Overview

- **Problems with reuse**
- Problems with evolution
- What are reuse contracts?
- Reuse contracts at work
- Examining class hierarchies based on reuse contracts
- Reuse contract research
- Exercises: introduction to the browser

How do You Reuse a Class?

- Cloning (copy and paste)
- Inheritance / method overriding
- Composition / delegation

Reuse by Cloning

- Reused “components” are not easily adaptable
 - no support is provided for adaptation/reuse
- No relation between original and result
 - difficult to maintain since bug fixes and upgrades are not propagated to the derived application (proliferation of versions)

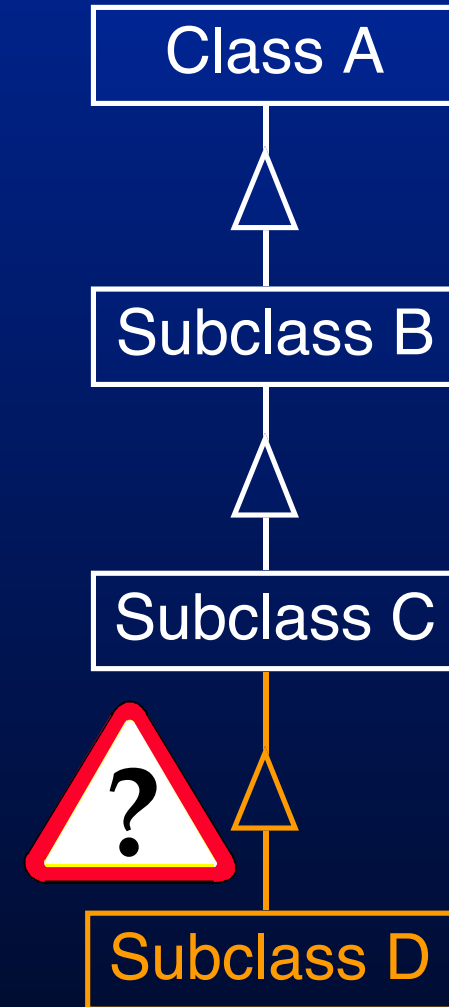

This kind of reuse should be avoided

Reuse by Inheritance

How do you determine

- what to reuse (inherit)?
- what to adapt (override)?
- what to write from scratch?

Example: Make a Subclass of Set

What to override?

- #add: if #addAll: uses #add:
- #add & addAll: if #addAll: does not use #add:

A CountingSet is a Set that counts all added elements

Reuse by Composition

How do you determine

- what to reuse (what to compose, what to delegate)?
- what to adapt (how to compose)?
- what to write from scratch?

Reusing a Class is Hard

- Current OOA / OOD notations do not provide enough information to reuse a class
- Usually, developers do not document how a class can be reused, they only document what each method does
- If a class comment contains reuse information, it usually has the form of a cookbook

Reusers are compelled to inspect the source code

Inspecting the Source Code

- To reuse a class:
 - inspect the class
 - inspect all its superclasses
 - inspect all the classes it co-operates with
- Source code inspection is error-prone
- If source code inspection doesn't work:
talk to the developer (i.e. the expert)!

What are You Looking for?

- **Self sends**
- Super sends
- Abstract methods
- Template methods
- Default methods
- Methods that are overridden frequently
- Methods that are part of a design pattern
- **Co-operation with other objects/classes**
- ...

**Reusers need the
specialisation interface**

Self Sends are Important

- Self sends & template methods & abstract methods reify the design of a class
- Method decomposition
 - distinguish “core” methods from “peripheral” methods
- Using self sends = planning for reuse
 - fine-grained overriding of methods

Self Sends: Planning for Reuse

ApplicationModel in VisualWorks 2.5

openInterface: aSymbol

```
builder := self builderClass new.
```

...

“a lot of expressions here”

...

can be reused with other builders

ApplicationModel in VisualWorks 2.0

openInterface: aSymbol

```
builder := UIBuilder new.
```

...

“a lot of expressions here”

...

same external interface
(#builderClass is private)

cannot be reused with other builders
without overriding all methods that
refer to UIBuilder

Co-operation with Other Objects/Classes is Important

- Delegation of responsibilities principle
- Using delegation= planning for reuse
 - a system can easily be extended by adding new classes
 - objects with “the same interface” can be substituted for each other

Delegation: Planning for Reuse

Menu in VisualWorks 2.0

can be reused for
different menu items

PopUpMenu in VisualWorks 1.0

Strings !

same external behaviour
same interface
for instance creation

cannot be reused for
different menu items

Overview

- Problems with reuse
- **Problems with evolution**
- What are reuse contracts?
- Reuse contracts at work
- Examining class hierarchies based on reuse contracts
- Reuse contract research
- Exercises: introduction to the browser

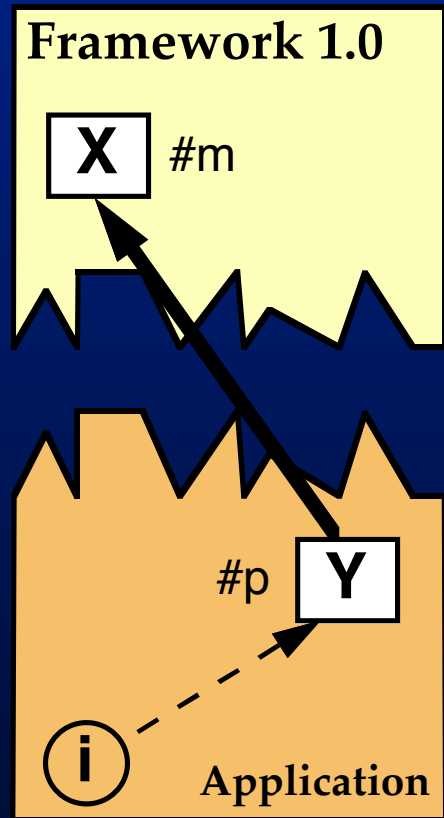

Evolution is Important

- Iterative development
 - a framework is never finished
- Changing requirements
 - functional: user requirements
 - non-functional: maintainability, adaptability, reusability, customisability, ...

What to do When the Framework Changes?

Example Evolution Conflict (1)

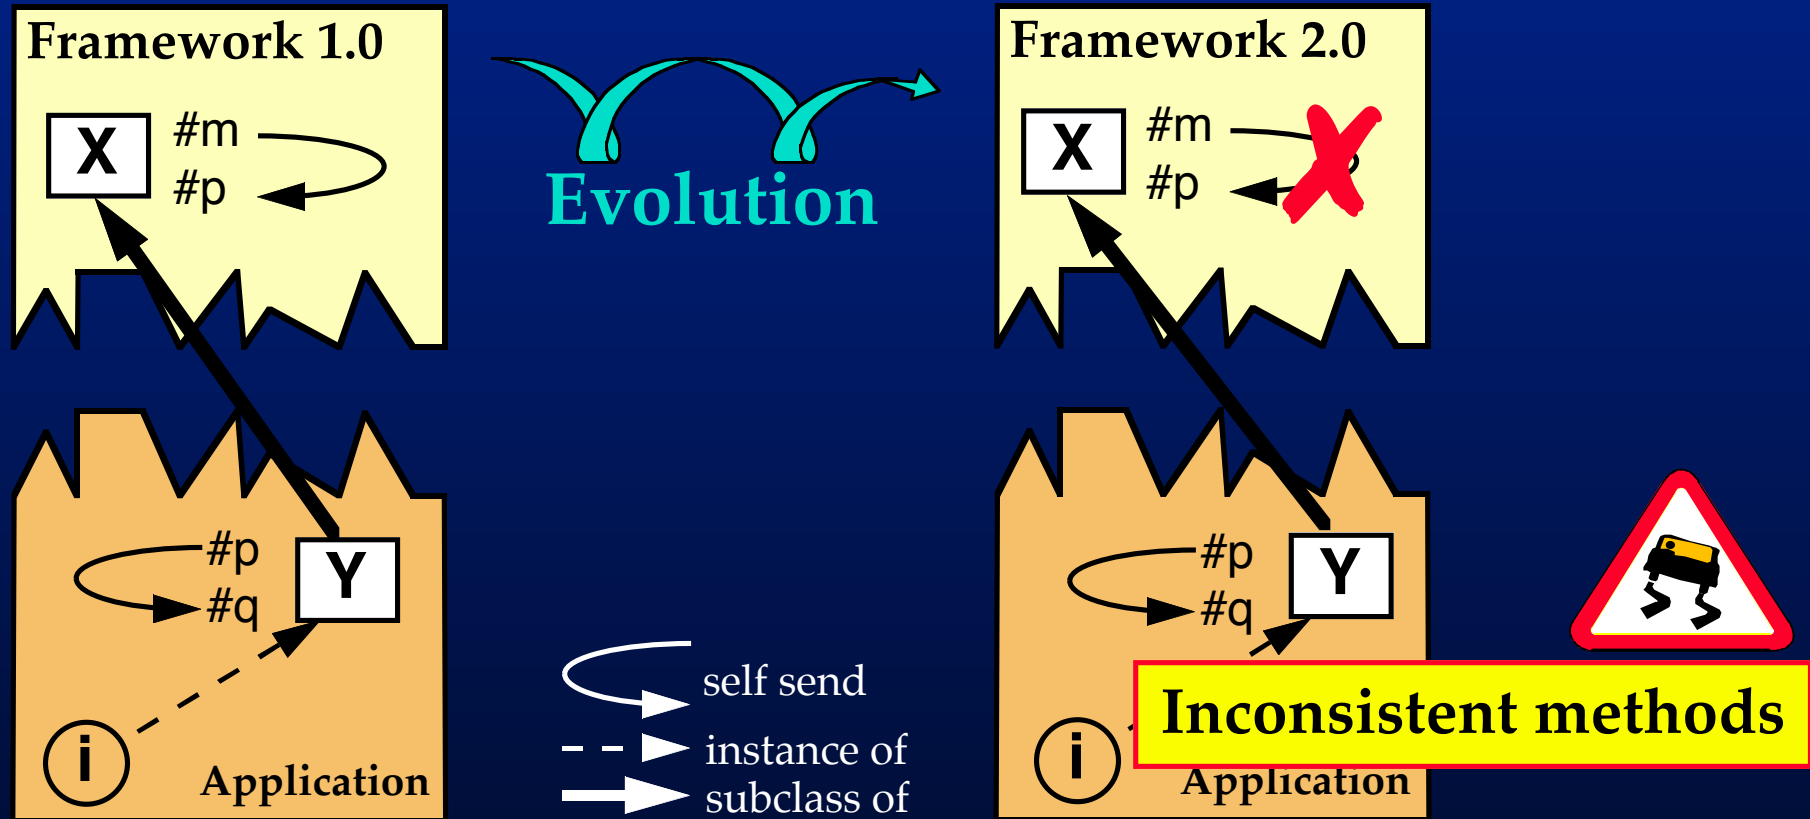

Evolution

--> instance of
-> subclass of

Example Evolution Conflict (2)

More Evolution Conflicts

- Interface conflicts
 - the name of a reused method / class has been changed
 - a method that was added by a reuser has been introduced by the new version of the framework
- Unanticipated recursion
 - a method invokes another one in the application while the new version of the framework introduces an invocation of the first by the latter

Spotting Evolution Problems

- Unless the changes to the framework are well-documented (informally), the application developer is condemned to perform code inspection to determine what has changed
- Often evolution conflicts are not spotted until the application is running based on the new version of the framework

What are the Challenges?

- Supporting reuse
 - what can be reused, what must be adapted, and what must be built from scratch ?
 - formal documentation on how classes are reused
- Supporting evolution
 - change propagation
- Support for estimates / testing / metrics
 - feasibility of reusing a class
 - the cost of “upgrading” the class repository

Overview

- Problems with reuse
- Problems with evolution
- **What are reuse contracts?**
- Reuse contracts at work
- Examining class hierarchies based on reuse contracts
- Reuse contract research
- Exercises: introduction to the browser

Reuse Contracts

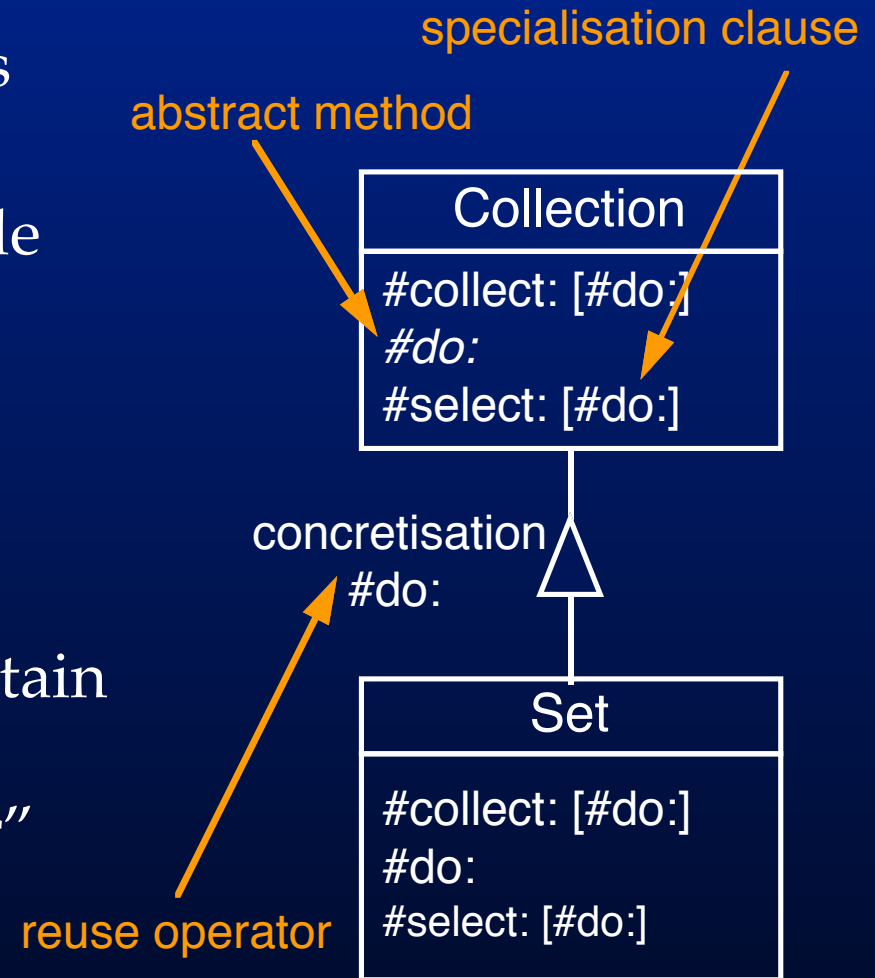

- Are contracts between the framework developer and the application developer
- State what assumptions can be made about reusable components
- State how components are actually reused

Reuse Contract Notation

- Notation based on OMT (UML)
- Methods are annotated with specialisation clauses to make the specialisation interface explicit
- “Reuse operators”, or “modifiers”, lay down how reuse is achieved

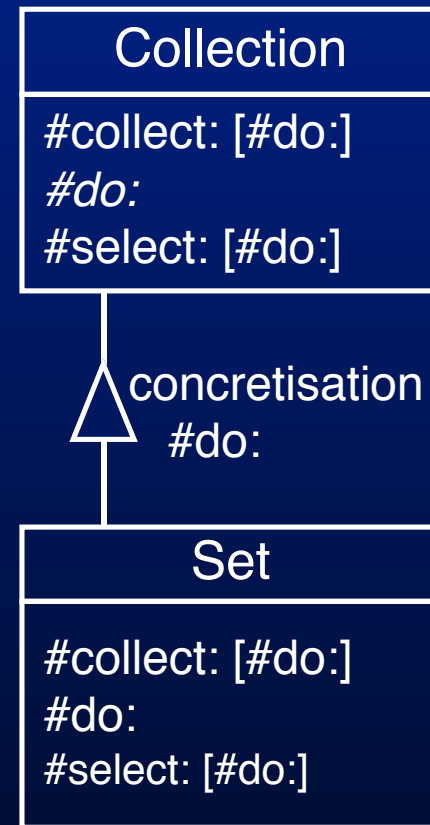

Reuse Contracts for Inheritance

- Enhance the interface of a class with specialisation clauses
- Identify what changes are made when a class is subclassed:
 - concretisation / abstraction
 - extension / cancellation
 - refinement / coarsening
- Specialisation clauses may contain names of methods invoked through self sends, and “super”

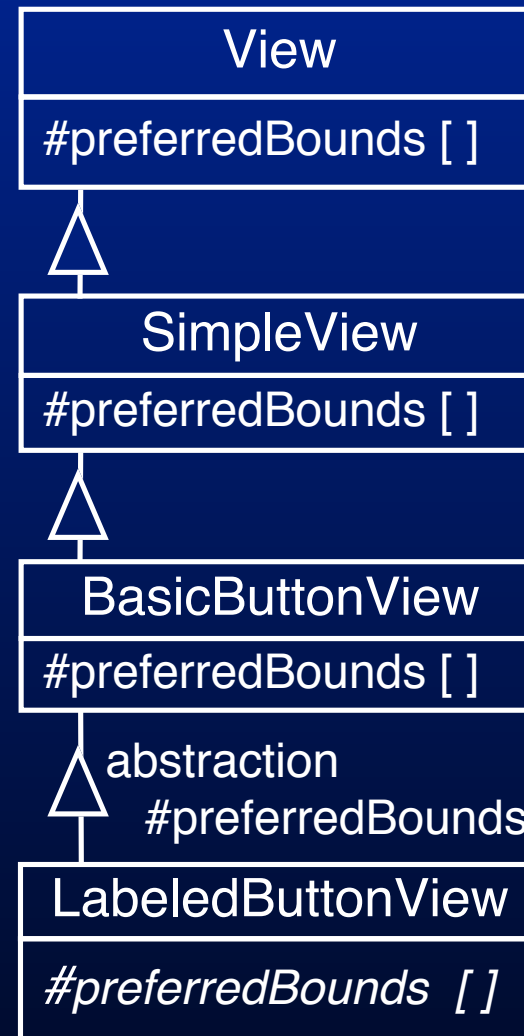

Reuse Operator: Concretisation

- Makes abstract methods concrete
- Does not change the specialisation clause of the concretised methods
- Design preserving
- Inverse = abstraction

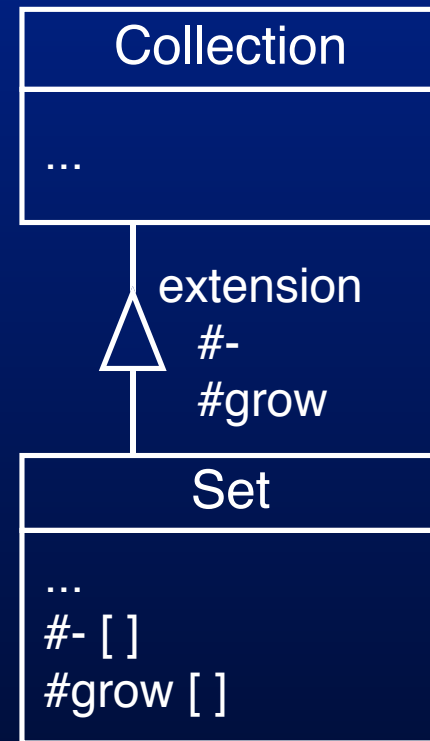

Reuse Operator: Abstraction

- Makes a concrete method abstract
- Design breaching
- Inverse = concretisation

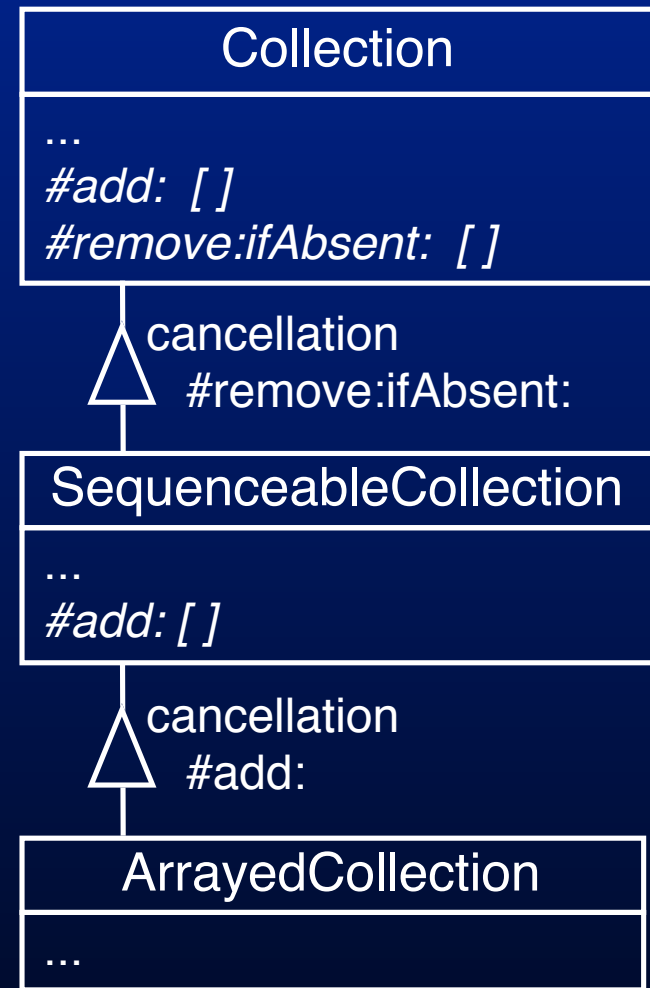

Reuse Operator: Extension

- Typically performed by an application developer to add application specific behaviour
- Adds new methods to the interface of a class
- Design preserving
- Inverse = cancellation

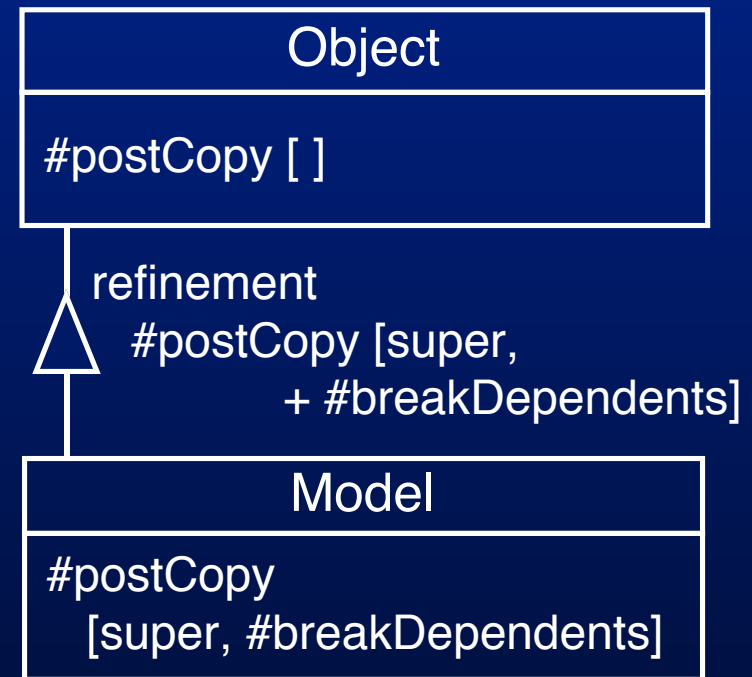

Reuse Operator: Cancellation

- Typically performed by an application developer to remove behaviour
- Removes methods from the interface of a class
- Design breaching
- Inverse = extension

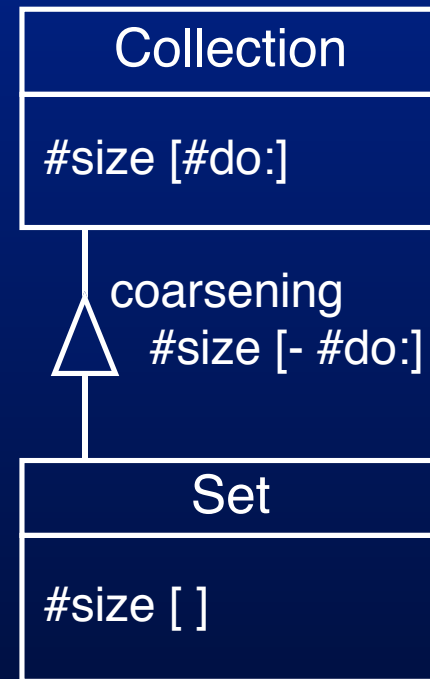

Reuse Operator: Refinement

- Adds elements to the specialisation clause of a method
- Used to e.g. :
 - reduce redundancy
 - specialise the behaviour of an existing method with an existing behaviour
- Design preserving
- Inverse = coarsening

Reuse Operator: Coarsening

- Removes elements from the specialisation clause of a method
- Used to e.g.:
 - optimize performance
- Design breaching
- Inverse = refinement

Reuse Operators

- Make a distinction between different kinds of inheritance
- State how a class is derived from its superclass
- Are orthogonal basic operators
- Usually, one subclassing step is a combination of several reuse operators

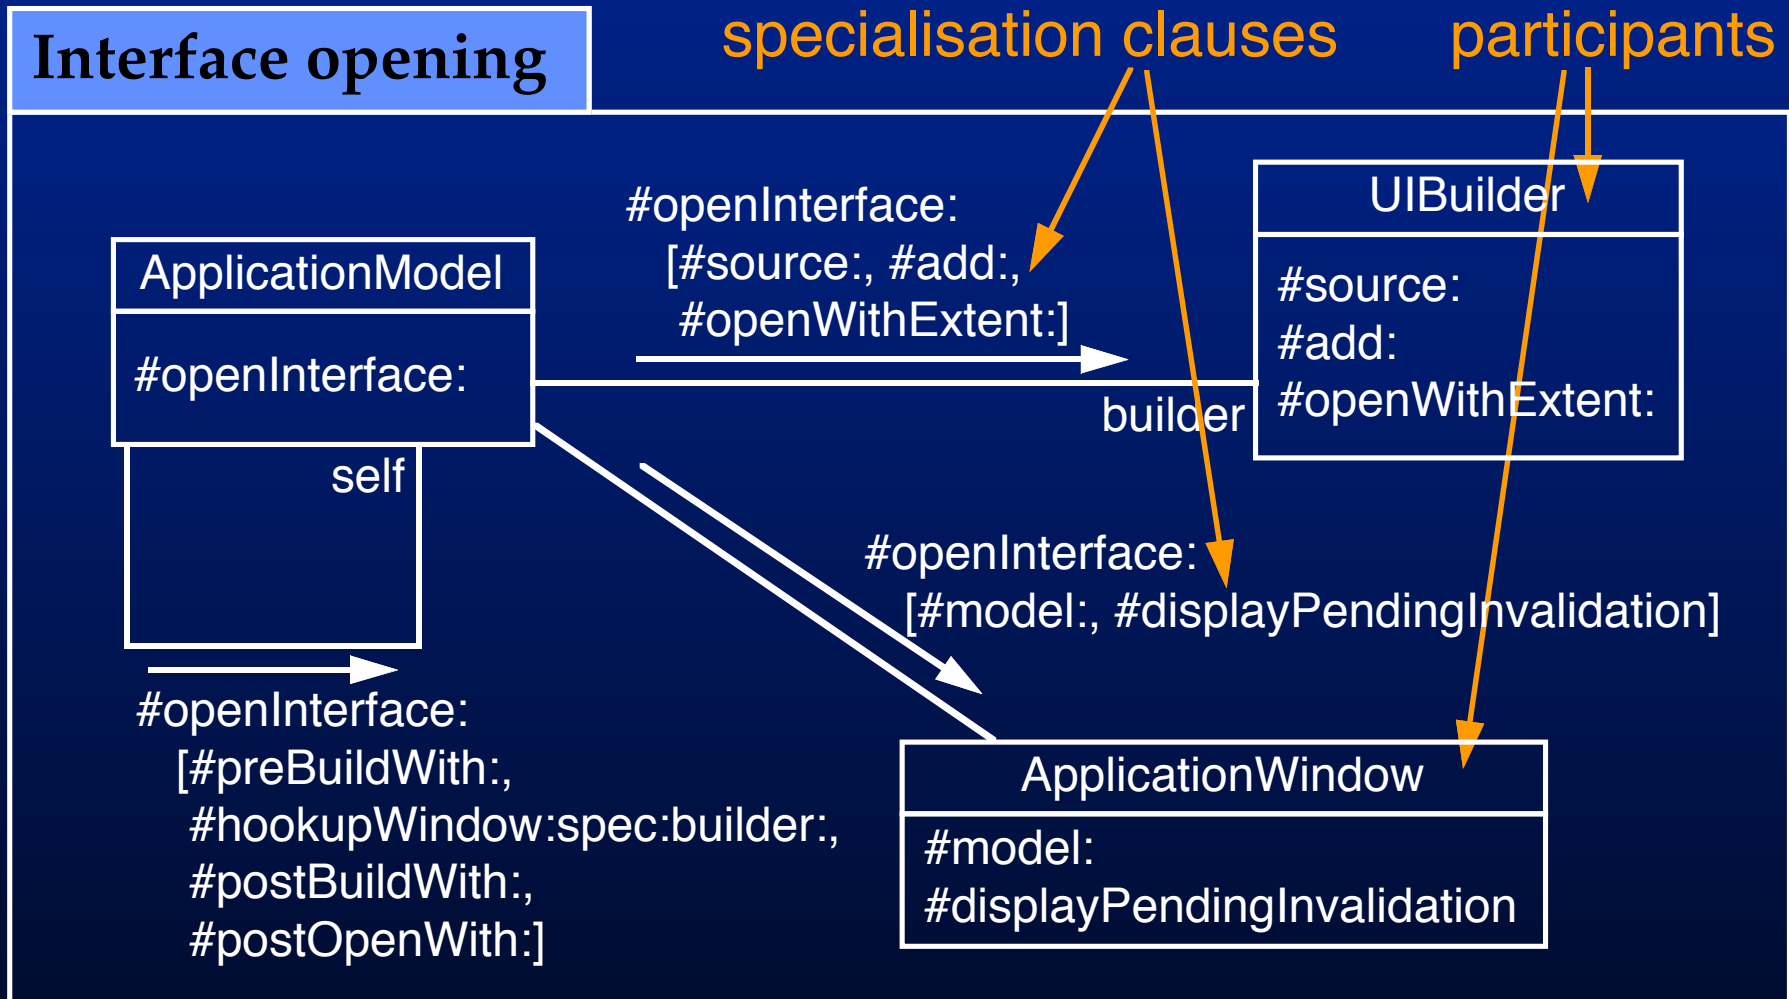

Frequently Used Combinations of Reuse Operators

- Extension & refinement
- Coarsening & cancellation
- Concretisation & refinement
- Concretisation & extension & refinement
- Coarsening & refinement = redefinition
- Coarsening & extension & refinement
= factorization

Multi-Class Reuse Contracts (in short)

- Co-operating classes are put in one reuse contract; these classes are called “participants”
- Interfaces of classes as in reuse contracts for inheritance
- Specialisation clauses are extended with names of methods invoked on other classes
- Reuse operators identify what changes are made to a whole contract

Reuse Contract Notation

Overview

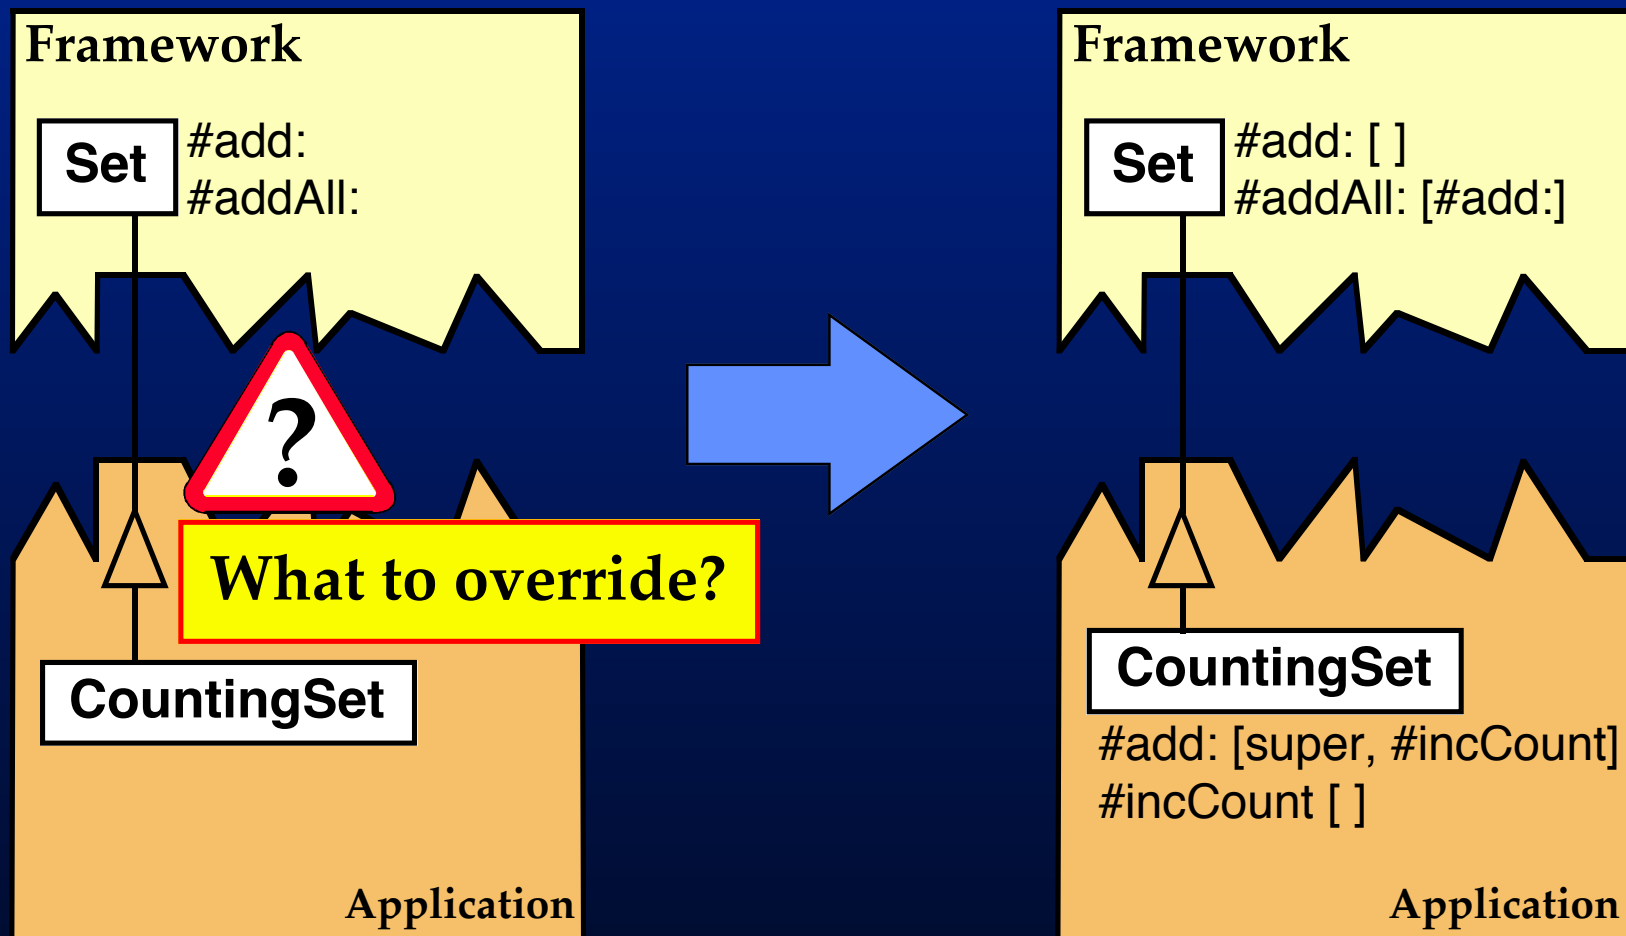

- Problems with reuse
- Problems with evolution
- What are reuse contracts?
- **Reuse contracts at work**

- Reuse contract research
- Exercises: introduction to the browser

Reuse Contracts at Work

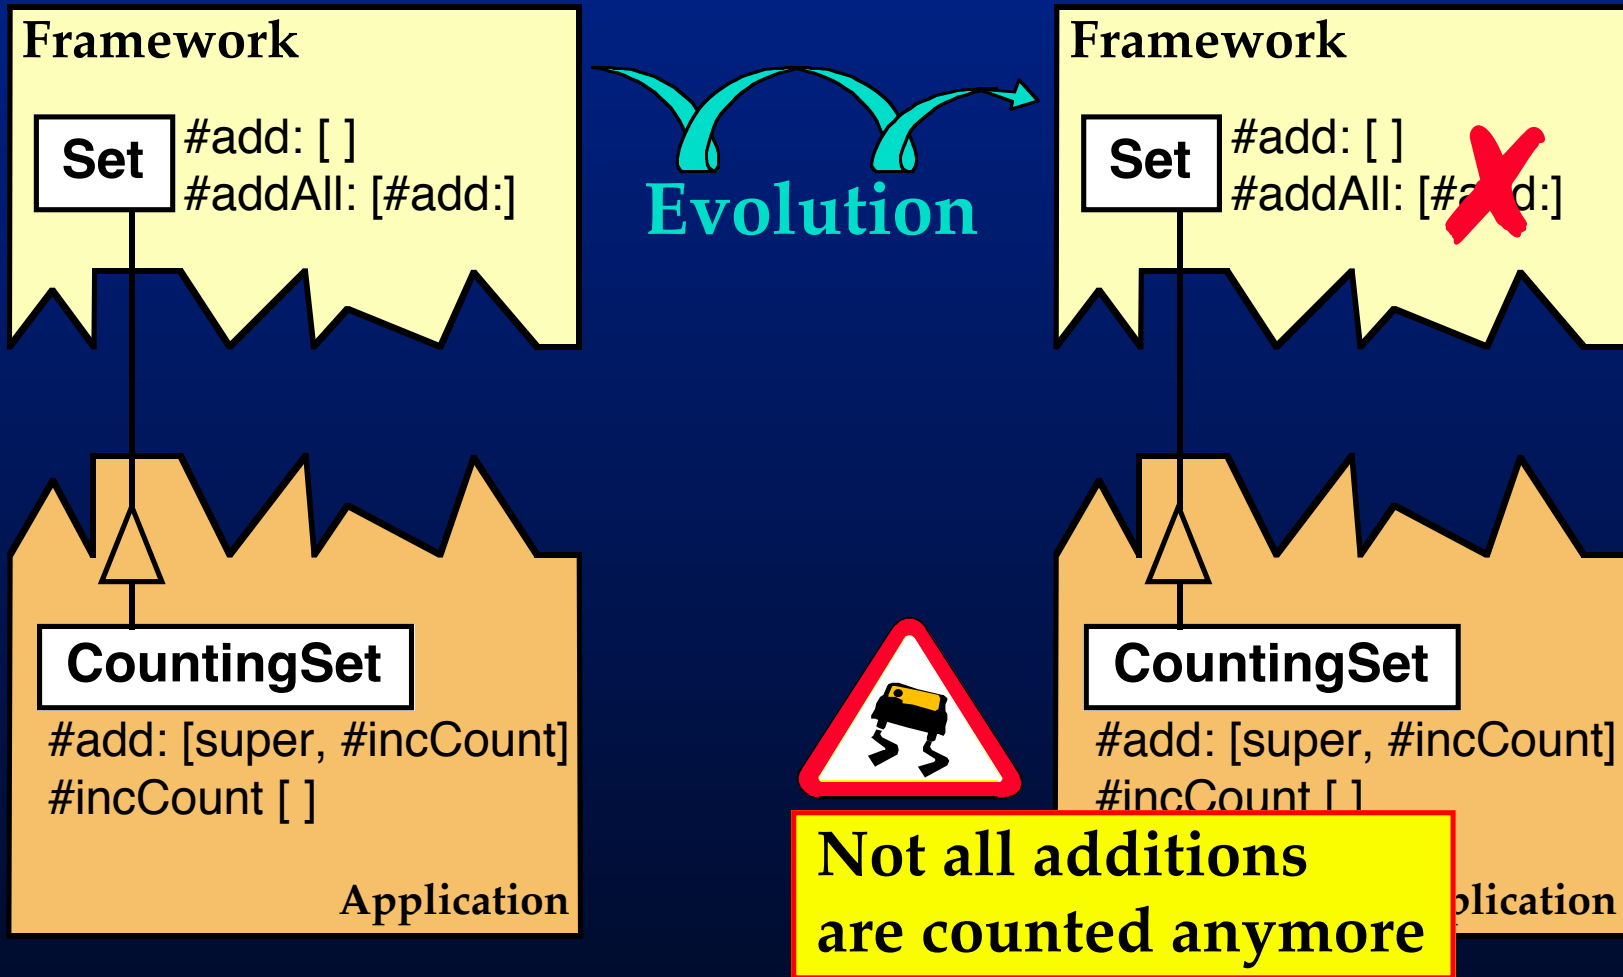

The formal nature of reuse contracts enables their use in a development environment

- code generation from reuse contracts
- impact analysis when a framework changes (assessing evolution conflicts)
- effort estimation for framework customisation
- extraction from source code

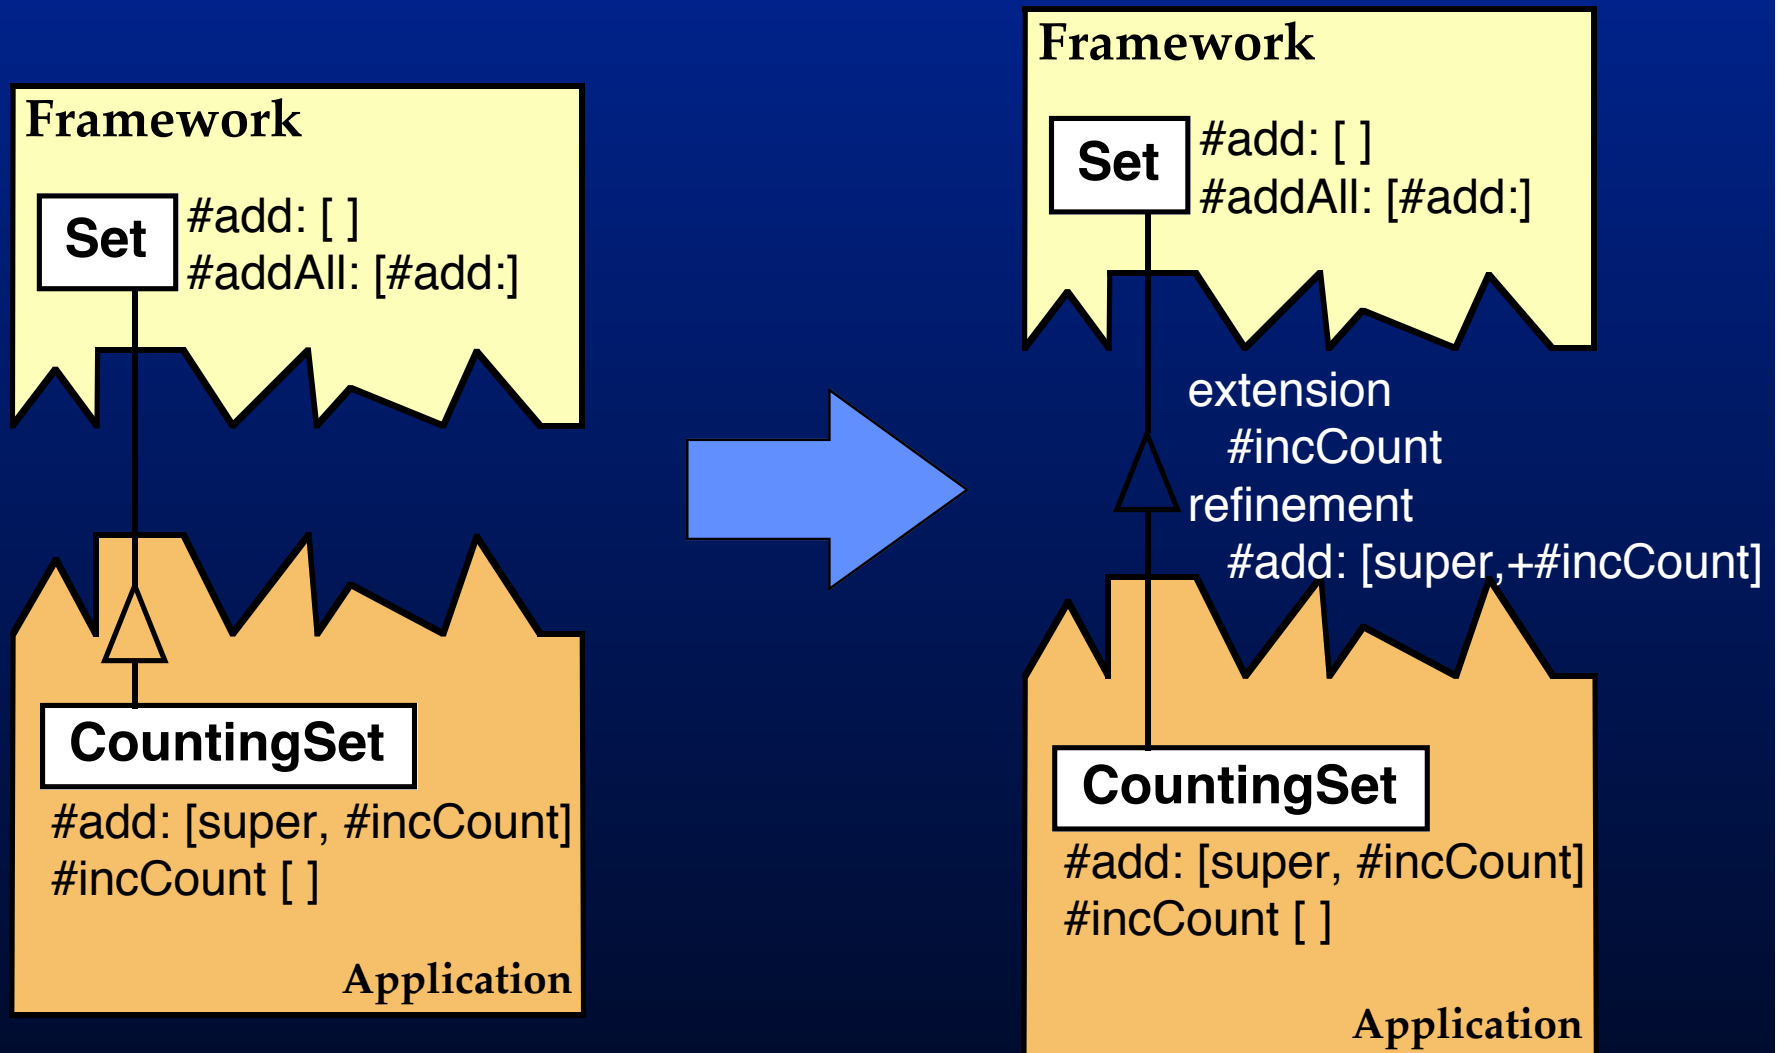

Estimating Reuse

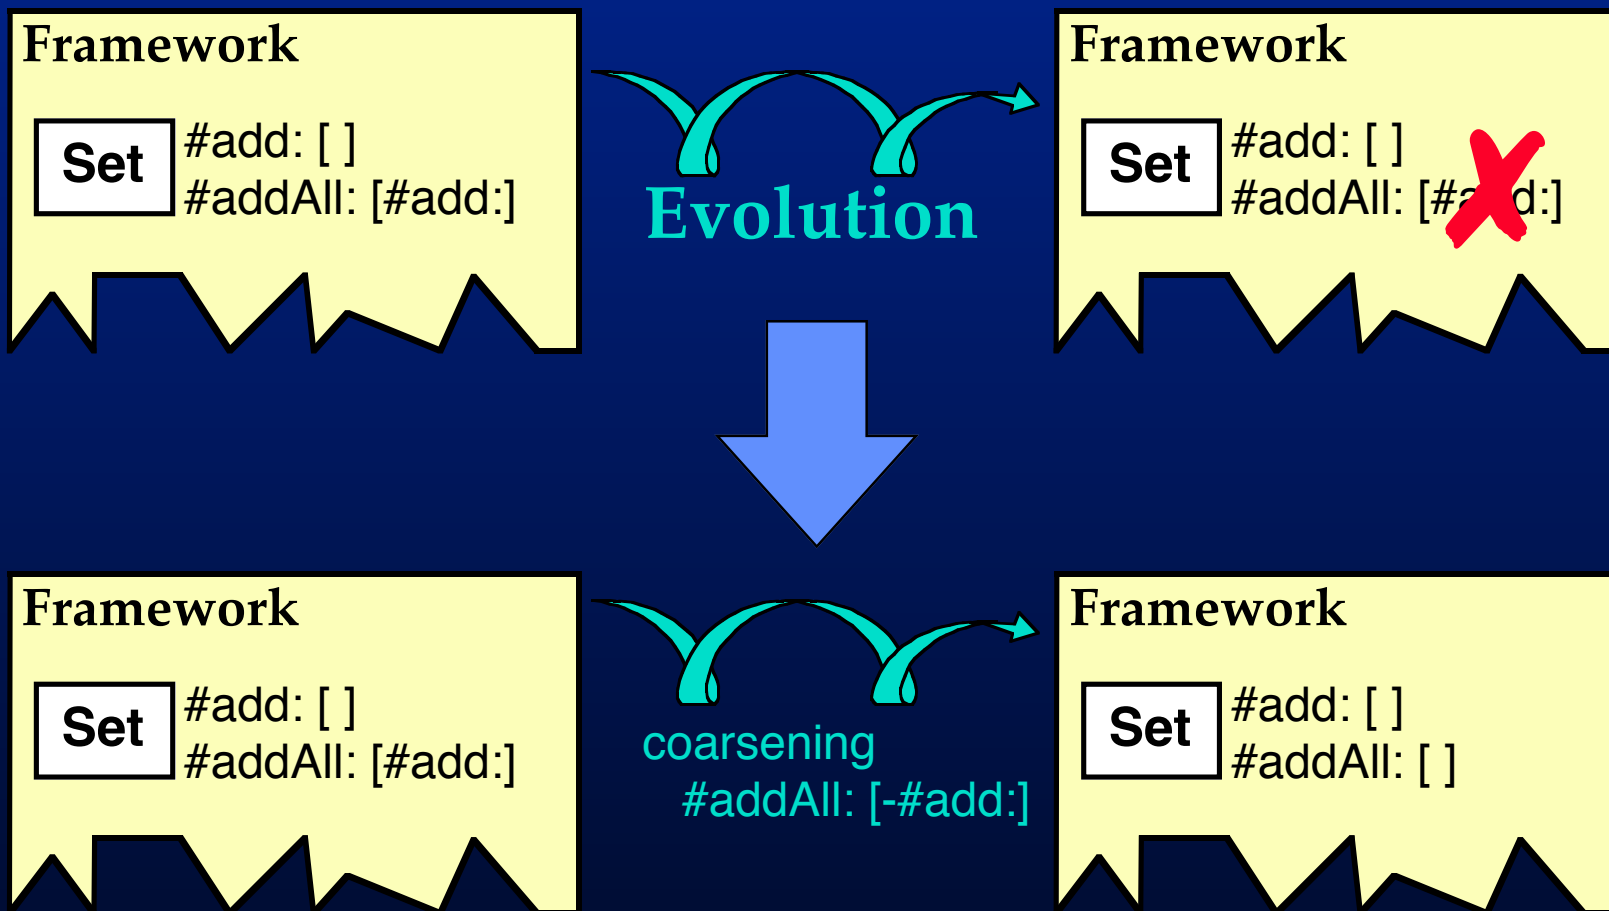

Evolution

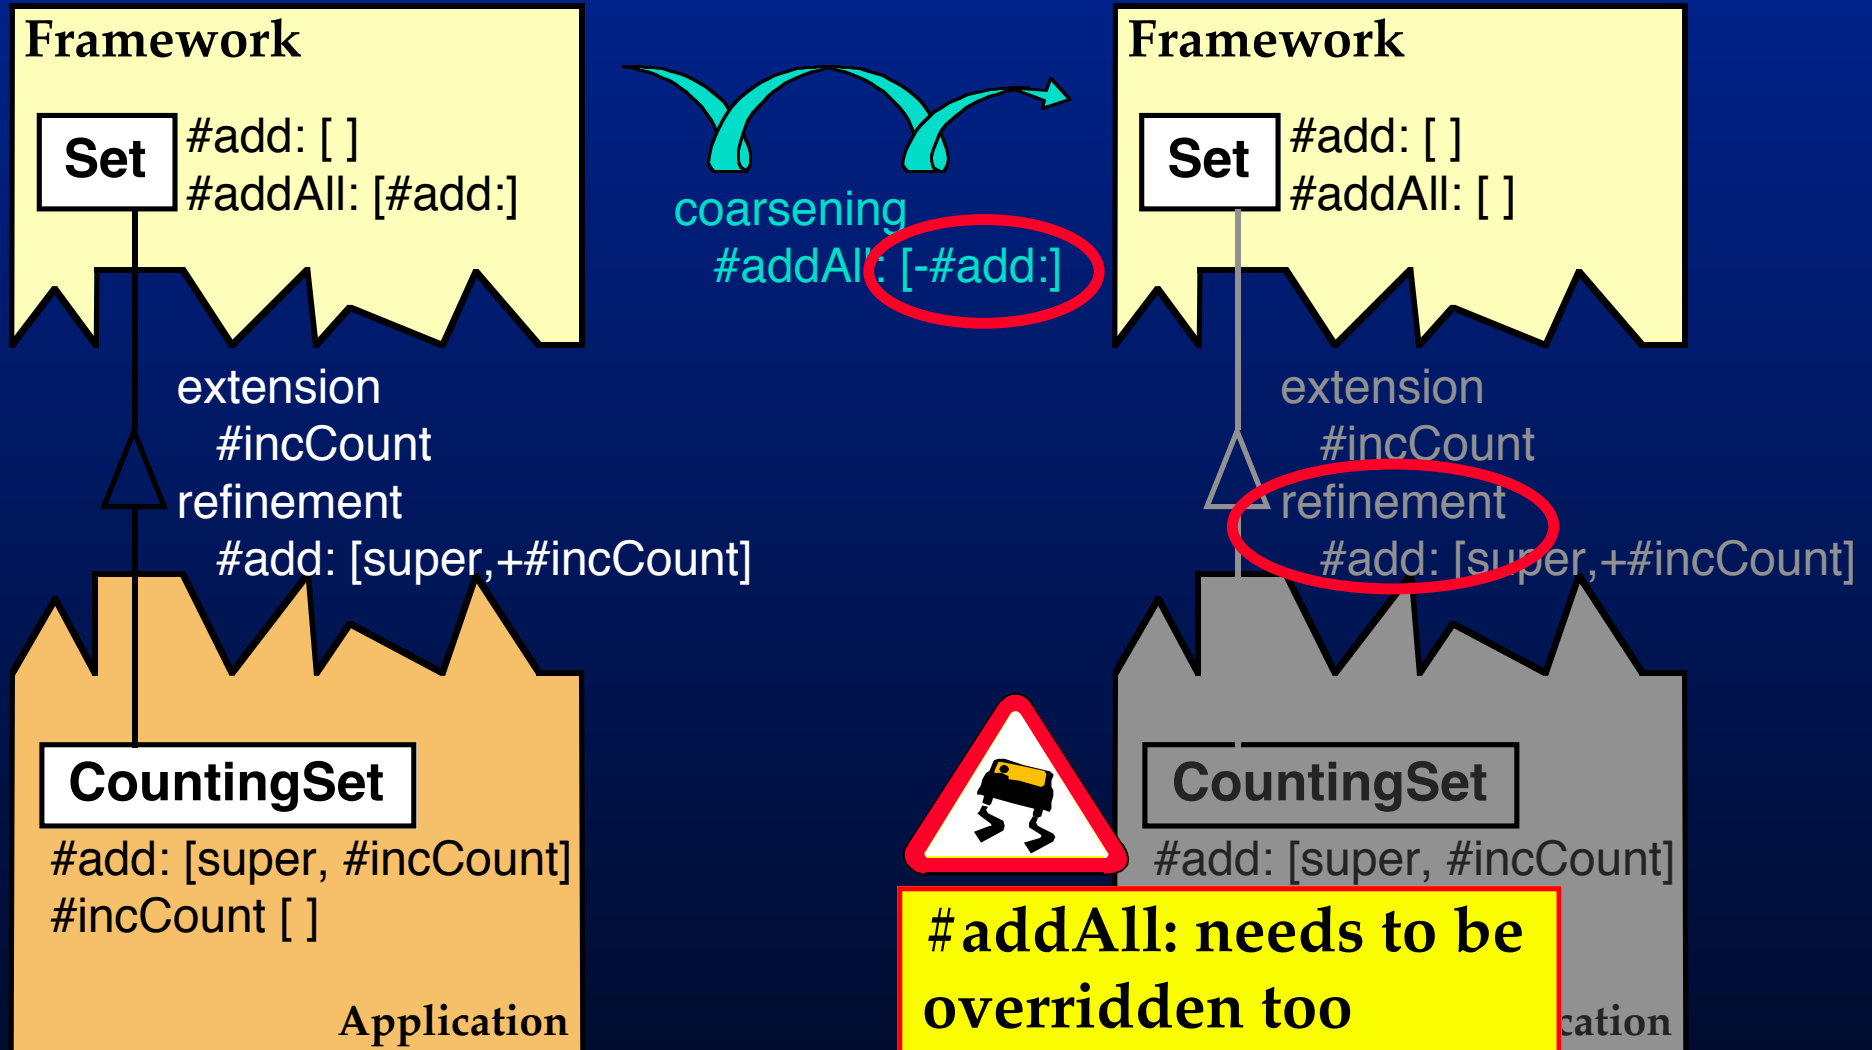

Documenting Reuse

Documenting Evolution

Estimating Impact of Changes

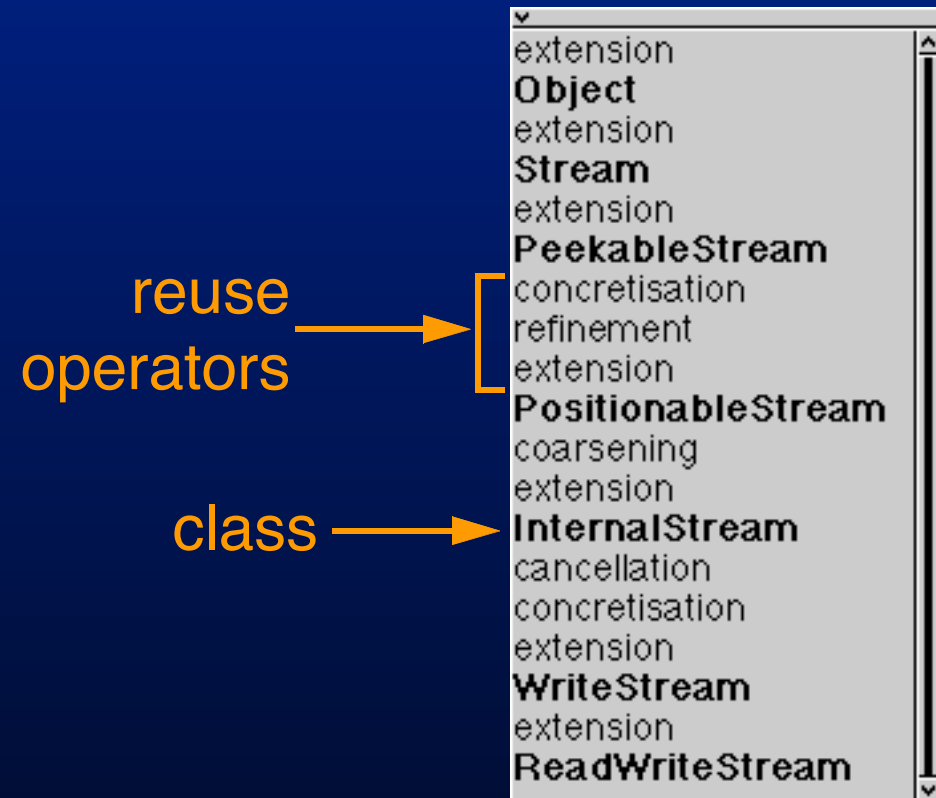

Overview

- Problems with reuse
- Problems with evolution
- What are reuse contracts?
- Reuse contracts at work
- **Examining class hierarchies based on reuse contracts**
- Reuse contract research
- Exercises: introduction to the browser

Extraction of Reuse Contracts

- Reuse contracts for inheritance can be extracted from Smalltalk code
- Each subclassing step is decomposed in a combination of maximum 6 different reuse operators

Too Much Extracted Information

- The extractor does not know which methods are important
- Interaction with a developer is required to strip implementation details

Inspecting Extracted Extensions

The screenshot displays a software development environment with two main panes. The left pane shows a class hierarchy with the following items:

- extension
- Object**
- extension
- Stream**
- extension
- PeekableStream**
- concretisation
- refinement
- extension
- PositionableStream**
- coarsening
- extension
- InternalStream**
- cancellation
- concretisation
- extension
- WriteStream**
- extension
- ReadWriteStream**

The right pane shows the code for the selected class, **Stream**. It is divided into **Abstract** and **Concrete** sections:

```
Abstract
  skip: {}

Concrete
  fileIn {close nextChunk skipSeparators peekFor: atEnd}
  nextChunk {class skipSeparators peekFor: next}
  peek {next skip: atEnd}
  peekFor: {next skip: atEnd}
  skipSeparators {class skip: next}
  skipUpTo: {next skip: atEnd}
```

Inspecting Extracted Concretisations

The screenshot displays an IDE interface. On the left, a class hierarchy is shown with the following items: extension, **Object**, extension, **Stream**, extension, **PeekableStream**, concretisation, refinement, extension, **PositionableStream**, coarsening, extension, **InternalStream**, cancellation, concretisation, extension, **WriteStream**, extension, and **ReadWriteStream**. The **concretisation** item is highlighted. On the right, a code editor shows the implementation of the **Abstract Concrete** class with the following methods: `atEnd {}`, `contents {}`, and `skip: {}`.

Inspecting Extracted Refinements

The screenshot displays a software interface with two main panels. The left panel is a list of classes and their relationships, including 'Object', 'Stream', 'PeekableStream', 'PositionableStream', 'InternalStream', 'WriteStream', and 'ReadWriteStream'. The 'refinement' entry is highlighted. The right panel is a code editor showing the implementation of the 'skip' method in a 'Concrete' class, which calls 'next' with 'atEnd' and 'position'.

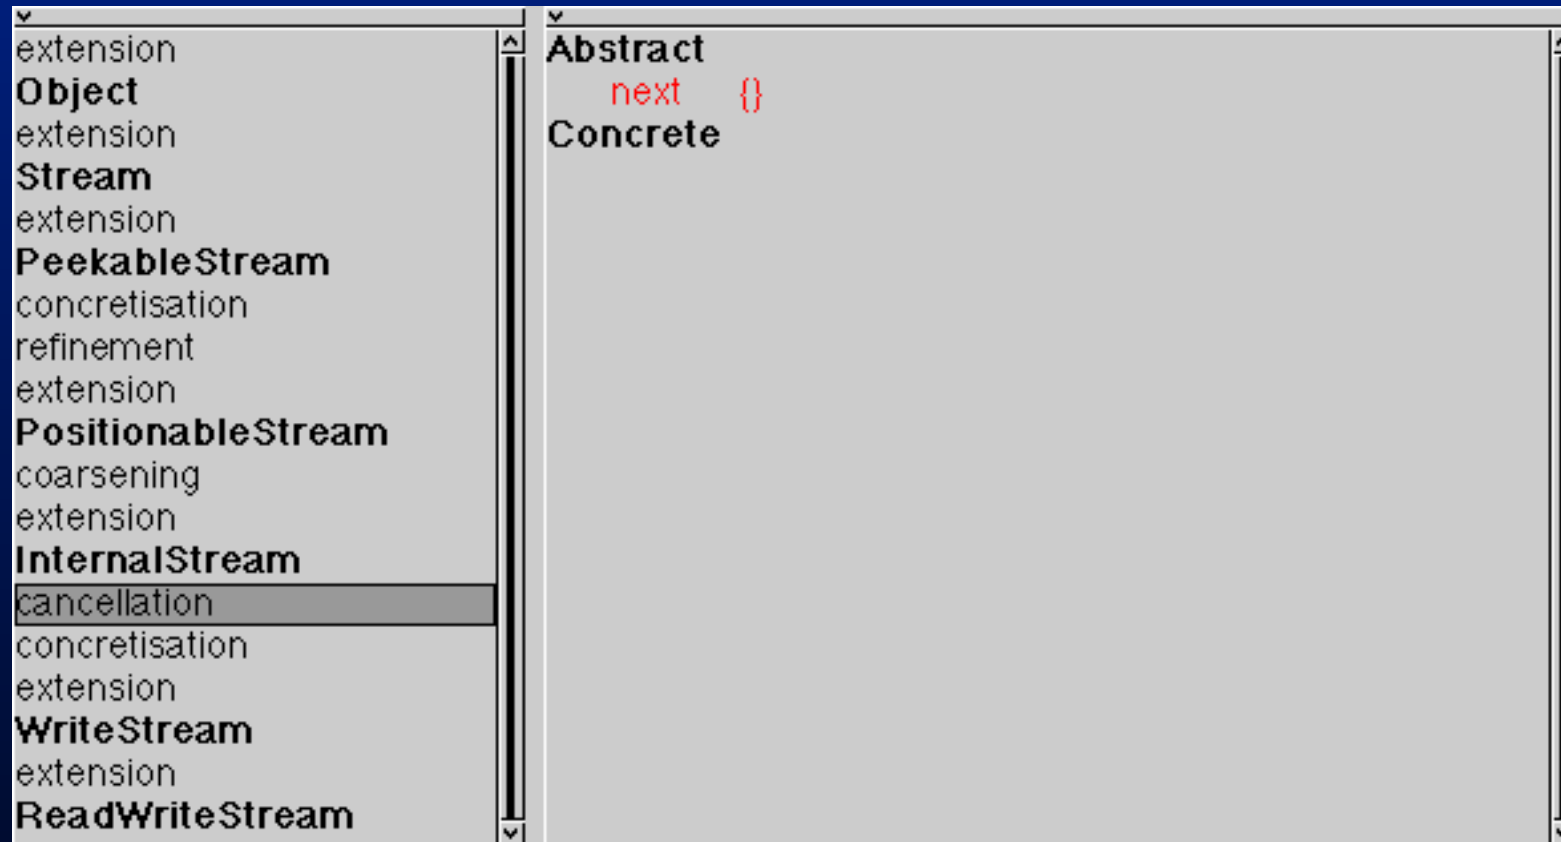

```
extension
Object
extension
Stream
extension
PeekableStream
concretisation
extension
refinement
PositionableStream
coarsening
extension
InternalStream
cancellation
concretisation
extension
WriteStream
extension
ReadWriteStream
```

```
Abstract
Concrete
  next:into:startingAt: {next atEnd}
  skip: {position:}
```

Inspecting Extracted Coarsenings

The screenshot displays two panels from an IDE. The left panel shows a class hierarchy with the following items: extension, **Object**, extension, **Stream**, extension, **PeekableStream**, concretisation, refinement, extension, **PositionableStream**, coarsening (highlighted), extension, **InternalStream**, cancellation, concretisation, extension, **WriteStream**, extension, and **ReadWriteStream**. The right panel shows a view of the selected 'coarsening' with the following content: **Abstract**, **Concrete**, and a method `displayString {printString}`.

Inspecting Extracted Cancellations

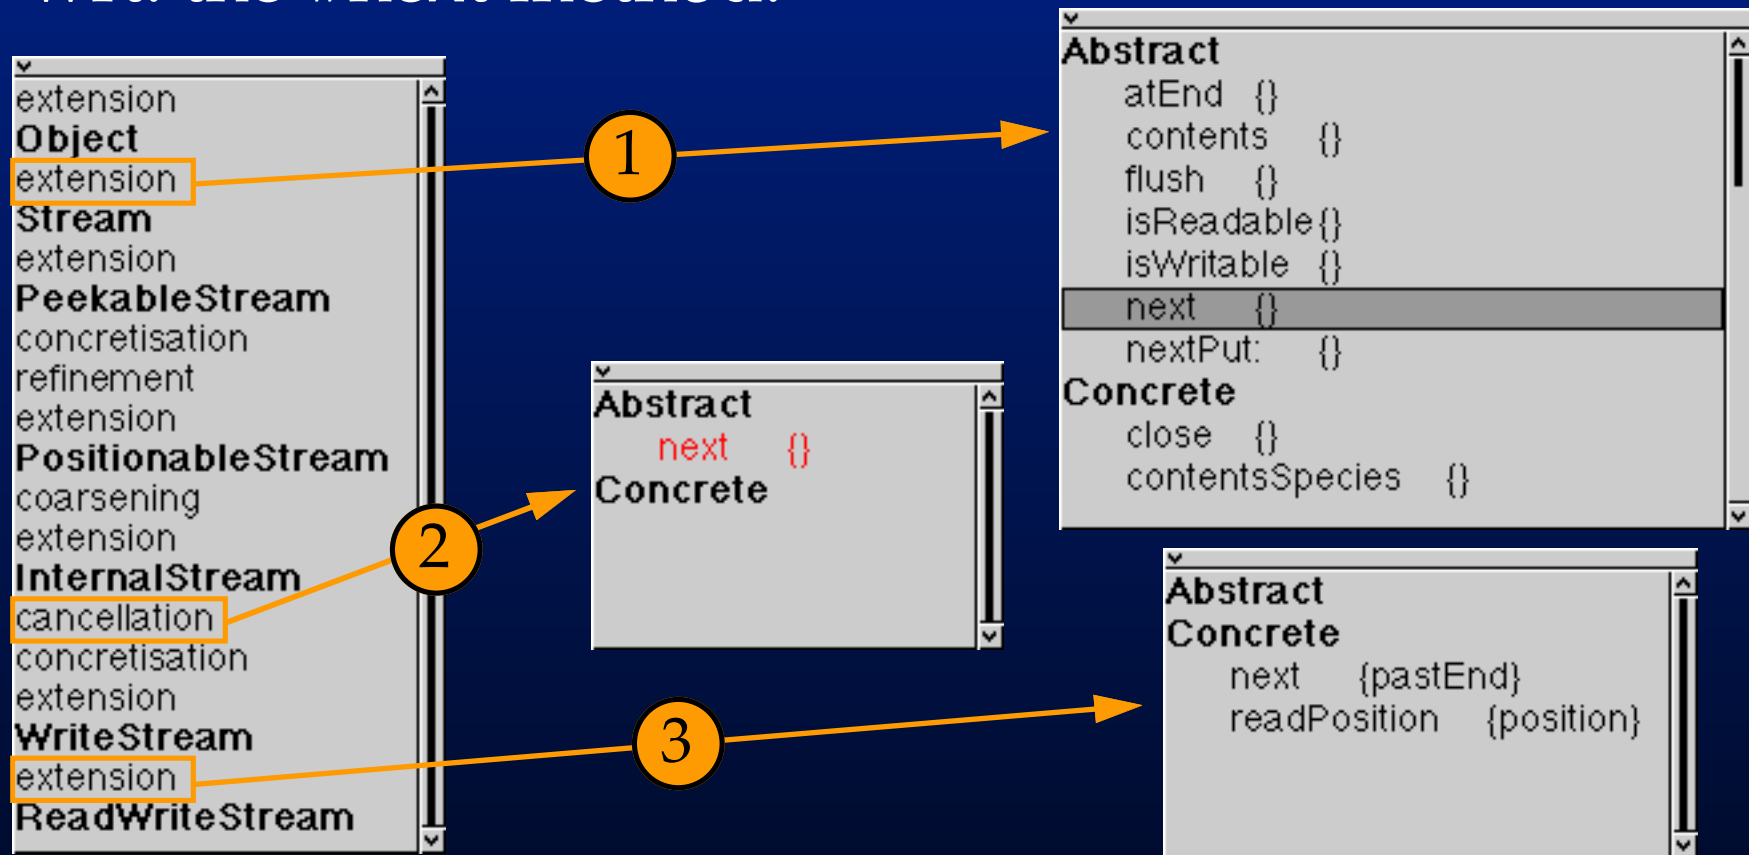

Spotting Bad Designs in a Class Hierarchy

- Look for design breaching reuse operators
 - they indicate methods that do not respect the design as laid down by a superclass
- Examine what happens with the affected methods in reuse operators that are applied later on

Spotting Bad Designs: Example

The Stream hierarchy is awkward wrt. the #next method.

Impact of Bad Coding Style

- Bad coding style is troublesome for the extractor
 - e.g. only super send, bad super send, ...
- This has driven us to make qualitative assessment of source code possible
- An analysis tool is integrated in our browser

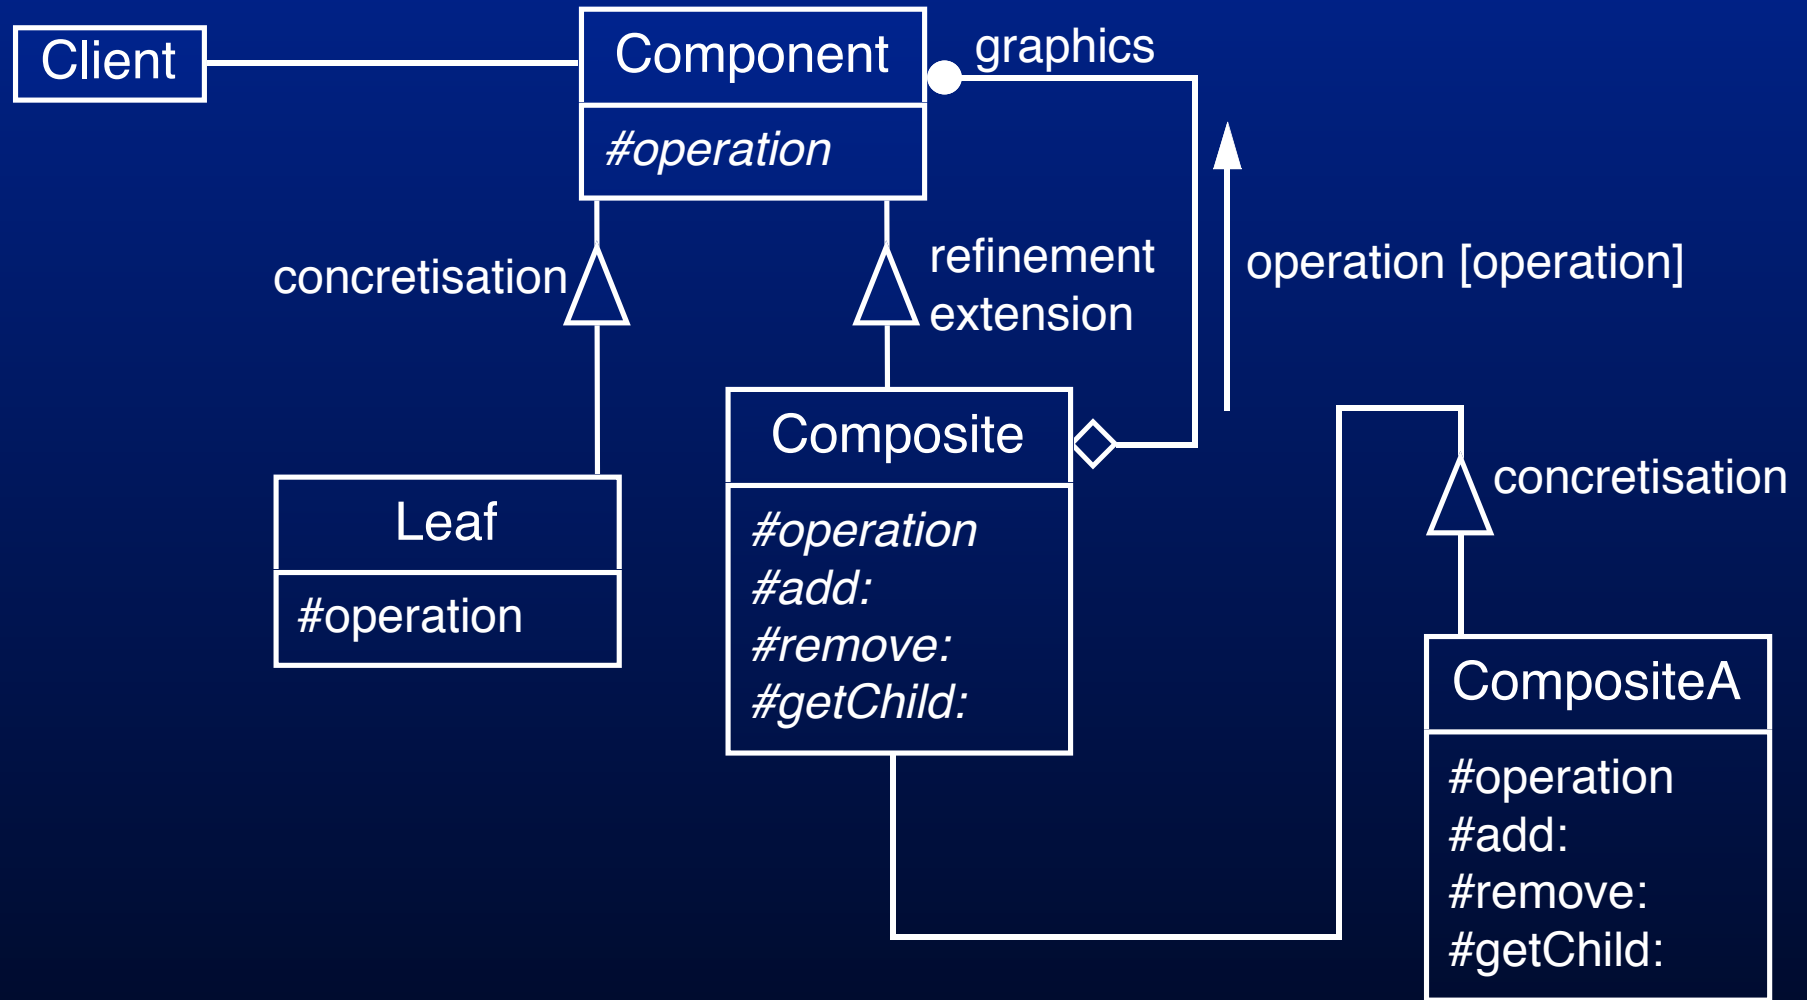

Overview

- Problems with reuse
- Problems with evolution
- What are reuse contracts?
- Reuse contracts at work
- Examining class hierarchies based on reuse contracts
- **Reuse contract research**
- Exercises: introduction to the browser

Reuse Contract Research

- Reuse contracts have been applied to
 - classes (inheritance)
 - sets of interacting classes / components
 - state diagrams
- Under investigation:
 - can reuse contracts describe design patterns?
 - generic reuse contracts
 - extraction of multi-class reuse contracts
 - software architectures and componentware
 - reuse contracts in a development environment
 - more documentation than interfaces and invocations

Design Pattern Example

Summary: Theory

- Reuse contracts formally document what a reuser can assume about a “reusable component”
- Reuse operators formally document how a reusable component is actually reused
- Formal rules for change propagation enable automatic detection of evolution conflicts

Summary: Practice

- Reuse contracts for inheritance can be extracted
 - examination of existing source code
 - understanding the design
 - human input is needed to filter out implementation details
 - bad coding style may give rise to extraction problems

Overview

- Problems with reuse
- Problems with evolution
- What are reuse contracts?
- Reuse contracts at work
- Examining class hierarchies based on reuse contracts
- Reuse contract research
- **Exercises: introduction to the browser**

The Browser for the Exercises

- Home-made fully-functional browser
- Composed of reusable “browser part components” built with ApplFLab
- Can easily be extended with other “class view / editor components”

See ESUG'96 Summer School
“ApplFLab: Custom-made user
interface components in VisualWorks”

Enhanced Browser — General

The screenshot shows the 'Browser' window in an IDE. It features a left-hand class tree, a top navigation bar, a central method list, and a bottom method editor. Several components are highlighted with orange boxes and labeled:

- Class selector:** The left-hand tree view showing a list of classes like 'AT-Supp', 'Collections-Abstract', etc.
- Method selector:** The top navigation bar with buttons for 'Definition', 'Methods', 'Hierarchy', 'Comment', and 'RC'.
- Different views / tools:** A toolbar above the class tree with icons for different views.
- Different views:** A toolbar above the method list with buttons for 'Text', 'Canvas', 'Menu', and 'Image'.
- Method editor:** The bottom pane showing the source code for the 'next' method, including a docstring and implementation logic.
- Different method editors:** The area containing the source code for the 'next' method.
- Different views:** A vertical toolbar on the right side of the window.

```
next
"Answer the receiver. Fail if
the collection of this stream is not an Array or a String. Fail if the
stream is positioned at its end, or if the position is out of bounds in the
collection."

<primitive: 65>
position >= readLimit
  ifTrue: [^self pastEnd]
  ifFalse: [^collection at: (position := position + 1)]
```

Browser — Reuse Contracts

The screenshot shows a software browser window titled "Browser". The interface includes a toolbar with icons for navigation and analysis, and a menu bar with "Comment" and "RC" options. The main area is divided into three panes:

- Left Pane:** A tree view of classes and contracts. The "Collections-Streams" folder is expanded, showing "ReadStream" and "ReadWriteStream" selected.
- Middle Pane:** A list of "Reuse Contracts" for the selected class. The "PositionableStream" contract is selected, showing its "coarsening" relationship.
- Right Pane:** A "Specialisation Interface" for the selected class. It shows the "displayString" method with a red "printString" annotation. Below it, the "Method Text" pane shows the implementation: `^"some internal stream"`.

At the bottom left, there are radio buttons for "Instance" (selected) and "Class".

Browser — Code Analysis

The screenshot shows the 'Browser' application window with the 'Analysis' tab selected. The left sidebar lists various UI components, with 'LabelAndIcon' selected. The main area displays a list of analysis rules with checkboxes and buttons to toggle them. Below the list, the analysis results for the selected class are shown.

Analysis Rules:

- self-sends
- typed-IV
- primitive
- factory
- accessor/mutator
- abstract
- template
- super-sends
- super-does-not-understand
- bad-per-send
- bad-super-sends
- multiple-sends
- self-does-not-understand
- started-by
- self-argument

Buttons: update !, invert, all on, allOff

Analysis Results:

```
gap typed-IV [required interface: {} assigned types: {SmallInteger} best type: {SmallInteger}]
beCheckMark
beFolder
displayOn: self-sends [offset] super-sends [displayOn:]
gap:
beFolder
  icon := Folder
```

Browser — Clusters

The screenshot shows a window titled "Browser" with a toolbar containing icons for Hierarchy, Comment, RC, Analysis, and Clusters. The Clusters tab is active.

Left Pane (Tree View):

- Collections-Streams
- Collections-String Support
- Collections-Support
- Collections-Text
- Collections-Unordered
- Computed Categories
- Database-Interface
- Database-Support
- Database-Tools
- Drag-And-Drop
- Bag
- Dictionary
- IdentityDictionary
- IdentitySet
- Set
- WeakDictionary

Right Pane (Cluster View):

readGeneralStructureOn:, findKey:ifAbsentRaise:, findKeyOrNil:, declare:from:, c
do:, includes:, values, collect:, occurrencesOf:
remove:ifAbsent:
traceWalkFrom:, bindingsDo:, changeCapacityTo:, associationsDo:, printOn:, ass

show cluster using: **Divided Clusters** Layer...

```
{do:,includes:,values,collect,occurrencesOf:}
```

Instance Class

Browser — Metrics

The screenshot shows a software browser window titled "Browser". The interface includes a toolbar with icons for "Comment", "RC", "Analysis", "Clusters", and "Metrics". On the left, there are two tree views. The top tree lists various collections and database-related items, with "Collections-Unordered" selected. The bottom tree lists dictionary-related items, with "Dictionary" selected. At the bottom left, there are radio buttons for "Instance" (selected) and "Class". The main area on the right displays a list of metrics for the selected class, each with a corresponding input field.

| | |
|-------------------------------------|---------|
| nr. of Superclasses: | 3 |
| nr. of Subclasses: | 16 |
| nr. of Class Methods: | 3 |
| nr. of Instance Methods: | 45 |
| nr. of Available Instance Methods: | 238 |
| nr. of Available Class Methods: | 406 |
| nr. of Class Variables: | 0 |
| nr. of Instance Variables: | 0 |
| % Commented Methods: | 88 |
| Average Number of Method Arguments: | 2.35556 |
| Response: | 129 |
| SpecialisationIndex: | 1.33333 |

Exercises

- Use the enhanced browser to investigate Smalltalk code
 - Examine class hierarchies based on extracted reuse contracts
 - Analyse the code to find methods that hinder reuse
 - Explore the different tools
- File in your own Smalltalk classes / frameworks
