a finite word, many functions from the word library are available:

```
sage: p.crochemore_factorization()
(a, b, a, c, c, ba)
sage: p.is_palindrome()
False
sage: p[:3]
Path: aba
sage: len(p)
7
```

`P` also inherits many functions from `Words`:

```
sage: P = WordPaths('rs', steps=[(1,2), (-1,4)]); P
Word Paths over 2 steps
sage: P.alphabet()
{'r', 's'}
sage: list(P.iterate_by_length(3))
[Path: rrr,
 Path: rrs,
 Path: rsr,
 Path: rss,
 Path: srr,
 Path: srs,
 Path: ssr,
 Path: sss]
```

When the number of given steps is half the size of alphabet, the opposite of vectors are used:

```
sage: P = WordPaths('abcd', [(1,0), (0,1)])
sage: sorted(P.letters_to_steps().items())
[('a', (1, 0)), ('b', (0, 1)), ('c', (-1, 0)), ('d', (0, -1))]
```

Some built-in combinatorial classes of paths:

```
sage: P = WordPaths('abAB', steps='square_grid'); P
Word Paths on the square grid
```

```
sage: D = WordPaths('()', steps='dyck'); D
Finite Dyck paths
sage: d = D('()()()()'); d
Path: ()()()()
sage: d.plot()
Graphics object consisting of 3 graphics primitives
```

```
sage: P = WordPaths('abcdef', steps='triangle_grid')
sage: p = P('babaddefadabcaadfaadfafabacdefa')
sage: p.plot()
Graphics object consisting of 3 graphics primitives
```

Vector steps may be in more than 2 dimensions:

```
sage: d = [(1,0,0), (0,1,0), (0,0,1)]
sage: P = WordPaths(alphabet='abc', steps=d); P
Word Paths over 3 steps
sage: p = P('abcabcabcabcaabacababcbacbabacacabcacbcac')
sage: p.plot()
Graphics3d Object
```

```
sage: d = [(1,3,5,1), (-5,1,-6,0), (0,0,1,9), (4,2,-1,0)]
sage: P = WordPaths(alphabet='rstu', steps=d); P
Word Paths over 4 steps
sage: p = P('rtusuusususuturrsust'); p
Path: rtusuusususuturrsust
sage: p.end_point()
(5, 31, -26, 30)
```

```
sage: CubePaths = WordPaths('abcABC', steps='cube_grid'); CubePaths
Word Paths on the cube grid
sage: CubePaths('abcabaabcabAAAA').plot()
Graphics3d Object
```

The input data may be a str, a list, a tuple, a callable or a finite iterator:

```
sage: P = WordPaths([0, 1, 2, 3])
sage: P([0,1,2,3,2,1,2,3,2])
Path: 012321232
sage: P((0,1,2,3,2,1,2,3,2))
Path: 012321232
sage: P(lambda n:n%4, length=10)
Path: 0123012301
sage: P(iter([0,3,2,1]), length='finite')
Path: 0321
```

class sage.combinat.words.paths.**FiniteWordPath_2d**

Bases: *sage.combinat.words.paths.FiniteWordPath_all*

animate()

Returns an animation object illustrating the path growing step by step.

EXAMPLES:

```
sage: P = WordPaths('abAB')
sage: p = P('aaababbb')
sage: a = p.animate(); a      # optional -- ImageMagick
Animation with 9 frames
sage: show(a)                 # optional -- ImageMagick
sage: a.gif(delay=35, iterations=3) # optional -- ImageMagick
doctest:...: DeprecationWarning: use tmp_filename instead
See http://trac.sagemath.org/17234 for details.
```

```
sage: P = WordPaths('abcdef', steps='triangle')
sage: p = P('abcdef')
sage: p.animate()             # optional -- ImageMagick
Animation with 8 frames
```

If the path is closed, the plain polygon is added at the end of the animation:

```
sage: P = WordPaths('abAB')
sage: p = P('ababAbABABaB')
sage: a = p.animate(); a      # optional -- ImageMagick
Animation with 14 frames
```

Another example illustrating a Fibonacci tile:

```
sage: w = words.fibonacci_tile(2)
sage: show(w.animate())      # optional -- ImageMagick
```

The first 4 Fibonacci tiles in an animation:

```
sage: a = words.fibonacci_tile(0).animate()
sage: b = words.fibonacci_tile(1).animate()
sage: c = words.fibonacci_tile(2).animate()
sage: d = words.fibonacci_tile(3).animate()
sage: (a*b*c*d).show()      # optional -- ImageMagick
```

Note: If ImageMagick is not installed, you will get an error message like this:

```
/usr/local/share/sage/local/bin/sage-native-execute: 8: convert:
not found

Error: ImageMagick does not appear to be installed. Saving an
animation to a GIF file or displaying an animation requires
ImageMagick, so please install it and try again.
```

See www.imagemagick.org, for example.

area()

Returns the area of a closed path.

INPUT:

- self - a closed path

EXAMPLES:

```
sage: P = WordPaths('abcd', steps=[(1,1), (-1,1), (-1,-1), (1,-1)])
sage: p = P('abcd')
sage: p.area()          #todo: not implemented
2
```

height()

Returns the height of self.

The height of a $2d$ -path is merely the difference between the highest and the lowest y -coordinate of each points traced by it.

OUTPUT:

non negative real number

EXAMPLES:

```
sage: Freeman = WordPaths('abAB')
sage: Freeman('aababaabbbAA').height()
5
```

The function is well-defined if self is not simple or close:

```
sage: Freeman('aabAAB').height()
1
sage: Freeman('abbABA').height()
2
```

This works for any $2d$ -paths:

```
sage: Paths = WordPaths('ab', steps=[(1,0), (1,1)])
sage: p = Paths('abbaa')
sage: p.height()
2
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.height()
2
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.height()
2.59807621135332
```

plot (pathoptions={‘rgbcolor’: ‘red’, ‘thickness’: 3}, fill=True, filloptions={‘alpha’: 0.2, ‘rgbcolor’: ‘red’}, startpoint=True, startoptions={‘pointsize’: 100, ‘rgbcolor’: ‘red’}, endarrow=True, arrowoptions={‘width’: 3, ‘rgbcolor’: ‘red’, ‘arrowsize’: 20}, gridlines=False, gridoptions={})
Returns a 2d Graphics illustrating the path.

INPUT:

- pathoptions - (dict, default:dict(rgbcolor=‘red’,thickness=3)), options for the path drawing
- fill - (boolean, default: True), if fill is True and if the path is closed, the inside is colored
- filloptions - (dict, default:dict(rgbcolor=‘red’,alpha=0.2)), options for the inside filling
- startpoint - (boolean, default: True), draw the start point?

- `startoptions` - (dict, default:dict(rgbcolor='red',pointsize=100)) options for the start point drawing
- `endarrow` - (boolean, default: True), draw an arrow end at the end?
- `arrowoptions` - (dict, default:dict(rgbcolor='red',arrowsize=20, width=3)) options for the end point arrow
- `gridlines` - (boolean, default: False), show gridlines?
- `gridoptions` - (dict, default: {}), options for the gridlines

EXAMPLES:

A non closed path on the square grid:

```
sage: P = WordPaths('abAB')
sage: P('abababAABAB').plot()
Graphics object consisting of 3 graphics primitives
```

A closed path on the square grid:

```
sage: P('abababAABABB').plot()
Graphics object consisting of 4 graphics primitives
```

A Dyck path:

```
sage: P = WordPaths('()', steps='dyck')
sage: P('()()()()').plot()
Graphics object consisting of 3 graphics primitives
```

A path in the triangle grid:

```
sage: P = WordPaths('abcdef', steps='triangle_grid')
sage: P('abcdedededefab').plot()
Graphics object consisting of 3 graphics primitives
```

A polygon of length 220 that tiles the plane in two ways:

```
sage: P = WordPaths('abAB')
sage: P(
↳ 'aBababAbabaBaBABAbaBabaBaBABAbABABaBABAbaBabaBaBABAbaBababAbabaBaBABAbaBabaBaBABAbABABaBABAbAbabAbABA
↳ ').plot()
Graphics object consisting of 4 graphics primitives
```

With gridlines:

```
sage: P('ababababab').plot(gridlines=True)
```

```
plot_directive_vector(options={'rgbcolor': 'blue'})
```

Returns an arrow 2d graphics that goes from the start of the path to the end.

INPUT:

- `options` - dictionary, default: `{'rgbcolor': 'blue'}` graphic options for the arrow

If the start is the same as the end, a single point is returned.

EXAMPLES:

```

sage: P = WordPaths('abcd'); P
Word Paths on the square grid
sage: p = P('aaaccaccacacacccccbbdd'); p
Path: aaaccaccacacacacccccbbdd
sage: R = p.plot() + p.plot_directive_vector()
sage: R.axes(False)
sage: R.set_aspect_ratio(1)
sage: R.plot()
Graphics object consisting of 4 graphics primitives

```

width()

Returns the width of self.

The height of a $2d$ -path is merely the difference between the rightmost and the leftmost x -coordinate of each points traced by it.

OUTPUT:

non negative real number

EXAMPLES:

```

sage: Freeman = WordPaths('abAB')
sage: Freeman('aababaabbbAA').width()
5

```

The function is well-defined if self is not simple or close:

```

sage: Freeman('aabAAB').width()
2
sage: Freeman('abbABa').width()
1

```

This works for any $2d$ -paths:

```

sage: Paths = WordPaths('ab', steps=[(1,0), (1,1)])
sage: p = Paths('abbaa')
sage: p.width()
5
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.width()
6
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.width()
4.500000000000000

```

xmax()

Returns the maximum of the x -coordinates of the path.

EXAMPLES:

```

sage: P = WordPaths('0123')
sage: p = P('0101013332')
sage: p.xmax()
3

```

This works for any $2d$ -paths:

```

sage: Paths = WordPaths('ab', steps=[(1,-1), (-1,1)])
sage: p = Paths('ababa')
sage: p.xmax()
1
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.xmax()
6
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.xmax()
4.500000000000000

```

xmin()

Returns the minimum of the x-coordinates of the path.

EXAMPLES:

```

sage: P = WordPaths('0123')
sage: p = P('0101013332')
sage: p.xmin()
0

```

This works for any $2d$ -paths:

```

sage: Paths = WordPaths('ab', steps=[(1,0), (-1,1)])
sage: p = Paths('abbba')
sage: p.xmin()
-2
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.xmin()
0
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.xmin()
0.000000000000000

```

ymax()

Returns the maximum of the y-coordinates of the path.

EXAMPLES:

```

sage: P = WordPaths('0123')
sage: p = P('0101013332')
sage: p.ymax()
3

```

This works for any $2d$ -paths:

```

sage: Paths = WordPaths('ab', steps=[(1,-1), (-1,1)])
sage: p = Paths('ababa')
sage: p.ymax()
0
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.ymax()
2
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')

```

```
sage: w.ymax()
2.59807621135332
```

ymin()

Returns the minimum of the y-coordinates of the path.

EXAMPLES:

```
sage: P = WordPaths('0123')
sage: p = P('0101013332')
sage: p.ymin()
0
```

This works for any $2d$ -paths:

```
sage: Paths = WordPaths('ab', steps=[(1,-1), (-1,1)])
sage: p = Paths('ababa')
sage: p.ymin()
-1
sage: DyckPaths = WordPaths('ab', steps='dyck')
sage: p = DyckPaths('abaabb')
sage: p.ymin()
0
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.ymin()
0.0000000000000000
```

```
class sage.combinat.words.paths.FiniteWordPath_2d_callable(parent, callable,
                                                             length=None)
Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_callable,
sage.combinat.words.paths.FiniteWordPath_2d, sage.combinat.words.
finite_word.FiniteWord_class
```

INPUT:

- parent - a parent
- callable - a callable defined on range(stop=length)
- length - (default: None) nonnegative integer or None

EXAMPLES:

```
sage: f = lambda n : 'x' if n % 2 == 0 else 'y'
sage: w = Word(f, length=9, caching=False); w
word: xyxyxyxyx
sage: type(w)
<class 'sage.combinat.words.word.FiniteWord_callable'>
sage: w.length()
9
```

```
sage: w = Word(f, caching=False); w
word: xyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxy...
sage: type(w)
<class 'sage.combinat.words.word.InfiniteWord_callable'>
sage: w.length() is None
False
sage: w.length()
+Infinity
```

```
class sage.combinat.words.paths.FiniteWordPath_2d_callable_with_caching(parent,  
                                                                           callable,  
                                                                           length=None)  
    Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_callable_with_caching,  
           sage.combinat.words.paths.FiniteWordPath_2d,           sage.combinat.words.  
           finite_word.FiniteWord_class
```

INPUT:

- parent - a parent
- callable - a callable defined on `range(stop=length)`
- length - (default: None) nonnegative integer or None

EXAMPLES:

```
sage: f = lambda n : 'x' if n % 2 == 0 else 'y'
sage: w = Word(f, length=9, caching=True); w
word: xyxyxyxyx
sage: type(w)
<class 'sage.combinat.words.word.FiniteWord_callable_with_caching'>
sage: w.length()
9
```

```
sage: w = Word(f, caching=True); w
word: xyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxy...
sage: type(w)
<class 'sage.combinat.words.word.InfiniteWord_callable_with_caching'>
sage: w.length() is None
False
sage: w.length()
+Infinity
```

```
class sage.combinat.words.paths.FiniteWordPath_2d_iter (parent, iter, length=None)
  Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_iter, sage.combinat.words.paths.FiniteWordPath_2d, sage.combinat.words.finite_word.FiniteWord class
```

INPUT:

- parent - a parent
- iter - an iterator
- length - (default: None) the length of the word

EXAMPLES:

```
sage: w = Word(iter("abbabaab"), length="unknown", caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
sage: w.length() is None
False
sage: w.length()
8
sage: s = "abbabaabbaababbabaababbaabbabaabbaababbaabbabaabab"
sage: w = Word(iter(s), length="unknown", caching=False); w
word: abbabaabbaababbabaababbaabbabaabbaababba...
```

```
sage: w.length() is None
True
```

```
sage: w = Word(iter("abbabaab"), length="finite", caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length=8, caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
sage: w.length()
8
```

class `sage.combinat.words.paths.FiniteWordPath_2d_iter_with_caching` (*parent, iter, length=None*)
 Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_iter_with_caching`,
`sage.combinat.words.paths.FiniteWordPath_2d`, `sage.combinat.words.finite_word.FiniteWord_class`

INPUT:

- parent - a parent
- iter - an iterator
- length - (default: None) the length of the word

EXAMPLES:

```
sage: import itertools
sage: Word(itertools.cycle("abbabaab"))
word: abbabaababbabaababbabaababbabaababbabaab...
sage: w = Word(iter("abbabaab"), length="finite"); w
word: abbabaab
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length="unknown"); w
word: abbabaab
sage: w.length()
8
sage: list(w)
['a', 'b', 'b', 'a', 'b', 'a', 'a', 'b']
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length=8)
sage: w._len
8
```

class `sage.combinat.words.paths.FiniteWordPath_2d_list`
 Bases: `sage.combinat.words.word_datatypes.WordDatatype_list`, `sage.combinat.words.paths.FiniteWordPath_2d`, `sage.combinat.words.finite_word.FiniteWord_class`

class `sage.combinat.words.paths.FiniteWordPath_2d_str`
 Bases: `sage.combinat.words.word_datatypes.WordDatatype_str`, `sage.combinat.words.paths.FiniteWordPath_2d`, `sage.combinat.words.finite_word.FiniteWord_class`

```
combinat.words.paths.FiniteWordPath_2d,    sage.combinat.words.finite_word.
FiniteWord_class
```

class sage.combinat.words.paths.**FiniteWordPath_2d_tuple**

Bases: *sage.combinat.words.word_datatypes.WordDatatype_tuple, sage.combinat.words.paths.FiniteWordPath_2d, sage.combinat.words.finite_word.FiniteWord_class*

class sage.combinat.words.paths.**FiniteWordPath_3d**

Bases: *sage.combinat.words.paths.FiniteWordPath_all*

plot (pathoptions={‘arrow_head’: True, ‘rgbcolor’: ‘red’, ‘thickness’: 3}, startpoint=True, startoptions={‘rgbcolor’: ‘red’, ‘size’: 10})

INPUT:

- pathoptions - (dict, default: dict(rgbcolor=‘red’, arrow_head=True, thickness=3)), options for the path drawing
- startpoint - (boolean, default: True), draw the start point?
- startoptions - (dict, default: dict(rgbcolor=‘red’, size=10)) options for the start point drawing

EXAMPLES:

```
sage: d = ( vector((1,3,2)), vector((2,-4,5)) )
sage: P = WordPaths(alphabet='ab', steps=d); P
Word Paths over 2 steps
sage: p = P('ababab'); p
Path: ababab
sage: p.plot()
Graphics3d Object

sage: P = WordPaths('abcABC', steps='cube_grid')
sage: p = P('abcabcAABBC')
sage: p.plot()
Graphics3d Object
```

class sage.combinat.words.paths.**FiniteWordPath_3d_callable** (parent, callable, length=None)

Bases: *sage.combinat.words.word_infinite_datatypes.WordDatatype_callable, sage.combinat.words.paths.FiniteWordPath_3d, sage.combinat.words.finite_word.FiniteWord_class*

INPUT:

- parent - a parent
- callable - a callable defined on range (stop=length)
- length - (default: None) nonnegative integer or None

EXAMPLES:

```
sage: f = lambda n : 'x' if n % 2 == 0 else 'y'
sage: w = Word(f, length=9, caching=False); w
word: xyxyxyxyx
sage: type(w)
<class 'sage.combinat.words.word.FiniteWord_callable'>
sage: w.length()
9
```

```

sage: w.length() is None
False
sage: w.length()
+Infinity

```

```

class sage.combinat.words.paths.FiniteWordPath_3d_iter(parent, iter, length=None)
Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_iter, sage.
combinat.words.paths.FiniteWordPath_3d, sage.combinat.words.finite_word.
FiniteWord_class

```

INPUT:

- parent - a parent
- iter - an iterator
- length - (default: None) the length of the word

EXAMPLES:

```

sage: w = Word(iter("abbabaab"), length="unknown", caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)

```

```

True
sage: w.length() is None
False
sage: w.length()
8
sage: s = "abbabaabbaababbabaababbabaabbaababbabaabab"
sage: w = Word(iter(s), length="unknown", caching=False); w
word: abbabaabbaababbabaababbabaabbaababba...
sage: w.length() is None
True

```

```

sage: w = Word(iter("abbabaab"), length="finite", caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length=8, caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
sage: w.length()
8

```

class `sage.combinat.words.paths.FiniteWordPath_3d_iter_with_caching` (*parent, iter, length=None*)

Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_iter_with_caching`,
`sage.combinat.words.paths.FiniteWordPath_3d`, `sage.combinat.words.finite_word.FiniteWord_class`

INPUT:

- parent - a parent
- iter - an iterator
- length - (default: None) the length of the word

EXAMPLES:

```

sage: import itertools
sage: Word(itertools.cycle("abbabaab"))
word: abbabaababbabaababbabaababbabaababbabaab...
sage: w = Word(iter("abbabaab"), length="finite"); w
word: abbabaab
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length="unknown"); w
word: abbabaab
sage: w.length()

```
class sage.combinat.words.paths.FiniteWordPath_all
    Bases: sage.structure.sage_object.SageObject
```

directive_vector()

Returns the directive vector of self.

The directive vector is the vector starting at the start point and ending at the end point of the path self.

EXAMPLES:

```
sage: WordPaths('abcdef')('abababab').directive_vector()
(6, 2*sqrt(3))
sage: WordPaths('abAB')('abababab').directive_vector()
(4, 4)
sage: P = WordPaths('abcABC', steps='cube_grid')
sage: P('ababababCC').directive_vector()
(4, 4, -2)
sage: WordPaths('abcdef')('abcdef').directive_vector()
(0, 0)
sage: P = WordPaths('abc', steps=[(1, 3, 7, 9), (-4, 1, 0, 0), (0, 32, 1, 8)])
sage: P('abcabababacaacccbbcac').directive_vector()
(-16, 254, 63, 128)
```

end_point()

Returns the end point of the path.

EXAMPLES:

```
sage: WordPaths('abcdef')('abababab').end_point()
(6, 2*sqrt(3))
sage: WordPaths('abAB')('abababab').end_point()
(4, 4)
sage: P = WordPaths('abcABC', steps='cube_grid')
sage: P('ababababCC').end_point()
(4, 4, -2)
sage: WordPaths('abcdef')('abcdef').end_point()
(0, 0)
sage: P = WordPaths('abc', steps=[(1, 3, 7, 9), (-4, 1, 0, 0), (0, 32, 1, 8)])
sage: P('abcabababacaacccbbcac').end_point()
(-16, 254, 63, 128)
```

is_closed()

Returns True if the path is closed, i.e. if the origin and the end of the path are equal.

EXAMPLES:

```

sage: P = WordPaths('abcd', steps=[(1,0), (0,1), (-1,0), (0,-1)])
sage: P('abcd').is_closed()
True
sage: P('abc').is_closed()
False
sage: P().is_closed()
True
sage: P('aacacc').is_closed()
True

```

is_simple()

Returns True if the path is simple, i.e. if all its points are distincts.

If the path is closed, the last point is not considered.

EXAMPLES:

```

sage: P = WordPaths('abcdef', steps='triangle_grid'); P
Word Paths on the triangle grid
sage: P('abc').is_simple()
True
sage: P('abcde').is_simple()
True
sage: P('abcdef').is_simple()
True
sage: P('ad').is_simple()
True
sage: P('aabdee').is_simple()
False

```

is_tangent()

The `is_tangent()` method, which is implemented for words, has an extended meaning for word paths, which is not implemented yet.

AUTHOR:

- Thierry Monteil

plot_projection (*v=None, letters=None, color=None, ring=None, size=12, kind='right'*)

Return an image of the projection of the successive points of the path into the space orthogonal to the given vector.

INPUT:

- `self` - a word path in a 3 or 4 dimension vector space
- `v` - vector (optional, default: None) If None, the directive vector (i.e. the end point minus starting point) of the path is considered.
- `letters` - iterable (optional, default: None) of the letters to be projected. If None, then all the letters are considered.
- `color` - dictionary (optional, default: None) of the letters mapped to colors. If None, automatic colors are chosen.
- `ring` - ring (optional, default: None) where to do the computations. If None, `RealField(53)` is used.
- `size` - number (optional, default: 12) size of the points.
- `kind` - string (optional, default 'right') either 'right' or 'left'. The color of a letter is given to the projected prefix to the right or the left of the letter.

OUTPUT:

2d or 3d Graphic object.

EXAMPLES:

The Rauzy fractal:

```
sage: s = WordMorphism('1->12,2->13,3->1')
sage: D = s.fixed_point('1')
sage: v = s.pisot_eigenvector_right()
sage: P = WordPaths('123', [(1,0,0), (0,1,0), (0,0,1)])
sage: w = P(D[:200])
sage: w.plot_projection(v) # long time (2s)
Graphics object consisting of 200 graphics primitives
```

In this case, the abelianized vector doesn't give a good projection:

```
sage: w.plot_projection() # long time (2s)
Graphics object consisting of 200 graphics primitives
```

You can project only the letters you want:

```
sage: w.plot_projection(v, letters='12') # long time (2s)
Graphics object consisting of 168 graphics primitives
```

You can increase or decrease the precision of the computations by changing the ring of the projection matrix:

```
sage: w.plot_projection(v, ring=RealField(20)) # long time (2s)
Graphics object consisting of 200 graphics primitives
```

You can change the size of the points:

```
sage: w.plot_projection(v, size=30) # long time (2s)
Graphics object consisting of 200 graphics primitives
```

You can assign the color of a letter to the projected prefix to the right or the left of the letter:

```
sage: w.plot_projection(v, kind='left') # long time (2s)
Graphics object consisting of 200 graphics primitives
```

To remove the axis, do like this:

```
sage: r = w.plot_projection(v)
sage: r.axes(False)
sage: r # long time (2s)
Graphics object consisting of 200 graphics primitives
```

You can assign different colors to each letter:

```
sage: color = {'1': 'purple', '2': (.2, .3, .4), '3': 'magenta'}
sage: w.plot_projection(v, color=color) # long time (2s)
Graphics object consisting of 200 graphics primitives
```

The 3d-Rauzy fractal:

```
sage: s = WordMorphism('1->12,2->13,3->14,4->1')
sage: D = s.fixed_point('1')
```

```

sage: v = s.pisot_eigenvector_right()
sage: P = WordPaths('1234', [(1,0,0,0), (0,1,0,0), (0,0,1,0), (0,0,0,1)])
sage: w = P(D[:200])
sage: w.plot_projection(v)
Graphics3d Object

```

The dimension of vector space of the parent must be 3 or 4:

```

sage: P = WordPaths('ab', [(1, 0), (0, 1)])
sage: p = P('aabbabbab')
sage: p.plot_projection()
Traceback (most recent call last):
...
TypeError: The dimension of the vector space (=2) must be 3 or 4

```

points (*include_last=True*)

Returns an iterator yielding a list of points used to draw the path represented by this word.

INPUT:

- *include_last* - bool (default: True) whether to include the last point

EXAMPLES:

A simple closed square:

```

sage: P = WordPaths('abAB')
sage: list(P('abAB').points())
[(0, 0), (1, 0), (1, 1), (0, 1), (0, 0)]

```

A simple closed square without the last point:

```

sage: list(P('abAB').points(include_last=False))
[(0, 0), (1, 0), (1, 1), (0, 1)]

```

```

sage: list(P('abaB').points())
[(0, 0), (1, 0), (1, 1), (2, 1), (2, 0)]

```

projected_path (*v=None, ring=None*)

Return the path projected into the space orthogonal to the given vector.

INPUT:

- *v* - vector (optional, default: None) If None, the directive vector (i.e. the end point minus starting point) of the path is considered.
- *ring* - ring (optional, default: None) where to do the computations. If None, `RealField(53)` is used.

OUTPUT:

word path

EXAMPLES:

The projected path of the tribonacci word:

```

sage: s = WordMorphism('1->12,2->13,3->1')
sage: D = s.fixed_point('1')
sage: v = s.pisot_eigenvector_right()
sage: P = WordPaths('123', [(1,0,0), (0,1,0), (0,0,1)])
sage: w = P(D[:1000])

```

```

sage: p = w.projected_path(v)
sage: p
Path: 1213121121312121312112131213121121312121...
sage: p[:20].plot()
Graphics object consisting of 3 graphics primitives

```

The ring argument allows to change the precision of the projected steps:

```

sage: p = w.projected_path(v, RealField(10))
sage: p
Path: 1213121121312121312112131213121121312121...
sage: p.parent().letters_to_steps()
{'1': (-0.53, 0.00), '2': (0.75, -0.48), '3': (0.41, 0.88)}

```

projected_point_iterator ($v=None$, $ring=None$)

Return an iterator of the projection of the orbit points of the path into the space orthogonal to the given vector.

INPUT:

- v - vector (optional, default: None) If None, the directive vector (i.e. the end point minus starting point) of the path is considered.
- $ring$ - ring (optional, default: None) where to do the computations. If None, `RealField(53)` is used.

OUTPUT:

iterator of points

EXAMPLES:

Projected points of the Rauzy fractal:

```

sage: s = WordMorphism('1->12,2->13,3->1')
sage: D = s.fixed_point('1')
sage: v = s.pisot_eigenvector_right()
sage: P = WordPaths('123', [(1,0,0), (0,1,0), (0,0,1)])
sage: w = P(D[:200])
sage: it = w.projected_point_iterator(v)
sage: for i in range(6): next(it)
(0.000000000000000, 0.000000000000000)
(-0.526233343362516, 0.000000000000000)
(0.220830337618112, -0.477656250512816)
(-0.305403005744404, -0.477656250512816)
(0.100767309386062, 0.400890564600664)
(-0.425466033976454, 0.400890564600664)

```

Projected points of a 2d path:

```

sage: P = WordPaths('ab', 'ne')
sage: p = P('aabbabbab')
sage: it = p.projected_point_iterator(ring=RealField(20))
sage: for i in range(8): next(it)
(0.00000)
(0.78087)
(1.5617)
(0.93704)
(0.31235)
(1.0932)

```

```
(0.46852)
(-0.15617)
```

start_point()

Return the starting point of self.

OUTPUT:

vector

EXAMPLES:

```
sage: WordPaths('abcdef')('abcdef').start_point()
(0, 0)
sage: WordPaths('abcdef', steps='cube_grid')('abcdef').start_point()
(0, 0, 0)
sage: P = WordPaths('ab', steps=[(1,0,0,0),(0,1,0,0)])
sage: P('abbba').start_point()
(0, 0, 0, 0)
```

tikz_trajectory()

Returns the trajectory of self as a tikz str.

EXAMPLES:

```
sage: P = WordPaths('abcdef')
sage: p = P('abcde')
sage: p.tikz_trajectory()
'(0.000, 0.000) -- (1.00, 0.000) -- (1.50, 0.866) -- (1.00, 1.73) -- (0.000, 1.73) -- (-0.500, 0.866)'
```

class sage.combinat.words.paths.**FiniteWordPath_all_callable**(parent, callable, length=None)

Bases: *sage.combinat.words.word_infinite_datatypes.WordDatatype_callable*,
sage.combinat.words.paths.FiniteWordPath_all, *sage.combinat.words.finite_word.FiniteWord_class*

INPUT:

- parent - a parent
- callable - a callable defined on range(stop=length)
- length - (default: None) nonnegative integer or None

EXAMPLES:

```
sage: f = lambda n : 'x' if n % 2 == 0 else 'y'
sage: w = Word(f, length=9, caching=False); w
word: xyxyxyxyx
sage: type(w)
<class 'sage.combinat.words.word.FiniteWord_callable'>

FiniteWord_class

```

```

class sage.combinat.words.paths.FiniteWordPath_square_grid
Bases: sage.combinat.words.paths.FiniteWordPath_2d

```

area()

Returns the area of a closed path.

INPUT:

- self - a closed path

EXAMPLES:

```

sage: P = WordPaths('abAB', steps='square_grid')
sage: P('abAB').area()
1
sage: P('aabbAABB').area()
4
sage: P('aabbABAB').area()
3

```

The area of the Fibonacci tiles:

```

sage: [words.fibonacci_tile(i).area() for i in range(6)]
[1, 5, 29, 169, 985, 5741]
sage: [words.dual_fibonacci_tile(i).area() for i in range(6)]
[1, 5, 29, 169, 985, 5741]
sage: oeis(_) [0] # optional -- internet
A001653: Numbers n such that 2*n^2 - 1 is a square.
sage: _.first_terms() # optional -- internet
(1,

10181446324101389,
59341817924539925)

```

is_closed()

Returns True if self represents a closed path and False otherwise.

EXAMPLES:

```

sage: P = WordPaths('abAB', steps='square_grid')
sage: P('aA').is_closed()
True
sage: P('abAB').is_closed()
True
sage: P('ababAABB').is_closed()
True
sage: P('aaabbbAABB').is_closed()
False
sage: P('ab').is_closed()
False

```

is_simple()

Returns True if the path is simple, i.e. if all its points are distincts.

If the path is closed, the last point is not considered.

Note: The linear algorithm described in the thesis of Xavier Provençal should be implemented here.

EXAMPLES:

```

sage: P = WordPaths('abAB', steps='square_grid')
sage: P('abab').is_simple()
True
sage: P('abAB').is_simple()
True
sage: P('abA').is_simple()
True
sage: P('aabABB').is_simple()
False
sage: P().is_simple()
True
sage: P('A').is_simple()
True
sage: P('aA').is_simple()
True
sage: P('aaA').is_simple()
False

```

REFERENCES:

- Provençal, X., Combinatoires des mots, geometrie discrete et pavages, These de doctorat en Mathematiques, Montreal, UQAM, septembre 2008, 115 pages.

tikz_trajectory()

Returns the trajectory of self as a tikz str.

EXAMPLES:

```
sage: f = words.fibonacci_tile(1)
sage: f.tikz_trajectory()
'(0, 0) -- (0, -1) -- (-1, -1) -- (-1, -2) -- (0, -2) -- (0, -3) -- (1, -3) --
→ (1, -2) -- (2, -2) -- (2, -1) -- (1, -1) -- (1, 0) -- (0, 0)'
```

8
```

class `sage.combinat.words.paths.FiniteWordPath_square_grid_iter_with_caching` (*parent*, *iter*, *length=None*)

Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_iter_with_caching`, `sage.combinat.words.paths.FiniteWordPath_square_grid`, `sage.combinat.words.finite_word.FiniteWord_class`

INPUT:

- *parent* - a parent
- *iter* - an iterator
- *length* - (default: None) the length of the word

EXAMPLES:

```
sage: import itertools
sage: Word(itertools.cycle("abbabaab"))
word: abbabaababbabaababbabaababbabaababbabaab...
sage: w = Word(iter("abbabaab"), length="finite"); w
word: abbabaab
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length="unknown"); w
word: abbabaab
sage: w.length()
8
sage: list(w)
['a', 'b', 'b', 'a', 'b', 'a', 'a', 'b']
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length=8)
sage: w._len
8
```

class `sage.combinat.words.paths.FiniteWordPath_square_grid_list`

Bases: `sage.combinat.words.word_datatypes.WordDatatype_list`, `sage.combinat.words.paths.FiniteWordPath_square_grid`, `sage.combinat.words.finite_word.FiniteWord_class`

class `sage.combinat.words.paths.FiniteWordPath_square_grid_str`

Bases: `sage.combinat.words.word_datatypes.WordDatatype_str`, `sage.combinat.words.paths.FiniteWordPath_square_grid`, `sage.combinat.words.finite_word.FiniteWord_class`

class `sage.combinat.words.paths.FiniteWordPath_square_grid_tuple`

Bases: `sage.combinat.words.word_datatypes.WordDatatype_tuple`, `sage.combinat.words.paths.FiniteWordPath_square_grid`, `sage.combinat.words.finite_word.FiniteWord_class`

class `sage.combinat.words.paths.FiniteWordPath_triangle_grid`

Bases: `sage.combinat.words.paths.FiniteWordPath_2d`

xmax ()

Returns the maximum of the x-coordinates of the path.

EXAMPLES:

```
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.xmax()
4.500000000000000
sage: w = WordPaths('abcABC', steps='triangle')('ABAcacacababababcbcbAC')
sage: w.xmax()
4.000000000000000
```

xmin()

Returns the minimum of the x-coordinates of the path.

EXAMPLES:

```
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.xmin()
0.000000000000000
sage: w = WordPaths('abcABC', steps='triangle')('ABAcacacababababcbcbAC')
sage: w.xmin()
-3.000000000000000
```

ymax()

Returns the maximum of the y-coordinates of the path.

EXAMPLES:

```
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.ymax()
2.59807621135332
sage: w = WordPaths('abcABC', steps='triangle')('ABAcacacababababcbcbAC')
sage: w.ymax()
8.66025403784439
```

ymin()

Returns the minimum of the y-coordinates of the path.

EXAMPLES:

```
sage: w = WordPaths('abcABC', steps='triangle')('ababcaaBC')
sage: w.ymin()
0.000000000000000
sage: w = WordPaths('abcABC', steps='triangle')('ABAcacacababababcbcbAC')
sage: w.ymin()
-0.866025403784439
```

```
class sage.combinat.words.paths.FiniteWordPath_triangle_grid_callable (parent,
                                                                    callable,
                                                                    length=None)
Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_callable,
sage.combinat.words.paths.FiniteWordPath_triangle_grid, sage.combinat.
words.finite_word.FiniteWord_class
```

INPUT:

- parent - a parent
- callable - a callable defined on range (stop=length)
- length - (default: None) nonnegative integer or None

EXAMPLES:

```

sage: f = lambda n : 'x' if n % 2 == 0 else 'y'
sage: w = Word(f, length=9, caching=False); w
word: xyxyxyxyx
sage: type(w)
<class 'sage.combinat.words.word.FiniteWord_callable'>
sage: w.length()
9

```

```

sage: w = Word(f, caching=False); w
word: xyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxy...
sage: type(w)
<class 'sage.combinat.words.word.InfiniteWord_callable'>
sage: w.length() is None
False
sage: w.length()
+Infinity

```

class `sage.combinat.words.paths.FiniteWordPath_triangle_grid_callable_with_caching` (*parent, callable, length=None*)

Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_callable_with_caching`,
`sage.combinat.words.paths.FiniteWordPath_triangle_grid`, `sage.combinat.words.finite_word.FiniteWord_class`

INPUT:

- parent - a parent
- callable - a callable defined on range (stop=length)
- length - (default: None) nonnegative integer or None

EXAMPLES:

```

sage: f = lambda n : 'x' if n % 2 == 0 else 'y'
sage: w = Word(f, length=9, caching=True); w
word: xyxyxyxyx
sage: type(w)
<class 'sage.combinat.words.word.FiniteWord_callable_with_caching'>
sage: w.length()
9

```

```

sage: w = Word(f, caching=True); w
word: xyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxy...
sage: type(w)
<class 'sage.combinat.words.word.InfiniteWord_callable_with_caching'>
sage: w.length() is None
False
sage: w.length()
+Infinity

```

class `sage.combinat.words.paths.FiniteWordPath_triangle_grid_iter` (*parent, iter, length=None*)

Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_iter`, `sage.combinat.words.paths.FiniteWordPath_triangle_grid`, `sage.combinat.words.finite_word.FiniteWord_class`

INPUT:

- parent - a parent
- iter - an iterator
- length - (default: None) the length of the word

EXAMPLES:

```
sage: w = Word(iter("abbabaab"), length="unknown", caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
sage: w.length() is None
False
sage: w.length()
8
sage: s = "abbabaabbaababbabaababbabaabbaababbabaababab"
sage: w = Word(iter(s), length="unknown", caching=False); w
word: abbabaabbaababbabaababbabaabbaababbabaabba...
sage: w.length() is None
True
```

```
sage: w = Word(iter("abbabaab"), length="finite", caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length=8, caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
sage: w.length()
8
```

class `sage.combinat.words.paths.FiniteWordPath_triangle_grid_iter_with_caching` (*parent*, *iter*, *length=None*)

Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_iter_with_caching`, `sage.combinat.words.paths.FiniteWordPath_triangle_grid`, `sage.combinat.words.finite_word.FiniteWord_class`

INPUT:

- parent - a parent
- iter - an iterator
- length - (default: None) the length of the word

EXAMPLES:

```
sage: import itertools
sage: Word(itertools.cycle("abbabaab"))
word: abbabaababbabaababbabaababbabaababbabaab...
sage: w = Word(iter("abbabaab"), length="finite"); w
word: abbabaab
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length="unknown"); w
word: abbabaab
```

```

sage: w.length()
8
sage: list(w)
['a', 'b', 'b', 'a', 'b', 'a', 'a', 'b']
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length=8)
sage: w._len
8

```

class `sage.combinat.words.paths.FiniteWordPath_triangle_grid_list`

Bases: `sage.combinat.words.word_datatypes.WordDatatype_list`, `sage.combinat.words.paths.FiniteWordPath_triangle_grid`, `sage.combinat.words.finite_word.FiniteWord_class`

class `sage.combinat.words.paths.FiniteWordPath_triangle_grid_str`

Bases: `sage.combinat.words.word_datatypes.WordDatatype_str`, `sage.combinat.words.paths.FiniteWordPath_triangle_grid`, `sage.combinat.words.finite_word.FiniteWord_class`

class `sage.combinat.words.paths.FiniteWordPath_triangle_grid_tuple`

Bases: `sage.combinat.words.word_datatypes.WordDatatype_tuple`, `sage.combinat.words.paths.FiniteWordPath_triangle_grid`, `sage.combinat.words.finite_word.FiniteWord_class`

`sage.combinat.words.paths.WordPaths` (*alphabet, steps=None*)

Returns the combinatorial class of paths of the given type of steps.

INPUT:

- `alphabet` - ordered alphabet
- `steps` - (default is None). It can be one of the following:
 - an iterable ordered container of as many vectors as there are letters in the alphabet. The vectors are associated to the letters according to their order in steps. The vectors can be a tuple or anything that can be passed to vector function.
 - an iterable ordered container of k vectors where k is half the size of alphabet. The vectors and their opposites are associated to the letters according to their order in steps (given vectors first, opposite vectors after).
 - None: In this case, the type of steps are guessed from the length of alphabet.
 - ‘square_grid’ or ‘square’: (default when size of alphabet is 4) The order is : East, North, West, South.
 - ‘triangle_grid’ or ‘triangle’:
 - ‘hexagonal_grid’ or ‘hexagon’: (default when size of alphabet is 6)
 - ‘cube_grid’ or ‘cube’:
 - ‘north_east’, ‘ne’ or ‘NE’: (the default when size of alphabet is 2)
 - ‘dyck’:

OUTPUT:

- The combinatorial class of all paths of the given type.

EXAMPLES:

The steps can be given explicitly:

```
sage: WordPaths('abc', steps=[(1,2), (-1,4), (0,-3)])
Word Paths over 3 steps
```

Different type of input alphabet:

```
sage: WordPaths(range(3), steps=[(1,2), (-1,4), (0,-3)])
Word Paths over 3 steps
sage: WordPaths(['cric', 'crac', 'croc'], steps=[(1,2), (1,4), (0,3)])
Word Paths over 3 steps
```

Directions can be in three dimensions as well:

```
sage: WordPaths('ab', steps=[(1,2,2), (-1,4,2)])
Word Paths over 2 steps
```

When the number of given steps is half the size of alphabet, the opposite of vectors are used:

```
sage: P = WordPaths('abcd', [(1,0), (0,1)])
sage: P
Word Paths over 4 steps
sage: sorted(P.letters_to_steps().items())
[('a', (1, 0)), ('b', (0, 1)), ('c', (-1, 0)), ('d', (0, -1))]
```

When no steps are given, default classes are returned:

```
sage: WordPaths('ab')
Word Paths in North and East steps
sage: WordPaths(range(4))
Word Paths on the square grid
sage: WordPaths(range(6))
Word Paths on the hexagonal grid
```

There are many type of built-in steps...

On a two letters alphabet:

```
sage: WordPaths('ab', steps='north_east')
Word Paths in North and East steps
sage: WordPaths('()', steps='dyck')
Finite Dyck paths
```

On a four letters alphabet:

```
sage: WordPaths('ruld', steps='square_grid')
Word Paths on the square grid
```

On a six letters alphabet:

```
sage: WordPaths('abcdef', steps='hexagonal_grid')
Word Paths on the hexagonal grid
sage: WordPaths('abcdef', steps='triangle_grid')
Word Paths on the triangle grid
sage: WordPaths('abcdef', steps='cube_grid')
Word Paths on the cube grid
```

```
class sage.combinat.words.paths.WordPaths_all(alphabet, steps)
Bases: sage.combinat.words.words.FiniteWords
```

The combinatorial class of all paths, i.e of all words over an alphabet where each letter is mapped to a step (a vector).

letters_to_steps()

Returns the dictionary mapping letters to vectors (steps).

EXAMPLES:

```
sage: d = WordPaths('ab').letters_to_steps()
sage: sorted(d.items())
[('a', (0, 1)), ('b', (1, 0))]
sage: d = WordPaths('abcd').letters_to_steps()
sage: sorted(d.items())
[('a', (1, 0)), ('b', (0, 1)), ('c', (-1, 0)), ('d', (0, -1))]
sage: d = WordPaths('abcdef').letters_to_steps()
sage: sorted(d.items())
[('a', (1, 0)),
 ('b', (1/2, 1/2*sqrt(3))),
 ('c', (-1/2, 1/2*sqrt(3))),
 ('d', (-1, 0)),
 ('e', (-1/2, -1/2*sqrt(3))),
 ('f', (1/2, -1/2*sqrt(3)))]
```

vector_space()

Return the vector space over which the steps of the paths are defined.

EXAMPLES:

```
sage: WordPaths('ab', steps='dyck').vector_space()
Ambient free module of rank 2 over the principal ideal domain Integer Ring
sage: WordPaths('ab', steps='north_east').vector_space()
Ambient free module of rank 2 over the principal ideal domain Integer Ring
sage: WordPaths('abcd', steps='square_grid').vector_space()
Ambient free module of rank 2 over the principal ideal domain Integer Ring
sage: WordPaths('abcdef', steps='hexagonal_grid').vector_space()
Vector space of dimension 2 over Number Field in sqrt(3) with defining_
↳ polynomial x^2 - 3
sage: WordPaths('abcdef', steps='cube_grid').vector_space()
Ambient free module of rank 3 over the principal ideal domain Integer Ring
sage: WordPaths('abcdef', steps='triangle_grid').vector_space()
Vector space of dimension 2 over Number Field in sqrt(3) with defining_
↳ polynomial x^2 - 3
```

class sage.combinat.words.paths.**WordPaths_cube_grid**(*alphabet*)

Bases: *sage.combinat.words.paths.WordPaths_all*

The combinatorial class of all paths on the cube grid.

class sage.combinat.words.paths.**WordPaths_dyck**(*alphabet*)

Bases: *sage.combinat.words.paths.WordPaths_all*

The combinatorial class of all Dyck paths.

class sage.combinat.words.paths.**WordPaths_hexagonal_grid**(*alphabet*)

Bases: *sage.combinat.words.paths.WordPaths_triangle_grid*

The combinatorial class of all paths on the hexagonal grid.

class sage.combinat.words.paths.**WordPaths_north_east**(*alphabet*)

Bases: *sage.combinat.words.paths.WordPaths_all*

The combinatorial class of all paths using North and East directions.

class `sage.combinat.words.paths.WordPaths_square_grid(alphabet)`

Bases: `sage.combinat.words.paths.WordPaths_all`

The combinatorial class of all paths on the square grid.

class `sage.combinat.words.paths.WordPaths_triangle_grid(alphabet)`

Bases: `sage.combinat.words.paths.WordPaths_all`

The combinatorial class of all paths on the triangle grid.

5.1.339 Shuffle product of words

See also:

The module `sage.combinat.shuffle` contains a more general implementation of shuffle product.

class `sage.combinat.words.shuffle_product.ShuffleProduct_overlapping(w1, w2)`

Bases: `sage.combinat.combinat.CombinatorialClass`

The overlapping shuffle product of the two words `w1` and `w2`.

If u and v are two words whose letters belong to an additive monoid or to another kind of alphabet on which addition is well-defined, then the *overlapping shuffle product* of u and v is a certain multiset of words defined as follows: Let a and b be the lengths of u and v , respectively. Let A be the set $\{(0, 1), (0, 2), \dots, (0, a)\}$, and let B be the set $\{(1, 1), (1, 2), \dots, (1, b)\}$. Notice that the sets A and B are disjoint. We can make A and B into posets by setting $(k, i) \leq (k, j)$ for all $k \in \{0, 1\}$ and $i \leq j$. Then, $A \cup B$ becomes a poset by disjoint union (we don't set $(0, i) \leq (1, i)$). Let p be the map from $A \cup B$ to the set of all letters which sends every $(0, i)$ to the i -th letter of u , and every $(1, j)$ to the j -th letter of v . For every nonnegative integer c and every surjective map $f : A \cup B \rightarrow \{1, 2, \dots, c\}$ for which both restrictions $f|_A$ and $f|_B$ are strictly increasing, let $w(f)$ be the length- c word such that for every $1 \leq k \leq c$, the k -th letter of $w(f)$ equals $\sum_{j \in f^{-1}(k)} p(j)$ (this sum always has either one or two addends). The overlapping shuffle product of u and v is then the multiset of all $w(f)$ with c ranging over all nonnegative integers and f ranging over the surjective maps $f : A \cup B \rightarrow \{1, 2, \dots, c\}$ for which both restrictions $f|_A$ and $f|_B$ are strictly increasing.

If one restricts c to a particular fixed nonnegative integer, then the multiset is instead called the *overlapping shuffle product with precisely ' $a + b - c$ ' overlaps*. This is nonempty only if $\max\{a, b\} \leq c \leq a + b$.

If $c = a + b$, then the overlapping shuffle product with precisely $a + b - c$ overlaps is plainly the shuffle product (`ShuffleProduct_w1w2`).

EXAMPLES:

```
sage: from sage.combinat.words.shuffle_product import ShuffleProduct_overlapping
sage: w, u = map(Words(range(20)), [[2, 9], [9, 1]])
sage: S = ShuffleProduct_overlapping(w, u)
sage: sorted([list(i) for i in list(S)])
[[2, 9, 1, 9],
 [2, 9, 9, 1],
 [2, 9, 9, 1],
 [2, 9, 10],
 [2, 18, 1],
 [9, 1, 2, 9],
 [9, 2, 1, 9],
 [9, 2, 9, 1],
 [9, 2, 10],
 [9, 3, 9],
 [11, 1, 9],
 [11, 9, 1],
 [11, 10]]
```

```
sage: S == loads(dumps(S))
True
```

class `sage.combinat.words.shuffle_product.ShuffleProduct_overlapping_r(w1, w2, r)`

Bases: `sage.combinat.combinat.CombinatorialClass`

The overlapping shuffle product of the two words `w1` and `w2` with precisely `r` overlaps.

See `ShuffleProduct_overlapping` for a definition.

EXAMPLES:

```
sage: from sage.combinat.words.shuffle_product import ShuffleProduct_overlapping_r
sage: w, u = map(Words(range(20)), [[2, 9], [9, 1]])
sage: S = ShuffleProduct_overlapping_r(w, u, 1)
sage: S == loads(dumps(S))
True
```

class `sage.combinat.words.shuffle_product.ShuffleProduct_shifted(w1, w2)`

Bases: `sage.combinat.words.shuffle_product.ShuffleProduct_w1w2`

Shifted shuffle product of `w1` with `w2`.

This is the shuffle product of `w1` with the word obtained by adding the length of `w1` to every letter of `w2`.

Note that this class is meant to be used for words; it misbehaves when `w1` is a permutation or composition.

EXAMPLES:

```
sage: from sage.combinat.words.shuffle_product import ShuffleProduct_shifted
sage: w, u = Word([1, 2]), Word([3, 4])
sage: S = ShuffleProduct_shifted(w, u)
sage: S == loads(dumps(S))
True
```

class `sage.combinat.words.shuffle_product.ShuffleProduct_w1w2(w1, w2)`

Bases: `sage.combinat.combinat.CombinatorialClass`

The shuffle product of the two words `w1` and `w2`.

If u and v are two words, then the *shuffle product* of u and v is a certain multiset of words defined as follows: Let a and b be the lengths of u and v , respectively. For every a -element subset I of $\{1, 2, \dots, a + b\}$, let $w(I)$ be the length- $a + b$ word such that:

- for every $1 \leq k \leq a$, the i_k -th letter of $w(I)$ is the k -th letter of u , where i_k is the k -th smallest element of I ;
- for every $1 \leq l \leq b$, the j_l -th letter of $w(I)$ is the l -th letter of v , where j_l is the l -th smallest element of $\{1, 2, \dots, a + b\} \setminus I$.

The shuffle product of u and v is then the multiset of all $w(I)$ with I ranging over the a -element subsets of $\{1, 2, \dots, a + b\}$.

EXAMPLES:

```
sage: from sage.combinat.words.shuffle_product import ShuffleProduct_w1w2
sage: W = Words([1, 2, 3, 4])
sage: s = ShuffleProduct_w1w2(W([1, 2]), W([3, 4]))
sage: sorted(list(s))
[word: 1234, word: 1324, word: 1342, word: 3124, word: 3142, word: 3412]
sage: s == loads(dumps(s))
```

```

True

sage: s = ShuffleProduct_w1w2(W([1,4,3]),W([2]))
sage: sorted(list(s))
[word: 1243, word: 1423, word: 1432, word: 2143]

sage: s = ShuffleProduct_w1w2(W([1,4,3]),W([]))
sage: sorted(list(s))
[word: 143]

```

cardinality()

Return the number of words in the shuffle product of w_1 and w_2 .

This is understood as a multiset cardinality, not as a set cardinality; it does not count the distinct words only.

It is given by $\binom{l_1+l_2}{l_1}$, where l_1 is the length of w_1 and where l_2 is the length of w_2 .

EXAMPLES:

```

sage: from sage.combinat.words.shuffle_product import ShuffleProduct_w1w2
sage: w, u = map(Words("abcd"), ["ab", "cd"])
sage: S = ShuffleProduct_w1w2(w,u)
sage: S.cardinality()
6

sage: w, u = map(Words("ab"), ["ab", "ab"])
sage: S = ShuffleProduct_w1w2(w,u)
sage: S.cardinality()
6

```

5.1.340 Suffix Tries and Suffix Trees

class `sage.combinat.words.suffix_trees.ImplicitSuffixTree(word)`

Bases: `sage.structure.sage_object.SageObject`

Construct the implicit suffix tree of a word w .

The suffix tree of a word w is a compactification of the suffix trie for w . The compactification removes all nodes that have exactly one incoming edge and exactly one outgoing edge. It consists of two components: a tree and a word. Thus, instead of labelling the edges by factors of w , we can label them by indices of the occurrence of the factors in w .

The following is a straightforward implementation of Ukkonen's on-line algorithm for constructing the implicit suffix tree [1]. It constructs the suffix tree for $w[i:]$ from that of $w[i-1:]$.

GENERAL IDEA. The suffix tree of $w[i+1:]$ can be obtained from that of $w[i:]$ by visiting each node corresponding to a suffix of $w[i:]$ and modifying the tree by applying one of two rules (either append a new node to the tree, or split an edge into two). The "active state" is the node where the algorithm begins and the "suffix link" carries us to the next node that needs to be dealt with.

TREE. The tree is modelled as an automaton, which is stored as a dictionary of dictionaries: it is keyed by the nodes of the tree, and the corresponding dictionary is keyed by pairs (i, j) of integers representing the word $w[i-1:j]$. This makes it faster to look up a particular transition beginning at a specific node.

STATES/NODES. The states will always be $-1, 0, 1, \dots, n$. The state -1 is special and is only used for the purposes of the algorithm. All transitions map -1 to 0 , so this information is not explicitly stored in the transition function.

EXPLICIT/IMPLICIT NODES. By definition, some of the nodes will not be states, but merely locations along an edge; these are called implicit nodes. A node r (implicit or explicit) is referenced as a pair $(s, (k, p))$ where s is an ancestor of r and $w[k-1:p]$ is the word read by transitioning from s to r in the suffix trie. A reference pair is canonical if s is the closest ancestor of r .

SUFFIX LINK. The algorithm makes use of a map from (some) nodes to other nodes, called the suffix link. This is stored as a dictionary.

ACTIVE STATE. We store as `._active_state` the active state of the tree, the state where the algorithm will begin when processing the next letter.

RUNNING TIME. The running time and storage space of the algorithm is linear in the length of the word w (whereas for a suffix tree it is quadratic).

REFERENCES:

- [1] E. Ukkonen, “On-line construction of suffix trees”, *Algorithmica*, 1995, volume 14, number 3, pages 249–260.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: w = Words("aco") ("cacao")
sage: t = ImplicitSuffixTree(w); t
Implicit Suffix Tree of the word: cacao
sage: ababb = Words([0,1])([0,1,0,1,1])
sage: s = ImplicitSuffixTree(ababb); s
Implicit Suffix Tree of the word: 01011
```

active_state()

Returns the active state of the suffix tree.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.active_state()
(0, (6, 6))
```

edge_iterator()

Returns an iterator over the edges of the suffix tree. The edge from u to v labelled by (i, j) is returned as the tuple $(u, v, (i, j))$.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: sorted( ImplicitSuffixTree(Word("aaaaa")).edge_iterator() )
[(0, 1, (0, None))]
sage: sorted( ImplicitSuffixTree(Word([0,1,0,1])).edge_iterator() )
[(0, 1, (0, None)), (0, 2, (1, None))]
sage: sorted( ImplicitSuffixTree(Word()).edge_iterator() )
[]
```

factor_iterator(n=None)

Generate distinct factors of `self`.

INPUT:

- n - an integer, or `None`.

OUTPUT:

- If n is an integer, returns an iterator over all distinct factors of length n . If n is `None`, returns an iterator generating all distinct factors.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: sorted( ImplicitSuffixTree(Word("cacao")).factor_iterator() )
[word: , word: a, word: ac, word: aca, word: acao, word: ao, word: c, word:
↪ca, word: cac, word: caca, word: cacao, word: cao, word: o]

sage: sorted( ImplicitSuffixTree(Word()).factor_iterator(2) )
[]
```

number_of_factors ($n=None$)

Count the number of distinct factors of `self.word()`.

INPUT:

- n - an integer, or `None`.

OUTPUT:

- If n is an integer, returns the number of distinct factors of length n . If n is `None`, returns the total number of distinct factors.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: t = ImplicitSuffixTree(Word([1,2,1,3,1,2,1]))
sage: t.number_of_factors()
22
sage: t.number_of_factors(1)
3
sage: t.number_of_factors(9)
0
sage: t.number_of_factors(0)
1
```

```
sage: t = ImplicitSuffixTree(Word("cacao"))
sage: t.number_of_factors()
13
sage: list(map(t.number_of_factors, range(10)))
[1, 3, 3, 3, 2, 1, 0, 0, 0, 0]
```

```
sage: t = ImplicitSuffixTree(Word("c"*1000))
sage: t.number_of_factors()
1001
sage: t.number_of_factors(17)
1
```

```
sage: t.number_of_factors(0)
1
```

```
sage: ImplicitSuffixTree(Word()).number_of_factors()
1
```

```
sage: blueberry = ImplicitSuffixTree(Word("blueberry"))
sage: blueberry.number_of_factors()
43
sage: list(map(blueberry.number_of_factors, range(10)))
[1, 6, 8, 7, 6, 5, 4, 3, 2, 1]
```

plot (*word_labels=False*, *layout='tree'*, *tree_root=0*, *tree_orientation='up'*, *vertex_colors=None*, *edge_labels=True*, **args*, ***kwds*)
Returns a Graphics object corresponding to the transition graph of the suffix tree.

INPUT:

- *word_labels* - boolean (default: False) if False, labels the edges by pairs (i, j) ; if True, labels the edges by `word[i:j]`.
- *layout* - (default: 'tree')
- *tree_root* - (default: 0)
- *tree_orientation* - (default: 'up')
- *vertex_colors* - (default: None)
- *edge_labels* - (default: True)

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: ImplicitSuffixTree(Word('cacao')).plot(word_labels=True)
Graphics object consisting of 23 graphics primitives
sage: ImplicitSuffixTree(Word('cacao')).plot(word_labels=False)
Graphics object consisting of 23 graphics primitives
```

process_letter (*letter*)

Modifies the current implicit suffix tree producing the implicit suffix tree for `self.word() + letter`.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: w = Words("aco")("cacao")
sage: t = ImplicitSuffixTree(w[:-1]); t
Implicit Suffix Tree of the word: caca
sage: t.process_letter(w[-1]); t
Implicit Suffix Tree of the word: cacao
```

```
sage: W = Words([0,1])
sage: s = ImplicitSuffixTree(W([0,1,0,1])); s
Implicit Suffix Tree of the word: 0101
sage: s.process_letter(W([1])[0]); s
Implicit Suffix Tree of the word: 01011
```

show (*word_labels=None*, **args*, ***kwds*)

Displays the output of `self.plot()`.

INPUT:

- word_labels - (default: None) if False, labels the edges by pairs (i, j) ; if True, labels the edges by word[i:j].

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: w = Words("cao")("cacao")
sage: t = ImplicitSuffixTree(w)
sage: t.show(word_labels=True)
sage: t.show(word_labels=False)
```

states()

Returns the states (explicit nodes) of the suffix tree.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.states()
[0, 1, 2, 3, 4, 5, 6, 7]
```

suffix_link(state)

Evaluates the suffix link map of the implicit suffix tree on state. Note that the suffix link is not defined for all states.

The suffix link of a state x' that corresponds to the suffix x is defined to be -1 if x' is the root (0) and y' otherwise, where y' is the state corresponding to the suffix $x[1:]$.

INPUT:

- state - a state

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.suffix_link(3)
5
sage: t.suffix_link(5)
0
sage: t.suffix_link(0)
-1
sage: t.suffix_link(-1)
Traceback (most recent call last):
...
TypeError: there is no suffix link from -1
```

to_digraph(word_labels=False)

Returns a DiGraph object of the transition graph of the suffix tree.

INPUT:

- word_labels - boolean (default: False) if False, labels the edges by pairs (i, j) ; if True, labels the edges by word[i:j].

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.to_digraph()
Digraph on 8 vertices
```

to_explicit_suffix_tree()

Converts self to an explicit suffix tree. It is obtained by processing an end of string letter as if it were a regular letter, except that no new leaf nodes are created (thus, the only thing that happens is that some implicit nodes become explicit).

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: w = Words("aco")("cacao")
sage: t = ImplicitSuffixTree(w)
sage: t.to_explicit_suffix_tree()
```

```
sage: W = Words([0,1])
sage: s = ImplicitSuffixTree(W([0,1,0,1,1]))
sage: s.to_explicit_suffix_tree()
```

transition_function(word, node=0)

Returns the node obtained by starting from node and following the edges labelled by the letters of word. Returns ("explicit", end_node) if we end at end_node, or ("implicit", edge, d) if we end d spots along an edge.

INPUT:

- word - a word
- node - (default: 0) starting node

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.transition_function(W([0,1,0]))
('implicit', (3, 1), 1)
sage: t.transition_function(W([0,1,2]))
('explicit', 4)
sage: t.transition_function(W([0,1,2]), 5)
('explicit', 2)
sage: t.transition_function(W([0,1]), 5)
('implicit', (5, 2), 2)
```

transition_function_dictionary()

Returns the transition function as a dictionary of dictionaries. The format is consistent with the input format for DiGraph.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words("aco")
sage: t = ImplicitSuffixTree(W("cac"))
sage: t.transition_function_dictionary()
{0: {1: (0, None), 2: (1, None)}}
```

```
sage: W = Words([0,1])
sage: t = ImplicitSuffixTree(W([0,1,0]))
sage: t.transition_function_dictionary()
{0: {1: (0, None), 2: (1, None)}}
```

trie_type_dict()

Returns a dictionary in a format compatible with that of the suffix trie transition function.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree, SuffixTrie
sage: W = Words("ab")
sage: t = ImplicitSuffixTree(W("aba"))
sage: d = t.trie_type_dict()
sage: len(d)
5
sage: d
{(4, word: b): 5, (0, word: a): 4, (0, word: b): 3, (5, word: a): 1, (3, word: a): 2}
```

uncompactify()

Returns the tree obtained from self by splitting edges so that they are labelled by exactly one letter. The resulting tree is isomorphic to the suffix trie.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree, SuffixTrie
sage: abbab = Words("ab")("abbab")
sage: s = SuffixTrie(abbab)
sage: t = ImplicitSuffixTree(abbab)
sage: t.uncompactify().is_isomorphic(s.to_digraph())
True
```

word()

Returns the word whose implicit suffix tree this is.

class sage.combinat.words.suffix_trees.**SuffixTrie**(word)

Bases: sage.structure.sage_object.SageObject

Construct the suffix trie of the word w.

The suffix trie of a finite word w is a data structure representing the factors of w. It is a tree whose edges are labelled with letters of w, and whose leafs correspond to suffixes of w.

This is a straightforward implementation of Algorithm 1 from [1]. It constructs the suffix trie of $w[i:]$ from that of $w[i-1]$.

A suffix trie is modelled as a deterministic finite-state automaton together with the suffix_link map. The set of states corresponds to factors of the word (below we write x' for the state corresponding to x); these are always 0, 1, ... The state 0 is the initial state, and it corresponds to the empty word. For the purposes of the algorithm, there is also an auxiliary state -1. The transition function t is defined as:

```
t(-1,a) = 0 for all letters a; and
t(x',a) = y' for all x',y' \in Q such that y = xa,
```

and the suffix link function is defined as:

```
suffix_link(0) = -1;
suffix_link(x') = y', if x = ay for some letter a.
```

REFERENCES:

- [1] E. Ukkonen, “On-line construction of suffix trees”, Algorithmica, 1995, volume 14, number 3, pages 249–260.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w); t
Suffix Trie of the word: cacao
```

```
sage: e = Words("ab")()
sage: t = SuffixTrie(e); t
Suffix Trie of the word:
sage: t.process_letter("a"); t
Suffix Trie of the word: a
sage: t.process_letter("b"); t
Suffix Trie of the word: ab
sage: t.process_letter("a"); t
Suffix Trie of the word: aba
```

active_state()

Returns the active state of the suffix trie. This is the state corresponding to the word as a suffix of itself.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
sage: t.active_state()
8
```

```
sage: u = Words([0,1])([0,1,1,0,1,0,0,1])
sage: s = SuffixTrie(u)
sage: s.active_state()
22
```

final_states()

Returns the set of final states of the suffix trie. These are the states corresponding to the suffixes of `self.word()`. They are obtained by repeatedly following the suffix link from the active state until we reach 0.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
sage: t.final_states() == Set([8, 9, 10, 11, 12, 0])
True
```

has_suffix(word)

Return True if and only if `word` is a suffix of `self.word()`.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
sage: [t.has_suffix(w[i:]) for i in range(w.length()+1)]
[True, True, True, True, True, True]
sage: [t.has_suffix(w[:i]) for i in range(w.length()+1)]
[True, False, False, False, False, True]
```

node_to_word (*state=0*)

Returns the word obtained by reading the edge labels from 0 to *state*.

INPUT:

- *state* - (default: 0) a state

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("abc")("abcba")
sage: t = SuffixTrie(w)
sage: t.node_to_word(10)
word: abcba
sage: t.node_to_word(7)
word: abcb
```

plot (*layout='tree', tree_root=0, tree_orientation='up', vertex_colors=None, edge_labels=True, *args, **kwds*)

Returns a Graphics object corresponding to the transition graph of the suffix trie.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: SuffixTrie(Word("cacao")).plot()
Graphics object consisting of 38 graphics primitives
```

process_letter (*letter*)

Modify self to produce the suffix trie for `self.word() + letter`.

Note: *letter* must occur within the alphabet of the word.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("ab")("ababba")
sage: t = SuffixTrie(w); t
Suffix Trie of the word: ababba
sage: t.process_letter("a"); t
Suffix Trie of the word: ababbaa
```

show (**args, **kwds*)

Displays the output of `self.plot()`.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cac")
sage: t = SuffixTrie(w)
sage: t.show()
```

states()

Returns the states of the automaton defined by the suffix trie.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words([0,1])([0,1,1])
sage: t = SuffixTrie(w)
sage: t.states()
[0, 1, 2, 3, 4]
```

```
sage: u = Words("aco")("cacao")
sage: s = SuffixTrie(u)
sage: s.states()
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]
```

suffix_link(state)

Evaluates the suffix link map of the suffix trie on state. Note that the suffix link map is not defined on -1.

INPUT:

- state - a state

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
sage: list(map(t.suffix_link, range(13)))
[-1, 0, 3, 0, 5, 1, 7, 2, 9, 10, 11, 12, 0]
sage: t.suffix_link(0)
-1
```

to_digraph()

Returns a DiGraph object of the transition graph of the suffix trie.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cac")
sage: t = SuffixTrie(w)
sage: d = t.to_digraph(); d
Digraph on 6 vertices
sage: d.adjacency_matrix()
[0 1 0 1 0 0]
[0 0 1 0 0 0]
[0 0 0 0 1 0]
[0 0 0 0 0 1]
[0 0 0 0 0 0]
[0 0 0 0 0 0]
```

transition_function(node, word)

Returns the state reached by beginning at node and following the arrows in the transition graph labelled by the letters of word.

INPUT:

- node - a node
- word - a word

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words([0,1])([0,1,0,1,1])
sage: t = SuffixTrie(w)
sage: all(t.transition_function(u, letter) == v
....:      for ((u, letter), v) in t._transition_function.items())
True
```

word()

Returns the word whose suffix tree this is.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("abc")("abcba")
sage: t = SuffixTrie(w)
sage: t.word()
word: abcba
sage: t.word() == w
True
```

5.1.341 Word classes

AUTHORS:

- Arnaud Bergeron
- Amy Glen
- Sébastien Labbé
- Franco Saliola

class `sage.combinat.words.word.FiniteWord_callable` (*parent, callable, length=None*)
 Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_callable`,
`sage.combinat.words.finite_word.FiniteWord_class`

Finite word represented by a callable.

For such word w , type `w.` and hit TAB key to see the list of functions defined on w .

EXAMPLES:

```
sage: f = lambda n : 3 if n > 8 else 6
sage: w = Word(f, length=30, caching=False)
sage: w
word: 666666666333333333333333333333
sage: w.is_symmetric()
True
```

class `sage.combinat.words.word.FiniteWord_callable_with_caching` (*parent, callable, length=None*)
 Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_callable_with_caching`,
`sage.combinat.words.finite_word.FiniteWord_class`

Finite word represented by a callable (with caching).

For such word w , type `w.` and hit TAB key to see the list of functions defined on w .

EXAMPLES:

```

sage: f = lambda n : n % 3
sage: w = Word(f, length=32)
sage: w
word: 01201201201201201201201201201201
sage: w.border()
word: 01201201201201201201201201201

```

class `sage.combinat.words.word.FiniteWord_char`

Bases: `sage.combinat.words.word_char.WordDatatype_char`, `sage.combinat.words.finite_word.FiniteWord_class`

Finite word represented by an array unsigned char * (i.e. integers between 0 and 255).

For any word `w`, type `w.<TAB>` to see the functions that can be applied to `w`.

EXAMPLES:

```

sage: W = Words(range(20))

sage: w = W(list(range(1, 10)) * 2)
sage: type(w)
<class 'sage.combinat.words.word.FiniteWord_char'>
sage: w
word: 123456789123456789

sage: w.is_palindrome()
False
sage: (w*w[::-1]).is_palindrome()
True
sage: (w[::-1]*w[::-1]).is_palindrome()
True

sage: w.is_lyndon()
False
sage: W(list(range(10)) + [10, 10]).is_lyndon()
True

sage: w.is_square_free()
False
sage: w[:-1].is_square_free()
True

sage: u = W([randint(0,10) for i in range(10)])
sage: (u*u).is_square()
True
sage: (u*u*u).is_cube()
True

sage: len(w.factor_set())
127
sage: w.rauzy_graph(5)
Looped digraph on 9 vertices

sage: u = W([1,2,3])
sage: u.first_pos_in(w)
0
sage: u.first_pos_in(w[1:])
8

```

```
class sage.combinat.words.word.FiniteWord_iter (parent, iter, length=None)
Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_iter, sage.combinat.words.finite_word.FiniteWord_class
```

Finite word represented by an iterator.

For such word w , type $w.$ and hit TAB key to see the list of functions defined on w .

EXAMPLES:

```
sage: w = Word(iter(range(10)), caching=False)
sage: w
word: 0123456789
sage: w.finite_differences()
word: 111111111
```

```
class sage.combinat.words.word.FiniteWord_iter_with_caching (parent, iter,
length=None)
Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_iter_with_caching,
sage.combinat.words.finite_word.FiniteWord_class
```

Finite word represented by an iterator (with caching).

For such word w , type $w.$ and hit TAB key to see the list of functions defined on w .

EXAMPLES:

```
sage: w = Word(iter('abcdef'))
sage: w.conjugate(2)
word: cdefab
```

```
class sage.combinat.words.word.FiniteWord_list
Bases: sage.combinat.words.word_datatypes.WordDatatype_list, sage.combinat.words.finite_word.FiniteWord_class
```

Finite word represented by a Python list.

For any word w , type $w.$ and hit TAB key to see the list of functions defined on w .

EXAMPLES:

```
sage: w = Word(range(10))
sage: w.iterated_right_palindromic_closure()
word: 0102010301020104010201030102010501020103...
```

```
class sage.combinat.words.word.FiniteWord_str
Bases: sage.combinat.words.word_datatypes.WordDatatype_str, sage.combinat.words.finite_word.FiniteWord_class
```

Finite word represented by a Python str.

For such word w , type $w.$ and hit TAB key to see the list of functions defined on w .

EXAMPLES:

```
sage: w = Word('abcdef')
sage: w.is_square()
False
```

```
class sage.combinat.words.word.FiniteWord_tuple
Bases: sage.combinat.words.word_datatypes.WordDatatype_tuple, sage.combinat.words.finite_word.FiniteWord_class
```

Finite word represented by a Python tuple.

For such word w , type w . and hit TAB key to see the list of functions defined on w .

EXAMPLES:

```
sage: w = Word(())
sage: w.is_empty()
True
```

```
class sage.combinat.words.word.InfiniteWord_callable (parent, callable, length=None)
Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_callable,
sage.combinat.words.infinite_word.InfiniteWord_class
```

Infinite word represented by a callable.

For such word w , type w . and hit TAB key to see the list of functions defined on w .

Infinite words behave like a Python list : they can be sliced using square brackets to define for example a prefix or a factor.

EXAMPLES:

```
sage: w = Word(lambda n:n, caching=False)
sage: w
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,27,
↪28,29,30,31,32,33,34,35,36,37,38,39,...
sage: w.iterated_right_palindromic_closure()
word: 0102010301020104010201030102010501020103...
```

```
class sage.combinat.words.word.InfiniteWord_callable_with_caching (parent,
                                                                    callable,
                                                                    length=None)
Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_callable_with_caching,
sage.combinat.words.infinite_word.InfiniteWord_class
```

Infinite word represented by a callable (with caching).

For such word w , type w . and hit TAB key to see the list of functions defined on w .

Infinite words behave like a Python list : they can be sliced using square brackets to define for example a prefix or a factor.

EXAMPLES:

```
sage: w = Word(lambda n:n)
sage: factor = w[4:13]
sage: factor
word: 4,5,6,7,8,9,10,11,12
```

```
class sage.combinat.words.word.InfiniteWord_iter (parent, iter, length=None)
Bases: sage.combinat.words.word_infinite_datatypes.WordDatatype_iter, sage.
combinat.words.infinite_word.InfiniteWord_class
```

Infinite word represented by an iterable.

For such word w , type w . and hit TAB key to see the list of functions defined on w .

Infinite words behave like a Python list : they can be sliced using square brackets to define for example a prefix or a factor.

EXAMPLES:

```

sage: from itertools import chain, cycle
sage: w = Word(chain('letsgo', cycle('forever')), caching=False)
sage: w
word: letsgoeverforeverforeverforeverforeve...
sage: prefix = w[:100]
sage: prefix
word: letsgoeverforeverforeverforeverforeve...
sage: prefix.is_lyndon()
False

```

class `sage.combinat.words.word.InfiniteWord_iter_with_caching` (*parent*, *iter*, *length=None*)
 Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_iter_with_caching`,
`sage.combinat.words.infinite_word.InfiniteWord_class`

Infinite word represented by an iterable (with caching).

For such word w , type `w`. and hit TAB key to see the list of functions defined on w .

Infinite words behave like a Python list : they can be sliced using square brackets to define for example a prefix or a factor.

EXAMPLES:

```

sage: from itertools import cycle
sage: w = Word(cycle([9,8,4]))
sage: w
word: 9849849849849849849849849849849849849849849...
sage: prefix = w[:23]
sage: prefix
word: 98498498498498498498498498
sage: prefix.minimal_period()
3

```

sage.combinat.words.word.Word (*data=None*, *alphabet=None*, *length=None*, *datatype=None*, *caching=True*, *RSK_data=None*)

Construct a word.

INPUT:

- *data* – (default: None) list, string, tuple, iterator, free monoid element, None (shorthand for `[]`), or a callable defined on `[0, 1, ..., length]`.
- *alphabet* – any argument accepted by Words
- *length* – (default: None) This is dependent on the type of data. It is ignored for words defined by lists, strings, tuples, etc., because they have a naturally defined length. For callables, this defines the domain of definition, which is assumed to be `[0, 1, 2, ..., length-1]`. For iterators: Infinity if you know the iterator will not terminate (default); "unknown" if you do not know whether the iterator terminates; "finite" if you know that the iterator terminates, but do not know the length.
- *datatype* – (default: None) None, "list", "str", "tuple", "iter", "callable". If None, then the function tries to guess this from the data.
- *caching* – (default: True) True or False. Whether to keep a cache of the letters computed by an iterator or callable.
- *RSK_data* – (Optional. Default: None) A semistandard and a standard Young tableau to run the inverse RSK bijection on.

Note: Be careful when defining words using callables and iterators. It appears that `islice` does not pickle correctly causing various errors when reloading. Also, most iterators do not support copying and should not support pickling by extension.

EXAMPLES:

Empty word:

```
sage: Word()
word:
```

Word with string:

```
sage: Word("abbabaab")
word: abbabaab
```

Word with string constructed from other types:

```
sage: Word([0,1,1,0,1,0,0,1], datatype="str")
word: 01101001
sage: Word((0,1,1,0,1,0,0,1), datatype="str")
word: 01101001
```

Word with list:

```
sage: Word([0,1,1,0,1,0,0,1])
word: 01101001
```

Word with list constructed from other types:

```
sage: Word("01101001", datatype="list")
word: 01101001
sage: Word((0,1,1,0,1,0,0,1), datatype="list")
word: 01101001
```

Word with tuple:

```
sage: Word((0,1,1,0,1,0,0,1))
word: 01101001
```

Word with tuple constructed from other types:

```
sage: Word([0,1,1,0,1,0,0,1], datatype="tuple")
word: 01101001
sage: Word("01101001", datatype="str")
word: 01101001
```

Word with iterator:

```
sage: from itertools import count
sage: Word(count())
word: 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,27,
↪28,29,30,31,32,33,34,35,36,37,38,39,...
sage: Word(iter("abbabaab")) # iterators default to infinite words
word: abbabaab
sage: Word(iter("abbabaab"), length="unknown")
word: abbabaab
```

```
sage: Word(iter("abbabaab"), length="finite")
word: abbabaab
```

Word with function (a ‘callable’):

```
sage: f = lambda n : add(Integer(n).digits(2)) % 2
sage: Word(f)
word: 0110100110010110100101100110100110010110...
sage: Word(f, length=8)
word: 01101001
```

Word over a string with a parent:

```
sage: w = Word("abbabaab", alphabet="abc"); w
word: abbabaab
sage: w.parent()
Finite words over {'a', 'b', 'c'}
```

Word from a free monoid element:

```
sage: M.<x,y,z> = FreeMonoid(3)
sage: Word(x^3*y*x*z^2*x)
word: xxxyxzzx
```

The default parent is the combinatorial class of all words:

```
sage: w = Word("abbabaab"); w
word: abbabaab
sage: w.parent()
Finite words over Set of Python objects of type 'object'
```

We can also input a semistandard tableau and a standard tableau to obtain a word from the inverse RSK algorithm using the `RSK_data` option:

```
sage: p = Tableau([[1,2,2],[3]]); q = Tableau([[1,2,4],[3]])
sage: Word(RSK_data=[p, q])
word: 1322
```

```
sage: W = Words()
sage: w = W('abc')
sage: w is W(w)
True
sage: w is Word(w, alphabet='abc')
False
```

class `sage.combinat.words.word.Word_iter` (*parent, iter, length=None*)

Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_iter`, `sage.combinat.words.abstract_word.Word_class`

Word of unknown length (finite or infinite) represented by an iterable.

For such word w , type `w.` and hit TAB key to see the list of functions defined on w .

Words behave like a Python list : they can be sliced using square brackets to define for example a prefix or a factor.

EXAMPLES:

```

sage: w = Word(iter([1,1,4,9]*1000), length='unknown', caching=False)
sage: w
word: 114911491149114911491149114911491149114911491149...
sage: w.delta()
word: 21121121121121121121121121121121121121121121121...

```

class `sage.combinat.words.word.Word_iter_with_caching` (*parent, iter, length=None*)
 Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_iter_with_caching`,
`sage.combinat.words.abstract_word.Word_class`

Word of unknown length (finite or infinite) represented by an iterable (with caching).

For such word w , type `w.` and hit TAB key to see the list of functions defined on w .

Words behave like a Python list : they can be sliced using square brackets to define for example a prefix or a factor.

EXAMPLES:

```

sage: w = Word(iter([1,2,3]*1000), length='unknown')
sage: w
word: 1231231231231231231231231231231231231231231231...
sage: w.finite_differences(mod=2)
word: 1101101101101101101101101101101101101101101101...

```

5.1.342 Fast word datatype using an array of unsigned char

class `sage.combinat.words.word_char.WordDatatype_char`
 Bases: `sage.combinat.words.word_datatypes.WordDatatype`

A Fast class for words represented by an array unsigned char *.

Currently, only handles letters in [0,255].

has_prefix (*other*)

Test whether *other* is a prefix of *self*.

INPUT:

- *other* – a word or a sequence (e.g. tuple, list)

EXAMPLES:

```

sage: W = Words([0,1,2])
sage: w = W([0,1,1,0,1,2,0])
sage: w.has_prefix([0,1,1])
True
sage: w.has_prefix([0,1,2])
False
sage: w.has_prefix(w)
True
sage: w.has_prefix(w[:-1])
True
sage: w.has_prefix(w[1:])
False

```

is_empty ()

Return whether the word is empty.

EXAMPLES:

```

sage: W = Words([0,1,2])
sage: W([0,1,2,2]).is_empty()
False
sage: W([]).is_empty()
True

```

is_square()

Returns True if self is a square, and False otherwise.

EXAMPLES:

```

sage: w = Word([n % 4 for n in range(48)], alphabet=[0,1,2,3])
sage: w.is_square()
True

```

```

sage: w = Word([n % 4 for n in range(49)], alphabet=[0,1,2,3])
sage: w.is_square()
False
sage: (w*w).is_square()
True

```

```

sage: Word([], alphabet=[0,1]).is_square()
True
sage: Word([0], alphabet=[0,1]).is_square()
False
sage: Word([0,0], alphabet=[0,1]).is_square()
True

```

length()

Return the length of the word as a Sage integer.

EXAMPLES:

```

sage: W = Words([0,1,2,3,4])
sage: w = W([0,1,2,0,3,2,1])
sage: w.length()
7
sage: type(w.length())
<type 'sage.rings.integer.Integer'>
sage: type(len(w))
<... 'int'>

```

letters()

Return the list of letters that appear in this word, listed in the order of first appearance.

EXAMPLES:

```

sage: W = Words(5)
sage: W([1,3,1,2,2,3,1]).letters()
[1, 3, 2]

```

longest_common_prefix(*other*)

Return the longest common prefix of this word and *other*.

EXAMPLES:

```

sage: W = Words([0,1,2])
sage: W([0,1,0,2]).longest_common_prefix([0,1])

```

```

word: 01
sage: u = W([0,1,0,0,1])
sage: v = W([0,1,0,2])
sage: u.longest_common_prefix(v)
word: 010
sage: v.longest_common_prefix(u)
word: 010

```

Using infinite words is also possible (and the return type is also a of the same type as self):

```

sage: W([0,1,0,0]).longest_common_prefix(words.FibonacciWord())
word: 0100
sage: type(_)
<class 'sage.combinat.words.word.FiniteWord_char'>

```

An example of an intensive usage:

```

sage: W = Words([0,1])
sage: w = words.FibonacciWord()
sage: w = W(list(w[:5000]))
sage: L = [[len(w[n:].longest_common_prefix(w[n+fibonacci(i):]))
....:      for i in range(5,15)] for n in range(1,1000)]
sage: for n,l in enumerate(L):
....:     if l.count(0) > 4:
....:         print("{} {}".format(n+1,l))
375 [0, 13, 0, 34, 0, 89, 0, 233, 0, 233]
376 [0, 12, 0, 33, 0, 88, 0, 232, 0, 232]
608 [8, 0, 21, 0, 55, 0, 144, 0, 377, 0]
609 [7, 0, 20, 0, 54, 0, 143, 0, 376, 0]
985 [0, 13, 0, 34, 0, 89, 0, 233, 0, 610]
986 [0, 12, 0, 33, 0, 88, 0, 232, 0, 609]

```

```

sage: Word([2,2], (1,2)).longest_common_prefix([])
word:

```

longest_common_suffix(*other*)

Return the longest common suffix between this word and *other*.

EXAMPLES:

```

sage: W = Words([0,1,2])
sage: W([0,1,0,2]).longest_common_suffix([2,0,2])
word: 02
sage: u = W([0,1,0,0,1])
sage: v = W([1,2,0,0,1])
sage: u.longest_common_suffix(v)
word: 001
sage: v.longest_common_suffix(u)
word: 001

```

```

sage: Word([2,2], (1,2)).longest_common_suffix([])
word:

```

`sage.combinat.words.word_char.reversed_word_iterator`(*w*)

This function exists only because it is not possible to use `yield` in the special method `__reversed__`.

EXAMPLES:

```

sage: W = Words([0,1,2])
sage: w = W([0,1,0,0,1,2])
sage: list(reversed(w)) # indirect doctest
[2, 1, 0, 0, 1, 0]

```

5.1.343 Datatypes for finite words

class `sage.combinat.words.word_datatypes.WordDatatype`

Bases: `object`

The generic WordDatatype class.

Any word datatype must contain two attributes (at least):

```

- _parent
- _hash

```

They are automatically defined here and it's not necessary (and forbidden) to define them anywhere else.

class `sage.combinat.words.word_datatypes.WordDatatype_list`

Bases: `sage.combinat.words.word_datatypes.WordDatatype`

Datatype class for words defined by lists.

count (*a*)

Returns the number of occurrences of the letter *a* in the word `self`.

INPUT:

- *a* - a letter

OUTPUT:

- integer

EXAMPLES:

```

sage: w = Word([0,1,1,0,1])
sage: w.count(0)
2
sage: w.count(1)
3
sage: w.count(2)
0

```

length ()

Return the length of the word.

EXAMPLES:

```

sage: w = Word([0,1,1,0])
sage: w.length()
4

```

class `sage.combinat.words.word_datatypes.WordDatatype_str`

Bases: `sage.combinat.words.word_datatypes.WordDatatype`

Datatype for words defined by strings.

count (*letter*)Count the number of occurrences of *letter*.

INPUT:

- *letter* - a letter

OUTPUT:

- integer

EXAMPLES:

```
sage: w = Word("abbabaabababa")
sage: w.count('a')
7
sage: w.count('b')
6
sage: w.count('c')
0
```

find (*sub*, *start*=0, *end*=None)Returns the index of the first occurrence of *sub* in *self*, such that *sub* is contained within *self*[*start*:*end*]. Returns -1 on failure.

INPUT:

- *sub* - string or word to search for.
- *start* - non negative integer (default: 0) specifying the position from which to start the search.
- *end* - non negative integer (default: None) specifying the position at which the search must stop. If None, then the search is performed up to the end of the string.

OUTPUT:

non negative integer or -1

EXAMPLES:

```
sage: w = Word("abbabaabababa")
sage: w.find("a")
0
sage: w.find("a", 4)
5
sage: w.find("a", 4, 5)
-1
```

has_prefix (*other*)Test whether *self* has *other* as a prefix.

INPUT:

- *other* - a word (an instance of *Word_class*) or a *str*.

OUTPUT:

- boolean

EXAMPLES:

```
sage: w = Word("abbabaabababa")
sage: u = Word("abbab")
sage: w.has_prefix(u)
```

```

True
sage: u.has_prefix(w)
False
sage: u.has_prefix("abbab")
True

```

has_suffix (*other*)

Test whether self has other as a suffix.

INPUT:

- other - a word (an instance of Word_class) or a str.

OUTPUT:

- boolean

EXAMPLES:

```

sage: w = Word("abbabaabababa")
sage: u = Word("ababa")
sage: w.has_suffix(u)
True
sage: u.has_suffix(w)
False
sage: u.has_suffix("ababa")
True

```

is_prefix (*other*)

Test whether self is a prefix of other.

INPUT:

- other - a word (an instance of Word_class) or a str.

OUTPUT:

- boolean

EXAMPLES:

```

sage: w = Word("abbabaabababa")
sage: u = Word("abbab")
sage: w.is_prefix(u)
False
sage: u.is_prefix(w)
True
sage: u.is_prefix("abbabaabababa")
True

```

is_suffix (*other*)

Test whether self is a suffix of other.

INPUT:

- other - a word (an instance of Word_class) or a str.

OUTPUT:

- boolean

EXAMPLES:

```
sage: w = Word("abbabaabababa")
sage: u = Word("ababa")
sage: w.is_suffix(u)
False
sage: u.is_suffix(w)
True
sage: u.is_suffix("abbabaabababa")
True
```

length()

Return the length of the word.

EXAMPLES:

```
sage: w = Word("abbabaabababa")
sage: w.length()
13
```

partition(*sep*)

Search for the separator *sep* in *S*, and return the part before it, the separator itself, and the part after it. The concatenation of the terms in the list gives back the initial word.

See also the `split` method.

Note: This just wraps Python's builtin `str.partition()` for `str`.

INPUT:

- *sep* - string or word

EXAMPLES:

```
sage: w = Word("MyTailorIsPoor")
sage: w.partition("Tailor")
[word: My, word: Tailor, word: IsPoor]
```

```
sage: w = Word("3230301030323212323032321210121232121010")
sage: l = w.partition("323")
sage: print(l)
[word: , word: 323, word: 0301030323212323032321210121232121010]
sage: sum(l, Word('')) == w
True
```

If the separator is not a string an error is raised:

```
sage: w = Word("le papa du papa du papa etait un petit pioupiou")
sage: w.partition(Word(['p', 'a', 'p', 'a']))
Traceback (most recent call last):
...
ValueError: the separator must be a string.
```

rfind(*sub*, *start*=0, *end*=None)

Returns the index of the last occurrence of *sub* in *self*, such that *sub* is contained within *self*[*start*:*end*]. Returns -1 on failure.

INPUT:

- *sub* - string or word to search for.

- start - non negative integer (default: 0) specifying the position at which the search must stop.
- end - non negative integer (default: None) specifying the position from which to start the search. If None, then the search is performed up to the end of the string.

OUTPUT:

non negative integer or -1

EXAMPLES:

```
sage: w = Word("abbabaabababa")
sage: w.rfind("a")
12
sage: w.rfind("a", 4, 8)
6
sage: w.rfind("a", 4, 5)
-1
```

split (*sep=None, maxsplit=None*)

Returns a list of words, using *sep* as a delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done.

See also the partition method.

Note: This just wraps Python's builtin `str::split()` for `str`.

INPUT:

- sep - string or word (optional, default: None)
- maxsplit - positive integer (optional, default: None)

OUTPUT:

- a list of words

EXAMPLES:

You can split along white space to find words in a sentence:

```
sage: w = Word("My tailor is poor")
sage: w.split(" ")
[word: My, word: tailor, word: is, word: poor]
```

The python behavior is kept when no argument is given:

```
sage: w.split()
[word: My, word: tailor, word: is, word: poor]
```

You can split in two words letters to get the length of blocks in the other letter:

```
sage: w = Word("ababbabaaba")
sage: w.split('a')
[word: , word: b, word: bb, word: b, word: , word: b, word: ]
sage: w.split('b')
[word: a, word: a, word: , word: a, word: aa, word: a]
```

You can split along words:

```
sage: w = Word("3230301030323212323032321")
sage: w.split("32")
[word: , word: 30301030, word: , word: 12, word: 30, word: , word: 1]
```

If the separator is not a string a `ValueError` is raised:

```
sage: w = Word("le papa du papa du papa etait un petit pioupiou")
sage: w.split(Word(['p', 'a', 'p', 'a']))
Traceback (most recent call last):
...
ValueError: the separator must be a string.
```

class `sage.combinat.words.word_datatypes.WordDatatype_tuple`

Bases: `sage.combinat.words.word_datatypes.WordDatatype`

Datatype class for words defined by tuples.

length()

Return the length of the word.

EXAMPLES:

```
sage: w = Word((0,1,1,0))
sage: w.length()
4
```

5.1.344 Common words

AUTHORS:

- Franco Saliola (2008-12-17): merged into sage
- Sebastien Labbe (2008-12-17): merged into sage
- Arnaud Bergeron (2008-12-17): merged into sage
- Amy Glen (2008-12-17): merged into sage
- Sebastien Labbe (2009-12-19): Added S-adic words ([trac ticket #7543](#))

USE:

To see a list of all word constructors, type `words.` and then press the tab key. The documentation for each constructor includes information about each word, which provides a useful reference.

REFERENCES:

EXAMPLES:

```
sage: t = words.ThueMorseWord(); t
word: 0110100110010110100101100110100110010110...
```

class `sage.combinat.words.word_generators.LowerChristoffelWord`(*p*, *q*, *alphabet*=(0, 1), *algorithm*='cf')

Bases: `sage.combinat.words.word.FiniteWord_list`

Returns the lower Christoffel word of slope p/q , where p and q are relatively prime non-negative integers, over the given two-letter alphabet.

The *Christoffel word of slope* ' p/q ' is obtained from the Cayley graph of $\mathbf{Z}/(p+q)\mathbf{Z}$ with generator q as follows. If $u \rightarrow v$ is an edge in the Cayley graph, then $v = u + p \pmod{p+q}$. Label the edge $u \rightarrow v$ by `alphabet[1]`

if $u < v$ and `alphabet[0]` otherwise. The Christoffel word is the word obtained by reading the edge labels along the cycle beginning from 0.

EXAMPLES:

```
sage: words.LowerChristoffelWord(4,7)
word: 00100100101
```

```
sage: words.LowerChristoffelWord(4,7,alphabet='ab')
word: aabaabaabab
```

markoff_number()

Returns the Markoff number associated to the Christoffel word `self`.

The *Markoff number* of a Christoffel word w is $\text{trace}(M(w))/3$, where $M(w)$ is the 2×2 matrix obtained by applying the morphism: $0 \rightarrow \text{matrix}(2,[2,1,1,1])$ $1 \rightarrow \text{matrix}(2,[5,2,2,1])$

EXAMPLES:

```
sage: w0 = words.LowerChristoffelWord(4,7)
sage: w1, w2 = w0.standard_factorization()
sage: (m0,m1,m2) = (w.markoff_number() for w in (w0,w1,w2))
sage: (m0,m1,m2)
(294685, 13, 7561)
sage: m0**2 + m1**2 + m2**2 == 3*m0*m1*m2
True
```

standard_factorization()

Returns the standard factorization of the Christoffel word `self`.

The *standard factorization* of a Christoffel word w is the unique factorization of w into two Christoffel words.

EXAMPLES:

```
sage: w = words.LowerChristoffelWord(5,9)
sage: w
word: 00100100100101
sage: w1, w2 = w.standard_factorization()
sage: w1
word: 001
sage: w2
word: 00100100101
```

```
sage: w = words.LowerChristoffelWord(51,37)
sage: w1, w2 = w.standard_factorization()
sage: w1
word: 0101011010101101011
sage: w2
word: 010101101010110101101011010110101101101...
sage: w1 * w2 == w
True
```

class `sage.combinat.words.word_generators.WordGenerator`

Bases: `object`

Constructor of several famous words.

EXAMPLES:

```
sage: words.ThueMorseWord()
word: 0110100110010110100101100110100110010110...
```

```
sage: words.FibonacciWord()
word: 01001010010010100101001001001001001010010...
```

```
sage: words.ChristoffelWord(5, 8)
word: 0010010100101
```

```
sage: words.RandomWord(10, 4)      # not tested random
word: 1311131221
```

```
sage: words.CodingOfRotationWord(alpha=0.618, beta=0.618)
word: 1010110101101101011010110110101101101011...
```

```
sage: tm = WordMorphism('a->ab,b->ba')
sage: fib = WordMorphism('a->ab,b->a')
sage: tmword = words.ThueMorseWord([0, 1])
sage: from itertools import repeat
sage: words.s_adic(tmword, repeat('a'), {0:tm, 1:fib})
word: abbaababbaabbaabbaababbaabbaabbaabbaabba...
```

Note: To see a list of all word constructors, type `words.` and then hit the TAB key. The documentation for each constructor includes information about each word, which provides a useful reference.

BaumSweetWord()

Returns the Baum-Sweet Word.

The Baum-Sweet Sequence is an infinite word over the alphabet $\{0, 1\}$ defined by the following string substitution rules:

$00 \rightarrow 0000$

$01 \rightarrow 1001$

$10 \rightarrow 0100$

$11 \rightarrow 1101$

The substitution rule above can be considered as a morphism on the submonoid of $\{0, 1\}^*$ generated by $\{00, 01, 10, 11\}$ (which is a free monoid on these generators).

It is also defined as the concatenation of the terms from the Baum-Sweet Sequence:

$$b_n = \begin{cases} 0, & \text{if } n = 0 \\ 1, & \text{if } m \text{ is even} \\ b_{\frac{m-1}{2}}, & \text{if } m \text{ is odd} \end{cases}$$

where $n = m4^k$ and m is not divisible by 4 if $m \neq 0$.

The individual terms of the Baum-Sweet Sequence are also given by:

$$b_n = \begin{cases} 1, & \text{if the binary representation of } n \text{ contains no block of consecutive 0's of odd length} \\ 0, & \text{otherwise} \end{cases}$$

for $n > 0$ with $b_0 = 1$.

For more information see: [Wikipedia article Baum-Sweet_sequence](#).

EXAMPLES:

Baum-Sweet Word:

```
sage: w = words.BaumSweetWord(); w
word: 1101100101001001100100000100100101001001...
```

Block Definition:

```
sage: w = words.BaumSweetWord()
sage: f = lambda n: '1' if all(len(x)%2==0 for x in bin(n)[2:].split('1'))
else '0'
sage: all(f(i) == w[i] for i in range(1,100))
True
```

CharacteristicSturmianWord (*slope*, *alphabet*=(0, 1), *bits*=None)

Returns the characteristic Sturmian word (also called standard Sturmian word) of given slope.

Over a binary alphabet $\{a, b\}$, the characteristic Sturmian word c_α of irrational slope α is the infinite word satisfying $s_{\alpha,0} = ac_\alpha$ and $s'_{\alpha,0} = bc_\alpha$, where $s_{\alpha,0}$ and $s'_{\alpha,0}$ are respectively the lower and upper mechanical words with slope α and intercept 0. Equivalently, for irrational α , $c_\alpha = s_{\alpha,\alpha} = s'_{\alpha,\alpha}$.

Let $\alpha = [0, d_1 + 1, d_2, d_3, \dots]$ be the continued fraction expansion of α . It has been shown that the characteristic Sturmian word of slope α is also the limit of the sequence: $s_0 = b, s_1 = a, \dots, s_{n+1} = s_n^{d_n} s_{n-1}$ for $n > 0$.

See Section 2.1 of [\[Loth02\]](#) for more details.

INPUT:

- *slope* - the slope of the word. It can be one of the following :
 - real number in $]0, 1[$
 - iterable over the continued fraction expansion of a real number in $]0, 1[$
- *alphabet* - any container of length two that is suitable to build an instance of `OrderedAlphabet` (list, tuple, str, ...)
- *bits* - integer (optional and considered only if *slope* is a real number) the number of bits to consider when computing the continued fraction.

OUTPUT:

word

ALGORITHM:

Let $[0, d_1 + 1, d_2, d_3, \dots]$ be the continued fraction expansion of α . Then, the characteristic Sturmian word of slope α is the limit of the sequence: $s_0 = b, s_1 = a$ and $s_{n+1} = s_n^{d_n} s_{n-1}$ for $n > 0$.

EXAMPLES:

From real slope:

```
sage: words.CharacteristicSturmianWord(1/golden_ratio^2)
word: 0100101001001010010100100101001001010010...
sage: words.CharacteristicSturmianWord(4/5)
word: 11110
sage: words.CharacteristicSturmianWord(5/14)
word: 01001001001001
```

```
sage: words.CharacteristicSturmianWord(pi-3)
word: 0000001000000100000010000001000000100000...
```

From an iterator of the continued fraction expansion of a real:

```
sage: def cf():
....:     yield 0
....:     yield 2
....:     while True: yield 1
sage: F = words.CharacteristicSturmianWord(cf()); F
word: 01001010010010100101001001001001010010...
sage: Fib = words.FibonacciWord(); Fib
word: 01001010010010100101001001001001010010...
sage: F[:10000] == Fib[:10000]
True
```

The alphabet may be specified:

```
sage: words.CharacteristicSturmianWord(cf(), 'rs')
word: rsrrsrsrrsrrsrrsrrsrrsrrsrrsrrsrrsrrsrrsr...
```

The characteristic sturmian word of slope $(\sqrt{3}-1)/2$:

```
sage: words.CharacteristicSturmianWord((sqrt(3)-1)/2)
word: 0100100101001001001010010010010100100101...
```

The same word defined from the continued fraction expansion of $(\sqrt{3}-1)/2$:

```
sage: from itertools import cycle, chain
sage: it = chain([0], cycle([2, 1]))
sage: words.CharacteristicSturmianWord(it)
word: 0100100101001001001010010010010100100101...
```

The first terms of the standard sequence of the characteristic sturmian word of slope $(\sqrt{3}-1)/2$:

```
sage: words.CharacteristicSturmianWord([0,2])
word: 01
sage: words.CharacteristicSturmianWord([0,2,1])
word: 010
sage: words.CharacteristicSturmianWord([0,2,1,2])
word: 01001001
sage: words.CharacteristicSturmianWord([0,2,1,2,1])
word: 01001001010
sage: words.CharacteristicSturmianWord([0,2,1,2,1,2])
word: 010010010100100100101001001001
sage: words.CharacteristicSturmianWord([0,2,1,2,1,2,1])
word: 0100100101001001001010010010010100100101...
```

```
sage: words.CharacteristicSturmianWord(5/4)
Traceback (most recent call last):

True
```

```
sage: a, b = 207, 232
sage: u = words.ChristoffelWord(a, b)
sage: v = words.CharacteristicSturmianWord(a/(a+b))
sage: v.length()
439
sage: u[1:-1] == v[:-2]
True
```

ChristoffelWord

alias of *LowerChristoffelWord*

CodingOfRotationWord(*alpha*, *beta*, *x*=0, *alphabet*=(0, 1))

Returns the infinite word obtained from the coding of rotation of parameters (α, β, x) over the given two-letter alphabet.

The *coding of rotation* corresponding to the parameters (α, β, x) is the symbolic sequence $u = (u_n)_{n \geq 0}$ defined over the binary alphabet $\{0, 1\}$ by $u_n = 1$ if $x + n\alpha \in [0, \beta[$ and $u_n = 0$ otherwise. See [AC03].

EXAMPLES:

```
sage: alpha = 0.45
sage: beta = 0.48
sage: words.CodingOfRotationWord(0.45, 0.48)
word: 11010101010010101010101010101010010101010...
```

```
sage: words.CodingOfRotationWord(0.45, 0.48, alphabet='xy')
word: yxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxy...
```

FibonacciWord(*alphabet*=(0, 1), *construction_method*='recursive')

Returns the Fibonacci word on the given two-letter alphabet.

INPUT:

- *alphabet* – any container of length two that is suitable to build an instance of *OrderedAlphabet* (list, tuple, str, ...)
- *construction_method* – can be any of the following: “recursive”, “fixed point”, “function” (see below for definitions).

Recursive construction: the Fibonacci word is the limit of the following sequence of words: $S_0 = 0$, $S_1 = 01$, $S_n = S_{n-1}S_{n-2}$ for $n \geq 2$.

Fixed point construction: the Fibonacci word is the fixed point of the morphism: $0 \mapsto 01$ and $1 \mapsto 0$. Hence, it can be constructed by the following read-write process:

1. beginning at the first letter of 01,
2. if the next letter is 0, append 01 to the word;
3. if the next letter is 1, append 1 to the word;
4. move to the next letter of the word.

Function: Over the alphabet $\{1, 2\}$, the n -th letter of the Fibonacci word is $\lfloor (n+2)\varphi \rfloor - \lfloor (n+1)\varphi \rfloor$ where $\varphi = (1 + \sqrt{5})/2$ is the golden ratio.

EXAMPLES:

```
sage: w = words.FibonacciWord(construction_method="recursive"); w
word: 0100101001001010010100100101001001010010...
```

```
sage: v = words.FibonacciWord(construction_method="recursive", alphabet='ab');
↪ v
word: abaababaabaababaababaabaababaabaababaaba...
```

```
sage: u = words.FibonacciWord(construction_method="fixed point"); u
word: 0100101001001010010100100101001001010010...
```

```
sage: words.FibonacciWord(construction_method="fixed point", alphabet=[4, 1])
word: 414414144144141441414414414414414414414414...
```

```
sage: words.FibonacciWord([0, 1], 'function')
word: 0100101001001010010100100101001001010010...
sage: words.FibonacciWord('ab', 'function')
word: abaababaabaababaababaabaababaabaababaaba...
```

FixedPointOfMorphism (*morphism*, *first_letter*)

Returns the fixed point of the morphism beginning with *first_letter*.

A *fixed point* of a morphism φ is a word w such that $\varphi(w) = w$.

INPUT:

- *morphism* – endomorphism prolongable on *first_letter*. It must be something that WordMorphism's constructor understands (dict, str, ...).
- *first_letter* – the first letter of the fixed point

OUTPUT:

The fixed point of the morphism beginning with *first_letter*

EXAMPLES:

```
sage: mu = {0:[0, 1], 1:[1, 0]}
sage: tm = words.FixedPointOfMorphism(mu, 0); tm
word: 0110100110010110100101100110100110010110...
sage: TM = words.ThueMorseWord()
sage: tm[:1000] == TM[:1000]
True
```

```

sage: mu = {0:[0,1], 1:[0]}
sage: f = words.FixedPointOfMorphism(mu,0); f
word: 0100101001001010010100100101001001010010...
sage: F = words.FibonacciWord(); F
word: 0100101001001010010100100101001001010010...
sage: f[:1000] == F[:1000]
True

```

```

sage: fp = words.FixedPointOfMorphism('a->abc,b->,c->', 'a'); fp
word: abc

```

KolakoskiWord(*alphabet=(1, 2)*)

Returns the Kolakoski word over the given alphabet and starting with the first letter of the alphabet.

Let $A = \{a, b\}$ be an alphabet, where a and b are two distinct positive integers. The Kolakoski word $K_{a,b}$ over A and starting with a is the unique infinite word w such that $w = \Delta(w)$, where $\Delta(w)$ is the word encoding the runs of w (see `delta()` method on words for more details).

Note that $K_{a,b} \neq K_{b,a}$. On the other hand, the words $K_{a,b}$ and $K_{b,a}$ are the unique two words over A that are fixed by Δ .

INPUT:

- `alphabet` - (default: (1,2)) an iterable of two positive integers

OUTPUT:

infinite word

EXAMPLES:

The usual Kolakoski word:

```

sage: w = words.KolakoskiWord()
sage: w
word: 1221121221221121122121121221121121221221...
sage: w.delta()
word: 1221121221221121122121121221121121221221...

```

The other Kolakoski word on the same alphabet:

```

sage: w = words.KolakoskiWord(alphabet = (2,1))
sage: w
word: 221121221221121122121121221121121221221...
sage: w.delta()
word: 221121221221121122121121221121121221221...

```

It is naturally generalized to any two integers alphabet:

```

sage: w = words.KolakoskiWord(alphabet = (2,5))
sage: w
word: 2255222225555522552255225555522222555552...
sage: w.delta()
word: 2255222225555522552255225555522222555552...

```

```

sage: words.KolakoskiWord((0, 2))
Traceback (most recent call last):
...
ValueError: The alphabet (=(0, 2)) must consist of two distinct positive_
↳ integers

```

REFERENCES:

LowerChristoffelWordalias of *LowerChristoffelWord***LowerMechanicalWord** (*alpha*, *rho*=0, *alphabet*=None)Returns the lower mechanical word with slope α and intercept ρ The lower mechanical word $s_{\alpha,\rho}$ with slope α and intercept ρ is defined by $s_{\alpha,\rho}(n) = \lfloor \alpha(n+1) + \rho \rfloor - \lfloor \alpha n + \rho \rfloor$. [*Loth02*]

INPUT:

- *alpha* – real number such that $0 \leq \alpha \leq 1$
- *rho* – real number (optional, default: 0)
- *alphabet* – iterable of two elements or None (optional, default: None)

OUTPUT:

infinite word

EXAMPLES:

```
sage: words.LowerMechanicalWord(1/golden_ratio^2)
word: 00100101001001010010100100101001001001...
sage: words.LowerMechanicalWord(1/5)

word: 000100100100100100100100100100100100100...
```

MinimalSmoothPrefix (*n*)This function finds and returns the minimal smooth prefix of length *n*.See [*BMP07*] for a definition.

INPUT:

- *n* – the desired length of the prefix

OUTPUT:

word – the prefix

Note: Be patient, this function can take a really long time if asked for a large prefix.

EXAMPLES:

```
sage: words.MinimalSmoothPrefix(10)
word: 1212212112
```

REFERENCES:

PalindromicDefectWord (*k*=1, *alphabet*='ab')Returns the finite word $w = ab^k ab^{k-1} a ab^{k-1} ab^k a$.As described by Brlek, Hamel, Nivat and Reuteunaer in [*BHNR04*], this finite word w is such that the infinite periodic word w^ω have palindromic defect k .

INPUT:

- `k` – positive integer (optional, default: 1)
- `alphabet` – iterable (optional, default: 'ab') of size two

OUTPUT:

finite word

EXAMPLES:

```
sage: words.PalindromicDefectWord(10)
word: abbbbbbbbbbbabbbbbbbbaabbbbbbbbabbbbbbb...
```

```
sage: w = words.PalindromicDefectWord(3)
sage: w
word: abbbabbaabbabbba
sage: w.defect()
0
sage: (w^2).defect()
3
sage: (w^3).defect()
3
```

On other alphabets:

```
sage: words.PalindromicDefectWord(3, alphabet='cd')
word: cdddcddccddcdddc
sage: words.PalindromicDefectWord(3, alphabet=['c', 3])
word: c333c33cc33c333c
```

RandomWord (*n*, *m*=2, *alphabet*=None)

Returns a random word of length *n* over the given *m*-letter alphabet.

INPUT:

- `n` - integer, the length of the word
- `m` - integer (default 2), the size of the output alphabet
- `alphabet` - (default is $\{0, 1, \dots, m-1\}$) any container of length *m* that is suitable to build an instance of `OrderedAlphabet` (list, tuple, str, ...)

EXAMPLES:

```
sage: words.RandomWord(10)           # random results
word: 0110100101
sage: words.RandomWord(10, 4)        # random results
word: 0322313320
sage: words.RandomWord(100, 7)       # random results
word: 2630644023642516442650025611300034413310...
sage: words.RandomWord(100, 7, range(-3,4)) # random results
word: 1, 3, -1, -1, 3, 2, 2, 0, 1, -2, 1, -1, -3, -2, 2, 0, 3, 0, -3, 0, 3, 0, -2, -2, 2, 0, 1, -3, 2, -2, -
↪ 2, 2, 0, 2, 1, -2, -3, -2, -1, 0, ...
sage: words.RandomWord(100, 5, "abcde") # random results
word: acebeaacdbedbbddeadeebbbebeaaachadaac...
sage: words.RandomWord(17, 5, "abcde") # random results
word: dcacbbebdbdebaadd
```

StandardEpisturmianWord (*directive_word*)

Returns the standard episturmian word (or epistandard word) directed by *directive_word*. Over a 2-letter alphabet, this function gives characteristic Sturmian words.

An infinite word w over a finite alphabet A is said to be *standard episturmian* (or *epistandard*) iff there exists an infinite word $x_1x_2x_3\cdots$ over A (called the *directive word* of w) such that w is the limit as n goes to infinity of $Pal(x_1\cdots x_n)$, where Pal is the iterated palindromic closure function.

Note that an infinite word is *episturmian* if it has the same set of factors as some epistandard word.

See for instance [DJP01], [JP02], and [GJ07].

INPUT:

- `directive_word` - an infinite word or a period of a periodic infinite word

EXAMPLES:

```
sage: Fibonacci = words.StandardEpisturmianWord(Words('ab')('ab')); Fibonacci
word: abaababaabaababaababaabaababaabaababaaba...
sage: Tribonacci = words.StandardEpisturmianWord(Words('abc')('abc'));
↳ Tribonacci
word: abacabaabacababacabaabacabacabaabacababa...
sage: S = words.StandardEpisturmianWord(Words('abcd')('aabcabada')); S
word: aabaacaabaaabaacaabaabaacaabaaabaacaabaa...
sage: S = words.StandardEpisturmianWord(Fibonacci); S
word: abaabaababaabaabaababaabaababaabaabaabab...
sage: S[:25]
word: abaabaababaabaabaababaaba
sage: S = words.StandardEpisturmianWord(Tribonacci); S
word: abaabacabaabaabacabaababaabacabaabaabaca...
sage: words.StandardEpisturmianWord(123)
Traceback (most recent call last):
...
TypeError: directive_word is not a word, so it cannot be used to build an
↳ episturmian word
sage: words.StandardEpisturmianWord(Words('ab'))
Traceback (most recent call last):
...
TypeError: directive_word is not a word, so it cannot be used to build an
↳ episturmian word
```

REFERENCES:

ThueMorseWord (*alphabet*=(0, 1), *base*=2)

Returns the (Generalized) Thue-Morse word over the given alphabet.

There are several ways to define the Thue-Morse word t . We use the following definition: $t[n]$ is the sum modulo m of the digits in the given base expansion of n .

See [BmBGL07], [Brlek89], and [MH38].

INPUT:

- **alphabet** - (default: (0, 1)) any container that is suitable to build an instance of `OrderedAlphabet` (list, tuple, str, ...)
- **base** - an integer (default : 2) greater or equal to 2

EXAMPLES:

Thue-Morse word:

```
sage: t = words.ThueMorseWord(); t
word: 0110100110010110100101100110100110010110...
```

Thue-Morse word on other alphabets:

```
sage: t = words.ThueMorseWord('ab'); t
word: abbabaabbaababbabaababbabaabbaabbaabba...
```

```
sage: t = words.ThueMorseWord(['L1', 'L2'])
sage: t[:8]
word: L1,L2,L2,L1,L2,L1,L1,L2
```

Generalized Thue Morse word:

```
sage: words.ThueMorseWord(alphabet=(0,1,2), base=2)
word: 0112122012202001122020012001011212202001...
sage: t = words.ThueMorseWord(alphabet=(0,1,2), base=5); t
word: 0120112012201200120112012120122012001201...
sage: t[100:130].critical_exponent()
10/3
```

REFERENCES:

UpperChristoffelWord ($p, q, \text{alphabet}=(0, 1)$)

Returns the upper Christoffel word of slope p/q , where p and q are relatively prime non-negative integers, over the given alphabet.

The *upper Christoffel word of slope p/q* is equal to the reversal of the lower Christoffel word of slope p/q . Equivalently, if xuy is the lower Christoffel word of slope p/q , where x and y are letters, then yux is the upper Christoffel word of slope p/q (because u is a palindrome).

INPUT:

- `alphabet` - any container of length two that is suitable to build an instance of `OrderedAlphabet` (list, tuple, str, ...)

EXAMPLES:

```
sage: words.UpperChristoffelWord(1,0)
word: 1
```

```
sage: words.UpperChristoffelWord(0,1)
word: 0
```

```
sage: words.UpperChristoffelWord(1,1)
word: 10
```

```
sage: words.UpperChristoffelWord(4,7)
word: 10100100100
```

UpperMechanicalWord ($\alpha, \text{rho}=0, \text{alphabet}=\text{None}$)

Returns the upper mechanical word with slope α and intercept ρ

The upper mechanical word $s'_{\alpha,\rho}$ with slope α and intercept ρ is defined by $s'_{\alpha,\rho}(n) = \lceil \alpha(n+1) + \rho \rceil - \lceil \alpha n + \rho \rceil$. [Loth02]

INPUT:

- `alpha` – real number such that $0 \leq \alpha \leq 1$
- `rho` – real number (optional, default: 0)
- `alphabet` – iterable of two elements or `None` (optional, default: `None`)

OUTPUT:

infinite word

EXAMPLES:

```
sage: words.UpperMechanicalWord(1/golden_ratio^2)
word: 10100101001001010010100100101001001001001...

word: 100001000010000100001000010000100001000010000...
sage: words.UpperMechanicalWord(1/pi)
word: 100100100100100100100100100100100100100100100...
```

dual_fibonacci_tile(*n*)

Returns the *n*-th dual Fibonacci Tile [\[BmBGL09\]](#).

EXAMPLES:

```
sage: for i in range(4): words.dual_fibonacci_tile(i)
Path: 3210
Path: 32123032301030121012
Path: 3212303230103230321232101232123032123210...
Path: 3212303230103230321232101232123032123210...
```

fibonacci_tile(*n*)

Returns the *n*-th Fibonacci Tile [\[BmBGL09\]](#).

EXAMPLES:

```
sage: for i in range(3): words.fibonacci_tile(i)
Path: 3210
Path: 323030101212
Path: 3230301030323212323032321210121232121010...
```

s_adic(*sequence*, *letters*, *morphisms=None*)

Returns the *s*-adic infinite word obtained from a sequence of morphisms applied on a letter.

DEFINITION (from [\[Fogg\]](#)):

Let w be a infinite word over an alphabet $A = A_0$. A standard representation of w is obtained from a sequence of substitutions $\sigma_k : A_{k+1} \rightarrow A_k$ and a sequence of letters $a_k \in A_k$ such that:

$$\lim_{k \rightarrow \infty} \sigma_0 \circ \sigma_1 \circ \cdots \sigma_k(a_k).$$

Given a set of substitutions S , we say that the representation is *S*-adic standard if the substitutions are chosen in S .

INPUT:

- **sequence** - An iterable sequence of indices or of morphisms. It may be finite or infinite. If sequence is infinite, the image of the $(i + 1)$ -th letter under the $(i + 1)$ -th morphism must start with the i -th letter.
- **letters** - A letter or a sequence of letters.
- **morphisms** - dict, list, callable or None (optional, default None) an object that maps indices to morphisms. If None, then sequence must consist of morphisms.

OUTPUT:

A word.

EXAMPLES:

Let's define three morphisms and compute the first nested successive prefixes of the s -adic word:

```
sage: m1 = WordMorphism('e->gh,f->hg')
sage: m2 = WordMorphism('c->ef,d->e')
sage: m3 = WordMorphism('a->cd,b->dc')
sage: words.s_adic([m1], 'e')
word: gh
sage: words.s_adic([m1,m2], 'ec')
word: ghhg
sage: words.s_adic([m1,m2,m3], 'eca')
word: ghhggh
```

When the given sequence of morphism is finite, one may simply give the last letter, i.e. 'a', instead of giving all of them, i.e. 'eca':

```
sage: words.s_adic([m1,m2,m3], 'a')
word: ghhggh
sage: words.s_adic([m1,m2,m3], 'b')
word: ghghhg
```

If the letters don't satisfy the hypothesis of the algorithm (nested prefixes), an error is raised:

```
sage: words.s_adic([m1,m2,m3], 'ecb')
Traceback (most recent call last):
...
ValueError: The hypothesis of the algorithm used is not satisfied: the image
↳ of the 3-th letter (=b) under the 3-th morphism (=a->cd, b->dc) should
↳ start with the 2-th letter (=c).
```

Let's define the Thue-Morse morphism and the Fibonacci morphism which will be used below to illustrate more examples and let's import the repeat tool from the `itertools`:

```
sage: tm = WordMorphism('a->ab,b->ba')
sage: fib = WordMorphism('a->ab,b->a')
sage: from itertools import repeat
```

Two trivial examples of infinite s -adic words:

```
sage: words.s_adic(repeat(tm), repeat('a'))
word: abbabaabbaababbabaababbaabbaabbaabbaabba...
```

```
sage: words.s_adic(repeat(fib), repeat('a'))
word: abaababaabaababaababaabaababaabaababaaba...
```

A less trivial infinite s -adic word:

```
sage: t = words.ThueMorseWord([tm,fib])
sage: words.s_adic(t, repeat('a'))
word: abbaababbaabbaabbaababbaabbaabbaabbaabba...
```

The same thing using a sequence of indices:

```
sage: tmword = words.ThueMorseWord([0,1])
sage: words.s_adic(tmword, repeat('a'), [tm,fib])
word: abbaababbaabbaabbaababbaabbaabbaabbaabba...
```

The correspondance of the indices may be given as a dict:

```
word: bbbbbbba
sage: words.s_adic([sigma]*7, 'a')
word: bbbbbbba
```

The following examples illustrates an S -adic word defined over an infinite set S of morphisms x_h :

```
sage: x = lambda h: WordMorphism({1:[2], 2:[3]+[1]*(h+1), 3:[3]+[1]*h})
sage: for h in [0,1,2,3]:
....:     print("{} {}".format(h, x(h)))
0 1->2, 2->31, 3->3
1 1->2, 2->311, 3->31
2 1->2, 2->3111, 3->311
3 1->2, 2->31111, 3->3111
sage: w = Word(lambda n : valuation(n+1, 2)); w
word: 0102010301020104010201030102010501020103...
sage: s = words.s_adic(w, repeat(3), x); s
word: 323223223232232232232322323223223232232...
sage: prefixe = s[:10000]
sage: list(map(prefixe.number_of_factors, range(15)))
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15]
sage: [_[i+1] - _[i] for i in range(len(_)-1)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
```

```
sage: words.s_adic([fib,tm,tm,fib,tm,fib], 'aaaaaaa')
word: abaaabaababaabaaababaaababaaabaababa
```

```
sage: words.s_adic([0,1,0,1,0,1,0,1], 'a', [tm,fib])
word: abbaabababbaabbaababbaababbaabababbaabba...
```

```
sage: words.s_adic([fib,fib], 'bb')
Traceback (most recent call last):
...
ValueError: The hypothesis of the algorithm used is not satisfied: the image_
↳of the 2-th letter (=b) under the 2-th morphism (=a->ab, b->a) should start_
↳with the 1-th letter (=b).
```

Test on different letters:

```
sage: tm = WordMorphism({0:[0,1], 1:[1,0]})
sage: fib = WordMorphism({0:[0,1], 1:[0]})
sage: f = lambda n: tm if n == 0 else fib
sage: words.s_adic(words.ThueMorseWord(), repeat(0), f)
word: 01100101100110011001011001011001100110010110...
```

Testing the message error for the third argument:

```
sage: words.s_adic(words.ThueMorseWord(), repeat(0), 5)
Traceback (most recent call last):
...
TypeError: morphisms (=5) must be None, callable or provide a __getitem__
↳method.
```

AUTHORS:

- Sebastien Labbe (2009-12-18): initial version

5.1.345 Datatypes for words defined by iterators and callables

class `sage.combinat.words.word_infinite_datatypes.WordDatatype_callable` (*parent*,
callable,
length=None)

Bases: `sage.combinat.words.word_datatypes.WordDatatype`

Datatype for a word defined by a callable.

class `sage.combinat.words.word_infinite_datatypes.WordDatatype_callable_with_caching` (*parent*,
callable,
length=None)

Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_callable`

Datatype for a word defined by a callable.

flush()

Empty the associated cache of letters.

EXAMPLES:

The first 40 (by default) values are always cached:

```
sage: w = words.ThueMorseWord()
sage: w._letter_cache
{0: 0, 1: 1, 2: 1, 3: 0, 4: 1, 5: 0, 6: 0, 7: 1, 8: 1, 9: 0, 10: 0, 11: 1,
↪12: 0, 13: 1, 14: 1, 15: 0, 16: 1, 17: 0, 18: 0, 19: 1, 20: 0, 21: 1, 22: 1,
↪23: 0, 24: 0, 25: 1, 26: 1, 27: 0, 28: 1, 29: 0, 30: 0, 31: 1, 32: 1, 33:
↪0, 34: 0, 35: 1, 36: 0, 37: 1, 38: 1, 39: 0}
sage: w[100]
1
sage: w._letter_cache
{0: 0, 1: 1, 2: 1, 3: 0, 4: 1, 5: 0, 6: 0, 7: 1, 8: 1, 9: 0, 10: 0, 11: 1,
↪12: 0, 13: 1, 14: 1, 15: 0, 16: 1, 17: 0, 18: 0, 19: 1, 20: 0, 21: 1, 22: 1,
↪23: 0, 24: 0, 25: 1, 26: 1, 27: 0, 28: 1, 29: 0, 30: 0, 31: 1, 32: 1, 33:
↪0, 34: 0, 35: 1, 36: 0, 37: 1, 38: 1, 39: 0, 100: 1}
sage: w.flush()
sage: w._letter_cache
{}
```

class `sage.combinat.words.word_infinite_datatypes.WordDatatype_iter` (*parent*, *iter*,
length=None)

Bases: `sage.combinat.words.word_datatypes.WordDatatype`

INPUT:

- *parent* - a parent
- *iter* - an iterator
- *length* - (default: None) the length of the word

EXAMPLES:

```
sage: w = Word(iter("abbabaab"), length="unknown", caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
sage: w.length() is None
False
sage: w.length()
8
```

```

sage: s = "abbabaabbaababbabaababbabaabbaababbabaabab"
sage: w = Word(iter(s), length="unknown", caching=False); w
word: abbabaabbaababbabaababbabaabbaababbaba...
sage: w.length() is None
True

```

```

sage: w = Word(iter("abbabaab"), length="finite", caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length=8, caching=False); w
word: abbabaab
sage: isinstance(w, sage.combinat.words.word_infinite_datatypes.WordDatatype_iter)
True
sage: w.length()
8

```

class `sage.combinat.words.word_infinite_datatypes.WordDatatype_iter_with_caching` (*parent, iter, length=None*)

Bases: `sage.combinat.words.word_infinite_datatypes.WordDatatype_iter`

INPUT:

- parent - a parent
- iter - an iterator
- length - (default: None) the length of the word

EXAMPLES:

```

sage: import itertools
sage: Word(itertools.cycle("abbabaab"))
word: abbabaababbabaababbabaababbabaababbabaab...
sage: w = Word(iter("abbabaab"), length="finite"); w
word: abbabaab
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length="unknown"); w
word: abbabaab
sage: w.length()
8
sage: list(w)
['a', 'b', 'b', 'a', 'b', 'a', 'a', 'b']
sage: w.length()
8
sage: w = Word(iter("abbabaab"), length=8)
sage: w._len
8

```

flush()

Delete the cached values.

EXAMPLES:

```

sage: from itertools import count
sage: w = Word(count())

```

```

sage: w._last_index, len(w._list)
(39, 40)
sage: w[43]
43
sage: w._last_index, len(w._list)
(43, 44)
sage: w.flush()
sage: w._last_index, w._list
(-1, [])

```

5.1.346 User-customizable options for words

`sage.combinat.words.word_options.WordOptions(**kwargs)`

Sets the global options for elements of the word class. The defaults are for words to be displayed in list notation.

INPUT:

- `display` - 'string' (default), or 'list', words are displayed in string or list notation.
- `truncate` - boolean (default: True), whether to truncate the string output of long words (see `truncate_length` below).
- `truncate_length` - integer (default: 40), if the length of the word is greater than this integer, then the word is truncated.
- `letter_separator` - (string, default: ",") if the string representation of letters have length greater than 1, then the letters are separated by this string in the string representation of the word.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```

sage: w = Word([2,1,3,12])
sage: u = Word("abba")
sage: WordOptions(display='list')
sage: w
word: [2, 1, 3, 12]
sage: u
word: ['a', 'b', 'b', 'a']
sage: WordOptions(display='string')
sage: w
word: 2,1,3,12
sage: u
word: abba

```

5.1.347 Set of words

To define a new class of words, please refer to the documentation file: `sage/combinat/words/notes/word_inheritance_howto.txt`

AUTHORS:

- Franco Saliola (2008-12-17): merged into sage
- Sebastien Labbe (2008-12-17): merged into sage
- Arnaud Bergeron (2008-12-17): merged into sage
- Sebastien Labbe (2009-07-21): Improved morphism iterator ([trac ticket #6571](#)).

- Vincent Delecroix (2015): classes simplifications ([trac ticket #19619](#))

EXAMPLES:

```
sage: Words()
Finite and infinite words over Set of Python objects of type 'object'
sage: Words(4)
Finite and infinite words over {1, 2, 3, 4}
sage: Words(4,5)
Words of length 5 over {1, 2, 3, 4}

sage: FiniteWords('ab')
Finite words over {'a', 'b'}
sage: InfiniteWords('natural numbers')
Infinite words over Non negative integers
```

class sage.combinat.words.words.**AbstractLanguage** (*alphabet=None, category=None*)
 Bases: sage.structure.parent.Parent

Abstract base class

This is *not* to be used by any means. This class gather previous features of set of words (prior to [trac ticket #19619](#)). In the future that class might simply disappear or become a common base class for all languages. In the latter case, its name would possibly change to Language.

alphabet ()

EXAMPLES:

```
sage: Words(NN).alphabet()
Non negative integer semiring

sage: InfiniteWords([1,2,3]).alphabet()
{1, 2, 3}
sage: InfiniteWords('ab').alphabet()
{'a', 'b'}

sage: FiniteWords([1,2,3]).alphabet()
{1, 2, 3}
sage: FiniteWords().alphabet()
Set of Python objects of type 'object'
```

has_letter (*letter*)

Returns True if the alphabet of self contains the given letter.

INPUT:

- letter – a letter

EXAMPLES:

```
sage: W = Words()
sage: W.has_letter('a')
doctest:...: DeprecationWarning: has_letter is deprecated. Use 'letter'
in W.alphabet()' instead
See http://trac.sagemath.org/19619 for details.
True
sage: W.has_letter(1)
True
sage: W.has_letter({})
True
sage: W.has_letter([])
```

```

True
sage: W.has_letter(range(5))
True
sage: W.has_letter(Permutation([]))
True

sage: W = Words(['a', 'b', 'c'])
sage: W.has_letter('a')
True
sage: W.has_letter('d')
False
sage: W.has_letter(8)
False

```

identity_morphism()

Returns the identity morphism from self to itself.

EXAMPLES:

```

sage: W = Words('ab')
sage: W.identity_morphism()
WordMorphism: a->a, b->b

```

```

sage: W = Words(range(3))
sage: W.identity_morphism()
WordMorphism: 0->0, 1->1, 2->2

```

There is no support yet for infinite alphabet:

```

sage: W = Words(alphabet=Alphabet(name='NN'))
sage: W
Finite and infinite words over Non negative integers
sage: W.identity_morphism()
Traceback (most recent call last):
...
NotImplementedError: size of alphabet must be finite

```

size_of_alphabet()

Returns the size of the alphabet.

EXAMPLES:

```

sage: Words().size_of_alphabet()
doctest:...: DeprecationWarning: size_of_alphabet is deprecated. Use
W.alphabet().cardinality() instead
See http://trac.sagemath.org/19619 for details.
+Infinity
sage: Word('abaccefa').parent().size_of_alphabet()
+Infinity
sage: Words('abcdef').size_of_alphabet()
6
sage: Words('').size_of_alphabet()
0
sage: Words('456').size_of_alphabet()
3

```

class sage.combinat.words.words.**FiniteOrInfiniteWords**(*alphabet*)

Bases: *sage.combinat.words.words.AbstractLanguage*

INPUT:

- alphabet – the underlying alphabet

cardinality()

Return the cardinality of this set of words.

EXAMPLES:

```
sage: Words('abcd').cardinality()
+Infinity
sage: Words('a').cardinality()
+Infinity
sage: Words('').cardinality()
1
```

factors()

Return the set of finite words.

EXAMPLES:

```
sage: Words('ab').finite_words()
Finite words over {'a', 'b'}
```

finite_words()

Return the set of finite words.

EXAMPLES:

```
sage: Words('ab').finite_words()
Finite words over {'a', 'b'}
```

infinite_words()

Return the set of infinite words.

EXAMPLES:

```
sage: Words('ab').infinite_words()
Infinite words over {'a', 'b'}
```

iterate_by_length(length)

Return an iterator over the words of given length.

EXAMPLES:

```
sage: [w.string_rep() for w in Words('ab').iterate_by_length(3)]
['aaa', 'aab', 'aba', 'abb', 'baa', 'bab', 'bba', 'bbb']
```

shift()

Return the set of infinite words.

EXAMPLES:

```
sage: Words('ab').infinite_words()
Infinite words over {'a', 'b'}
```

class sage.combinat.words.words.**FiniteWords**(alphabet=None, category=None)

Bases: *sage.combinat.words.words.AbstractLanguage*

The set of finite words over a fixed alphabet.

EXAMPLES:

```
sage: W = FiniteWords('ab')
sage: W
Finite words over {'a', 'b'}
```

cardinality()

Return the cardinality of this set.

EXAMPLES:

```
sage: FiniteWords('').cardinality()
1
sage: FiniteWords('a').cardinality()
+Infinity
```

factors()

Return itself.

EXAMPLES:

```
sage: FiniteWords('ab').factors()
Finite words over {'a', 'b'}
```

iter_morphisms (*arg=None, codomain=None, min_length=1*)

Iterate over all morphisms with domain *self* and the given codomain.

INPUT:

- *arg* - (optional, default: None) It can be one of the following :
 - None - then the method iterates through all morphisms.
 - tuple (a, b) of two integers - It specifies the range $\text{range}(a, b)$ of values to consider for the sum of the length of the image of each letter in the alphabet.
 - list of nonnegative integers - The length of the list must be equal to the size of the alphabet, and the *i*-th integer of *arg* determines the length of the word mapped to by the *i*-th letter of the (ordered) alphabet.
- *codomain* - (default: None) a combinatorial class of words. By default, *codomain* is *self*.
- *min_length* - (default: 1) nonnegative integer. If *arg* is not specified, then iterate through all the morphisms where the length of the images of each letter in the alphabet is at least *min_length*. This is ignored if *arg* is a list.

OUTPUT:

iterator

EXAMPLES:

Iterator over all non-erasing morphisms:

```
sage: W = FiniteWords('ab')
sage: it = W.iter_morphisms()
sage: for _ in range(7): next(it)
WordMorphism: a->a, b->a
WordMorphism: a->a, b->b
WordMorphism: a->b, b->a
WordMorphism: a->b, b->b
WordMorphism: a->aa, b->a
WordMorphism: a->aa, b->b
WordMorphism: a->ab, b->a
```

Iterator over all morphisms including erasing morphisms:

```
sage: W = FiniteWords('ab')
sage: it = W.iter_morphisms(min_length=0)
sage: for _ in range(7): next(it)
WordMorphism: a->, b->
WordMorphism: a->a, b->
WordMorphism: a->b, b->
WordMorphism: a->, b->a
WordMorphism: a->, b->b
WordMorphism: a->aa, b->
WordMorphism: a->ab, b->
```

Iterator over morphisms where the sum of the lengths of the images of the letters is in a specific range:

```
sage: for m in W.iter_morphisms((0, 3), min_length=0): m
WordMorphism: a->aa, b->
WordMorphism: a->ab, b->
WordMorphism: a->ba, b->
WordMorphism: a->bb, b->
WordMorphism: a->a, b->a
WordMorphism: a->a, b->b
WordMorphism: a->b, b->a
WordMorphism: a->b, b->b
WordMorphism: a->a, b->
WordMorphism: a->b, b->
WordMorphism: a->, b->aa
WordMorphism: a->, b->ab
WordMorphism: a->, b->ba
WordMorphism: a->, b->bb
WordMorphism: a->, b->a
WordMorphism: a->, b->b
WordMorphism: a->, b->
```

```
sage: for m in W.iter_morphisms((2, 4)): m
WordMorphism: a->aa, b->a
WordMorphism: a->aa, b->b
WordMorphism: a->ab, b->a
WordMorphism: a->ab, b->b
WordMorphism: a->ba, b->a
WordMorphism: a->ba, b->b
WordMorphism: a->bb, b->a
WordMorphism: a->bb, b->b
WordMorphism: a->a, b->aa
WordMorphism: a->a, b->ab
WordMorphism: a->a, b->ba
WordMorphism: a->a, b->bb
WordMorphism: a->b, b->aa
WordMorphism: a->b, b->ab
WordMorphism: a->b, b->ba
WordMorphism: a->b, b->bb
WordMorphism: a->a, b->a
WordMorphism: a->a, b->b
WordMorphism: a->b, b->a
WordMorphism: a->b, b->b
```

Iterator over morphisms with specific image lengths:

```

sage: for m in W.iter_morphisms([0, 0]): m
WordMorphism: a->, b->
sage: for m in W.iter_morphisms([0, 1]): m
WordMorphism: a->, b->a
WordMorphism: a->, b->b
sage: for m in W.iter_morphisms([2, 1]): m
WordMorphism: a->aa, b->a
WordMorphism: a->aa, b->b
WordMorphism: a->ab, b->a
WordMorphism: a->ab, b->b
WordMorphism: a->ba, b->a
WordMorphism: a->ba, b->b
WordMorphism: a->bb, b->a
WordMorphism: a->bb, b->b
sage: for m in W.iter_morphisms([2, 2]): m
WordMorphism: a->aa, b->aa
WordMorphism: a->aa, b->ab
WordMorphism: a->aa, b->ba
WordMorphism: a->aa, b->bb
WordMorphism: a->ab, b->aa
WordMorphism: a->ab, b->ab
WordMorphism: a->ab, b->ba
WordMorphism: a->ab, b->bb
WordMorphism: a->ba, b->aa
WordMorphism: a->ba, b->ab
WordMorphism: a->ba, b->ba
WordMorphism: a->ba, b->bb
WordMorphism: a->bb, b->aa
WordMorphism: a->bb, b->ab
WordMorphism: a->bb, b->ba
WordMorphism: a->bb, b->bb

```

The codomain may be specified as well:

```

sage: Y = FiniteWords('xyz')
sage: for m in W.iter_morphisms([0, 2], codomain=Y): m
WordMorphism: a->, b->xx
WordMorphism: a->, b->xy
WordMorphism: a->, b->xz
WordMorphism: a->, b->yx
WordMorphism: a->, b->yy
WordMorphism: a->, b->yz
WordMorphism: a->, b->zx
WordMorphism: a->, b->zy
WordMorphism: a->, b->zz
sage: for m in Y.iter_morphisms([0, 2, 1], codomain=W): m
WordMorphism: x->, y->aa, z->a
WordMorphism: x->, y->aa, z->b
WordMorphism: x->, y->ab, z->a
WordMorphism: x->, y->ab, z->b
WordMorphism: x->, y->ba, z->a
WordMorphism: x->, y->ba, z->b
WordMorphism: x->, y->bb, z->a
WordMorphism: x->, y->bb, z->b
sage: it = W.iter_morphisms(codomain=Y)
sage: for _ in range(10): next(it)
WordMorphism: a->x, b->x
WordMorphism: a->x, b->y

```

```

WordMorphism: a->x, b->z
WordMorphism: a->y, b->x
WordMorphism: a->y, b->y
WordMorphism: a->y, b->z
WordMorphism: a->z, b->x
WordMorphism: a->z, b->y
WordMorphism: a->z, b->z
WordMorphism: a->xx, b->x

```

iterate_by_length (*l=1*)

Returns an iterator over all the words of self of length *l*.

INPUT:

- *l* - integer (default: 1), the length of the desired words

EXAMPLES:

```

sage: W = FiniteWords('ab')
sage: list(W.iterate_by_length(1))
[word: a, word: b]
sage: list(W.iterate_by_length(2))
[word: aa, word: ab, word: ba, word: bb]
sage: list(W.iterate_by_length(3))
[word: aaa,
 word: aab,
 word: aba,
 word: abb,
 word: baa,
 word: bab,
 word: bba,
 word: bbb]
sage: list(W.iterate_by_length('a'))
Traceback (most recent call last):
...
TypeError: the parameter l ('a') must be an integer

```

random_element (*length=None, *args, **kwargs*)

Returns a random finite word on the given alphabet.

INPUT:

- *length* – (optional) the length of the word. If not set, will use a uniformly random number between 0 and 10.
- all other argument are transmitted to the random generator of the alphabet

EXAMPLES:

```

sage: W = FiniteWords(5)
sage: W.random_element() # random
word: 5114325445423521544531411434451152142155...

sage: W = FiniteWords(ZZ)
sage: W.random_element() # random
word: 5,-1,-1,-1,0,0,0,0,-3,-11
sage: W.random_element(length=4, x=0, y=4) # random
word: 1003

```

shift()

Return the set of infinite words on the same alphabet.

EXAMPLES:

```
sage: FiniteWords('ab').shift()
Infinite words over {'a', 'b'}
```

class sage.combinat.words.words.**InfiniteWords**(*alphabet=None, category=None*)Bases: *sage.combinat.words.words.AbstractLanguage*

INPUT:

•alphabet – the underlying alphabet

cardinality()

Return the cardinality of this set

EXAMPLES:

```
sage: InfiniteWords('ab').cardinality()
+Infinity
sage: InfiniteWords('a').cardinality()
1
sage: InfiniteWords('').cardinality()
0
```

factors()

Return the set of finite words on the same alphabet.

EXAMPLES:

```
sage: InfiniteWords('ab').factors()
Finite words over {'a', 'b'}
```

random_element(**args, **kws*)

Return a random infinite word.

EXAMPLES:

```
sage: W = InfiniteWords('ab')
sage: W.random_element() # random
word: abbbabbaabbbabbabbaabaabbabbbbbbbbaabbbb...

sage: W = InfiniteWords(ZZ)
sage: W.random_element(x=2,y=4) # random
word: 333322332223223333322332322322233233233...
```

shift()

Return itself.

EXAMPLES:

```
sage: InfiniteWords('ab').shift()
Infinite words over {'a', 'b'}
```

sage.combinat.words.words.Words(*alphabet=None, length=None, finite=True, infinite=True*)

Returns the combinatorial class of words of length k over an alphabet.

EXAMPLES:

```

sage: Words()
Finite and infinite words over Set of Python objects of type 'object'
sage: Words(length=7)
Words of length 7 over Set of Python objects of type 'object'
sage: Words(5)
Finite and infinite words over {1, 2, 3, 4, 5}
sage: Words(5, 3)
Words of length 3 over {1, 2, 3, 4, 5}
sage: Words(5, infinite=False)
Finite words over {1, 2, 3, 4, 5}
sage: Words(5, finite=False)
Infinite words over {1, 2, 3, 4, 5}
sage: Words('ab')
Finite and infinite words over {'a', 'b'}
sage: Words('ab', 2)
Words of length 2 over {'a', 'b'}
sage: Words('ab', infinite=False)
Finite words over {'a', 'b'}
sage: Words('ab', finite=False)
Infinite words over {'a', 'b'}
sage: Words('positive integers', finite=False)
Infinite words over Positive integers
sage: Words('natural numbers')
Finite and infinite words over Non negative integers

```

class `sage.combinat.words.words.Words_all`
 Bases: `sage.combinat.words.words.FiniteOrInfiniteWords`

Deprecated class used for unpickle support only!

class `sage.combinat.words.words.Words_n(words, n)`
 Bases: `sage.structure.parent.Parent`

The set of words of fixed length on a given alphabet.

alphabet()
 Return the underlying alphabet.

EXAMPLES:

```

sage: Words([0,1], 4).alphabet()
{0, 1}

```

cardinality()
 Returns the number of words of length n from alphabet.

EXAMPLES:

```

sage: Words(['a', 'b', 'c'], 4).cardinality()
81
sage: Words(3, 4).cardinality()
81
sage: Words(0,0).cardinality()
1
sage: Words(5,0).cardinality()
1
sage: Words(['a', 'b', 'c'], 0).cardinality()
1
sage: Words(0,1).cardinality()
0

```

```

sage: Words(5,1).cardinality()
5
sage: Words(['a','b','c'],1).cardinality()
3
sage: Words(7,13).cardinality()
96889010407
sage: Words(['a','b','c','d','e','f','g'],13).cardinality()
96889010407

```

iterate_by_length (*length*)

All words in this class are of the same length, so use iterator instead.

list ()

Returns a list of all the words contained in self.

EXAMPLES:

```

sage: Words(0,0).list()
[word: ]
sage: Words(5,0).list()
[word: ]
sage: Words(['a','b','c'],0).list()
[word: ]
sage: Words(5,1).list()
[word: 1, word: 2, word: 3, word: 4, word: 5]
sage: Words(['a','b','c'],2).list()
[word: aa, word: ab, word: ac, word: ba, word: bb, word: bc, word: ca, word:
↪cb, word: cc]

```

random_element (*args, **kws)

Return a random word in this set.

EXAMPLES:

```

sage: W = Words('ab', 4)
sage: W.random_element() # random
word: bbab
sage: W.random_element() in W
True

sage: W = Words(ZZ, 5)
sage: W.random_element() # random
word: 1,2,2,-1,12
sage: W.random_element() in W
True

```

5.1.348 Yang-Baxter Graphs

class sage.combinat.yang_baxter_graph.**SwapIncreasingOperator** (*i*)

Bases: [sage.combinat.yang_baxter_graph.SwapOperator](#)

The operator that swaps the items in positions *i* and *i*+1.

EXAMPLES:

```

sage: from sage.combinat.yang_baxter_graph import SwapOperator
sage: s3 = SwapOperator(3)

```

```
sage: s3 == loads(dumps(s3))
True
```

class `sage.combinat.yang_baxter_graph.SwapOperator(i)`
 Bases: `sage.structure.sage_object.SageObject`

The operator that swaps the items in positions i and $i+1$.

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapOperator
sage: s3 = SwapOperator(3)
sage: s3 == loads(dumps(s3))
True
```

position()

self is the operator that swaps positions i and $i+1$. This method returns i .

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapOperator
sage: s3 = SwapOperator(3)
sage: s3.position()
3
```

`sage.combinat.yang_baxter_graph.YangBaxterGraph(partition=None, root=None, operators=None)`

Construct the Yang-Baxter graph from `root` by repeated application of operators, or the Yang-Baxter graph associated to `partition`.

INPUT:

The user needs to provide either `partition` or both `root` and `operators`, where

- `partition` – a partition of a positive integer
- `root` – the root vertex
- `operator` – a function that maps vertices u to a list of tuples of the form (v, l) where v is a successor of u and l is the label of the edge from u to v .

OUTPUT:

- Either:
 - `YangBaxterGraph_partition` – if `partition` is defined
 - `YangBaxterGraph_generic` – if `partition` is None

EXAMPLES:

The Yang-Baxter graph defined by a partition $[p_1, \dots, p_k]$ is the labelled directed graph with vertex set obtained by bubble-sorting $(p_k - 1, p_k - 2, \dots, 0, \dots, p_1 - 1, p_1 - 2, \dots, 0)$; there is an arrow from u to v labelled by i if v is obtained by swapping the i -th and $(i+1)$ -th elements of u . For example, if the partition is $[3, 1]$, then we begin with $(0, 2, 1, 0)$ and generate all tuples obtained from it by swapping two adjacent entries if they are increasing:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: bubbleswaps = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(0, 2, 1, 0), operators=bubbleswaps); Y
Yang-Baxter graph with root vertex (0, 2, 1, 0)
```

```
sage: Y.vertices()
[(2, 0, 1, 0), (2, 1, 0, 0), (0, 2, 1, 0)]
```

The `partition` keyword is a shorthand for the above construction.

```
sage: Y = YangBaxterGraph(partition=[3,1]); Y
Yang-Baxter graph of [3, 1], with top vertex (0, 2, 1, 0)
sage: Y.vertices()
[(0, 2, 1, 0), (2, 0, 1, 0), (2, 1, 0, 0)]
```

The permutahedron can be realized as a Yang-Baxter graph.

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: swappers = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(1,2,3,4), operators=swappers); Y
Yang-Baxter graph with root vertex (1, 2, 3, 4)
sage: Y.plot()
Graphics object consisting of 97 graphics primitives
```

The Cayley graph of a finite group can be realized as a Yang-Baxter graph.

```
sage: def left_multiplication_by(g):
....:     return lambda h : h*g
sage: G = CyclicPermutationGroup(4)
sage: operators = [ left_multiplication_by(gen) for gen in G.gens() ]
sage: Y = YangBaxterGraph(root=G.identity(), operators=operators); Y
Yang-Baxter graph with root vertex ()
sage: Y.plot(edge_labels=False)
Graphics object consisting of 9 graphics primitives

sage: G = SymmetricGroup(4)
sage: operators = [left_multiplication_by(gen) for gen in G.gens()]
sage: Y = YangBaxterGraph(root=G.identity(), operators=operators); Y
Yang-Baxter graph with root vertex ()
sage: Y.plot(edge_labels=False)
Graphics object consisting of 96 graphics primitives
```

AUTHORS:

- Franco Saliola (2009-04-23)

```
class sage.combinat.yang_baxter_graph.YangBaxterGraph_generic (root, operators)
Bases: sage.structure.sage_object.SageObject
```

A class to model the Yang-Baxter graph defined by `root` and `operators`.

INPUT:

- `root` – the root vertex of the graph
- `operators` – a list of callables that map vertices to (new) vertices.

Note: This is a lazy implementation: the digraph is only computed when it is needed.

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(4)]
```

```

sage: Y = YangBaxterGraph(root=(1,0,2,1,0), operators=ops); Y
Yang-Baxter graph with root vertex (1, 0, 2, 1, 0)
sage: loads(dumps(Y)) == Y
True

```

AUTHORS:

•Franco Saliola (2009-04-23)

edges()

Returns the (labelled) edges of self.

EXAMPLES:

```

sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)
sage: Y.edges()
[(0, 2, 1, 0), (2, 0, 1, 0), Swap-if-increasing at position 0), ((2, 0, 1, 0),
↪0), (2, 1, 0, 0), Swap-if-increasing at position 1)]

```

plot(*args, **kws)

Plots self as a digraph.

EXAMPLES:

```

sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(4)]
sage: Y = YangBaxterGraph(root=(1,0,2,1,0), operators=ops)
sage: Y.plot()
Graphics object consisting of 16 graphics primitives
sage: Y.plot(edge_labels=False)
Graphics object consisting of 11 graphics primitives

```

relabel_edges(edge_dict, inplace=True)

Relabel the edges of self.

INPUT:

•edge_dict – a dictionary keyed by the (unlabelled) edges.

EXAMPLES:

```

sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)
sage: def relabel_op(op, u):
....:     i = op.position()
....:     return u[:i] + u[i:i+2][::-1] + u[i+2:]
sage: Y.edges()
[(0, 2, 1, 0), (2, 0, 1, 0), Swap-if-increasing at position 0), ((2, 0, 1, 0),
↪0), (2, 1, 0, 0), Swap-if-increasing at position 1)]
sage: d = {(0,2,1,0),(2,0,1,0)}:17, ((2,0,1,0),(2,1,0,0)):27}
sage: Y.relabel_edges(d, inplace=False).edges()
[(0, 2, 1, 0), (2, 0, 1, 0), 17), ((2, 0, 1, 0), (2, 1, 0, 0), 27)]
sage: Y.edges()
[(0, 2, 1, 0), (2, 0, 1, 0), Swap-if-increasing at position 0), ((2, 0, 1, 0),
↪0), (2, 1, 0, 0), Swap-if-increasing at position 1)]
sage: Y.relabel_edges(d, inplace=True)

```

```
sage: Y.edges()
[(0, 2, 1, 0), (2, 0, 1, 0), 17), ((2, 0, 1, 0), (2, 1, 0, 0), 27)]
```

relabel_vertices (*v*, *relabel_operator*, *inplace=True*)

Relabel the vertices *u* of *self* by the object obtained from *u* by applying the *relabel_operator* to *v* along a path from *self.root()* to *u*.

Note that the *self.root()* is paired with *v*.

INPUT:

- *v* – tuple, Permutation, CombinatorialObject
- *inplace* – if True, modifies *self*; otherwise returns a modified copy of *self*.

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)
sage: def relabel_op(op, u):
....:     i = op.position()
....:     return u[:i] + u[i:i+2][::-1] + u[i+2:]
sage: d = Y.relabel_vertices((1,2,3,4), relabel_op, inplace=False); d
Yang-Baxter graph with root vertex (1, 2, 3, 4)
sage: Y.vertices()
[(2, 0, 1, 0), (2, 1, 0, 0), (0, 2, 1, 0)]
sage: e = Y.relabel_vertices((1,2,3,4), relabel_op); e
sage: Y.vertices()
[(2, 1, 3, 4), (1, 2, 3, 4), (2, 3, 1, 4)]
```

root()

Returns the root vertex of *self*.

If *self* is the Yang-Baxter graph of the partition $[p_1, p_2, \dots, p_k]$, then this is the vertex $(p_k - 1, p_k - 2, \dots, 0, \dots, p_1 - 1, p_1 - 2, \dots, 0)$.

EXAMPLES:

```
sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(4)]
sage: Y = YangBaxterGraph(root=(1,0,2,1,0), operators=ops)
sage: Y.root()
(1, 0, 2, 1, 0)
sage: Y = YangBaxterGraph(root=(0,1,0,2,1,0), operators=ops)
sage: Y.root()
(0, 1, 0, 2, 1, 0)
sage: Y = YangBaxterGraph(root=(1,0,3,2,1,0), operators=ops)
sage: Y.root()
(1, 0, 3, 2, 1, 0)
sage: Y = YangBaxterGraph(partition=[3,2])
sage: Y.root()
(1, 0, 2, 1, 0)
```

successors (*v*)

Return the successors of the vertex *v*.

EXAMPLES:

```

sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(4)]
sage: Y = YangBaxterGraph(root=(1,0,2,1,0), operators=ops)
sage: Y.successors(Y.root())
[(1, 2, 0, 1, 0)]
sage: Y.successors((1, 2, 0, 1, 0))
[(1, 2, 1, 0, 0), (2, 1, 0, 1, 0)]

```

vertex_relabelling_dict (*v*, *relabel_operator*)

Return a dictionary pairing vertices *u* of *self* with the object obtained from *v* by applying the *relabel_operator* along a path from the root to *u*. Note that the root is paired with *v*.

INPUT:

- *v* – an object
- *relabel_operator* – function mapping a vertex and a label to the image of the vertex

OUTPUT:

- dictionary pairing vertices with the corresponding image of *v*

EXAMPLES:

```

sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)
sage: def relabel_operator(op, u):
....:     i = op.position()
....:     return u[:i] + u[i:i+2][::-1] + u[i+2:]
sage: Y.vertex_relabelling_dict((1,2,3,4), relabel_operator)
{(0, 2, 1, 0): (1, 2, 3, 4),
 (2, 0, 1, 0): (2, 1, 3, 4),
 (2, 1, 0, 0): (2, 3, 1, 4)}

```

vertices ()

Returns the vertices of *self*.

EXAMPLES:

```

sage: from sage.combinat.yang_baxter_graph import SwapIncreasingOperator
sage: ops = [SwapIncreasingOperator(i) for i in range(3)]
sage: Y = YangBaxterGraph(root=(0,2,1,0), operators=ops)
sage: Y.vertices()
[(2, 0, 1, 0), (2, 1, 0, 0), (0, 2, 1, 0)]

```

class `sage.combinat.yang_baxter_graph.YangBaxterGraph_partition` (*partition*)

Bases: `sage.combinat.yang_baxter_graph.YangBaxterGraph_generic`

A class to model the Yang-Baxter graph of a partition.

The Yang-Baxter graph defined by a partition $[p_1, \dots, p_k]$ is the labelled directed graph with vertex set obtained by bubble-sorting $(p_k - 1, p_k - 2, \dots, 0, \dots, p_1 - 1, p_1 - 2, \dots, 0)$; there is an arrow from *u* to *v* labelled by *i* if *v* is obtained by swapping the *i*-th and (*i* + 1)-th elements of *u*.

Note: This is a lazy implementation: the digraph is only computed when it is needed.

EXAMPLES:

```

sage: Y = YangBaxterGraph(partition=[3,2,1]); Y
Yang-Baxter graph of [3, 2, 1], with top vertex (0, 1, 0, 2, 1, 0)
sage: loads(dumps(Y)) == Y
True

```

AUTHORS:

- Franco Saliola (2009-04-23)

relabel_vertices (*v*, *inplace=True*)

Relabel the vertices of *self* with the object obtained from *v* by applying the transpositions corresponding to the edge labels along some path from the root to the vertex.

INPUT:

- v* – tuple, Permutation, CombinatorialObject
- inplace* – if True, modifies *self*; otherwise returns a modified copy of *self*.

EXAMPLES:

```

sage: Y = YangBaxterGraph(partition=[3,1]); Y
Yang-Baxter graph of [3, 1], with top vertex (0, 2, 1, 0)
sage: d = Y.relabel_vertices((1,2,3,4), inplace=False); d
Digraph on 3 vertices
sage: Y.vertices()
[(0, 2, 1, 0), (2, 0, 1, 0), (2, 1, 0, 0)]
sage: e = Y.relabel_vertices((1,2,3,4)); e
sage: Y.vertices()
[(1, 2, 3, 4), (2, 1, 3, 4), (2, 3, 1, 4)]

```

vertex_relabelling_dict (*v*)

Return a dictionary pairing vertices *u* of *self* with the object obtained from *v* by applying transpositions corresponding to the edges labels along a path from the root to *u*.

Note that the root is paired with *v*.

INPUT:

- v* – an object

OUTPUT:

- dictionary pairing vertices with the corresponding image of *v*

EXAMPLES:

```

sage: Y = YangBaxterGraph(partition=[3,1])
sage: Y.vertex_relabelling_dict((1,2,3,4))
{(0, 2, 1, 0): (1, 2, 3, 4),
 (2, 0, 1, 0): (2, 1, 3, 4),
 (2, 1, 0, 0): (2, 3, 1, 4)}
sage: Y.vertex_relabelling_dict((4,3,2,1))
{(0, 2, 1, 0): (4, 3, 2, 1),
 (2, 0, 1, 0): (3, 4, 2, 1),
 (2, 1, 0, 0): (3, 2, 4, 1)}

```

5.1.349 C-Finite Sequences

C-finite infinite sequences satisfy homogenous linear recurrences with constant coefficients:

$$a_{n+d} = c_0 a_n + c_1 a_{n+1} + \cdots + c_{d-1} a_{n+d-1}, \quad d > 0.$$

CFiniteSequences are completely defined by their ordinary generating function (o.g.f., which is always a fraction of polynomials over $\mathbb{Z}$ or $\mathbb{Q}$).

EXAMPLES:

```
sage: fibo = CFiniteSequence(x/(1-x-x^2))          # the Fibonacci sequence
sage: fibo
C-finite sequence, generated by x/(-x^2 - x + 1)
sage: fibo.parent()
The ring of C-Finite sequences in x over Rational Field
sage: fibo.parent().category()
Category of commutative rings
sage: C.<x> = CFiniteSequences(QQ);
sage: fibo.parent() == C
True
sage: C
The ring of C-Finite sequences in x over Rational Field
sage: C(x/(1-x-x^2))
C-finite sequence, generated by x/(-x^2 - x + 1)
sage: C(x/(1-x-x^2)) == fibo
True
sage: var('y')
y
sage: CFiniteSequence(y/(1-y-y^2))
C-finite sequence, generated by y/(-y^2 - y + 1)
sage: CFiniteSequence(y/(1-y-y^2)) == fibo
False
```

Finite subsets of the sequence are accessible via python slices:

```
sage: fibo[137]          #the 137th term of the Fibonacci sequence
19134702400093278081449423917
sage: fibo[137] == fibonacci(137)
True
sage: fibo[0:12]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
sage: fibo[14:4:-2]
[377, 144, 55, 21, 8]
```

They can be created also from the coefficients and start values of a recurrence:

```
sage: r = C.from_recurrence([1,1],[0,1])
sage: r == fibo
True
```

Given enough values, the o.g.f. of a C-finite sequence can be guessed:

```
sage: r = C.guess([0,1,1,2,3,5,8])
sage: r == fibo
True
```

See also:

fibonacci(), *BinaryRecurrenceSequence*

AUTHORS:

- Ralf Stephan (2014): initial version

REFERENCES:

class `sage.rings.cfinite_sequence.CFiniteSequence` (*parent, ogf*)
 Bases: `sage.structure.element.FieldElement`

Create a C-finite sequence given its ordinary generating function.

INPUT:

- *ogf* – a rational function, the ordinary generating function (can be a an element from the symbolic ring, fraction field or polynomial ring)

OUTPUT:

- A `CFiniteSequence` object

EXAMPLES:

```
sage: CFiniteSequence((2-x)/(1-x-x^2))      # the Lucas sequence
C-finite sequence, generated by (-x + 2)/(-x^2 - x + 1)
sage: CFiniteSequence(x/(1-x)^3)           # triangular numbers
C-finite sequence, generated by x/(-x^3 + 3*x^2 - 3*x + 1)
```

Polynomials are interpreted as finite sequences, or recurrences of degree 0:

```
sage: CFiniteSequence(x^2-4*x^5)
Finite sequence [1, 0, 0, -4], offset = 2
sage: CFiniteSequence(1)
Finite sequence [1], offset = 0
```

This implementation allows any polynomial fraction as o.g.f. by interpreting any power of x dividing the o.g.f. numerator or denominator as a right or left shift of the sequence offset:

```
sage: CFiniteSequence(x^2+3/x)
Finite sequence [3, 0, 0, 1], offset = -1
sage: CFiniteSequence(1/x+4/x^3)
Finite sequence [4, 0, 1], offset = -3
sage: P = LaurentPolynomialRing(QQ.fraction_field(), 'X')
sage: X=P.gen()
sage: CFiniteSequence(1/(1-X))
C-finite sequence, generated by 1/(-X + 1)
```

The o.g.f. is always normalized to get a denominator constant coefficient of +1:

```
sage: CFiniteSequence(1/(x-2))
C-finite sequence, generated by -1/2/(-1/2*x + 1)
```

The given *ogf* is used to create an appropriate parent: it can be a symbolic expression, a polynomial, or a fraction field element as long as it can be coerced into a proper fraction field over the rationals:

```
sage: var('x')
x
sage: f1 = CFiniteSequence((2-x)/(1-x-x^2))
sage: P.<x> = QQ[]
sage: f2 = CFiniteSequence((2-x)/(1-x-x^2))
sage: f1 == f2
```

```

True
sage: f1.parent()
The ring of C-Finite sequences in x over Rational Field
sage: f1.ogf().parent()
Fraction Field of Univariate Polynomial Ring in x over Rational Field
sage: CFiniteSequence(log(x))
Traceback (most recent call last):
...
TypeError: unable to convert log(x) to a rational

```

closed_form (*n='n'*)

Return a symbolic expression in *n*, which equals the *n*-th term of the sequence.

It is a well-known property of C-finite sequences a_n that they have a closed form of the type:

$$a_n = \sum_{i=1}^d c_i(n) \cdot r_i^n,$$

where r_i are the roots of the characteristic equation and $c_i(n)$ is a polynomial (whose degree equals the multiplicity of r_i minus one). This is a natural generalization of Binet's formula for Fibonacci numbers. See, for instance, [KP, Theorem 4.1].

Note that if the o.g.f. has a polynomial part, that is, if the numerator degree is not strictly less than the denominator degree, then this closed form holds only when *n* exceeds the degree of that polynomial part. In that case, the returned expression will differ from the sequence for small *n*.

EXAMPLES:

```

sage: CFiniteSequence(1/(1-x)).closed_form()
1
sage: CFiniteSequence(x^2/(1-x)).closed_form()
1
sage: CFiniteSequence(1/(1-x^2)).closed_form()
1/2*(-1)^n + 1/2
sage: CFiniteSequence(1/(1+x^3)).closed_form()
1/3*(-1)^n + 1/3*(1/2*I*sqrt(3) + 1/2)^n + 1/3*(-1/2*I*sqrt(3) + 1/2)^n
sage: CFiniteSequence(1/(1-x)/(1-2*x)/(1-3*x)).closed_form()
9/2*3^n - 4*2^n + 1/2

```

Binet's formula for the Fibonacci numbers:

```

sage: CFiniteSequence(x/(1-x-x^2)).closed_form()
1/5*sqrt(5)*(1/2*sqrt(5) + 1/2)^n - 1/5*sqrt(5)*(-1/2*sqrt(5) + 1/2)^n
sage: [_.subs(n=k).full_simplify() for k in range(6)]
[0, 1, 1, 2, 3, 5]

sage: CFiniteSequence((4*x+3)/(1-2*x-5*x^2)).closed_form()
1/12*(sqrt(6) + 1)^n*(7*sqrt(6) + 18) - 1/12*(-sqrt(6) + 1)^n*(7*sqrt(6) - 18)

```

Examples with multiple roots:

```

sage: CFiniteSequence(x*(x^2+4*x+1)/(1-x)^5).closed_form()
1/4*n^4 + 1/2*n^3 + 1/4*n^2
sage: CFiniteSequence((1+2*x-x^2)/(1-x)^4/(1+x)^2).closed_form()
1/12*n^3 - 1/8*(-1)^n*(n + 1) + 3/4*n^2 + 43/24*n + 9/8
sage: CFiniteSequence(1/(1-x)^3/(1-2*x)^4).closed_form()
4/3*(n^3 - 3*n^2 + 20*n - 36)*2^n + 1/2*n^2 + 19/2*n + 49
sage: CFiniteSequence((x/(1-x-x^2))^2).closed_form()
1/25*(5*n - sqrt(5))*(1/2*sqrt(5) + 1/2)^n + 1/25*(5*n + sqrt(5))*(-1/
-2*sqrt(5) + 1/2)^n

```

coefficients()

Return the coefficients of the recurrence representation of the C-finite sequence.

OUTPUT:

- A list of values

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: lucas = C((2-x)/(1-x-x^2)) # the Lucas sequence
sage: lucas.coefficients()
[1, 1]
```

denominator()

Return the numerator of the o.g.f of self.

EXAMPLES:

```
sage: f = CFiniteSequence((2-x)/(1-x-x^2)); f
C-finite sequence, generated by (-x + 2)/(-x^2 - x + 1)
sage: f.denominator()
-x^2 - x + 1
```

numerator()

Return the numerator of the o.g.f of self.

EXAMPLES:

```
sage: f = CFiniteSequence((2-x)/(1-x-x^2)); f
C-finite sequence, generated by (-x + 2)/(-x^2 - x + 1)
sage: f.numerator()
-x + 2
```

ogf()

Return the ordinary generating function associated with the CFiniteSequence.

This is always a fraction of polynomials in the base ring.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: r = C.from_recurrence([2], [1])
sage: r.ogf()
1/(-2*x + 1)
sage: C(0).ogf()
0
```

recurrence_repr()

Return a string with the recurrence representation of the C-finite sequence.

OUTPUT:

- A string

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C((2-x)/(1-x-x^2)).recurrence_repr()
'Homogenous linear recurrence with constant coefficients of degree 2: a(n+2)
= a(n+1) + a(n), starting a(0...) = [2, 1]'
```

```

sage: C(x/(1-x)^3).recurrence_repr()
'Homogenous linear recurrence with constant coefficients of degree 3: a(n+3)
↳ 3*a(n+2) - 3*a(n+1) + a(n), starting a(1...) = [1, 3, 6]'
sage: C(1).recurrence_repr()
'Finite sequence [1], offset 0'
sage: r = C((-2*x^3 + x^2 - x + 1)/(2*x^2 - 3*x + 1))
sage: r.recurrence_repr()
'Homogenous linear recurrence with constant coefficients of degree 2: a(n+2)
↳ 3*a(n+1) - 2*a(n), starting a(0...) = [1, 2, 5, 9]'
sage: r = CFiniteSequence(x^3/(1-x-x^2))
sage: r.recurrence_repr()
'Homogenous linear recurrence with constant coefficients of degree 2: a(n+2)
↳ a(n+1) + a(n), starting a(3...) = [1, 1, 2, 3]'

```

series (*n*)

Return the Laurent power series associated with the CFiniteSequence, with precision *n*.

INPUT:

- *n* – a nonnegative integer

EXAMPLES:

```

sage: C.<x> = CFiniteSequences(QQ)
sage: r = C.from_recurrence([-1,2],[0,1])
sage: s = r.series(4); s
x + 2*x^2 + 3*x^3 + 4*x^4 + O(x^5)
sage: type(s)
<type 'sage.rings.laurent_series_ring_element.LaurentSeries'>

```

`sage.rings.cfinite_sequence.CFiniteSequences` (*base_ring*, *names=None*, *category=None*)

Return the ring of C-Finite sequences.

The ring is defined over a base ring ($\mathbb{Z}$ or $\mathbb{Q}$) and each element is represented by its ordinary generating function (ogf) which is a rational function over the base ring.

INPUT:

- *base_ring* – the base ring to construct the fraction field representing the C-Finite sequences
- *names* – (optional) the list of variables.

EXAMPLES:

```

sage: C.<x> = CFiniteSequences(QQ)
sage: C
The ring of C-Finite sequences in x over Rational Field
sage: C.an_element()
C-finite sequence, generated by (-x + 2)/(-x^2 - x + 1)
sage: C.category()
Category of commutative rings
sage: C.one()
Finite sequence [1], offset = 0
sage: C.zero()
Constant infinite sequence 0.
sage: C(x)
Finite sequence [1], offset = 1
sage: C(1/x)
Finite sequence [1], offset = -1
sage: C((-x + 2)/(-x^2 - x + 1))
C-finite sequence, generated by (-x + 2)/(-x^2 - x + 1)

```

```
class sage.rings.cfinite_sequence.CFiniteSequences_generic (polynomial_ring, category)
Bases: sage.rings.ring.CommutativeRing, sage.structure.unique_representation.UniqueRepresentation
```

The class representing the ring of C-Finite Sequences

Element

alias of *CFiniteSequence*

an_element()

Return an element of C-Finite Sequences.

OUTPUT:

The Lucas sequence.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ);
sage: C.an_element()
C-finite sequence, generated by (-x + 2)/(-x^2 - x + 1)
```

fraction_field()

Return the fraction field used to represent the elements of self.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ);
sage: C.fraction_field()
Fraction Field of Univariate Polynomial Ring in x over Rational Field
```

from_recurrence (coefficients, values)

Create a C-finite sequence given the coefficients c and starting values a of a homogenous linear recurrence.

$$a_{n+d} = c_0 a_n + c_1 a_{n+1} + \cdots + c_{d-1} a_{n+d-1}, \quad d \geq 0.$$

INPUT:

- coefficients – a list of rationals
- values – start values, a list of rationals

OUTPUT:

- A CFiniteSequence object

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ)
sage: C.from_recurrence([1,1],[0,1]) # Fibonacci numbers
C-finite sequence, generated by x/(-x^2 - x + 1)
sage: C.from_recurrence([-1,2],[0,1]) # natural numbers
C-finite sequence, generated by x/(x^2 - 2*x + 1)
sage: r = C.from_recurrence([-1],[1])
sage: s = C.from_recurrence([-1],[1,-1])
sage: r == s
True
sage: r = C(x^3/(1-x-x^2))
sage: s = C.from_recurrence([1,1],[0,0,0,1,1])
sage: r == s
```

```

True
sage: C.from_recurrence(1,1)
Traceback (most recent call last):
...
ValueError: Wrong type for recurrence coefficient list.

```

gen (*i=0*)

Return the *i*-th generator of *self*.

INPUT:

- *i* – an integer (default:0)

EXAMPLES:

```

sage: C.<x> = CFiniteSequences(QQ);
sage: C.gen()
x
sage: x == C.gen()
True

```

guess (*sequence*, *algorithm='sage'*)

Return the minimal CFiniteSequence that generates the sequence.

Assume the first value has index 0.

INPUT:

- *sequence* – list of integers
- **algorithm** – string
 - ‘sage’ - the default is to use Sage’s matrix kernel function
 - ‘pari’ - use Pari’s implementation of LLL
 - ‘bm’ - use Sage’s Berlekamp-Massey algorithm

OUTPUT:

- a CFiniteSequence, or 0 if none could be found

With the default kernel method, trailing zeroes are chopped off before a guessing attempt. This may reduce the data below the accepted length of six values.

EXAMPLES:

```

sage: C.<x> = CFiniteSequences(QQ)
sage: C.guess([1,2,4,8,16,32])
C-finite sequence, generated by 1/(-2*x + 1)
sage: r = C.guess([1,2,3,4,5])
Traceback (most recent call last):
...
ValueError: Sequence too short for guessing.

```

With Berlekamp-Massey, if an odd number of values is given, the last one is dropped. So with an odd number of values the result may not generate the last value:

```

sage: r = C.guess([1,2,4,8,9], algorithm='bm'); r
C-finite sequence, generated by 1/(-2*x + 1)
sage: r[0:5]
[1, 2, 4, 8, 16]

```

ngens()

Return the number of generators of `self`

EXAMPLES:

```
sage: from sage.rings.cfinite_sequence import CFiniteSequences
sage: C.<x> = CFiniteSequences(QQ);
sage: C.ngens()
1
```

polynomial_ring()

Return the polynomial ring used to represent the elements of `self`.

EXAMPLES:

```
sage: C.<x> = CFiniteSequences(QQ);
sage: C.polynomial_ring()
Univariate Polynomial Ring in x over Rational Field
```
