Table of Contents

Preface	xix	Scenario 1: Inserting data in a defined table in a MicrosoftAX server	65
General information	xix	Scenario 2: Deleting data from a defined table in a MicrosoftAX server	67
Purpose	xix	tOpenbravoERPInput	70
Audience	xix	tOpenbravoERPInput properties	70
Typographical conventions	xix	Related Scenario	71
History of changes	xix	tOpenbravoERPOutput	72
Feedback and Support	xx	tOpenbravoERPOutput properties	72
Big Data components	1	Related scenario	72
tHiveClose	2	tSageX3Input	73
tHiveClose properties	2	tSageX3Input Properties	73
Related scenario	2	Scenario: Using query key to extract data from a given Sage X3 system.....	74
tHiveConnection	3	tSageX3Output	78
tHiveConnection properties	3	tSageX3Output Properties	78
Related scenario	4	Scenario: Using a Sage X3 Web service to insert data into a given Sage X3 system	79
tHiveRow	5	tSalesforceBulkExec	83
tHiveRow properties	5	tSalesforceBulkExec Properties	83
Related scenarios	7	Related Scenario:	84
Business components	9	tSalesforceConnection	85
tAlfrescoOutput	10	tSalesforceConnection properties	85
tAlfrescoOutput Properties	10	Related scenario	85
Scenario: Creating documents on an Alfresco server	15	tSalesforceGetDeleted	86
tBonitaDeploy	20	tSalesforceGetDeleted properties	86
tBonitaDeploy Properties	20	Scenario: Recovering deleted data from the Salesforce server	87
Related Scenario	21	tSalesforceGetServerTimestamp	90
tBonitaInstantiateProcess	22	tSalesforceGetServerTimestamp properties	90
tBonitaInstantiateProcess Properties	22	Related scenarios	91
Scenario: Executing a Bonita process via a Talend Job	23	tSalesforceGetUpdated	92
tCentricCRMInput	29	tSalesforceGetUpdated properties	92
tCentricCRMInput Properties	29	Related scenarios	93
Related Scenario	29	tSalesforceInput	94
tCentricCRMOutput	30	tSalesforceInput Properties	94
tCentricCRMOutput Properties	30	Scenario: Using queries to extract data from a Salesforce database	96
Related Scenario	30	tSalesforceOutput	100
tHL7Input	31	tSalesforceOutput Properties	100
tHL7Input Properties	31	Scenario 1: Deleting data from the Account object	102
Scenario: Retrieving information about patients and events from an HL7 file	32	Scenario 2: Gathering erroneous data while inserting data to a module at Salesforce.com	104
tHL7Output	35	tSalesforceOutputBulk	107
tHL7Output Properties	35	tSalesforceOutputBulk Properties	107
Related scenario	35	Scenario: Inserting transformed bulk data into your Salesforce.com	107
tMarketoInput	36	tSalesforceOutputBulkExec	112
tMarketoInput Properties	36	tSalesforceOutputBulkExec Properties	112
Related Scenario	38	Scenario: Inserting bulk data into your Salesforce.com	113
tMarketoListOperation	39	tSAPBWInput	117
tMarketoListOperation Properties	39	tSAPBWInput Properties	117
Scenario: Adding a lead record to a list in the Marketo DB	40	Scenario: Reading data from SAP BW database	118
tMarketoOutput	44	tSAPCommit	122
tMarketoOutput Properties	44	tSAPCommit Properties	122
Scenario: Data transmission between Marketo DB and an external system.....	45	Related scenario	122
tMicrosoftCrmInput	51	tSAPConnection	123
tMicrosoftCrmInput Properties	51	tSAPConnection properties	123
Scenario: Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows	52	Related scenarios	123
tMicrosoftCrmOutput	59	tSAPInput	124
tMicrosoftCrmOutput Properties	59	tSAPInput Properties	124
Related Scenario	60	Scenario 1: Retrieving metadata from the SAP system	126
tMSAXInput	61		
tMSAXInput properties	61		
Related scenarios	62		
tMSAXOutput	63		
tMSAXOutput properties	63		

Scenario 2: Reading data in the different schemas of the RFC_READ_TABLE function	133	Related Scenario	207
tSAPOutput	139	tPaloCheckElements	208
tSAPOutput Properties	139	tPaloCheckElements Properties	208
Related scenario	140	Related scenario	209
tSAPRollback	141	tPaloConnection	210
tSAPRollback properties	141	tPaloConnection Properties	210
Related scenarios	141	Related scenario	210
tSugarCRMInput	142	tPaloCube	211
tSugarCRMInput Properties	142	tPaloCube Properties	211
Scenario: Extracting account data from SugarCRM	142	Scenario: Creating a cube in an existing database	213
tSugarCRMOutput	145	tPaloCubeList	215
tSugarCRMOutput Properties	145	tPaloCubeList Properties	215
Related Scenario	145	Discovering the read-only output schema of tPaloCubeList	216
tVtigerCRMInput	146	Scenario: Retrieving detailed cube information from a given database	217
tVtigerCRMInput Properties	146	tPaloDatabase	219
Related Scenario	147	tPaloDatabase Properties	219
tVtigerCRMOutput	148	Scenario: Creating a database	220
tVtigerCRMOutput Properties	148	tPaloDatabaseList	222
Related Scenario	149	tPaloDatabaseList Properties	222
Business Intelligence components	151	Discovering the read-only output schema of tPaloDatabaseList	223
tBarChart	152	Scenario: Retrieving detailed database information from a given Palo server	224
tBarChart properties	152	tPaloDimension	226
Scenario: Creating a bar chart from the input data	153	tPaloDimension Properties	226
tDB2SCD	159	Scenario: Creating a dimension with elements	230
tDB2SCD properties	159	tPaloDimensionList	235
Related scenarios	160	tPaloDimensionList Properties	235
tDB2SCDELT	161	Discovering the read-only output schema of tPaloDimensionList	237
tDB2SCDELT Properties	161	Scenario: Retrieving detailed dimension information from a given database	237
Related Scenario	163	tPaloInputMulti	239
tGreenplumSCD	164	tPaloInputMulti Properties	239
tGreenplumSCD Properties	164	Scenario: Retrieving dimension elements from a given cube	241
Related scenario	165	tPaloOutput	245
tInformixSCD	166	tPaloOutput Properties	245
tInformixSCD properties	166	Related scenario	246
Related scenario	167	tPaloOutputMulti	247
tIngresSCD	168	tPaloOutputMulti Properties	247
tIngresSCD Properties	168	Scenario 1: Writing data into a given cube	249
Related scenario	169	Scenario 2: Rejecting inflow data when the elements to be written do not exist in a given cube	252
tJasperOutput	170	tPaloRule	256
tJasperOutput Properties	170	tPaloRule Properties	256
Scenario: Generating a report against a .jrxml template	171	Scenario: Creating a rule in a given cube	257
tJasperOutputExec	174	tPaloRuleList	260
tJasperOutputExec Properties	174	tPaloRuleList Properties	260
Related Scenario	175	Discovering the read-only output schema of tPaloRuleList	261
tLineChart	176	Scenario: Retrieving detailed rule information from a given cube	262
tLineChart properties	176	tParAccelSCD	264
Scenario: Creating a line chart to ease trend analysis	177	tParAccelSCD Properties	264
tMondrianInput	183	Related scenario	265
tMondrianInput Properties	183	tPostgresPlusSCD	266
Scenario: Cross-join tables	184	tPostgresPlusSCD Properties	266
tMSSqlSCD	187	Related scenario	267
tMSSqlSCD Properties	187	tPostgresPlusSCDELT	268
Related scenario	188	tPostgresPlusSCDELT Properties	268
tMysqlSCD	189	Related Scenario	270
tMysqlSCD Properties	189	tPostgresqlSCD	271
Scenario: Tracking changes using Slowly Changing Dimensions (type 0 through type 3)	192		
tMysqlSCDELT	200		
tMysqlSCDELT Properties	200		
Related Scenario	202

Related Scenario	275	Related scenario	339
tSPSSInput	276	tAmazonOracleRow	340
tSPSSInput properties	276	tAmazonOracleRow properties	340
Scenario: Displaying the content of		Related scenarios	342
an SPSS .sav file	276	tMarketoInput	343
tSPSSOutput	279	tMarketoListOperation	344
tSPSSOutput properties	279	tMarketoOutput	345
Scenario: Writing data in an .sav file..	279	tSalesforceBulkExec	346
tSPSSProperties	282	tSalesforceConnection	347
tSPSSProperties properties	282	tSalesforceGetDeleted	348
Related scenarios	282	tSalesforceGetServerTimestamp	349
tSPSSStructure	283	tSalesforceGetUpdated	350
tSPSSStructure properties	283	tSalesforceInput	351
Related scenarios	283	tSalesforceOutput	352
tSybaseSCD	284	tSalesforceOutputBulk	353
tSybaseSCD properties	284	tSalesforceOutputBulkExec	354
Related scenarios	285	tSugarCRMInput	355
tSybaseSCDELTA	286	tSugarCRMOutput	356
tSybaseSCDELTA Properties	286	Custom Code components	357
Related Scenario	288	tGroovy	358
Cloud components	289	tGroovy properties	358
tAmazonMysqlClose	290	Related Scenarios	358
tAmazonMysqlClose properties	290	tGroovyFile	359
Related scenario	290	tGroovyFile properties	359
tAmazonMysqlCommit	291	Scenario: Calling a file which	
tAmazonMysqlCommit Properties	291	contains Groovy code	359
Related scenario	291	tJava	361
tAmazonMysqlConnection	292	tJava properties	361
tAmazonMysqlConnection		Scenario: Printing out a variable	
Properties	292	content	361
Scenario: Inserting data in mother/		tJavaFlex	365
daughter tables	293	tJavaFlex properties	365
tAmazonMysqlInput	297	Scenario 1: Generating data flow	366
tAmazonMysqlInput properties	297	Scenario 2: Processing rows of data	
Scenario1: Writing columns from a		with tJavaFlex	368
MySQL database to an output file	298	tJavaRow	372
tAmazonMysqlOutput	302	tJavaRow properties	372
tAmazonMysqlOutput properties	302	Scenario: Transforming data line by	
Scenario 1: Adding a new column		line using tJavaRow	372
and altering data in a DB table	306	tLibraryLoad	376
Scenario 2: Updating data in a		tLibraryLoad properties	376
database table	310	Scenario: Checking the format of an	
Scenario 3: Retrieve data in error		e-mail addressl	376
with a Reject link	313	tSetGlobalVar	379
tAmazonMysqlRollback	319	tSetGlobalVar properties	379
tAmazonMysqlRollback properties	319	Scenario: Printing out the content of	
Scenario: Rollback from inserting		a global variable	379
data in mother/daughter tables	319	Data Quality components	381
tAmazonMysqlRow	321	tAddCRCRow	382
tAmazonMysqlRow properties	321	tAddCRCRow properties	382
Scenario 1: Removing and		Scenario: Adding a surrogate key to	
regenerating a MySQL table index.....	323	a file	382
Scenario 2: Using PreparedStatement		tChangeFileEncoding	385
objects to query data	324	tExtractRegexFields	386
tAmazonOracleClose	329	tFuzzyMatch	387
tAmazonOracleClose properties	329	tFuzzyMatch properties	387
Related scenario	329	Scenario 1: Levenshtein distance of 0	
tAmazonOracleCommit	330	in first names	388
tAmazonOracleCommit Properties	330	Scenario 2: Levenshtein distance of 1	
Related scenario	330	or 2 in first names	390
tAmazonOracleConnection	331	Scenario 3: Metaphonic distance in	
tAmazonOracleConnection		first name	391
Properties	331	tIntervalMatch	392
Related scenario	332	tIntervalMatch properties	392
tAmazonOracleInput	333	Scenario: Identifying Ip country	392
tAmazonOracleInput properties	333	tReplaceList	395
Related scenarios	334	tReplaceList Properties	395
tAmazonOracleOutput	335		

Scenario: Replacement from a reference file	396	tAS400Input	464
tSchemaComplianceCheck	399	tAS400Input properties	464
tSchemaComplianceCheck		Related scenarios	465
Properties	399	tAS400LastInsertId	466
Scenario: Validating data against schema	400	tAS400LastInsertId properties	466
tUniqRow	404	Related scenario	466
tUniqRow Properties	404	tAS400Output	467
Scenario 1: Deduplicating entries	405	tAS400Output properties	467
tUniservBTGeneric	408	Related scenarios	470
tUniservBTGeneric properties	408	tAS400Rollback	471
Scenario: Execution of a Job in the	410	tAS400Rollback properties	471
tUniservRTConvertName	414	Related scenarios	471
tUniservRTConvertName properties	414	tAS400Row	472
Scenario: Analysis of a name line and assignment of the salutation	415	tAS400Row properties	472
tUniservRTMailBulk	419	Related scenarios	474
tUniservRTMailBulk properties	419	tCreateTable	475
Scenario: Creating an index pool	419	tCreateTable Properties	475
tUniservRTMailOutput	423	Scenario: Creating new table in a Mysql Database	477
tUniservRTMailOutput properties	423	tDB2BulkExec	480
Related scenarios	424	tDB2BulkExec properties	480
tUniservRTMailSearch	425	Related scenarios	482
tUniservRTMailSearch properties	425	tDB2Close	483
Scenario: Adding contacts to the mailRetrieval index pool	426	tDB2Close properties	483
tUniservRTPost	430	Related scenario	483
tUniservRTPost properties	430	tDB2Commit	484
Scenario 1: Checking and correcting the postal code, city and street	431	tDB2Commit Properties	484
Scenario 2: Checking and correcting the postal code, city and street, as well as rejecting the unfeasible	435	Related scenario	484
Database components	437	tDB2Connection	485
tAccessBulkExec	438	tDB2Connection properties	485
tAccessBulkExec properties	438	Related scenarios	486
Related scenarios	439	tDB2Input	487
tAccessCommit	440	tDB2Input properties	487
tAccessCommit Properties	440	Related scenarios	488
Related scenario	440	tDB2Output	489
tAccessConnection	441	tDB2Output properties	489
tAccessConnection Properties	441	Related scenarios	492
Scenario: Inserting data in parent/ child tables	441	tDB2Rollback	493
tAccessInput	445	tDB2Rollback properties	493
tAccessInput properties	445	Related scenarios	493
Related scenarios	446	tDB2Row	494
tAccessOutput	447	tDB2Row properties	494
tAccessOutput properties	447	Related scenarios	496
Related scenarios	450	tDB2SCD	497
tAccessOutputBulk	451	tDB2SCDELT	498
tAccessOutputBulk properties	451	tDB2SP	499
Related scenarios	452	tDB2SP properties	499
tAccessOutputBulkExec	453	Related scenarios	500
tAccessOutputBulkExec properties	453	tDBInput	501
Related scenarios	455	tDBInput properties	501
tAccessRollback	456	Scenario 1: Displaying selected data from DB table	502
tAccessRollback properties	456	Scenario 2: Using StoreSQLQuery variable	503
Related scenarios	456	tDBOutput	505
tAccessRow	457	tDBOutput properties	505
tAccessRow properties	457	Scenario: Writing a row to a table in the MySql database via an ODBC connection	507
Related scenarios	459	tDBSQLRow	509
tAS400Close	460	tDBSQLRow properties	509
tAS400Close properties	460	Scenario: Resetting a DB auto- increment	510
Related scenario	460	tEXAInput	512
tAS400Commit	461	tEXAInput properties	512
tAS400Commit Properties	461	Related scenarios	513
Related scenario	461	tEXAOutput	514
tAS400Connection	462	tEXAOutput properties	514

Preface

General information

Purpose

This Reference Guide provides use cases and details about how to set parameters for the major components found in the **Palette** of *Talend Open Studio*.

Information presented in this document applies to *Talend Open Studio* releases version **5.1.x**.

Audience

This guide is for users and administrators of *Talend Open Studio*.

The layout of GUI screens provided in this document may vary slightly from your actual GUI.

Typographical conventions

This guide uses the following typographical conventions:

- text in **bold**: window and dialog box buttons and fields, keyboard keys, menus, and menu options,
- text in [**bold**]: window, wizard, and dialog box titles,
- text in `courier`: system parameters typed in by the user,
- text in *italics*: file, schema, column, row, and variable names referred to in all use cases, and also names of the fields in the Basic and Advanced setting views referred to in the property table for each component,
- The  icon indicates an item that provides additional information about an important point. It is also used to add comments related to a table or a figure,
- The  icon indicates a message that gives information about the execution requirements or recommendation type. It is also used to refer to situations or information the end-user need to be aware of or pay special attention to.

History of changes

The following table lists changes made in the *Talend Open Studio Reference Guide*.

Version	Date	History of Change
v5.0_a	12/12/2011	<p>Updates in <i>Talend Open Studio Reference Guide</i> include:</p> <ul style="list-style-type: none"> • Post-migration restructuring. • Updated documentation to reflect new product names. For further information , see the Talend website. • Added Cloud, Technical and DotNET chapters. • New components in the Business Intelligence, Data Quality, ESB, Technical, Processing, Cloud, DotNET chapters include: tHashInput, tHashOutput, tJasperOutput, tSplitRow, tRESTRquest components... • Modifications in the settings and scenarios of many components to match the modifications in the GUI.
v5.0_b	13/02/2012	<p>Updates in <i>Talend Open Studio Reference Guide</i> include:</p> <ul style="list-style-type: none"> • Updated the formatting of parts of the Components Reference Guide. • Added a legal notice to the Components Reference Guide. • Added a new component in the Business chapter: tSAPBWInput. • Updated the properties tables and scenarios of certain components to match the modifications in the GUI.
v5.1_a	03/05/2012	<p>Updates in <i>Talend Open Studio Reference Guide</i> include:</p> <ul style="list-style-type: none"> • Updated the properties tables and scenarios of certain components to match the modifications in the GUI. • New components in the Internet family: tSetKerberosConfiguration. • New components in the Data Quality family: tUniservBTGeneric, tUniservRTConvertName, tUniservRTMailBulk, tUniservRTMailOutput, tUniservRTMailSearch and tUniservRTPost.

Feedback and Support

Your feedback is valuable. Do not hesitate to give your input, make suggestions or requests regarding this documentation or product and find support from the **Talend** team, on **Talend**'s Forum website at:

<http://talendforge.org/forum>

Big Data components

This chapter details the main components that you can find in **Big Data** family of the **Palette**.

This document will provide you with an overview of our big data components for Hadoop Distributed File System (HDFS), HBase, Hive, Pig and Sqoop. To reference the remainder of the studio, please refer to *Talend Open Studio User Guide*.

Also, if you have any questions, concerns or general comments please take part in our product forums which can be found at: <http://www.talendforge.org/forum/index.php>

Thank you for using Talend Open Studio.

tHiveClose

tHiveClose properties

Component Family	Big Data / Hive	
Function	tHiveClose closes an active connection to a database.	
Purpose	This component closes connection to a Hive databases.	
Basic settings	<i>Component list</i>	If there is more than one connection used in the Job, select tHiveConnection from the list.
Advanced settings	<i>tStatCatcher Statistics</i>	Select this check box to collect the log data at a component level.
Usage	This component is generally used as an input component. It requires an output component.	
Limitation	n/a	

Related scenario

This component is for use with **tHiveConnection**. It is generally used along with **tHiveConnection** as the latter allows you to open a connection for the transaction which is underway.

For a scenario in which **tHiveClose** might be used, see [the section called “tMysqlConnection”](#).

tHiveConnection

tHiveConnection properties

Database Family	Big Data / Hive	
Function	tHiveConnection opens a connection to a database in order that a transaction may be made.	
Purpose	This component allows you to commit all of the Job data to an output database in just a single transaction, once the data has been validated.	
Basic settings	<i>Property type</i>	Built-in or Repository.
		Built-in: No property data stored centrally.
		Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.
	<i>Hive version</i>	Select a Hive version from the list: Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper. Apache 0.20.203: You need to precise the access to the Apache 0.20.203 to be used. Apache 1.0.0: You need to precise the access to the Apache Hadoop 1.0.0 to be used in this mode.
	<i>Connection mode</i>	Select a connection mode from the list: Standalone: This connection mode is available when the Hive version is Apache 0.20.203 or Apache 1.0.0. Embedded: This connection mode is available when the Hive version is Apache 1.0.0 or Hortonworks Data Platform 1.0.
	<i>Host</i>	Database server IP address.
	<i>Port</i>	DB server listening port.
	<i>Database</i>	Fill this field with the name of the database.  This field is not available when you select Embedded from the Connection mode list.
	<i>Username</i> and <i>Password</i>	DB user authentication data.
	<i>Encoding</i>	Select the encoding type from the list or select Custom and define it manually. This field is compulsory for DB data handling.
	<i>Use or register a shared DB Connection</i>	Select this check box to share your connection or fetch a connection shared by a parent or child Job. This allows

		<p>you to share one single DB connection among several DB connection components from different Job levels that can be either parent or child.</p> <p>Shared DB Connection Name: set or type in the shared connection name.</p>
Advanced settings	<i>tStatCatcher Statistics</i>	Select this check box to collect the log data at a component level.
Usage	This component is generally used with other Informix components, particularly tHiveClose .	
Limitation	n/a	

Related scenario

For a scenario in which **tHiveConnection**, might be used, see [the section called “Scenario: Inserting data in mother/daughter tables”](#).

tHiveRow

tHiveRow properties

Component family	Big Data / Hive	
Function	tHiveRow is the dedicated component for this database. It executes the HiveQL query stated in the specified database. The row suffix means the component implements a flow in the Job design although it does not provide output.	
Purpose	Depending on the nature of the query and the database, tHiveRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write your HiveQL statements easily.	
Basic settings	<i>Property type</i>	Either Built-in or Repository .
		Built-in : No property data stored centrally.
		Repository : Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.
	<i>Use an existing connection</i>	<p>Select this check box and click the relevant tHiveConnection component from the Component List to reuse the connection details you already defined.</p> <p> When a Job contains the parent Job and the child Job, Component list presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, make sure that the available connection components are sharing the intended connection.</p> <p>For more information on how to share a DB connection across Job levels, see Use or register a shared DB connection in any database connection component corresponding to the database you are using.</p> <p>Otherwise, you can as well deactivate the connection components and use Dynamic settings of the component to specify the intended connection manually. In this case, make sure the connection name is unique and distinctive all over through the two Job levels. For more information about Dynamic settings, see your studio user guide.</p>
	<i>Hive version</i>	<p>Select a Hive version from the list:</p> <p>Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper.</p>

		<p>Apache 0.20.203: You need to precise the access to the Apache 0.20.203 to be used.</p> <p>Apache 1.0.0: You need to precise the access to the Apache Hadoop 1.0.0 to be used in this mode.</p>
	<i>Connection mode</i>	<p>Select a connection mode from the list:</p> <p>Standalone: This connection mode is available when the Hive version is Apache 0.20.203 or Apache 1.0.0.</p> <p>Embedded: This connection mode is available when the Hive version is Apache 1.0.0 or Hortonworks Data Platform 1.0.</p>
	<i>Host</i>	Database server IP address.
	<i>Port</i>	Listening port number of DB server.
	<i>Database</i>	<p>Fill this field with the name of the database.</p> <p> This field is not available when you select Embedded from the Connection mode list.</p>
	<i>Username</i> and <i>Password</i>	DB user authentication data.
	<i>Schema</i> and <i>Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository .
		Built-in: The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio User Guide</i> .
		Repository: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <i>Talend Open Studio User Guide</i> .
	<i>Table Name</i>	Name of the table to be processed.
	<i>Query type</i>	Either Built-in or Repository .
		Built-in: Fill in manually the query statement or build it graphically using SQLBuilder
		Repository: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.
	<i>Guess Query</i>	Click the Guess Query button to generate the query which corresponds to your table schema in the Query field.
	<i>Query</i>	Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.
	<i>Die on error</i>	This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.
Advanced settings	<i>Propagate QUERY's recordset</i>	Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.
	<i>tStat Catcher Statistics</i>	Select this check box to collect log data at the component level.

Usage	This component offers the benefit of flexible DB queries and covers all possible Hive QL queries.
--------------	---

Related scenarios

For related topics, see:

- [the section called “Scenario: Resetting a DB auto-increment”](#)
- [the section called “Scenario 1: Removing and regenerating a MySQL table index”](#).

Business components

This chapter details the major components that you can find in **Business** group of the **Palette** of *Talend Open Studio*.

The Business component family groups connectors that covers specific Business needs, such as reading and writing CRM, or ERP types of database and reading from or writing to an SAP system.

tAlfrescoOutput

tAlfrescoOutput Properties

Component family	Business	
Function	Creates dematerialized documents in an Alfresco server where they are indexed under meaningful models.	
Purpose	Allows to create and manage documents in an Alfresco server.	
Basic settings	<i>URL</i>	Type in the URL to connect to the Alfresco Web application.
	<i>Login and Password</i>	Type in the user authentication data to the Alfresco server.
	<i>Base</i>	Type in the base path where to put the document, or Select the Map... check box and then in the Column list, select the target location column. Note: When you type in the base name, make sure to use the double backslash (\\) escape character.
	<i>Document Mode</i>	Select in the list the mode you want to use for the created document. Create only: creates a document if it does not exist. Note that an error message will display if you try to create a document that already exists Create or update: creates a document if it does not exist or updates the document if it exists.
	<i>Container Mode</i>	Select in the list the mode you want to use for the destination folder in Alfresco. Update only: updates a destination folder if the folder exists. Note that an error message will display if you try to update a document that does not exist Create or update: creates a destination folder if it does not exist or updates the destination folder if it exists.
	<i>Define Document Type</i>	Click the three-dot button to display the tAlfrescoOutput editor. This editor enables you to: - select the file where you defined the metadata according to which you want to save the document in Alfresco -define the type of the document

		-select any of the aspects in the available aspects list of the model file and click the plus button to add it in the list to the left.
	<i>Property Mapping</i>	Displays the parameters you set in the tAlfrescoOutput editor and according to which the document will be created in the Alfresco server. Note that in the Property Mapping area, you can modify any of the input schemas.
	<i>Schema and Edit schema</i>	A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository. Click Edit Schema to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.
	<i>Result Log File Name</i>	Browse to the file where you want to save any logs related to the Job execution.
Advanced settings	<i>Configure Target Location Container</i>	Allows to configure the (by default) type of containers (folders) Select this check box to display new fields where you can modify the container type to use your own created types based on the father/child model.
	<i>Configure Permissions</i>	When selected, allows to manually configure access rights to containers and documents. Select the Inherit Permissions check box to synchronize access rights between containers and documents. Click the Plus button to add new lines to the Permissions list, then you can assign roles to user or group columns.
	<i>Encoding</i>	Select the encoding type from the list or select Custom and define it manually. This field is compulsory.
	<i>Association Target Mapping</i>	Allows to create new documents in Alfresco with associated links towards other documents already existing in Alfresco, to facilitate the navigation process for example. To create associations: 1. Open the tAlfresco editor. 2. Click the Add button and select a model where you have already defined aspects that contain associations. 3. Click the drop-down arrow at the top of the editor and select the corresponding document type. 4. Click OK to close the editor and display the created association in the Association Target Mapping list.

	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at a Job level as well as at each component level.
Usage	Usually used as an output component. An input component is required.	
Limitation/Prerequisites	To be able to use the tAlfrescoOutput component, few relevant resources need to be installed: check the <i>Installation Procedure</i> sub section for more information.	

Installation procedure

To be able to use **tAlfrescoOutput** in *Talend Open Studio*, you need first to install the Alfresco server with few relevant resources.

The below sub sections detail the prerequisite and the installation procedure.

Prerequisites

Start with the following operations:

1. Download the file `alfresco-community-tomcat-2.1.0.zip`
2. Unzip the file in an installation folder, for example:

```
C:\Program Files\Java\jdk1.6.0_27
```

3. Install JDK 1.6.0+
 4. Update the environment variable
- ```
JAVA_HOME (JAVA_HOME= C:\alfresco)
```
5. From the installation folder (`C:\alfresco`), launch the alfresco server using the script `alf_start.bat`

*Make sure that the Alfresco server is launched correctly before start using the **tAlfrescoOutput** component.*

### Installing the Talend Alfresco module

Note that the `talendalfresco_20081014.zip` is provided with the **tAlfrescoOutput** component in *Talend Open Studio*.

To install the `talendalfresco` module:

1. From `talendalfresco_20081014.zip` and in the `talendalfresco_20081014\alfresco` folder, look for the following jars: `stax-api-1.0.1.jar`, `wstx-lgpl-3.2.7.jar`, `talendalfresco-client_1.0.jar`, and `talendalfresco-alfresco_1.0.jar` and move them to `C:\alfresco\tomcat\webapps\alfresco\WEB-INF\lib`
2. Add the authentication filter of the commands to the `web.xml` file located in the path

```
C:\alfresco\tomcat\webapps\alfresco\WEB-INF
son WEB-INF/
```

following the model of the example provided in `talendalfresco_20081014/alfresco` folder of the zipped file `talendalfresco_20081014.zip`

The following figures show the portion of lines (in blue) to add in the file `web.xml alfresco`.

## Useful information for advanced use

### Installing new types for Alfresco:

From the package `jeu_test.zip` and in the `package_jeu_test/fichiers_conf_alfresco2.1` folder, look for the following files: `xml H76ModelCustom.xml` (description of the model), `web-client-config-custom.xml` (web interface of the model), and `custom-model-context.xml` (registration of the new model) and paste them in the following folder: `C:/alfresco/tomcat/shared/classes/alfresco/extension`

### Dates:

- The dates must be of the **Talend** date type `java.util.Date`.
- Columns without either mapping or default values, for example of the type `Date`, are written as empty strings.
- Solution: delete all columns without mapping or default values. Note that any modification of the type `Alfresco` will put them back.

### Content:

- Do not mix up between the file path which content you want to create in `Alfresco` and its target location in `Alfresco`.
- Provide a URL! It can target various protocols, among which are `file`, `HTTP` and so on.
- For URLs referring to files on the file system, precede them by `"file:"` for Windows used locally, and by `"file://"` for Windows on a network (which accepts as well `"file: \\"`) or for Linux.
- Do not double the backslash in the target base path (automatic escape), unless you type in the path in the basic settings of the **tAlfrescoOutput** component, or doing concatenation in the **tMap** editor for example.

**Multiple properties or associations:**

- It is possible to create only one association by document if it is mapped to a string value, or one or more associations by document if it is mapped to a list value (object).
- You can empty an association by mapping it to an empty list, which you can create, for example, by using `new java.util.ArrayList()` in the **tMap** component.

However, it is impossible to delete an association.

**Building List(object) with tAggregate:**

- define the table of the relation n-n in a file, containing a name line for example (included in the input rows), and a `category` line (that can be defined with its mapping in a third file).
- group by: input name, output name.
- operation: output `categoryList`, function `list(object)`, input `category`. ATTENTION `list(object)` and non simple list.

**- References (documents and folders):**

- References are created by mapping one or more existing reference nodes (xpath or namepath) using `String` type or `List(object)`.
- An error in the association or the property of the reference type does not prevent the creation of the node that holds the reference.
- Properties of the reference type are created in the **Basic Settings** view.
- Associations are created in the **Advanced Settings** view.

## Dematerialization, tAlfrescoOutput, and Enterprise Content Management

Dematerialization is the process that convert documents held in physical form into electronic form, and thus helps to move away from the use of physical documentation to the use of electronic Enterprise Content Management (ECM) systems. The range of documents that can be managed with an Enterprise Content Management system include just about everything from basic documents to stock certificates, for example.

Enterprises dematerialize their content via a manual document handling, done by man, or an automatic document handling, machine-based.

Considering the varied nature of the content to be dematerialized, enterprises have to use varied technologies to do it. Scanning paper documents, creating interfaces to capture electronic documents from other applications, converting document images into machine-readable/editable text documents, and so on are examples of the technologies available.

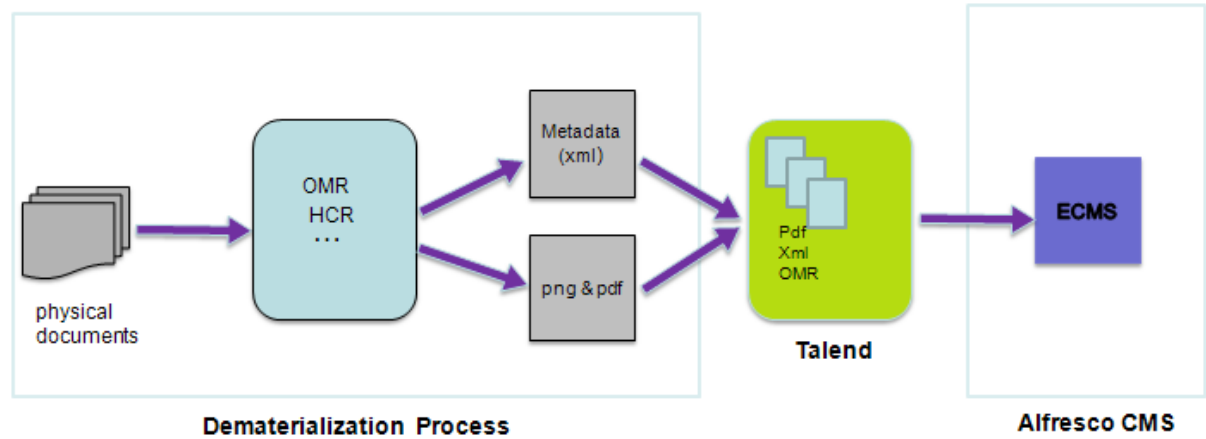

Furthermore, scanned documents and digital faxes are not readable texts. To convert them into machine-readable characters, different character recognition technologies are used. Handwritten Character Recognition (HCR) and Optical Mark Recognition (OMR) are two examples of such technologies.

Equally important as the content that is captured in various formats from numerous sources in the dematerialization process is the supporting metadata that allows efficient identification of the content via specific queries.

Now how can this document content along with the related metadata be aggregated and indexed in an Enterprise Content Management system so that it can be retrieved and managed in meaningful ways? **Talend** provides the answer through the **tAlfrescoOutput** component.

The **tAlfrescoOutput** component allows you to stock and manage your electronic documents and the related metadata on the Alfresco server, the leading open source enterprise content management system.

The following figure illustrates **Talend**'s role between the dematerialization process and the Enterprise Content Management system (Alfresco).

ECMS: Enterprise Content Management System  
HCR: Handwritten Character Recognition  
OMR: Optical Mark Recognition

## Scenario: Creating documents on an Alfresco server

This Java scenario describes a two-component Job which aims at creating two document files with the related metadata in an Alfresco server, the java-based Enterprise Control Management system.

### Setting up your Job

1. Drop the **tFileInputDelimited** and **tAlfrescoOutput** components from the **Palette** onto the design workspace.
2. Connect the two components together using a **Main > Row** connection.

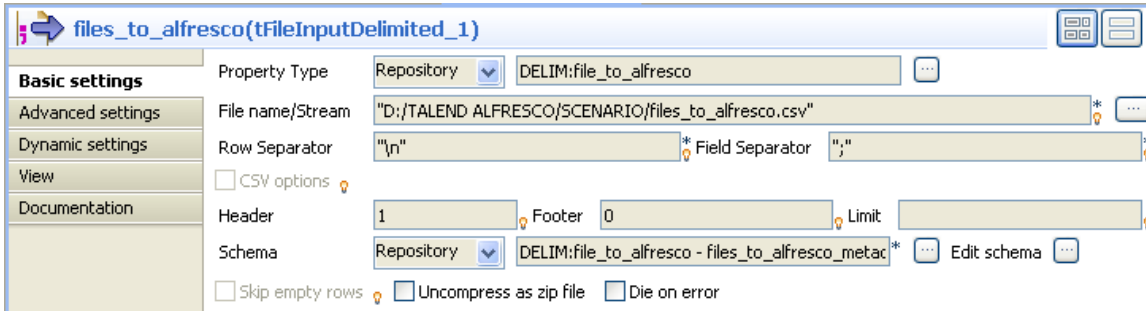

### Setting up the schema

1. In the design workspace, double-click **tFileInputDelimited** to display its basic settings.

- Set the **File Name** path and all related properties. Note that if you have already stored your input schemas locally in the **Repository**, you can simply drop the relevant file item from the **Metadata** folder onto the design workspace and the delimited file settings will automatically display in the relevant fields in the component **Basic settings** view.

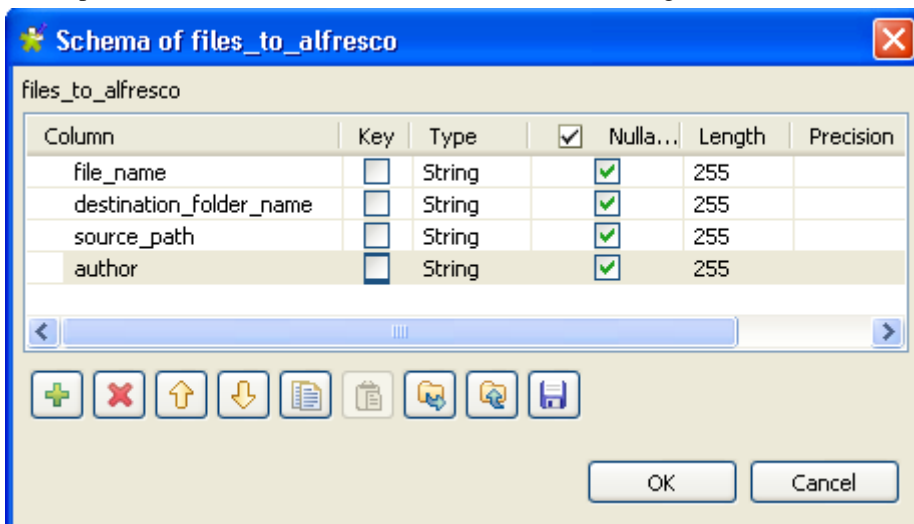

For more information about metadata, see *Setting up a File Delimited schema* in Talend Open Studio User Guide.

In this scenario, the delimited file provides the metadata and path of two documents we want to create in the Alfresco server. The input schema for the documents consists of four columns: *file\_name*, *destination\_folder\_name*, *source\_path*, and *author*.

|   | A             | B                        | C                                    | D      | E | F |
|---|---------------|--------------------------|--------------------------------------|--------|---|---|
| 1 | file_name;    | destination_folder_name; | source_path;                         | author |   |   |
| 2 | PO_43278.pdf; | FINANCE\PO;              | file:D:/PO/customer1_2009-03-24.pdf; | talend |   |   |
| 3 | PO_43279.pdf; | FINANCE\PO;              | file:D:/PO/customer2_2009-03-24.pdf; | talend |   |   |

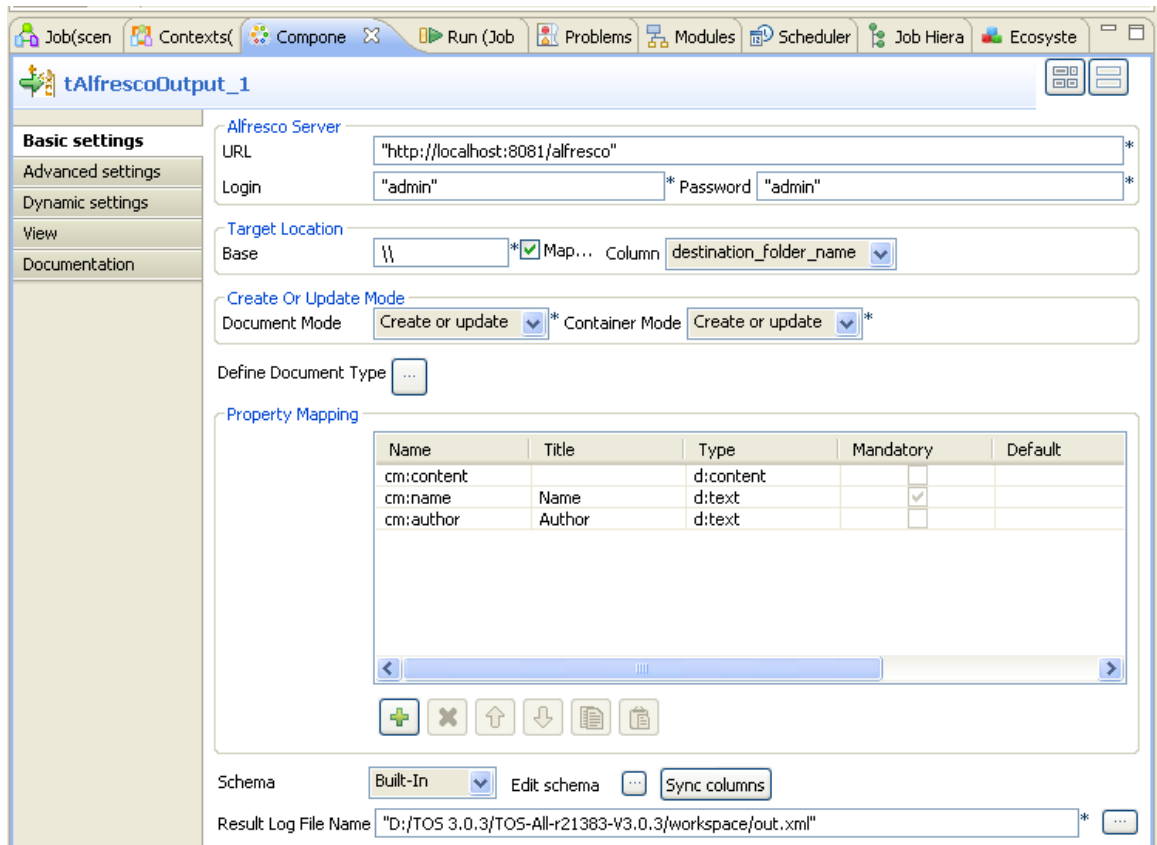

And therefore the input schema of the delimited file will be as the following:

## Setting up the connection to the Alfresco server

- In the design workspace, double-click **tAlfrescoOutput** to display its basic settings.

2. In the **Alfresco Server** area, enter the Alfresco server URL and user authentication information in the corresponding fields.
3. In the **TargetLocation** area, either type in the base name where to put the document in the server, or Select the **Map...** check box and then in the **Column** list, select the target location column, `destination_folder_name` in this scenario.

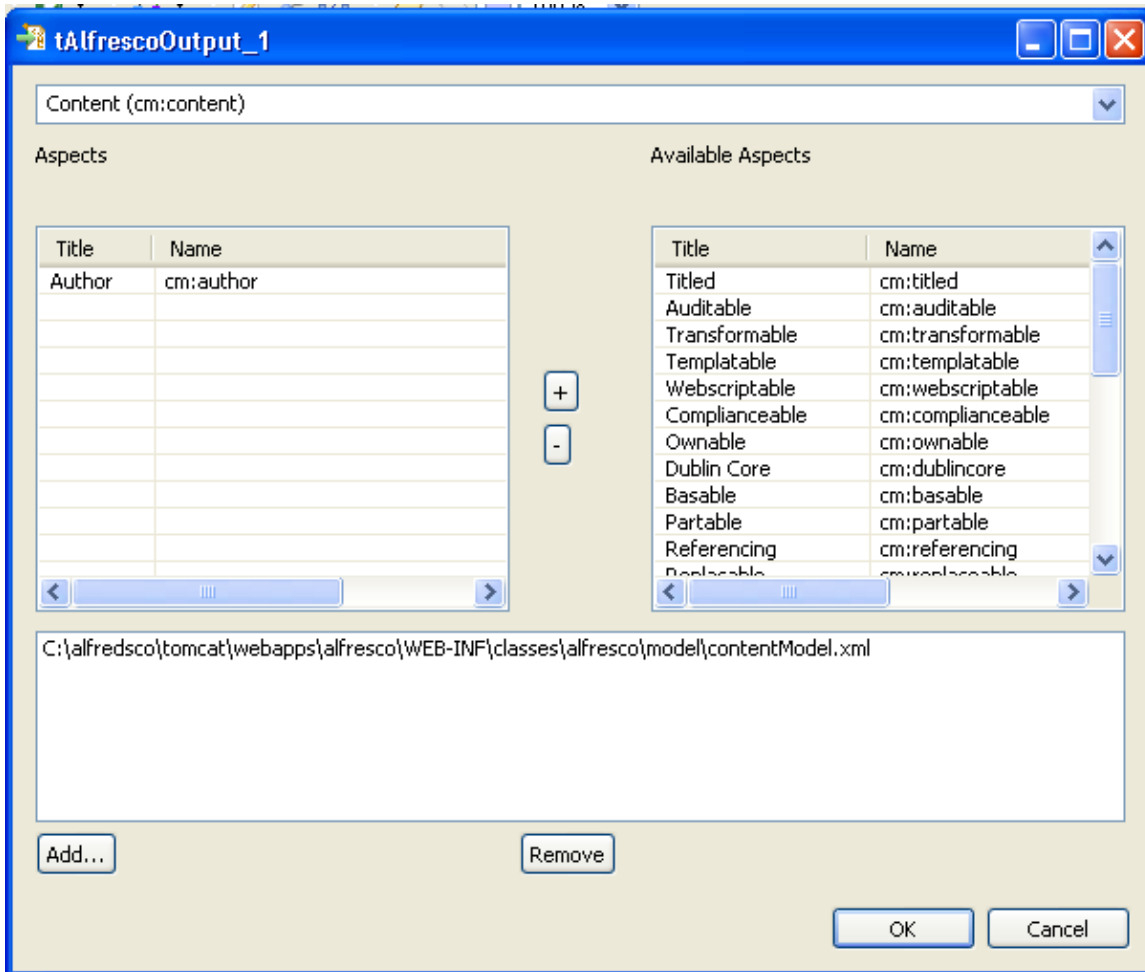

When you type in the base name, make sure to use the double backslash (\\) escape character.

4. In the **Document Mode** list, select the mode you want to use for the created documents.
5. In the **Container Mode** list, select the mode you want to use for the destination folder in Alfresco.

## Defining the document

1. Click the **Define Document Type** three-dot button to open the **tAlfrescoOutput** editor.

2. Click the **Add** button to browse and select the xml file that holds the metadata according to which you want to save the documents in Alfresco.

All available aspects in the selected model file display in the **Available Aspects** list.

You can browse for this model folder locally or on the network. After defining the aspects to use for the document to be created in Alfresco, this model folder is not needed any more.

3. If needed, select in the **Available Aspects** list the aspect(s) to be included in the metadata to write in the Alfresco server. In this scenario we want the author name to be part of the metadata registered in Alfresco.
4. Click the drop-down arrow at the top of the editor to select from the list the type to give to the created document in Alfresco, Content in this scenario.

All the defined aspects used to select the metadata to write in the Alfresco server display in the **Property Mapping** list in the **Basic Settings** view of **tAlfrescoOutput**, three aspects in this scenario, two basic for the Content type (content and name) and an additional one (author).

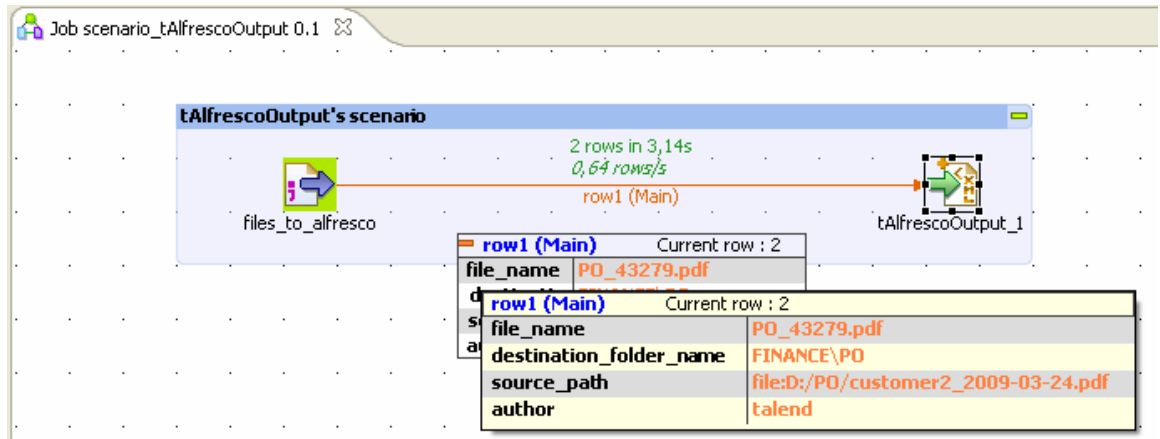

## Executing your Job

1. Click **Sync columns** to auto propagate all the columns of the delimited file.

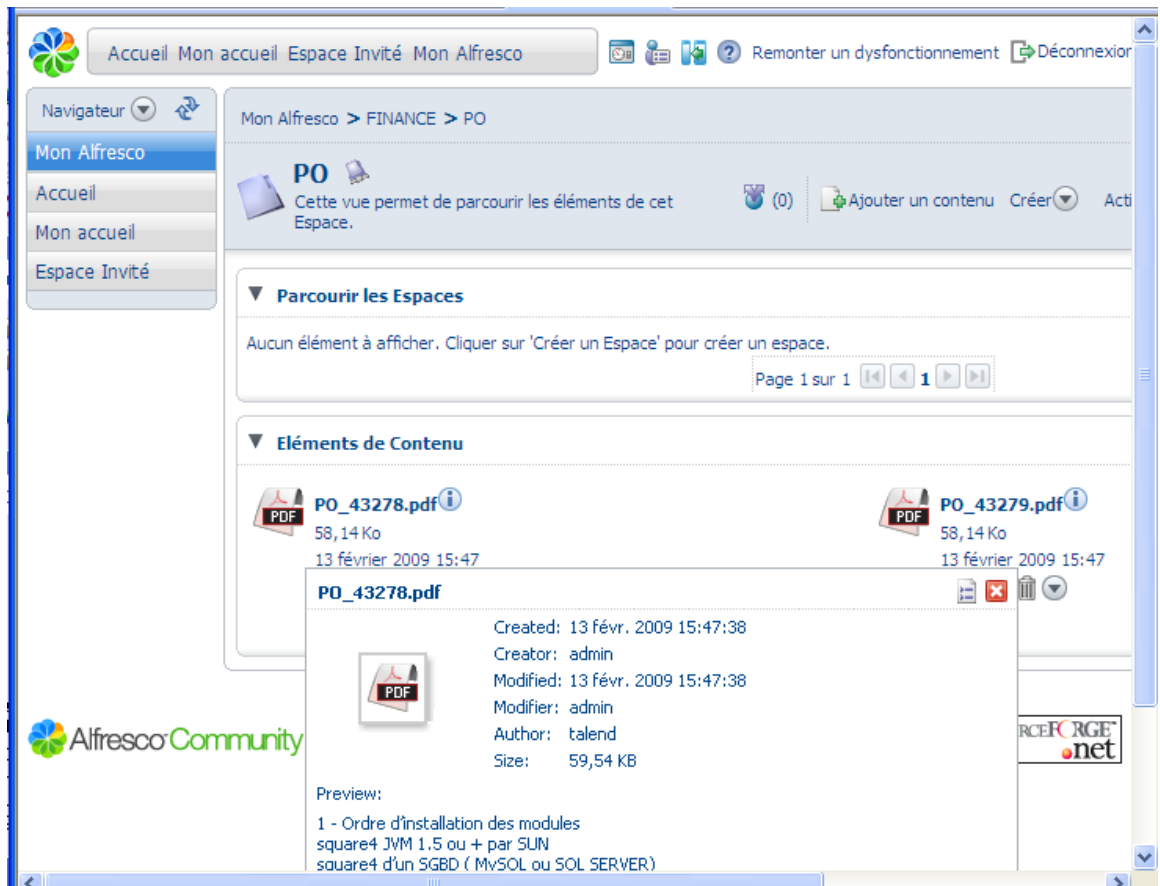

If needed, click **Edit schema** to view the output data structure of **tAlfrescoOutput**.

2. Click the three-dot button next to the **Result Log File Name** field and browse to the file where you want to save any logs after Job execution.
3. Save your Job, and press **F6** to execute it.

The two documents are created in Alfresco using the metadata provided in the input schemas.

# tBonitaDeploy

| <b>Limitation</b>        | n/a                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Scenario: Executing a Bonita process via a Talend Job

This scenario describes a Job that deploys a Bonita process into the Bonita Runtime and executes this process, in which a personnel request is treated.

The Job in this scenario uses three components.

- **tBonitaDeploy**: this component deploys a Bonita process into the Bonita Runtime.
- **tFixedFlowInput**: this component generates the schema used as execution parameters of this deployed process.
- **tBonitaInstantiateProcess**: this component executes this deployed process.

When generating schema using **tFixedFlowInput**, the column names of the schema must be identical with those of the Bonita parameters used to execute the same process by this Bonita.

Before beginning to replicate this schema, prepare your Bonita.bar file that is the process exported from the Bonita system and will be deployed into the Bonita Runtime engine. In this scenario, this file is *TEST--4.0.bar*. This process can be checked via the Bonita interface.

## Setting up the Job

1. Drop **tBonitaDeploy**, **tFixedFlowInput** and **tBonitaInstantiateProcess** onto the design workspace.
2. Right-click **tBonitaDeploy** and connect **tBonitaDeploy** to **tFixedFlowInput** using a **Trigger**> **On Subjob Ok** connection.
3. Right-click **tFixedFlowInput** and connect this component to **tBonitaInstantiateProcess** using a **Row** > **Main** connection.

## Configuring the Basic settings of tBonitaDeploy

To replicate this scenario, proceed as follows:

1. Double-click **tBonitaDeploy** to open its **Basic settings** view.

The screenshot shows the 'Basic settings' view for 'tBonitaDeploy\_1'. The 'Bonita version' is set to 5.3.1. The 'Bonita Runtime Configuration' section is expanded, showing the following fields:

- Bonita Runtime Environment File: `"/home/rdubois/Desktop/BonitaRuntime/runtime/conf/bonita-environment.xml"`
- Bonita Runtime Jaas File: `"/home/rdubois/Desktop/BonitaRuntime/conf/external/security/jaas-standard.cfg"`
- Bonita Runtime Logging File: `"/home/rdubois/Desktop/BonitaRuntime/conf/external/logging/logging.properties"`
- Login Module: `"BonitaStore"`
- Business Archive: `"/home/rdubois/Desktop/Bonita/TEST--4.0.bar"`
- Username: `"admin"`
- Password: `"bpm"`

The 'Die on error' checkbox is unchecked.

2. Select Bonita version 5.3.1 from the **Bonita version** list. The version you select should be in sync with the version number of the Bonita Runtime engine you are using.
3. In the **Bonita Runtime Configuration** area, browse to the Bonita Runtime variable files. In the **Bonita Runtime Environment file** field, browse to the `bonita-environnement.xml` file; in the **Bonita Runtime Jaas File** field, browse to the `jaas-standard.cfg` file; in the **Bonita Runtime Logging File** field, browse to the `logging.properties` file.

For users based on Bonita version 5.2.3, only the **Bonita Runtime Jaas File** field and the **Bonita Runtime Logging File** field need to be filled.

The screenshot shows the 'Basic settings' view for 'tBonitaDeploy\_1'. The 'Bonita version' is set to 5.2.3. The 'Bonita Runtime Configuration' section is expanded, showing the following fields:

- Bonita Runtime Jaas File: `"/home/rdubois/Desktop/BonitaRuntime/conf/external/security/jaas-standard.cfg"`
- Bonita Runtime Logging File: `"/home/rdubois/Desktop/BonitaRuntime/conf/external/logging/logging.properties"`
- Login Module: `"BonitaStore"`
- Business Archive: `"/home/rdubois/Desktop/Bonita/TEST--4.0.bar"`
- Username: `"admin"`
- Password: `"bpm"`

The 'Die on error' checkbox is unchecked.

For users based on Bonita version 5.6.1, in the **Bonita Runtime Home** field, browse to the Bonita Runtime environment directory.

The screenshot shows the 'Basic settings' view for 'tBonitaDeploy\_1'. The 'Bonita version' is set to 5.6.1. The 'Bonita Runtime Configuration' section is expanded, showing the following fields:

- Bonita Runtime Home: `"/home/rdubois/Desktop/BonitaRuntime/conf/bonita"`
- Bonita Runtime Jaas File: `"/home/rdubois/Desktop/BonitaRuntime/conf/external/security/jaas-standard.cfg"`
- Bonita Runtime Logging File: `"/home/rdubois/Desktop/BonitaRuntime/conf/external/logging/logging.properties"`
- Login Module: `"BonitaStore"`
- Business Archive: `"/home/rdubois/Desktop/Bonita/TEST--4.0.bar"`
- Username: `"admin"`
- Password: `"bpm"`

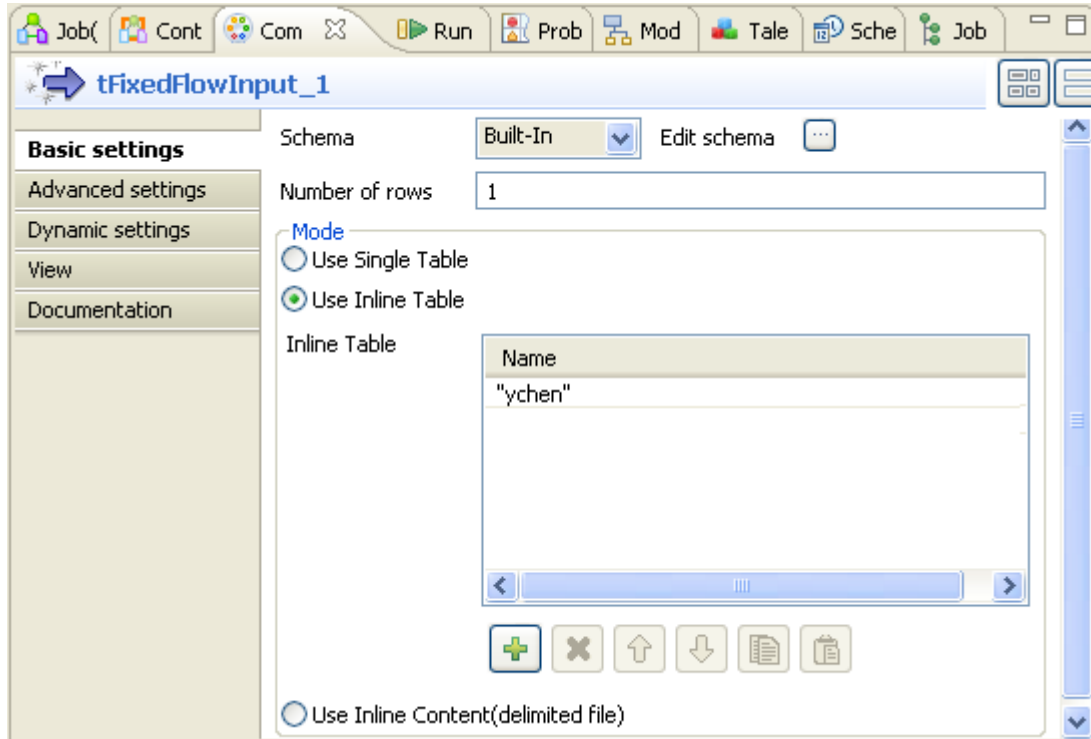

The 'Die on error' checkbox is unchecked.

4. In the **Business Archive** field, browse to the Bonita .bar file that is the process exported from your Bonita system and will be deployed into the Bonita Runtime engine.

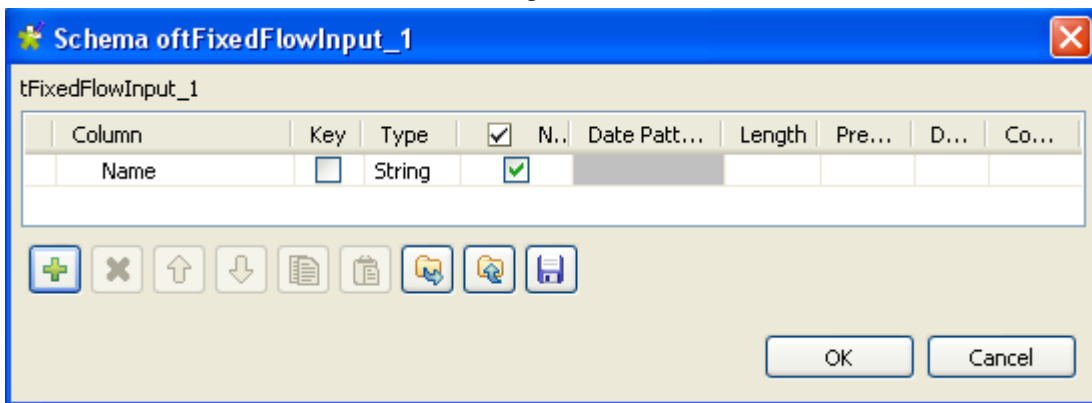

- In the **Username** and the **Password** fields, type in your authentication information to connect to your Bonita.

## Configuring the Basic settings of tFixedFlowInput

- Double-click **tFixedFlowInput** to open its **Basic settings** view.

- Click the three-dot button next to **Edit schema** to open the schema editor.

- In the schema editor, click the plus button to add one row.
- In the schema editor, click the new row and type in the new name: *Name* and click **OK**.
- In the **Mode** area of the **Basic settings** view, select the **Use inline table** option and click the plus button to add one row in the table.
- In the inline table, click the added row and type in the person's name from your personnel between the quotation marks: *ychen*, whose request will be treated by this deployed process.

## Configuring the Basic settings of tBonitaInstantiateProcess

1. Double-click **tBonitaInstantiateProcess** to open its **Basic settings** view.

The screenshot shows the configuration window for tBonitaInstantiateProcess\_1. The left sidebar has 'Basic settings' selected. The main area shows the following settings:

- Bonita version:** 5.3.1
- Schema:** Built-In
- Bonita Runtime Configuration:**
  - Bonita Runtime Environment File:** "/home/rdubois/Desktop/BonitaRuntime/runtime/conf/bonita-environment.xml"
  - Bonita Runtime Jaas File:** "/home/rdubois/Desktop/BonitaRuntime/conf/external/security/jaas-standard.cfg"
  - Bonita Runtime Logging File:** "/home/rdubois/Desktop/BonitaRuntime/conf/external/logging/logging.properties"
  - Login Module:** "BonitaStore"
- Use Process ID
- Process Definition Id:** "((String)globalMap.get("tBonitaDeploy\_1\_ProcessDefinitionUUID"))"
- Username:** "admin" | **Password:** "bpm"
- Die on error

2. Select Bonita version 5.3.1 from the **Bonita version** list. The version you select should be in sync with the version number of the Bonita Runtime engine you are using.
3. In the **Bonita Runtime Configuration** area, browse to the Bonita Runtime variable files. In the **Bonita Runtime Environment file** field, browse to the *bonita-environnement.xml* file; in the **Bonita Runtime Jaas File** field, browse to the *jaas-standard.cfg* file; in the **Bonita Runtime Logging File** field, browse to the *logging.properties* file.

For users based on Bonita version 5.2.3, only the **Bonita Runtime Jaas File** field and the **Bonita Runtime Logging File** field need to be filled.

The screenshot shows the configuration window for tBonitaInstantiateProcess\_1 with Bonita version 5.2.3 selected. The 'Bonita Runtime Environment File' field is empty. The other settings are the same as in the previous screenshot.

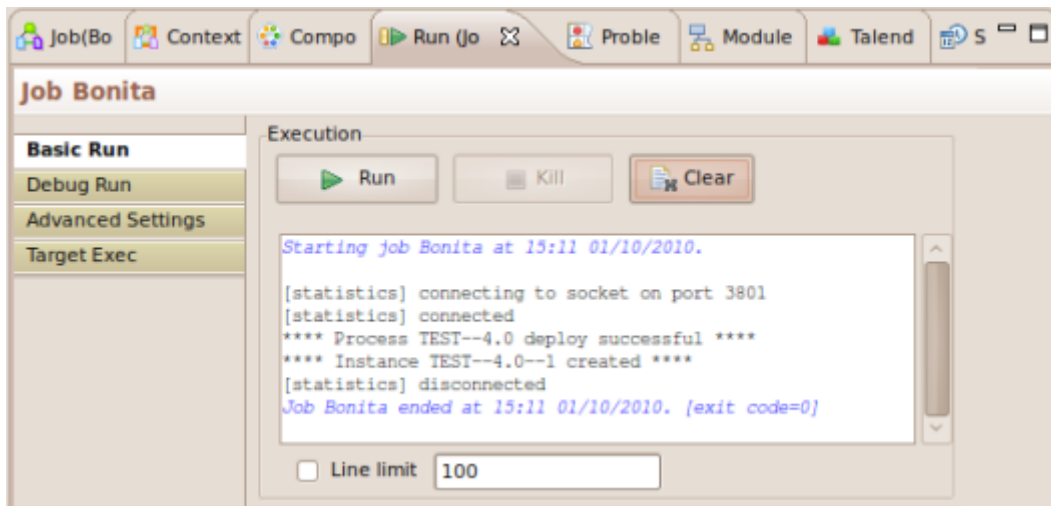

For users based on Bonita version 5.6.1, in the **Bonita Runtime Home** field, browse to the Bonita Runtime environment directory.

The screenshot shows the configuration window for tBonitaInstantiateProcess\_1 with Bonita version 5.6.1 selected. A new field, **Bonita Runtime Home**, is present and set to "/home/rdubois/Desktop/BonitaRuntime/conf/bonita".

4. Select the **Use Process ID** check box to activate the **Process Definition Id** field.
5. In the **Process Definition Id** field, click between the quotation marks and press **Ctrl+space** to open the auto-completion drop-down list containing the available global variables for this Job.
6. Double-click the variable you need use to add it between the quotation marks. In this scenario, double-click *tBonitaDeploy\_1\_ProcessDefinitionUUID*, which retrieves the process definition ID of the process being deployed by **tBonitaDeploy**.
  - 💡 If the process of interest was deployed and thus **tBonitaDeploy** is not used, clear the **Use Process ID** check box to activate the **Process name** and the **Process version** fields and fill in the corresponding information to the two fields. **tBonitaInstantiateProcess** concatenates the process name and the process version you type in to construct the process definition ID.
7. In the **Username** and **Password** fields, enter the username and password to connect to your Bonita.

## Job Execution

Press **F6** to run the Job.

This process is deployed into the Bonita Runtime and an instance is created for the personnel requests.

## Scenario: Retrieving information about patients and events from an HL7 file

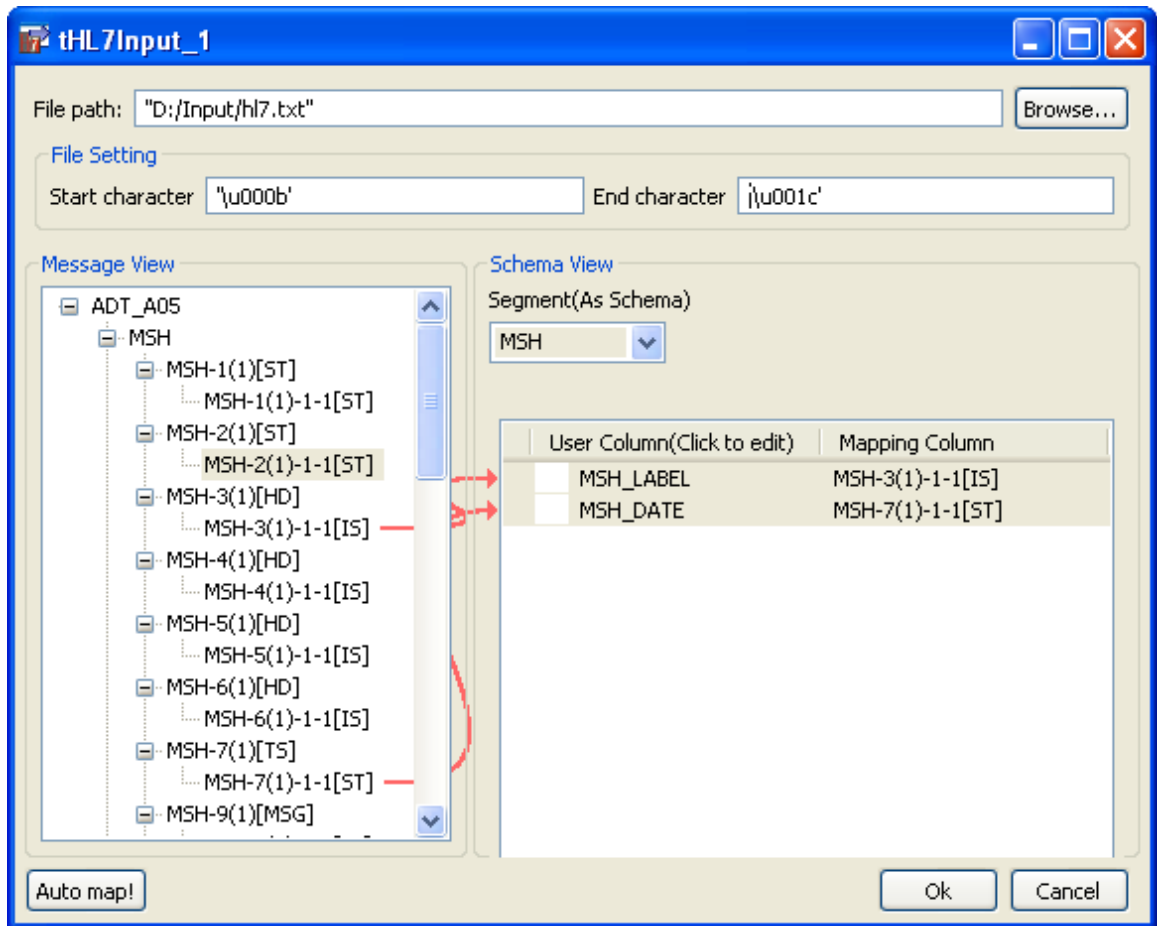

This scenario describes a four-component Job which retrieves information about patients and events from an HL7 file.

### Configuring the editor of tHL7Input

1. From the **Palette**, drop an **tHL7Input** and three **tLogRow** components onto the design workspace.
2. Double-click **tHL7Input** in order to open its editor.

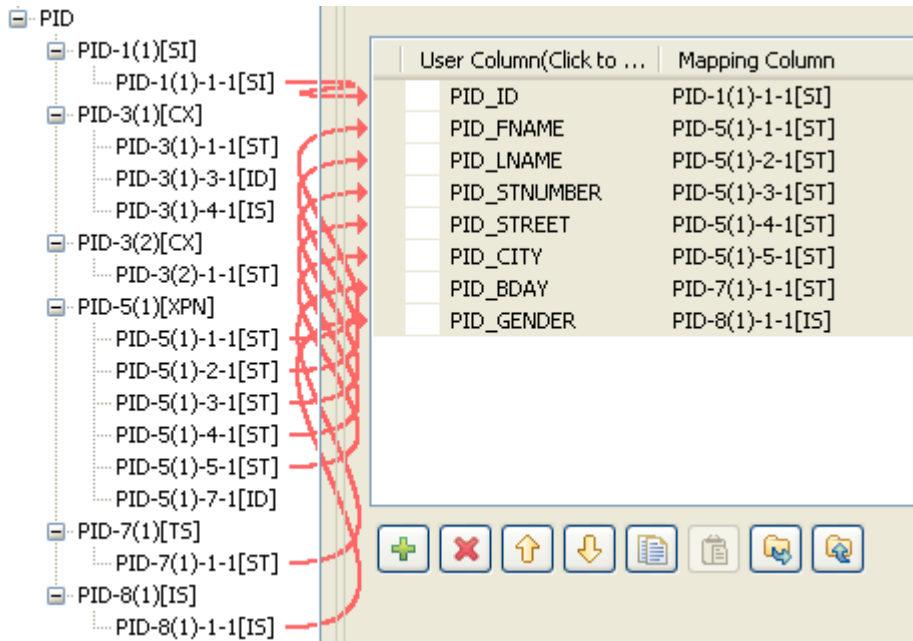

3. In the **File path** field, click [**Browse...**] and browse the directory to select your HL7 file.
4. In the **File Setting** area, type in your segment **Start character** and your segment **End character**.
5. Under **Segment(As Schema)**, in the Schema view area,select **MSH**.
6. Drop the *MSH-3(1)[HD]* and *MSH-7(1)[TS]* segments from the **Message View** onto the **Schema View**.

7. Under **Segment(As Schema)**, in the Schema view area,select **EVN**.
8. Drop the *EVN-1(1)-1-1[ID]* and *EVN-2(1)-1-1[ST]* segments from the **Message View** onto the **Schema View**.

9. Under **Segment(As Schema)**, in the Schema view area,select **PID**.
10. Drag and drop the following segments from the **Message View** onto the **Schema View**: *PID-1(1)-1-1[SI]*, *PID-5(1)-1-1[ST]*, *PID-5(1)-2-1[ST]*, *PID-5(1)-3-1[ST]*, *PID-5(1)-4-1[ST]*, *PID-5(1)-5-1[ST]*, *PID-5(1)-7-1[ID]* and click **Ok** to close the editor.

 If available, click the **Auto map!** button, located at the bottom left of the interface, to carry out the mapping operation automatically.

## Job Execution

1. Link **tHL7Input** to the three **tLogRow** components, using **MSH**, **EVN** and **PID** links respectively.
2. Save your Job and press **F6** to execute it.  
*Starting job HL7 at 10:15 02/04/2010.*

```

+-----+
| tLogRow_1 |
+-----+
| MSH_LABEL | MSH_DATE |
+-----+
| MedSeries | 200903230934 |
+-----+

```

```

+-----+
| tLogRow_2 |
+-----+
| PID_ID | PID_FNAME | PID_LNAME | PID_STNUMBER | PID_STREET | PID_CITY | PID_BDAY | PID_GENDER |
+-----+
| 1 | Marie | Charlotte | 456 | main_street | Richemont | 19770202 | F |
+-----+

```

```

+-----+
| tLogRow_3 |
+-----+
| EVN_ID | EVN_DATE |
+-----+
| A31 | 200903230934 |
+-----+

```

*Job HL7 ended at 10:15 02/04/2010. [exit code=0]*

The console displays the three **tLogRow** tables, which return different types of information. The first one give the message header label and its date. The second table shows the information about the patient. The third one displays the event ID and its date.

|--|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  |                               | <b>Repository:</b> Select the Repository file where Properties are stored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|  | <i>Columns Mapping</i>        | <p>You can set the mapping conditions by making changes in <b>Edit Schema</b>. By default, column names in <b>Column</b> fields are the same as what they are in the schema.</p> <p> Because some column names in Marketo database may contain blank space, which is not allowed in the component schema, you need to specify the corresponding column fields in the <b>Columns in Marketo</b> field. If the defined column names in schema are the same as column names in Marketo database, it is not necessary to set the columns mapping.</p> |
|  | <i>LeadKey type</i>           | The data types of <b>LeadKey</b> supported by Marketo DB.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <b>Row &gt; Reject</b> connection.      |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                                                               | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.                                                                                                                |
| <b>Usage</b>             | This component is used as an intermediate component, it requires an input component and an output component. |                                                                                                                                                                                                                               |
| <b>Limitation</b>        | n/a                                                                                                          |                                                                                                                                                                                                                               |

## Scenario: Adding a lead record to a list in the Marketo DB

The following scenario describes a three-component Job that adds a lead record into a list in the Marketo database.

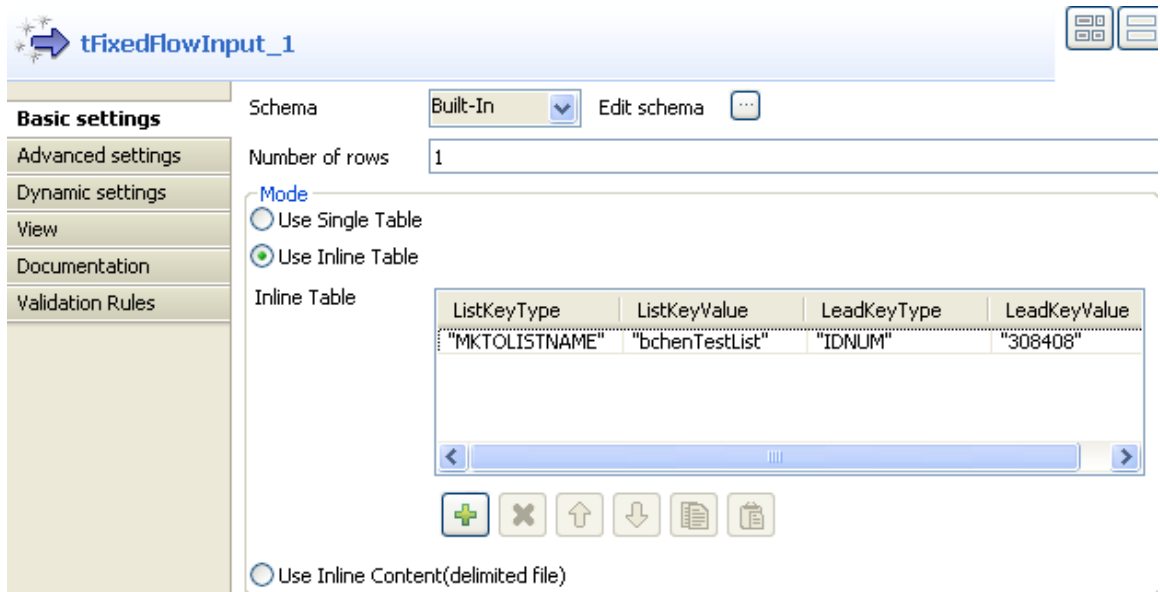

### Setting up the Job

1. Drop **tMarketoListOperation**, **tFixedFlowInput** and **tLogRow** onto the design workspace.
2. Connect **tFixedFlowInput** to **tMarketoListOperation** using a **Row > Main** connection.
3. Connect **tMarketoListOperation** to **tLogRow** using a **Row > Main** connection.

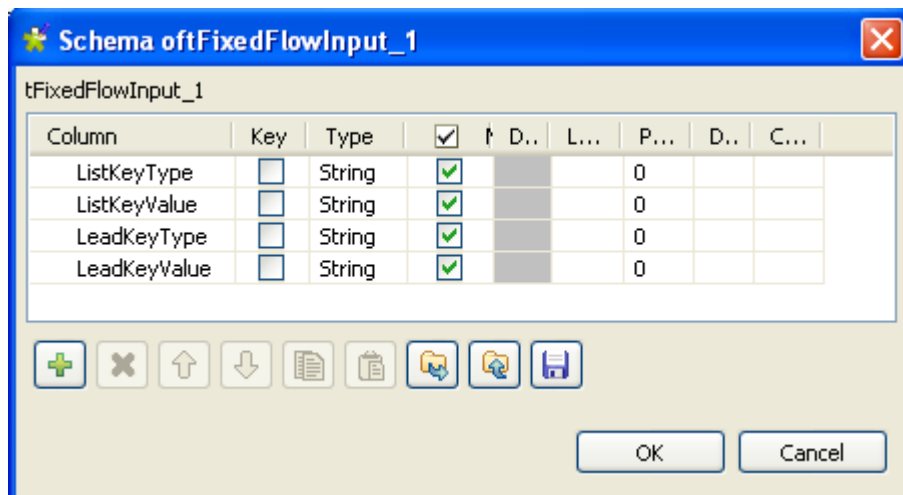

### Configuring the input component

1. Double-click **tFixedFlowInput** to define the component properties in its **Basic settings** view.

- Click the three-dot button next to **Edit schema** to set the schema manually.

- Click the plus button to add four columns: *ListKeyType*, *ListKeyValue*, *LeadKeyType* and *LeadKeyValue*. Keep the settings as default. Then click **OK** to save the settings.
- In the **Mode** area, select **Use Inline Table**.
- Click the plus button to add a new line and fill the line with respective values. In this example, these values are: *MKTOLISTNAME* for **ListKeyType**, *bchenTestList* for **ListKeyValue**, *IDNUM* for **LeadKeyType** and *308408* for **LeadKeyValue**.

## Configuring tMarketoListOperation

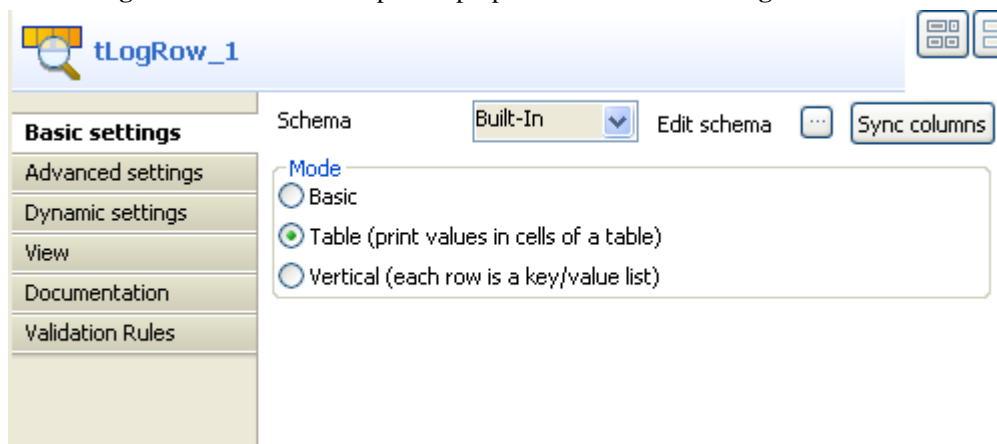

- Double-click **tMarketoListOperation** to define the component properties in its **Basic settings** view.

2. Click the **Sync columns** button to retrieve the schema defined in **tFixedFlowInput**.
3. Type in *1* in the **Number of rows** field.
4. Fill the **Endpoint address** field with the URL of the Marketo Web server. In this example, it is *https://na-c.marketo.com/soap/mktows/1\_5*.  
  
Note that the URL used in this scenario is for demonstration purpose only.
5. Fill the **Secret key** field with encrypted authentication code assigned by Marketo. In this example, it is *464407637703554044DD11AA2211998*.
6. Fill the **Client Access ID** field with the user ID. In this example, it is *mktodemo41\_785133934D1A219*.
7. From the **Operation** list, select **addTo**.
8. Type in the limit of query timeout in the **Timeout** field. In this example, use the default number: *60000*.

## Job Execution

1. Double-click **tLogRow** to define the component properties in its **Basic settings** view.

2. Click the **Sync columns** button to retrieve the schema defined in **tMarketoListOperation**.
3. In the **Mode** area, select **Table**.
4. Save your Job and press **F6** to execute it.

```
Starting job MarketoListOperation at 17:30 12/05/2011.
[statistics] connecting to socket on port 3497
[statistics] connected
-----+-----+-----+-----+-----
tLogRow_1
-----+-----+-----+-----+-----
ListKeyType | ListKeyValue | LeadKeyType | LeadKeyValue | Success
-----+-----+-----+-----+-----
MKTOLISTNAME | bchenTestList | IDNUM | 308408 | true
-----+-----+-----+-----+-----
[statistics] disconnected
Job MarketoListOperation ended at 17:30 12/05/2011. [exit
code=0]
```

The result of adding a lead record to a list in Marketo DB is displayed on the **Run** console.

# tMarketoOutput

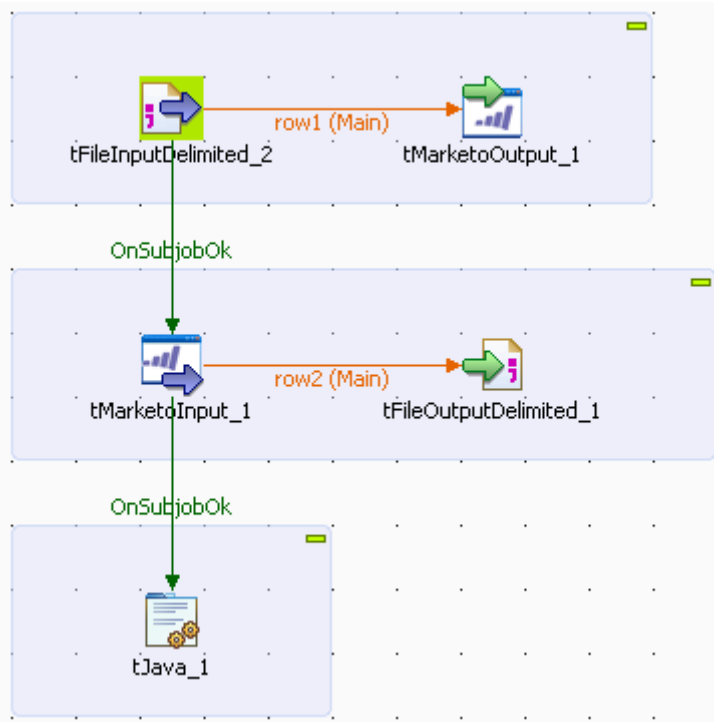

## tMarketoOutput Properties

|                         |                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Limitation</b>        | n/a                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Scenario: Data transmission between Marketo DB and an external system

The following scenario describes a five-component Job that inserts Lead records into Marketo database and retrieves these records from Marketo database to a local file. Upon completing the data accessing, the Job displays the number of relevant API calls on the **Run** console.

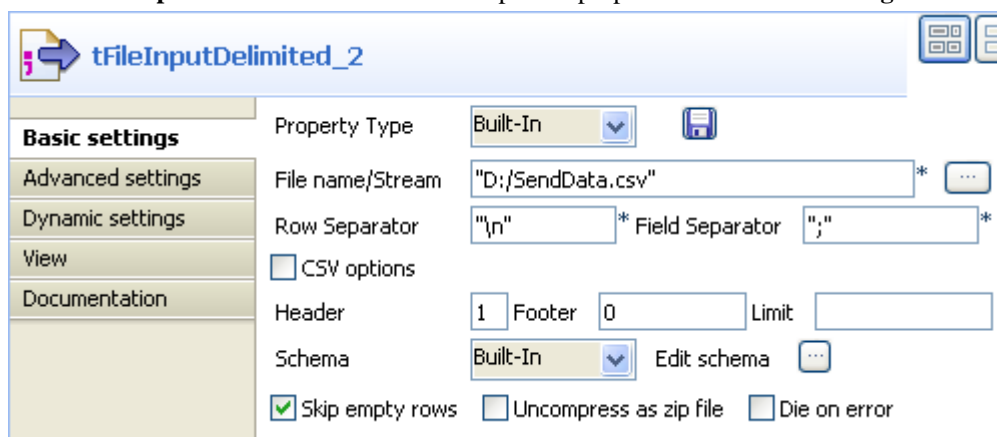

## Setting up the Job

1. Drop **tMarketoOutput**, **tMarketoInput**, **tFileInputDelimited**, **tFileOutputDelimited** and **tJava** from the **Palette** onto the design workspace.
2. Connect **tFileInputDelimited** to **tMarketoOutput** using a **Row > Main** connection.
3. Connect **tMarketoInput** to **tFileOutputDelimited** using a **Row > Main** connection.
4. Connect **tFileInputDelimited** to **tMarketoInput** using a **Trigger > OnSubjectOk** connection.
5. Connect **tMarketoInput** to **tJava** using a **Trigger > OnSubjectOk** connection.

## Configuring tFileInputDelimited

1. Double-click **tFileInputDelimited** to define the component properties in its **Basic settings** view.

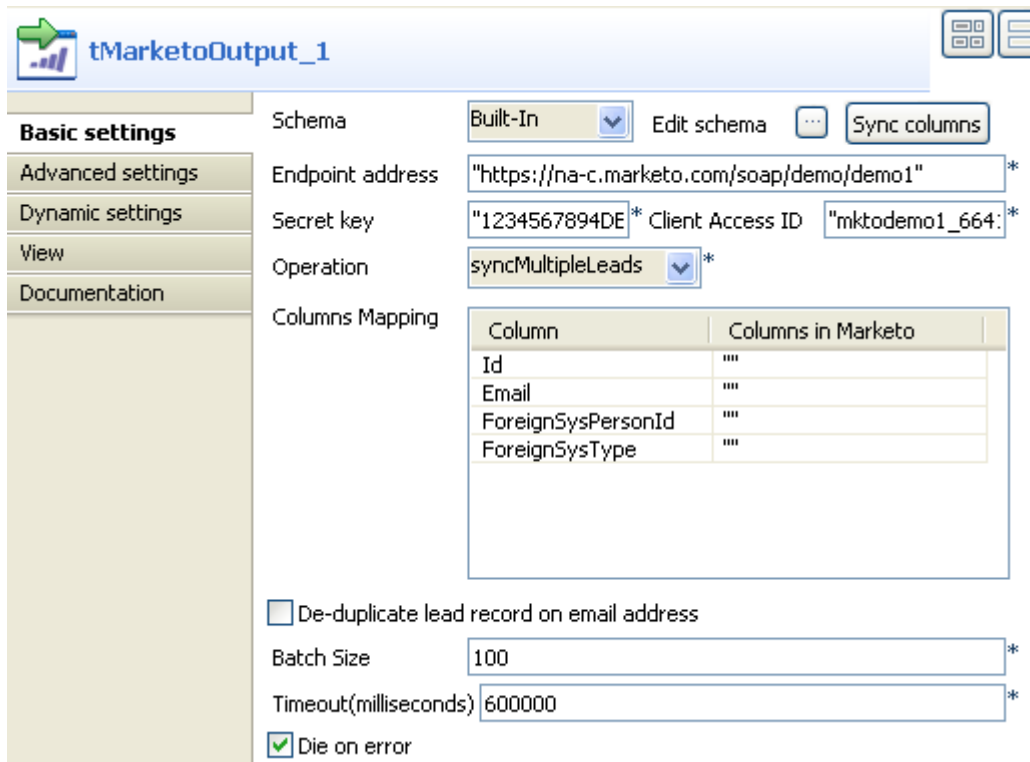

- Click the three-dot button next to the **File name/Stream** field to select the source file for data insertion. In this example, it is *D:/SendData.csv*.
- Click the three-dot button next to **Edit schema** to set the schema manually.

- Click the plus button to add four columns: *Id*, *Email*, *ForeignSysPersonId* and *ForeignSysType*. Set the **Type** of *Id* to Integer and keep the rest as default. Then click **OK** to save the settings.
- Type in *l* in the **Header** field and keep the other settings as default.

## Configuring tMarketoOutput

- Double-click **tMarketoOutput** to define the component properties in its **Basic settings** view.

- Click the **Sync columns** button to retrieve the schema defined in **tFileInputDelimited** and fill the **Endpoint address** field with the URL of the Marketo Web server. In this example, it is *https://na-c.marketo.com/soap/demo/demo1*.

Note that the URL used in this scenario is for demonstration purpose only.

- Fill the **Secret key** field with encrypted authentication code assigned by Marketo. In this example, it is *1234567894DEMOONLY987654321*.
- Fill the **Client Access ID** field with the user ID. In this example, it is *mktodemo1\_1234567894DEMOONLY987654321*.
- Select **syncMultipleLeads** from the **Operation** list and type in the limit of query timeout in the **Timeout** field. In this example, use the default number: *600000*.

## Configuring tMarketoInput

- Double-click **tMarketoInput** to define the component properties in its **Basic settings** view.

The screenshot shows the configuration window for the **tMarketoInput\_1** component. The **Basic settings** tab is selected. The configuration includes:

- Endpoint address:** "https://na-c.marketo.com/soap/demo/demo1"
- Secret key:** "1234567894DEMOONLY987654321"
- Client Access ID:** "mktodemo1\_66419D3P"
- Operation:** getLead
- Schema:** Built-In
- Columns Mapping:**

| Column             | Columns in Marketo |
|--------------------|--------------------|
| Id                 | ""                 |
| Email              | "test@talend"      |
| ForeignSysPersonId | ""                 |
| ForeignSysType     | ""                 |
- LeadKey type:** EMAIL
- LeadKey value:** "test@talend.com"
- Timeout(milliseconds):** 600000
- Die on error:**

- From the **Operation** list, select **getLead**.
- In **Columns Mapping** area, type in *test@talend.com* in **Columns in Marketo** column to set the **Email** column.

Note that all the data used in this scenario is for demonstration purpose only.

- From the **LeadKey type** list, select **EMAIL** and fill the **LeadKey value** field with *test@talend.com*.
- Keep the rest of the settings as the corresponding settings in **tMarketoOutput**.

## Configuring tFileOutputDelimited

- Double-click **tFileOutputDelimited** to define the component properties in its **Basic settings** view.

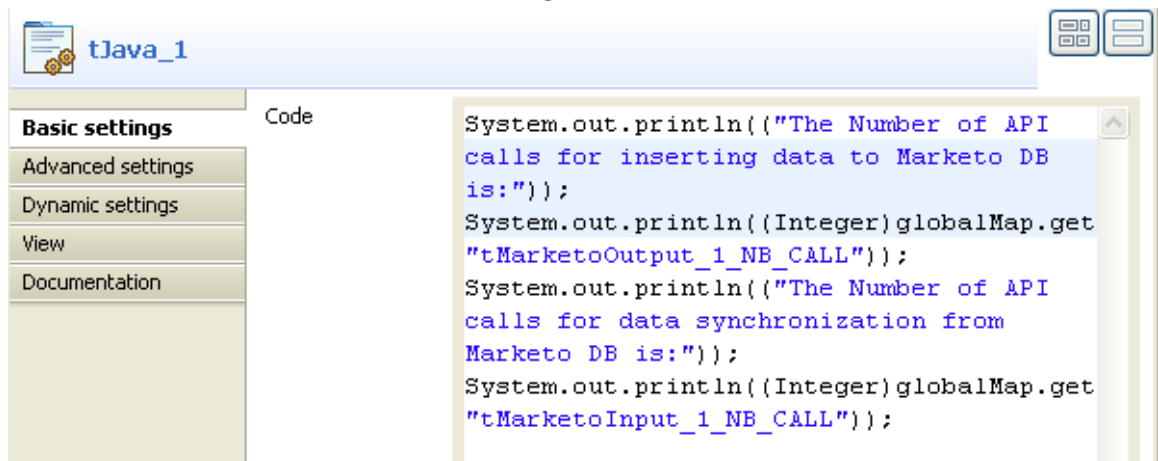

2. Click the three-dot button next to the **File name** field to synchronize data to a local file. In this example, it is *D:/ReceiveData.csv*.
3. Click the **Sync columns** button and keep the rest of the settings as default.

## Using Java scripts to count API calls

1. Double-click **tJava** to add code in its **Basic settings** view.

2. In the **Code** field, type in following code to count the number of API calls throughout the data operations:

```
System.out.println("The Number of API calls for inserting
data to Marketo DB is:");
System.out.println((Integer)globalMap.get("tMarketoOutput_1_NB_CALL"));
System.out.println("The Number of API calls for data synchronization
from Marketo DB is:");
System.out.println((Integer)globalMap.get("tMarketoInput_1_NB_CALL"));
```

## Job execution

1. Save your Job.
2. Press **F6** to execute it.

```
Id;Email;ForeignSysPersonId;ForeignSysType
308434;;;
308436;;;
308435;;;
308431;;;
308432;;;
308433;;;
```

The inserted lead records in the Marketo DB are synchronized to *D:/ReceiveData.csv*.  
*Starting job io at 18:03 25/03/2011.*

```
[statistics] connecting to socket on port 3829
[statistics] connected
The Number of API calls for inserting data to
Marketo DB is:
1
The Number of API calls for data synchronization
from Marketo DB is:
1
[statistics] disconnected
Job io ended at 18:03 25/03/2011. [exit code=0]
```

The number of API calls throughout each data operation is displayed on the **Run** console.

| <b>Limitation</b>        | n/a                                                                 |                                                                                                                                                                                                                                                                                                                                                                                   |

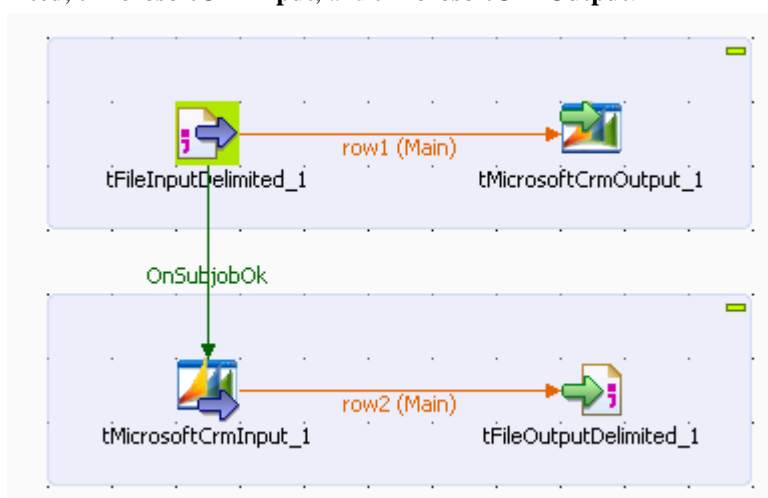

## Scenario: Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows

This scenario describes a four-component Job which aims at writing the data included in a delimited input file in a custom entity in a MicrosoftCRM database. It then extracts specified rows to an output file using the conditions set on certain input columns.

 *If you want to write in a CustomEntity in Microsoft CRM database, make sure to name the columns in accordance with the naming rule set by Microsoft, that is "name\_columnname" all in lower case.*

### Setting up the Job

- Drop the following components from the **Palette** to the design workspace: **tFileInputDelimited**, **tFileOutputDelimited**, **tMicrosoftCrmInput**, and **tMicrosoftCrmOutput**.

- Connect **tFileInputDelimited** to **tMicrosoftCrmOutput** using a **Row Main** connection.

3. Connect **tMicrosoftCrmInput** to **tFileOutputDelimited** using a **Row Main** connection.
4. Connect **tFileInputDelimited** to **tMicrosoftCrmInput** using **OnSubjobOk** connection.

## Configuring tFileInputDelimited

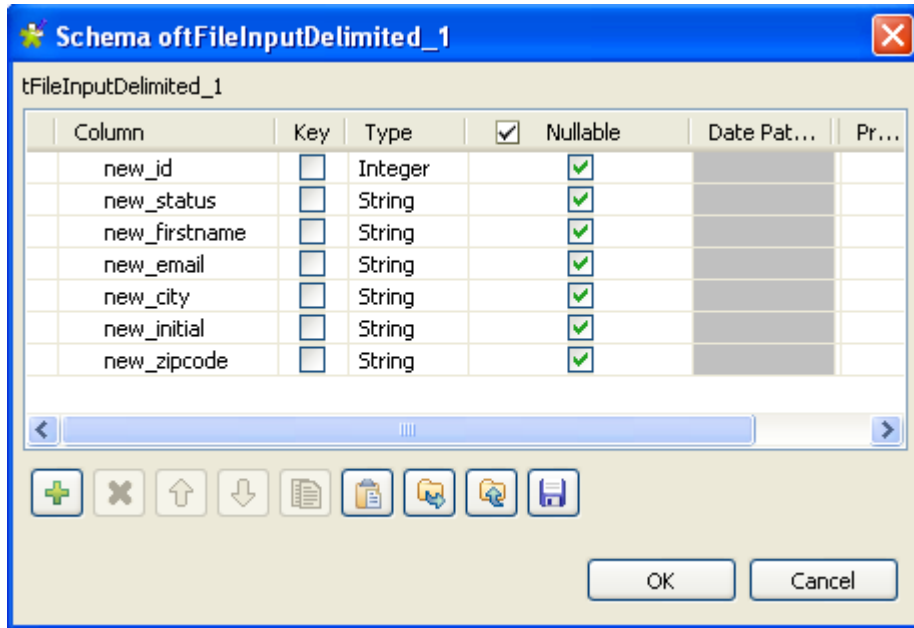

1. Double-click **tFileInputDelimited** to display its **Basic settings** view and define its properties

The screenshot shows the configuration window for the **tFileInputDelimited** component. The **Basic settings** tab is selected. The **Property Type** is set to **Built-In**. The **File name/Stream** is `"D:/TDQ_builds/input/CustomerInfo.txt"`. The **Row Separator** is `"\n"` and the **Field Separator** is `","`. The **Header** is `0`, **Footer** is `0`, and **Limit** is empty. The **Schema** is **Built-In**. There are checkboxes for **Skip empty rows** (checked), **Uncompress as zip file**, and **Die on error**.

2. Set the **Property Type** to **Repository** if you have stored the input file properties centrally in the **Metadata** node in the **Repository** tree view. Otherwise, select **Built-In** and fill the fields that follow manually. In this example, property is set to **Built-In**.
3. Click the three-dot button next to the **File Name/Input Stream** field and browse to the delimited file that holds the input data. The input file in this example contains the following columns: *new\_id*, *new\_status*, *new\_firstname*, *new\_email*, *new\_city*, *new\_initial* and *new\_zipcode*.

```
new_id;new_status;new_firstname;new_email;new_city;new_initial;new_zipcode
1;married;Paul;pnewman@comp.com;New York;P.M;55677
2;single;Raul;pnewman@comp.com;New York;R.L;55677
3;single;Mary;mnewman@comp.com;Chicago;M.B;66898
4;married;John;jnewman@comp.com;Chicago;J.M;66898
5;single;Martin;mnewman@comp.com;Sunnyvale,M.P;33662
6;married;Janet;jnewman@comp.com;Sunnyvale,J.P;33662
7;married;Harry;hnewman@comp.com;New York;H.M;55677
8;married;Jerry;jnewman@comp.com;New York;J.M;55677
9;married;Alice;anewman@comp.com;New York;A.M;55677
10;single;Jack;jnewman@comp.com;New York;J.M;55677
```

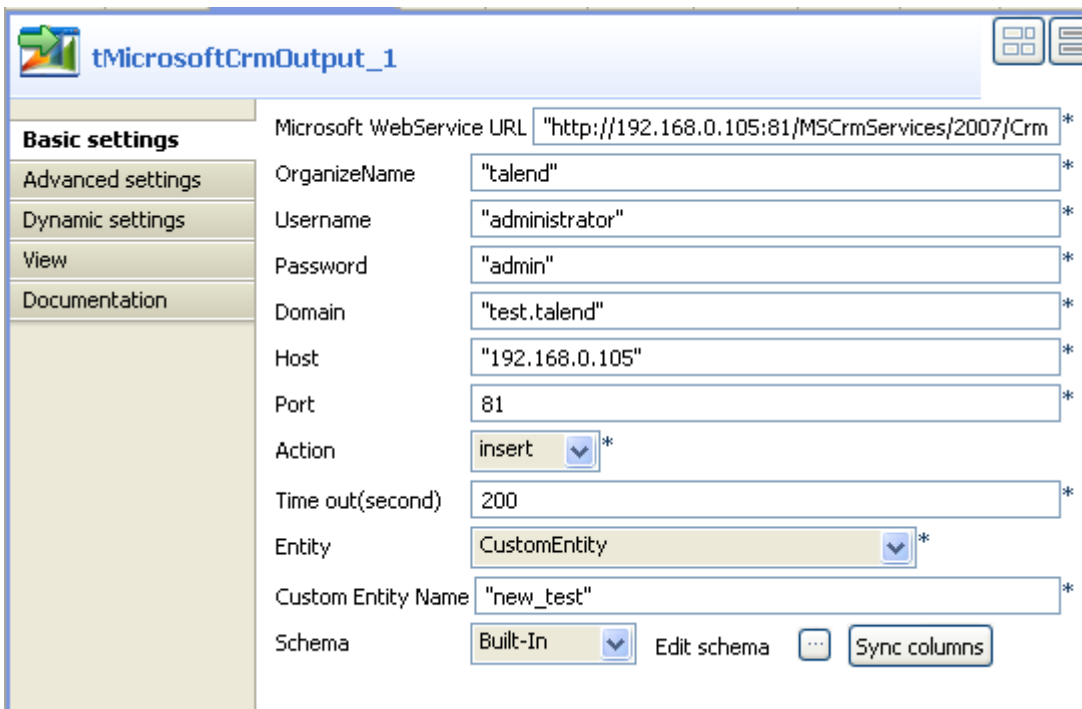

4. In the **Basic settings** view, define the **Row Separator** allowing to identify the end of a row. Then define the **Field Separator** used to delimit fields in a row.
5. If needed, define the header, footer and limit number of processed rows in the corresponding fields. In this example, the header, footer and limits are not set.
6. Click **Edit schema** to open a dialog box where you can define the input schema you want to write in Microsoft CRM database.

7. Click **OK** to close the dialog box.

## Configuring tMicrosoftCrmOutput

1. Double-click **tMicrosoftCrmOutput** to display the component **Basic settings** view and define its properties.

2. Enter the Microsoft Web Service URL as well as the user name and password in the corresponding fields.
3. In the **OrganizeName** field, enter the name that is given the right to access the Microsoft CRM database.
4. In the **Domain field**, enter the domain name of the server on which Microsoft CRM is hosted, and then enter the host IP address and the listening port number in the corresponding fields.

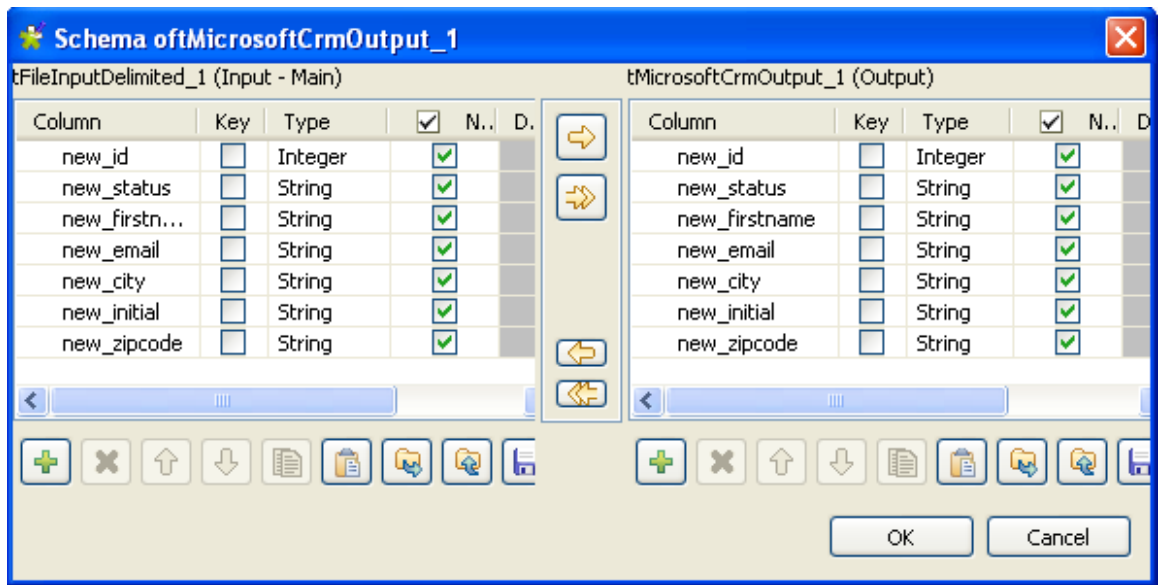

5. In the **Action** list, select the operation you want to carry on. In this example, we want to insert data in a custom entity in Microsoft Crm.
6. In the **Time out** field, set the amount of time (in seconds) after which the Job will time out.
7. In the **Entity** list, select one among those offered. In this example, *CustomEntity* is selected.

If *CustomEntity* is selected, a **Custom Entity Name** field displays where you need to enter a name for the custom entity.

The **Schema** is then automatically set according to the entity selected. If needed, click **Edit schema** to display a dialog box where you can modify this schema and remove the columns that you do not need in the output.

8. Click **Sync columns** to retrieve the schema from the preceding component.

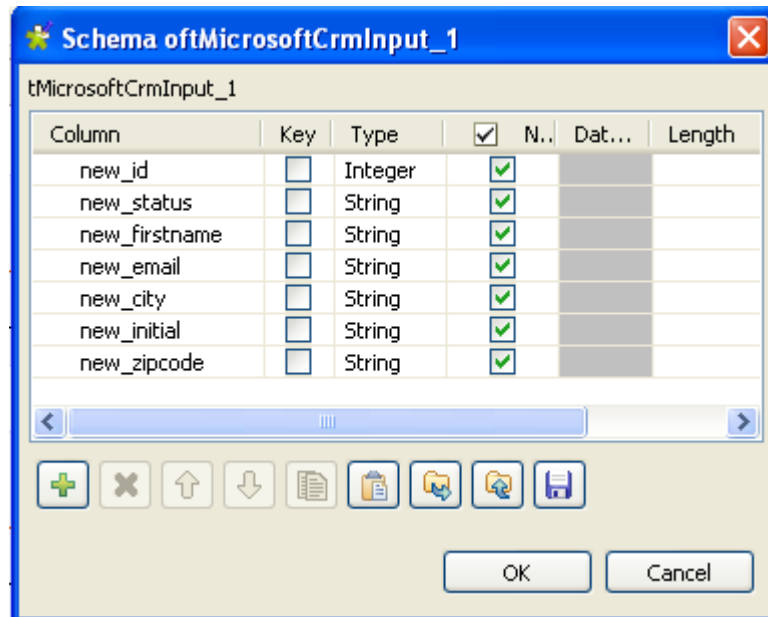

## Configuring tMicrosoftCrmInput

1. Double-click **tMicrosoftCrmInput** to display the component **Basic settings** view and define its properties.

| Input column | Operator    | Value      |
|--------------|-------------|------------|
| new_city     | Equal       | "New York" |
| new_id       | GreaterThan | "2"        |

2. Set the **Property Type** to **Repository** if you have stored the input file properties centrally in the **Metadata** node in the **Repository** tree view. Otherwise, select **Built-In** and fill the fields that follow manually. In this example, property is set to **Built-In**.
3. Enter the Microsoft Web Service URL as well as the user name and password in the corresponding fields and enter the name that is given the right to access the Microsoft CRM database in the **OrganizeName** field.
4. In the **Domain** field, enter the domain name of the server on which Microsoft CRM is hosted, and then enter the host IP address and the listening port number in the corresponding fields.
5. In the **Time out** field, set the amount of time (in seconds) after which the Job will time out.
6. In the **Entity** list, select the one among those offered you want to connect to. In this example, *CustomEntity* is selected.
7. The **Schema** is then automatically set according to the entity selected. But you can modify it according to your needs. In this example, you should set the schema manually since you want to access a custom entity. Copy the seven-column schema from **tMicrosoftCrmOutput** and paste it in the schema dialog box in **tMicrosoftCrmInput**.

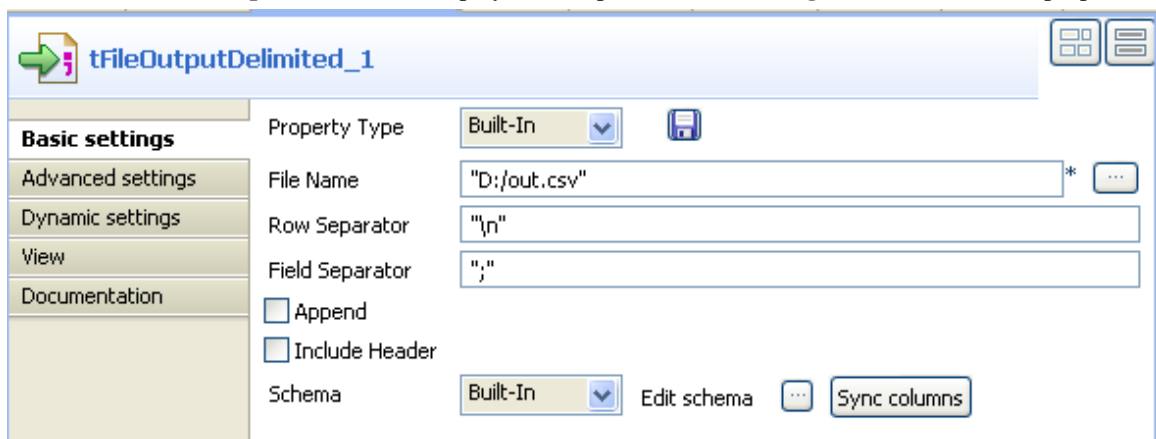

8. Click **OK** to close the dialog box. You will be prompted to propagate changes. Click **Yes** in the popup message.
9. In the **Basic settings** view, select **And** or **Or** as the logical operator you want to use to combine the conditions you set on the input columns. In this example, we want to set two conditions on two different input columns and we use **And** as the logical operator.
10. In the **Condition** area, click the plus button to add as many lines as needed and then click in each line in the **Input column** list and select the column you want to set condition on. In this example, we want to set conditions on two columns, *new-city* and *new\_id*. We want to extract all customer rows whose city is equal to “New York” and whose id is greater than 2.
11. Click in each line in the **Operator** list and select the operator to bind the input column with its value, in this example **Equal** is selected for *new-city* and **Greater Than** for *new\_id*.
12. Click in each line in the **Value** list and set the column value, New York for *new-city* and 2 for *new\_id* in this example. You can use a fixed or a context value in this field.

## Configuring tFileOutputDelimited

1. Double-click **tFileOutputdelimited** to display the component **Basic settings** view and define its properties.

Scenario: Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows

---

2. Set **Property Type** to **Built-In** and then click the three-dot button next to the **File Name** field and browse to the output file.
3. Set row and field separators in the corresponding fields.
4. Select the **Append** check box if you want to add the new rows at the end of the records.
5. Select the **Include Header** check box if the output file includes a header.
6. Click **Sync columns** to retrieve the schema from the preceding component.

## Job execution

Save the Job and press **F6** to execute it.

|   | A  | B       | C     | D                | E                  |

| <b>Usage</b>             | This component is used as an output component. An Input component is required. |                                                                                                                |
| <b>Limitation</b>        | n/a                                                                            |                                                                                                                |

## Scenario 1: Inserting data in a defined table in a MicrosoftAX server

*Before being able to use this component, make sure that you install and launch the MicrosoftAX server correctly.*

This Java scenario describes a two-component Job that uses **tMSAXOutput** to insert four columns in a defined table in a MicrosoftAX server after it alters values in one of the inserted columns.

### Setting up the Job

1. Drop **tFixedFlowInput** and **tMSAXOutput** from the **Palette** to the design workspace.
2. Connect the two components together using a **Row > Main** connection.

### Configuring tFixedFlowInput

1. Double-click **tFixedFlowInput** to display its **Basic settings** view and define the component properties.

| Column | Value               |
|--------|---------------------|
| name   | "Bryant Park"       |
| city   | "new york"          |
| street | "Midtown Manhattan" |

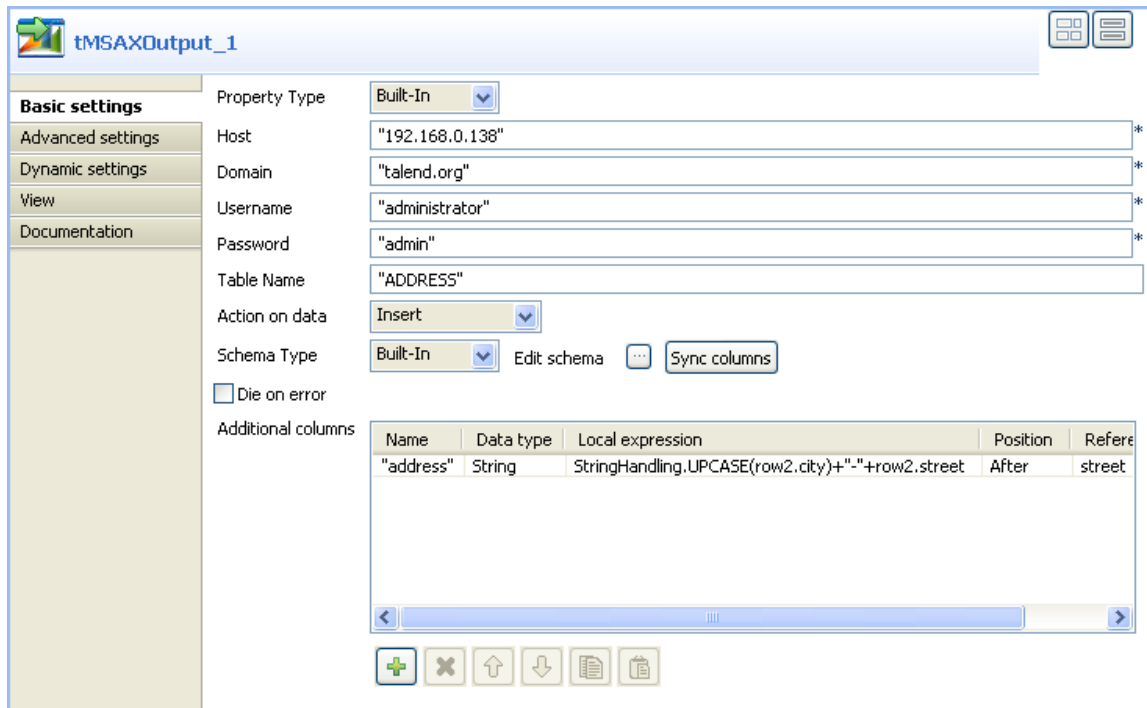

2. Set **Schema type** to **Built-in** and click the three-dot button next to **Edit schema** to display a dialog box where you can define the input schema.
3. Click the plus button and add the input schema columns, three in this example: *name*, *city* and *street*.
4. Click **OK** to close the dialog box and accept propagating the changes when prompted by the system.

The three schema columns display automatically in the **Values** list.

5. Click in the **Value** column and enter a value for each of the input columns.

## Configuring tMSAXOutput

1. Double-click **tMSAXOutput** to open its **Basic settings** view and define the component properties.

2. Set **Property type** to **Built-in**.
3. In the **Host** field, type in the IP address of the MicrosoftAX server and type in the domain name on which the MicrosoftAX server is hosted in the **Domain** field.
4. Enter your username and password for the server in the corresponding fields and enter the name of the table you want to write data in the **Table Name** field, *ADDRESS* in this example.
5. In the **Action on data** list, select the action you want to carry on, **Insert** in this example.
6. Click **Sync columns** to retrieve the schema from the preceding component.

In this example, we want to retrieve the three input columns: *name*, *city* and *street* and write the data included in the three input columns in the MicrosoftAX server without any changes.

If needed, click the three-dot button next to **Edit Schema** to verify the retrieved schema.

7. In the **Additional columns** list, click the plus button to add one line where you can define parameters for the new column to add to the row you want to write in the *ADDRESS* table.
8. Set a name, a data type, a position and a reference column in the corresponding columns for the line you added.

In this example, we want to add a new column we call “*address*” after the *street* column.

- Click in the **Local expression** column and press **Ctrl + space** on your keyboard to open the context variable list and select: `StringHandling.UPCASE(row2.city)+"-"+row2.street`. This expression will write the city name initially capped followed by the street name to form the address of *Bryant park*. Thus the address column in this example will contain the string: *New York-Midtown Manhattan*.

## Job execution

- Save your Job and press **F6** to execute it.

**tMSAXOutput** inserts in the *ADDRESS* table in the MicrosoftAX server a row that holds the three input columns, *name*, *city* and *street* in addition to the new *address* column that combines the city name and the street name.

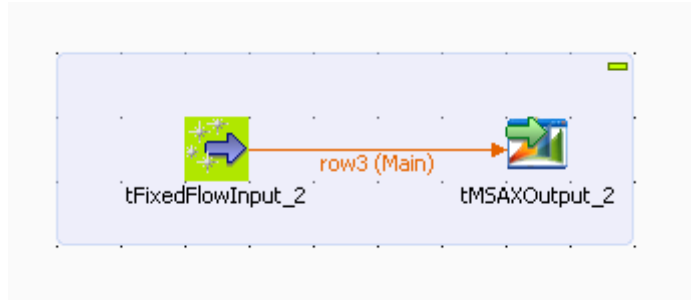

## Scenario 2: Deleting data from a defined table in a MicrosoftAX server

*Before being able to use this component, make sure that you install and launch the MicrosoftAX server correctly.*

This Java scenario describes a two-component Job that uses **tMSAXOutput** to delete from a defined table in a MicrosoftAX server all rows that do not match the data included in a key column.

In this example, the input schema we use is an *address* column that holds the following data: *New York-Midtown Manhattan*. We want to delete from the MicrosoftAX server all addresses that are not identical with this one.

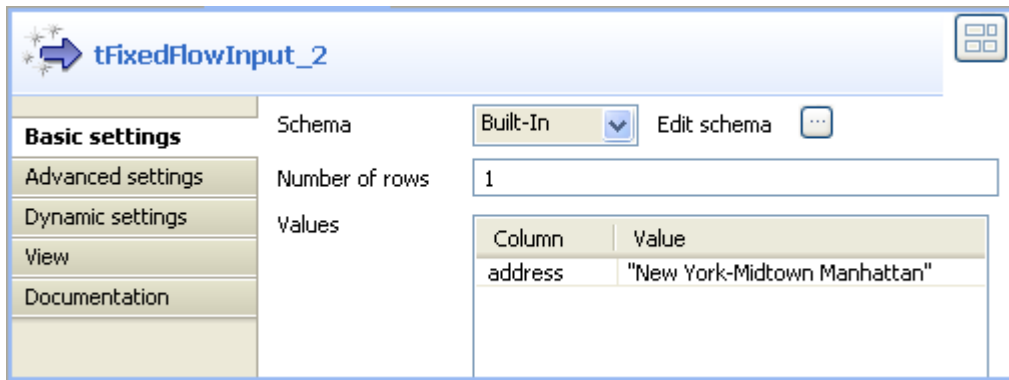

## Setting up the Job

- Drop **tFixedFlowInput** and **tMSAXOutput** from the **Palette** to the design workspace.
- Connect the two components together using a **Row > Main** connection.

## Configuring tFixedFlowInput

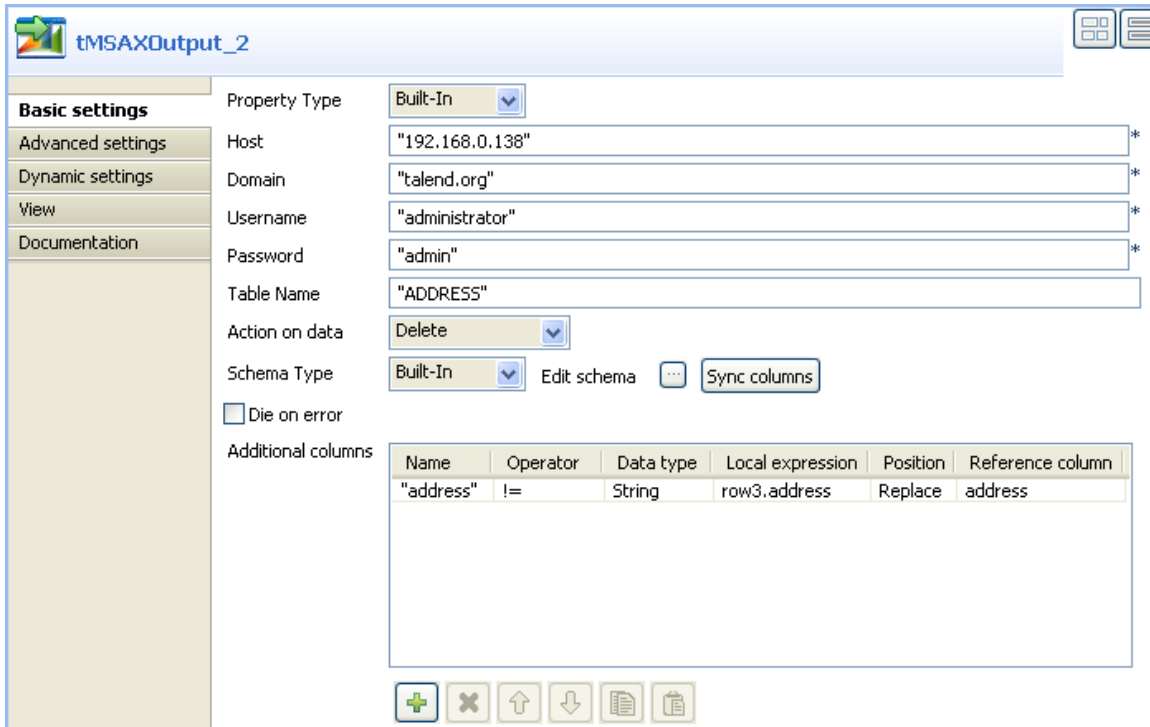

- Double-click **tFixedFlowInput** to display its **Basic settings** view and define the component properties.

2. Set **Schema type** to **Built-in** and click the three-dot button next to **Edit schema** to display a dialog box where you can define the input schema.
3. Click the plus button and add the input schema columns, *address* in this example.
4. Click **OK** to close the dialog box. The schema column displays automatically in the **Values** list.
5. Click in the **Value** column and enter a value for the input column.

## Setting up the connection to the MicrosoftAX server

1. Double-click **tMSAXOutput** to open its **Basic settings** view and define the component properties.

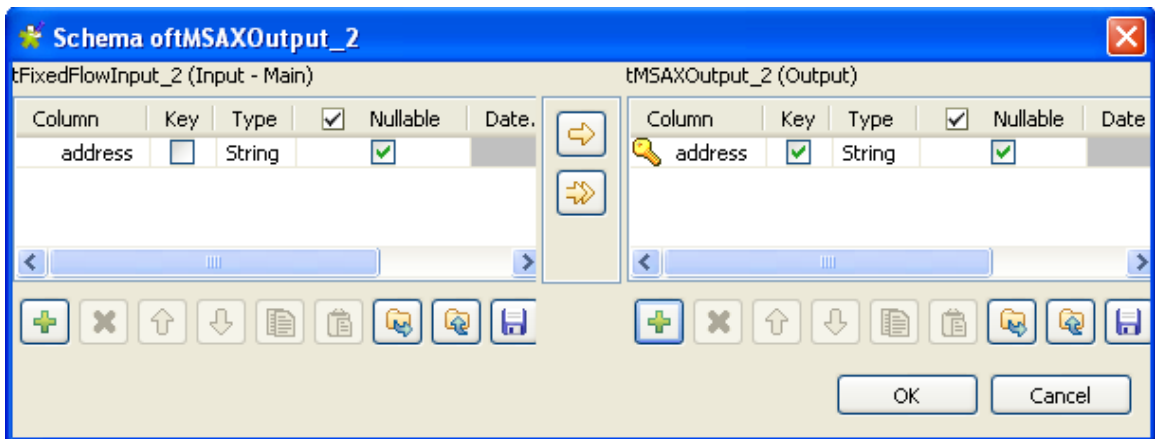

2. Set **Property type** to **Built-in**.
3. In the **Host** field, type in the IP address of the MicrosoftAX server.
4. In the **Domain** field, type in the domain name on which the MicrosoftAX server is hosted.
5. Enter your username and password for the server in the corresponding fields.

- In the **Table Name** field, enter the name of the table you want to delete data from, *ADDRESS* in this example.

## Defining the action on data

- In the **Action on data** list, select the action you want to carry on, **Delete** in this example.
- Click **Sync columns** to retrieve the schema from the preceding component. In this example, we want to retrieve the input column: *address*.
- Click the three-dot button next to **Edit Schema** to open a dialog box where you can verify the retrieved schema.

- In the output schema, select the **Key** check box next to the column name you want to define as a key column, and then click **OK** to validate your changes and close the dialog box.

When you select **Delete** as an action on data, you must always define the **Reference column** as a key column in order for **tMSAXOutput** to delete rows based on this key column.

- In the **Additional columns** list, click the plus button to add one line and define the parameters the component will use as basis for the delete operation.
- Set a name, an operator, a data type, a local expression, a position and a reference column in the corresponding columns for the line you added.

In this example, we want to delete from the *ADDRESS* table in the MicrosoftAX server all rows in which the address column is not equal to the address in the key *address* column and that reads as the following: New York-Midtown Manhattan.

When you select **Delete** as an action on data, you must always set **Position** to **Replace**. Otherwise, all settings in the **Additional columns** will not be taken into account when executing your Job.

## Job execution

- Save your Job and press **F6** to execute it.

**tMSAXOutput** deletes from the *ADDRESS* table in the MicrosoftAX server all rows where the address string is not equal to the address in the key column.

|                         | <i>Edit Schema</i>                                                                                                                       | <p>A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.</p> <p>Click <b>Edit Schema</b> to make changes to the schema.</p> <p> If you make any changes, the schema will automatically become built-in.</p>                                                                                            |
|                         | <i>Endpoint address</i>                                                                                                                  | Type in the address of the Web service provided by the given Sage X3 Web server.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                         | <i>Username</i> and <i>Password</i>                                                                                                      | Type in the Web service user authentication data that you have defined for configuring the Sage X3 Web server.                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                         | <i>Language</i>                                                                                                                          | Type in the name of the X3 language code used to start a connection group.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                         | <i>Pool alias</i>                                                                                                                        | Type in the name of the connection pool that distributes the received requests to available connections. This name was given from the Sage X3 configuration console.                                                                                                                                                                                                                                                                                                                                                            |
|                         | <i>Request config</i>                                                                                                                    | <p>Type in the configuration string if you want to retrieve the debug or trace information. For example, the string could be:</p> <pre>RequestConfigDebug="adxwss .trace.on=on" ;</pre> <p>If you need use several strings, separate them with a &amp;, for example,</p> <pre>RequestConfigDebug="adxwss.trace .on=on&amp;adxwss.trace.size=16384" ;</pre> <p> <i>A third party tool is needed to retrieve this kind of information.</i></p> |

|                          |                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>Publication name</i>        | Type in the publication name of the published object, list or sub-program you want your Studio to access.                                                                                                                                                                                                                                                                                                                                                                  |
|                          | <i>Mapping</i>                 | Complete this table to map the variable elements of the object, the sub-program or the list set in the given Sage X3 Web server. The columns to be completed include:<br><br><b>Column:</b> the columns defined in the schema editor for this component. <b>Group ID:</b> the identifier of each variable element group. For example, a variable element group could represent one of attributes of an object. <b>Field name:</b> the field name of each variable element. |
|                          | <i>Query condition</i>         | Select this check box to set up the query condition(s). The columns to be completed include:<br><br><b>Key:</b> the names of the variable elements used as the key for data extraction.<br><br><b>Value:</b> the value of the given key field used to extract the corresponding data.                                                                                                                                                                                      |
|                          | <i>Limit</i>                   | Type in a number to indicate the maximum row count of the data to be extracted.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i> | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.                                                                                                                                                                                                                                                                                                                                                             |
| <b>Usage</b>             |                                | Usually used as a Start component. An output component is required.                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Limitation</b>        |                                | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Scenario: Using query key to extract data from a given Sage X3 system

This scenario describes a two-component Job used to extract one row of data from a given Sage X3 system. The object method is to be called, that means the variable elements of this object thus are attributes. The data used in this scenario can be found in the example provided by Sage X3.

### Setting up the Job

1. Drop the **tSageX3Input** component and the **tLogRow** components onto the workspace from **Palette**.
2. Connect the **tSageX3Input** component to the **tLogRow** component using a **Row > Main** link.

## Configuring the schema of tSageX3Input

1. Double-click **tSageX3Input** to set its properties in the **Basic Settings** view.

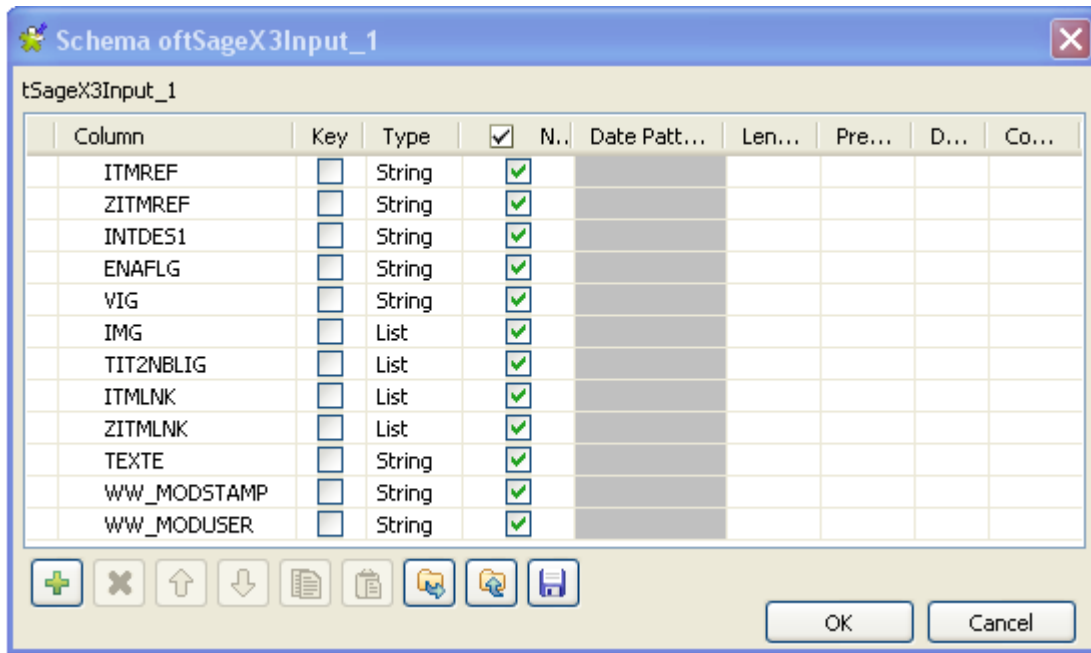

The screenshot shows the configuration window for the **tSageX3Input\_1** component. The **Basic settings** tab is active, displaying the following configuration:

- Schema:** Built-In (with an **Edit schema** button)
- Endpoint address:** "http://10.42.20.168:28880/adxwsvc/services/CAdxWebServiceXmlCC" \*
- User:** "ERP" \* **Password:** "" \*
- Language:** "FRA" \* **Pool alias:** "TALEND" \*
- Request config:** "" \*
- Publication name:** "ITMDET" \*
- Mapping:**

| Column      | Group ID | Field Name    |
|-------------|----------|---------------|
| ITMREF      | "TIT0_1" | "ITMREF"      |
| ZITMREF     | "TIT0_1" | "ZITMREF"     |
| INTDES1     | "TIT0_1" | "INTDES1"     |
| ENAF LG     | "TIT0_1" | "ENAF LG"     |
| VIG         | "TIT3_1" | "VIG"         |
| IMG         | "TIT3_1" | "IMG"         |
| TIT2NBLIG   | "TIT2_1" | "TIT2~NBLIG"  |
| ITMLNK      | "TIT2_1" | "ITMLNK"      |
| ZITMLNK     | "TIT2_1" | "ZITMLNK"     |
| TEXTE       | "TIT1_2" | "TEXTE"       |
| WW_MODSTAMP | "ADXTEC" | "WW_MODSTAMP" |
| WW_MODUSER  | "ADXTEC" | "WW_MODUSER"  |
- Query Condition**
- Conditions:**

| Key      | Value       |
|----------|-------------|
| "ITMREF" | "CONTS000!" |
- Limit:** 1 \*

2. In the **Schema** field, select **Built-In** and click the three-dot button next to **Edit schema** to open the schema editor.

3. In this editor, click the plus button 12 times beneath the schema table to add 12 rows into this table.
4. Type in the names you want to use for each row. In this example, these rows are named after the publication names of the object attributes set in the Sage X3 Web server. These columns are used to map the corresponding attribute fields in the Sage X3 system.
5. In the **Type** column, click the *IMG* row to display its drop-down list.
6. From the drop-down list, select **List** as this attribute appears twice or even more and do the same to switch the types of the *TIT2NBLIG* row, the *ITMLNK* row and the *ZITMLNK* row to **List** as well for the same reason.
7. Click **OK** to validate this change and accept the propagation prompted by a pop-up dialog box.

## Configuring the connection to the Sage X3 Web server

1. In the **Endpoint address** field, type in the URL address of the Web service provided by the Sage X3 Web server. In this example, it is *http://10.42.20.168:28880/adxwsvc/services/CAdxWebServiceXmlCC*
2. In the **User** field, type in the user name of the given Sage X3. In this example, it is *ERP*.
3. In the **Language** field, type in the name of the X3 language code used to start a connection group. In this example, it is *FRA*.
4. In the **Pool alias** field, type in the name of connection pool to be used. In this example, this connection pool is called *TALEND*.
5. In the **Publication name** field, type in the publication name of the object to be called. In this scenario, the publication name is *ITMDET*.

## Setting up the mapping and configuring the query condition

1. In the **Group ID** column and the **Field name** column of the **Mapping** table, type in values corresponding to the attribute group IDs and the attribute publication names defined in the Sage X3 Web server. In this example, the values are presented in the figure below.

| Column      | Group ID | Field Name     |
|-------------|----------|----------------|
| ITMREF      | "TIT0_1" | "ITMREF"       |
| ZITMREF     | "TIT0_1" | "ZITMREF"      |
| INTDES1     | "TIT0_1" | "INTDES1"      |
| ENAFLG      | "TIT0_1" | "ENAFLG"       |
| VIG         | "TIT3_1" | "VIG"          |
| IMG         | "TIT3_1" | "IMG"          |
| TIT2NBLIG   | "TIT2_1" | "TIT2~NBLIG"   |
| ITMLNK      | "TIT2_1" | "ITMLNK"       |
| ZITMLNK     | "TIT2_1" | "ZITMLNK"      |
| TEXTE       | "TIT1_2" | "TEXTE"        |
| WW_MODSTAMP | "ADXTEC" | "WW_MODSTA..." |
| WW_MODUSER  | "ADXTEC" | "WW_MODUSER"   |

In the **Mapping** table, the **Column** column has been filled automatically with the columns you created in the schema editor.

2. Select the **Query condition** check box to activate the **Conditions** table.
3. Under the **Conditions** table, click the plus button to add one row into the table.
4. In the **Key** column, type in the publication name associated with the object attribute you need to extract data from.
5. In the **Value** column, type in the value of the attribute you have selected as the key of the data extraction. In this scenario, it is *CONTS00059*, one of the product references.

## Job execution

1. Select **Built-In** as the **Schema** and click [...] next to **Edit schema** to open the schema editor.

| Key      | Value        |
|----------|--------------|
| "ITMREF" | "CONTS00059" |

2. Press **CTRL+S** to save your Job and **F6** to execute it.

The results are displayed on the **Run** console:

|                          | <i>Publication name</i>        | Type in the publication name of the published object, list or sub-program you want your Studio to access.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                          | <i>Action</i>                  | You can do any of the following operations on the data in a Sage X3 system:<br><br><b>Insert:</b> insert data<br><br><b>Update:</b> update data<br><br><b>Delete:</b> delete data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                          | <i>Mapping</i>                 | Complete this table to map the variable elements of the object, the list or the sub-program your Studio access. Only the elements you need to conduct the data action of your interest on are selected and typed in for the purpose of mapping. The columns to be completed include:<br><br><b>Column:</b> the columns defined in the schema editor for this component.<br><br><b>Key:</b> the variable element used as key for data insertion, update or deletion. Select the corresponding check box if a variable element is the key. <b>Group ID:</b> the identifier of each variable element group. For example, a variable element group could represent one of attributes of an object. <b>Field name:</b> the field name of each selected variable element. |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i> | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Usage</b>             |                                | Usually used as an output component. An input component is required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Limitation</b>        | n/a                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Scenario: Using a Sage X3 Web service to insert data into a given Sage X3 system

This scenario describes a two-component Job used to generate one row of data and insert the data into a given Sage X3 system. You can find the data used in this scenario in the example provided by Sage X3. The Sage X3 Web service is used to access an object.

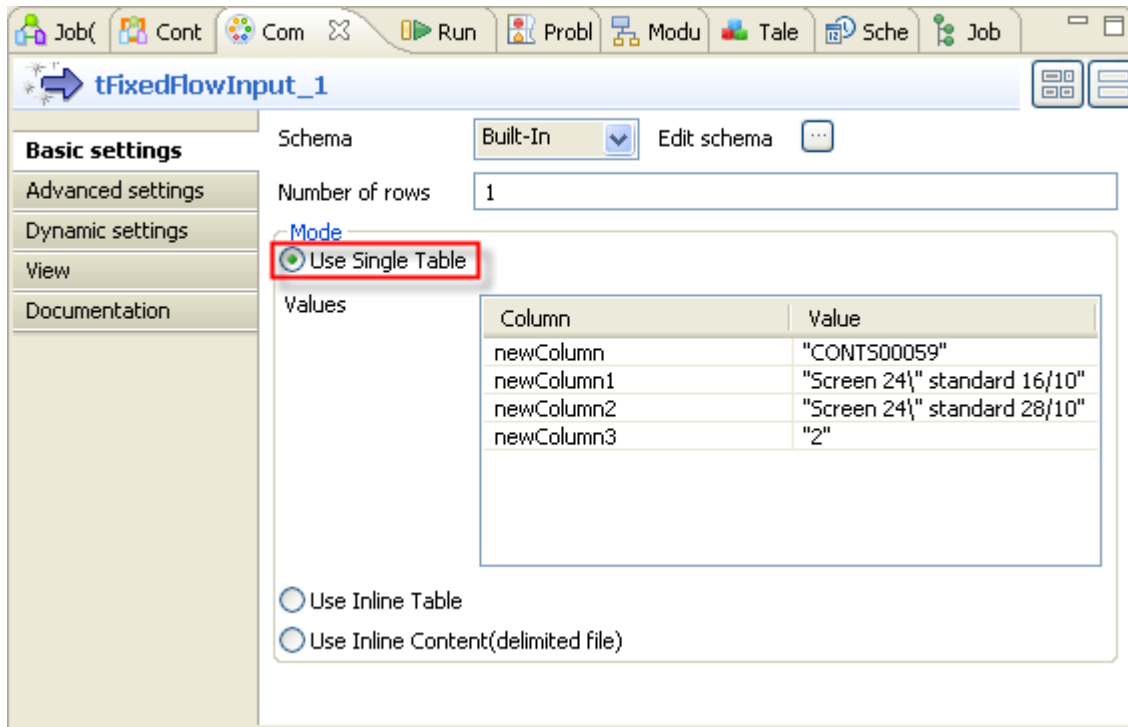

### Setting up the Job

1. Drop the **tFixedFlowInput** and the **tSageX3Output** components onto the workspace from **Palette**.

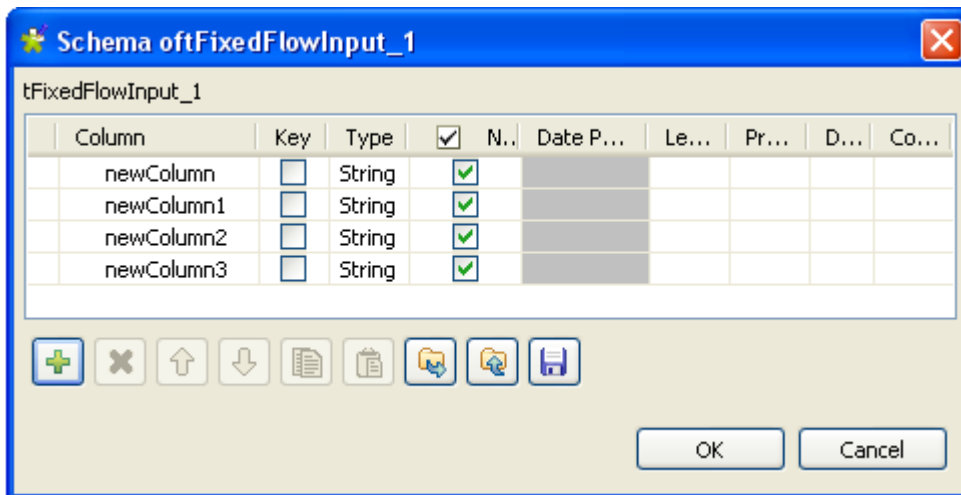

2. Connect the **tFixedFlowInput** component to the **tSageX3Output** component using a **Row > Main** connection.

## Configuring the schema for the input data

1. Double-click the **tFixedFlowInput** component to set its **Basic Settings** in the **Component** view

2. Click the three-dot button next to **Edit schema** to open the schema editor.

3. In the schema editor and then under the schema table, click the plus button four times to add four rows.
4. Click **OK** to validate this changes and then accept the propagation prompted by the pop-up dialog box. The four rows appear automatically in the **Values** table of the **Component** view.
5. In the **Values** table within the **Mode** area, type in the values for each of the four rows in the **Value** column. In this scenario, the values downward are:

CONTS00059, Screen 24\" standard 16/10, Screen 24\" standard 28/10, 2

These values in the Value column must be put between quotation marks.

## Setting up the connection to the Sage X3 Web server

1. Double-click **tSageX3Output** to set its properties from the **Basic Settings** view.

| Column     | <input type="checkbox"/> Key | Group ID | Field Name |
|------------|------------------------------|----------|------------|
| newColumn  | <input type="checkbox"/>     | "TITO_1" | "ITMREF"   |
| newColumn1 | <input type="checkbox"/>     | "TITO_1" | "ZITMREF"  |
| newColumn2 | <input type="checkbox"/>     | "TITO_1" | "INTDES1"  |
| newColumn3 | <input type="checkbox"/>     | "TITO_1" | "ENAF LG"  |

2. In the **Endpoint address** field, type in the URL address of the Web service provided by the Sage X3 Web server. In this example, it is `http://10.42.20.168:28880/adxwsvc/services/CAdxWebServiceXmlCC`
3. In the **User** field, type in the user name of the given Sage X3. In this example, it is `ERP`.
4. In the **Language** field, type in the name of the X3 language code used to start a connection group. In this example, it is `FRA`.
5. In the **Pool alias** field, type in the name of connection pool to be used. In this example, this connection pool is called `TALEND`.
6. In the **Publication name** field, type in the publication name of the object to be called. In this scenario, the publication name is `ITMDET`.
7. In the **Action** field, select **insert** from the drop-down list.

## Setting up the mapping

1. In the **Field name** column of the **Mapping** table, type in the field names of the attributes the selected data action is exercised on.

- In the **Group ID** column of the **Mapping** table, type in values corresponding to group IDs of the selected attributes. These IDs are defined in the Sage X3 Web server

| Column     | <input type="checkbox"/> Key | Group ID | Field Name |
|------------|------------------------------|----------|------------|
| newColumn  | <input type="checkbox"/>     | "TITO_1" | "ITMREF"   |
| newColumn1 | <input type="checkbox"/>     | "TITO_1" | "ZITMREF"  |
| newColumn2 | <input type="checkbox"/>     | "TITO_1" | "INTDES1"  |
| newColumn3 | <input type="checkbox"/>     | "TITO_1" | "ENAF LG"  |

In the **Mapping** table, the **Column** column has been filled automatically with the columns retrieved from the schema of the preceding component.

## Job execution

Press CTRL+S to save your Job and press **F6** to execute it.

To verify the data that you inserted in this scenario, you can use the **tSageX3Input** component to read the concerned data from the Sage X3 server.

For further information about how to use the **tSageX3Input** component to read data, see [the section called "Scenario: Using query key to extract data from a given Sage X3 system"](#).

# tSalesforceBulkExec

## tSalesforceBulkExec Properties

**tSalesforceOutputBulk** and **tSalesforceBulkExec** components are used together to output the needed file and then execute intended actions on the file for your Salesforce.com. These two steps compose the **tSalesforceOutputBulkExec** component, detailed in a separate section. The interest in having two separate elements lies in the fact that it allows transformations to be carried out before the data loading.

## Scenario: Recovering deleted data from the Salesforce server

This scenario describes a two-component Job that collects the deleted data over the past 5 days from the Salesforce server.

### Setting up the Job

1. Drop **tSalesforceGetDeleted** and **tLogRow** from the **Palette** onto the design workspace.
2. Connect the two components together using a **Row > Main** connection.

### Setting up the connection to the Salesforce server

1. Double-click **tSalesforceGetDeleted** to display its **Basic settings** view and define the component properties.

2. In the **Salesforce Webservice URL** field, use the by-default URL of the Salesforce Web service or enter the URL you want to access.
3. In the **Username** and **Password** fields, enter your login and password for the Web service.
4. From the **Module** list, select the object you want to access, **Account** in this example.

## Setting the search condition

1. From the **Schema** list, select **Repository** and then click the three-dot button to open a dialog box where you can select the repository schema you want to use for this component. If you have not defined your schema locally in the metadata, select **Built-in** from the **Schema** list and then click the three-dot button next to the **Edit schema** field to open the dialog box where you can set the schema manually.
2. In the **Start Date** and **End Date** fields, enter respectively the start and end dates for collecting the deleted data using the following date format: “yyyy-MM-dd HH:mm:ss”. You can collect deleted data over the past 30 days. In this example, we want to recover deleted data over the past 5 days.

## Job execution

1. Double-click **tLogRow** to display its **Basic settings** view and define the component properties.
2. Click **Sync columns** to retrieve the schema from the preceding component.
3. In the **Mode** area, select **Vertical** to display the results in a tabular form on the console.
4. Press **Ctrl+S** to save your Job and press **F6** to execute it.

*Starting job tSalesforceGetDeleted\_scenario at 17:17 25/06/2009.*

| <b>Usage</b>      | Usually used as a Start component. An output component is required. |                                                                                                                                    |
| <b>Limitation</b> | n/a                                                                 |                                                                                                                                    |

## Scenario: Using queries to extract data from a Salesforce database

This scenario describes a four-component Job used to extract specific sets of data from parent and child objects in a Salesforce database.

### Setting up the Job

1. Drop two **tSalesforceInput** components and two **tLogRow** components onto the workspace.
2. Connect each **tSalesforceInput** component to a **tLogRow** component using a **Row > Main** connection for each pair.
3. Connect **tSalesforceInput\_1** to **tSalesforceInput\_2** using an **OnSubjobOk** connection.

### Setting up the connection to the Salesforce server for the parent object

1. Double-click **tSalesforceInput\_1** to set its **Basic Settings** in the **Component** tab.

Property Type

Use an existing connection

Salesforce Webservice URL \*

Username \*

Password \*

Timeout(milliseconds)

Module \*

Schema

Manual input of SOQL query

Query

Query all records(include deleted records)

2. As the **Property Type**, select **Built-In**.
3. Enter the **Salesforce Webservice URL** of the database you want to connect to in the corresponding field.
4. Enter your authentication information in the corresponding **Username** and **Password** fields.
5. Enter the desired query **Timeout (milliseconds)** limit.

## Setting the query and the schema for the parent object

1. Select the **Module** (salesforce object) you want to query.
2. Select the **Manual input of SOQL Query** check box and enter your query scripts in the enabled **Query** field.  
The query scripts you enter should follow the SOQL syntax.
3. Select **Built-In** as the **Schema** and click [...] next to **Edit schema** to open the schema editor.

tSalesforceInput\_1

| Column                                                                                 | Key                                 | Type    | <input checked="" type="checkbox"/> | N.. | D... | L   | Precision | Default | Comment |
|----------------------------------------------------------------------------------------|-------------------------------------|---------|-------------------------------------|-----|------|-----|-----------|---------|---------|
|  Id | <input checked="" type="checkbox"/> | String  | <input checked="" type="checkbox"/> |     |      | 1.. | 0         |         |         |
| IsWon                                                                                  | <input type="checkbox"/>            | Boolean | <input checked="" type="checkbox"/> |     |      |     | 0         |         |         |
| FiscalYear                                                                             | <input type="checkbox"/>            | Integer | <input checked="" type="checkbox"/> |     |      |     | 0         |         |         |
| Opportunity_Account_Name                                                               | <input type="checkbox"/>            | String  | <input checked="" type="checkbox"/> |     |      |     |           |         |         |

In this example, the *IsWon* and *FiscalYear* columns in the query are located in the **Opportunity** module specified. The *Name* column is in a linked module called *Account*. To return a column from a linked module the correct syntax is to enter the name of the linked module, followed by the period character, then the name of the column of interest. Hence, the query required in this example is:

```
"SELECT IsWon, FiscalYear, Account.Name FROM Opportunity".
```

- Click the plus button to add a new column for the fields taken from the *Name* column in the *Account* module.
- Name this column *Opportunity\_Account\_Name* and click **OK** to save the changes.

To retrieve a column from a linked module, it is necessary to define the column in a particular manner in the **Edit schema** view. The correct syntax is: *NameofCurrentModule\_NameofLinkedModule\_NameofColumnofInterest*. Hence, in this example, the column must be named: *Opportunity\_Account\_Name*. If this syntax is not respected then the data from the linked table will not be returned.

## Setting up the connection to the Salesforce server for the child object

- Double-click **tSalesforceInput\_2** to set its **Basic settings** in the **Component** tab.

Property Type: Built-In

Use an existing connection

Salesforce Webservice URL: "https://www.salesforce.com/services/Soap/u/16.0"

Username: "cantoine@talend.com"

Password: "talendehmrEvHz2xZ8f2klmTCym50XU"

Timeout(milliseconds): 60000

Module: Case

Schema: Built-In

Manual input of SOQL query

Query: "SELECT Id, CaseNumber, Account.Name FROM Case"

Query all records(include deleted records)

- From the **Property Type** list, select **Built-In**.
- Enter the **Salesforce Webservice URL** of the database you want to connect to in the corresponding field.  
The query scripts you enter must follow the SOQL syntax.
- Enter your authentication information in the corresponding **Username** and **Password** fields.
- Enter the desired query **Timeout (milliseconds)** limit.

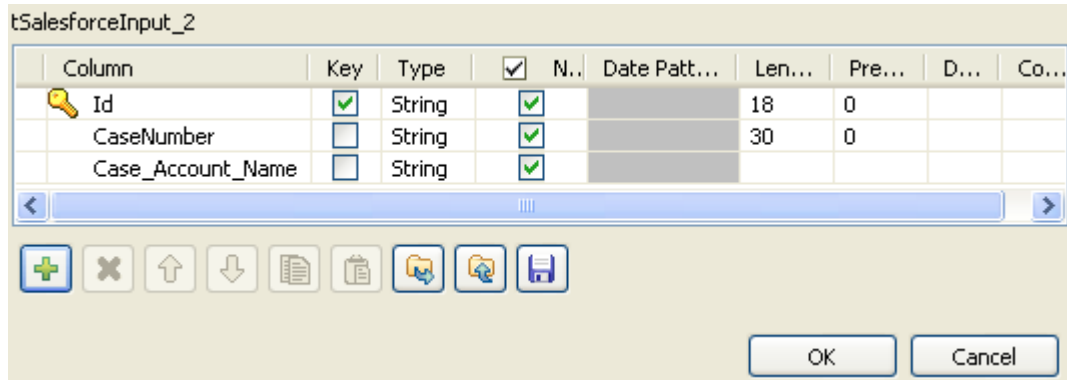

## Setting the query and the schema for the child object

- Select the **Module** (salesforce object) you want to query.
- Select the **Manual input of SOQL Query** check box and enter your query scripts in the enabled **Query** field.

In this example we want to extract the *Id* and *CaseNumber* fields from the *Case* module as well as the *Name* fields from the *Account* module. The query is therefore: .

```
"SELECT Id, CaseNumber, Account.Name FROM Case"
```

3. Select **Built-In** as the **Schema** and click [...] next to **Edit schema** to open the schema editor.

4. Click the plus button to add a new column for the fields taken from the *Name* column in the *Account* module.
5. Name this column *Case\_Account\_Name* and click **OK** to save the changes.

## Job execution

1. Click each **tLogRow** component and set their component properties in the **Basic settings** view as desired.

In this example, there is no need to modify the **tLogRow** settings.

2. Press **Ctrl+S** to save your Job and press **F6** to execute it.

The results are displayed in the **Run** tab:

|                         | <i>Use an existing connection</i>                                                                   | <p>Select this check box to use an established connection from <b>tSalesforceConnection</b>. Once you select it, the <b>Component list</b> field appear allowing you to choose the <b>tSalesforceConnection</b> component to be used.</p> <p>For more information on <b>tSalesforceConnection</b>, see <a href="#">the section called “tSalesforceConnection”</a>.</p> <p> When a Job contains the parent Job and the child Job, <b>Component list</b> presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, you can use <b>Dynamic settings</b> to share the intended connection. In this case, make sure that the connection name is unique and distinctive. For more information about <b>Dynamic settings</b>, see your studio user guide.</p> |
|                         | <i>Salesforce Webservice URL</i>                                                                    | Type in the Web service URL to connect to the Salesforce DB.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                         | <i>Username and Password</i>                                                                        | Type in the Web service user authentication data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                         | <i>Timeout (milliseconds)</i>                                                                       | Type in the intended number of query timeout in Salesforce.com.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                         | <i>Action</i>                                                                                       | <p>You can do any of the following operations on the data of the Salesforce object:</p> <p><b>Insert</b>: insert data.</p> <p><b>Update</b>: update data.</p> <p><b>Delete</b>: delete data.</p> <p><b>Upsert</b>: update and insert data.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                          |                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>Module</i>                  | <p>Select the relevant module in the list.</p> <p> if you select the <b>Use Custom module</b> option, you display the <b>Custom Module Name</b> field where you can enter the name of the module you want to connect to.</p>                                                                                                                                          |
|                          | <i>Schema and Edit Schema</i>  | <p>A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.</p> <p>Click <b>Edit Schema</b> to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.</p> <p>Click <b>Sync columns</b> to retrieve the schema from the previous component connected in the Job.</p>  |
| <b>Advanced settings</b> | <i>Extended Output</i>         | <p>This check box is selected by default. It allows to transfer output data in batches. You can specify the number of lines per batch in the <b>Rows to commit</b> field.</p>                                                                                                                                                                                                                                                                          |
|                          | <i>Die on error</i>            | <p>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <b>Row &gt; Reject</b> link.</p> <p> The <b>Reject</b> link is available only when you have deselected the <b>Extended Output</b> and <b>Die on error</b> check boxes.</p> |
|                          | <i>Error logging file</i>      | <p>If you want to create a file that holds all error logs, click the three-dot button next to this field and browse to the specified file to set its access path and its name.</p>                                                                                                                                                                                                                                                                     |
|                          | <i>Use Socks Proxy</i>         | <p>Select this check box if you want to use a proxy server. Once selected, you need enter the connection parameters that are the host, the port, the username and the password of the Proxy you need to use.</p>                                                                                                                                                                                                                                       |
|                          | <i>Use Soap Compression</i>    | <p>Select this check box to activate the SOAP compression.</p> <p> The compression of SOAP messages optimizes system performance.</p>                                                                                                                                                                                                                               |
|                          | <i>Retrieve inserted ID</i>    | <p>Select this check box to allow Salesforce.com to return the salesforce ID produced for a new row that is to be inserted. The ID column is added to the processed data schema in Salesforce.com.</p> <p> This option is available only when you have chosen <b>insert</b> action yet not in batch mode, i.e. not in the <b>Extended Output</b> option.</p>        |
|                          | <i>tStatCatcher Statistics</i> | <p>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</p>                                                                                                                                                                                                                                                                                                                                  |
|                          | <i>Client ID</i>               | <p>Set the ID of the real user to differentiate between those who use the same account and password to access the salesforce website.</p>                                                                                                                                                                                                                                                                                                              |
| <b>Usage</b>             |                                | Used as an output component. An Input component is required.                                                                                                                                                                                                                                                                                                                                                                                           |

## Scenario 1: Deleting data from the Account object

This scenario describes a two-component Job that removes an entry from the Account object.

### Dragging and dropping as well as connecting the components

1. Drop **tSalesforceInput** and **tSalesforceOutput** from the **Palette** onto the design workspace.
2. Connect the two components together using a **Row > Main** link.

### Configuring the components

#### Procedure 1. Querying the content to be deleted

1. Double-click **tSalesforceInput** to display its **Basic settings** view and define the component properties.

**salesforce(tSalesforceInput\_1)**

**Basic settings**

Property Type: Built-In

Salesforce WebService URL: "https://www.salesforce.com/services/Soap/u/10.0"

Username: "cantoine@talend.com"

Password: "talendSalesforcePassword"

Module: Account

Schema: Built-In

Query Condition: "name='sForce'"

Manual input of SOQL query

2. From the **Property Type** list, select **Repository** if you have already stored the connection to the salesforce server in the **Metadata** node of the **Repository** tree view. The property fields that follow are automatically filled in. If you have not defined the server connection locally in the Repository, fill in the details manually after selecting **Built-in** from the **Property Type** list.

For more information about how to create the salesforce metadata, see *Talend Open Studio User Guide*.

3. In the **Salesforce WebService URL** field, use the default URL of the Salesforce Web service or enter the URL you want to access or select the **Use an existing connection** check box to use an established connection.

4. In the **Username** and **Password** fields, enter your login and password for the Web service.
5. Type in your intended query timeout in the **Timeout (milliseconds)** field. In this example, use the default number.
6. From the **Module** list, select the object you want to access, **Account** in this example.
7. From the **Schema** list, select **Repository** and then click the three-dot button to open a dialog box where you can select the repository schema you want to use for this component. If you have not defined your schema locally in the metadata, select **Built-in** from the **Schema** list and then click the three-dot button next to the **Edit schema** field to open the dialog box where you can set the schema manually.
8. In the **Query Condition** field, enter the query you want to apply. In this example, we want to retrieve the clients whose names are *sForce*. To do this, we use the query: `"name=' sForce ' "`.
9. For a more advanced query, select the Manual input of SOQL query and enter the query manually.

## Procedure 2. Deleting the queried contents

1. Double-click **tSalesforceOutput** to display its **Basic settings** view and define the component properties.

| tSalesforceOutput_1   |                                                                             |
|-----------------------|-----------------------------------------------------------------------------|
| <b>Basic settings</b> | Salesforce WebService URL "https://www.salesforce.com/services/Soap/u/10.0" |
| Advanced settings     | Username "cantoine@talend.com"                                              |
| Dynamic settings      | Password "talendSalesforcePassword"                                         |
| View                  | Action delete*                                                              |
| Documentation         | Module Account*                                                             |
|                       | Schema Built-In Edit schema Sync columns                                    |

2. In the **Salesforce WebService URL** field, use the default URL of the Salesforce Web service or enter the URL you want to access.
3. In the **Username** and **Password** fields, enter your login and password for the Web service.
4. Type in your intended query timeout in the **Timeout (milliseconds)** field. In this example, use the default number.
5. From the **Action** list, select the operation you want to carry out. In this example we select **Delete** to delete the *sForce* account selected in the previous component.
6. From the **Module** list, select the object you want to access, **Account** in this example.
7. Click **Sync columns** to retrieve the schema of the preceding component.
8. Press **Ctrl+S** to save your Job.

## Executing the Job

- Press **F6** to execute the Job.

Check the content of the **Account** object and verify that the *sForce* account(s) is/are deleted from the server.

## Scenario 2: Gathering erroneous data while inserting data to a module at Salesforce.com

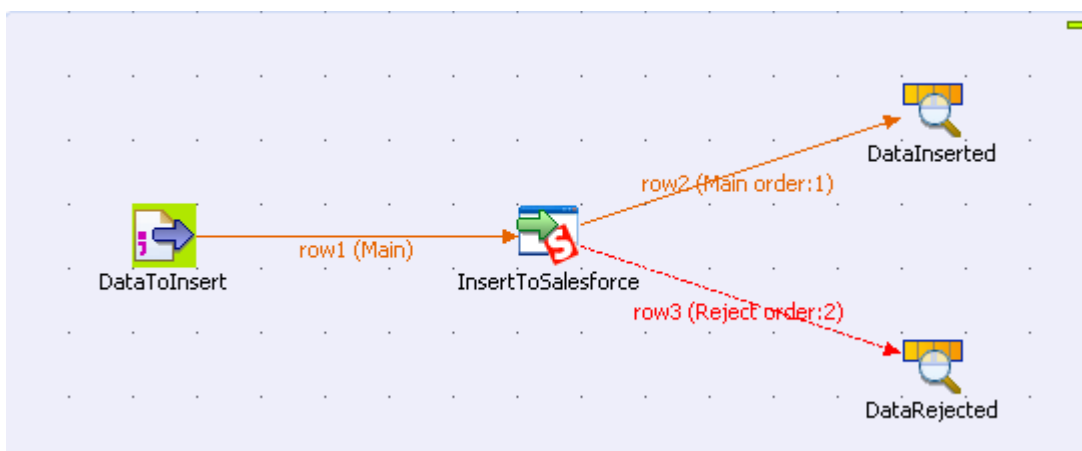

In this scenario, data in a local file is inserted to the **AdditionalNumber** module. Meanwhile, erroneous data in that file is collected via a **Row > Reject** link.

### Dragging and dropping components and linking them together

1. Drag and drop the following components from the **Palette** onto the workspace: **tFileInputDelimited**, **tSalesforceOutput** and two **tLogRow** components.
2. Rename **tFileInputDelimited** as **DataToInsert**, **tSalesforceOutput** as **InsertToSalesforce**, and the two **tLogRow** components as **DataInserted** as well as **DataRejected** respectively.
3. Link **DataToInsert** to **InsertToSalesforce** using a **Row > Main** connection.
4. Link **InsertToSalesforce** to **DataInserted** using a **Row > Main** connection.
5. Link **InsertToSalesforce** to **DataRejected** using a **Row > Reject** connection.

Deselect the **Extended Output** and **Die on error** check boxes in the **Advanced settings** view of the **tSalesforceOutput** component so that the **Reject** link is available .

### Configuring the components

#### Procedure 3. Configuring the data source

1. Double-click **DataToInsert** to open its **Basic settings** view in the **Component** tab.

2. In the **Property Type** drop-down list, select **Built-In**.

You can select **Repository** from the **Property Type** drop-down list to fill in the relevant fields automatically if the relevant metadata has been stored in the **Repository**. For more information about **Metadata**, see the *Talend Open Studio User Guide*.

3. In the **File name/Stream** field, type in the path of the source file, for example, *E:/salesforceout.csv*.
4. In the **Header** field, type in *1* to retrieve the column names. Keep the default settings for other fields.

#### Procedure 4. Configuring the module for data insertion

1. Double-click **InsertToSalesforce** to open its **Basic settings** view in the **Component** tab.

2. In the **Property Type** drop-down list, select **Built-In**.
3. In the **Username** field, enter your username, for example, *cantoine@talend.com*.
4. In the **Password** field, enter your password, for example, *talendehmrEvHz2xZ8f2KlmTCymS0XU*.
5. In the **Action** drop-down list, select **insert**.
6. In the **Module** drop-down list, select **AdditionalNumber**.

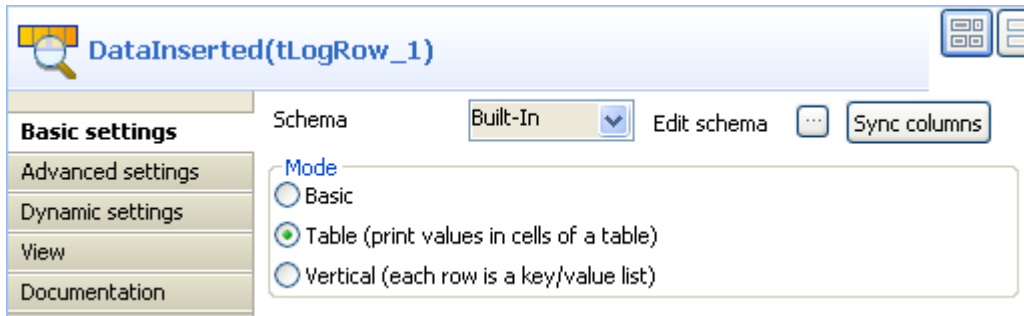

When linking the components earlier, the **Extended Output** and **Die on error** check boxes have been deselected in the **Advanced settings** view so that the **Reject** link can appear.

7. Keep the default settings for other fields.

### Procedure 5. Configuring the console display

1. Double-click **DataInserted** to open its **Basic settings** view in the **Component** tab.

2. In the **Mode** area, select **Table (print values in cells of a table)** for a better view.
3. Perform the same operation for **DataRejected**.
4. Press **Ctrl+S** to save your Job.

### Executing the Job

- Press **F6** to run the Job and you can find the erroneous data (if any) is displayed in the **Run** view.

```

tLogRow_2
|-----+-----+-----+-----+
|CallCenterId |Name |Description |Phone
|errorCode |errorFields |errorMessage
|-----+-----+-----+-----+
|-----+-----+-----+-----+
|03m70000000CaZBAA0|Talend Testing V19|Conduct testing on
TOS|0086-010-88888888|FIELD_INTEGRITY_EXCEPTION|CallCenterId|Call Center ID:
id value of incorrect type: 03m70000000CaZBAA0|
|04m70000000CaZBAA0|Talend Testing V19|Conduct testing on
TOS|0086-010-88888888|FIELD_INTEGRITY_EXCEPTION|CallCenterId|Call Center ID:
id value of incorrect type: 04m70000000CaZBAA0|
|-----+-----+-----+-----+

```

As shown above, there are two **Call Center ID** fields that have incorrect data.

# tSalesforceOutputBulk

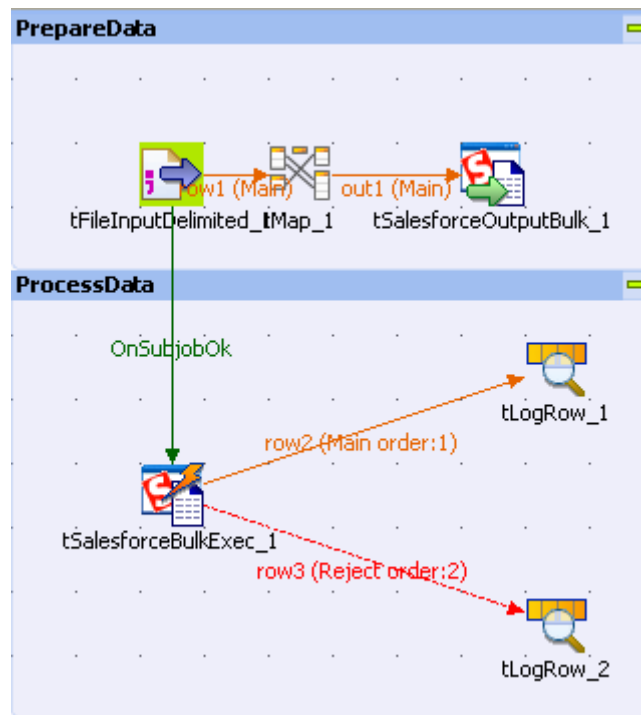

## tSalesforceOutputBulk Properties

**tSalesforceOutputBulk** and **tSalesforceBulkExec** components are used together to output the needed file and then execute intended actions on the file for your Salesforce.com. These two steps compose the **tSalesforceOutputBulkExec** component, detailed in a separate section. The interest in having two separate elements lies in the fact that it allows transformations to be carried out before the data loading.

|                          |                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Scenario: Inserting transformed bulk data into your Salesforce.com

This scenario describes a six-component Job that transforms *.csv* data suitable for bulk processing, load them in Salesforce.com and then displays the Job execution results in the console.

This Job is composed of two steps: preparing data by transformation and processing the transformed data.

Before starting this scenario, you need to prepare the input file which offers the data to be processed by the Job. In this use case, this file is *sforcebulk.txt*, containing some customer information.

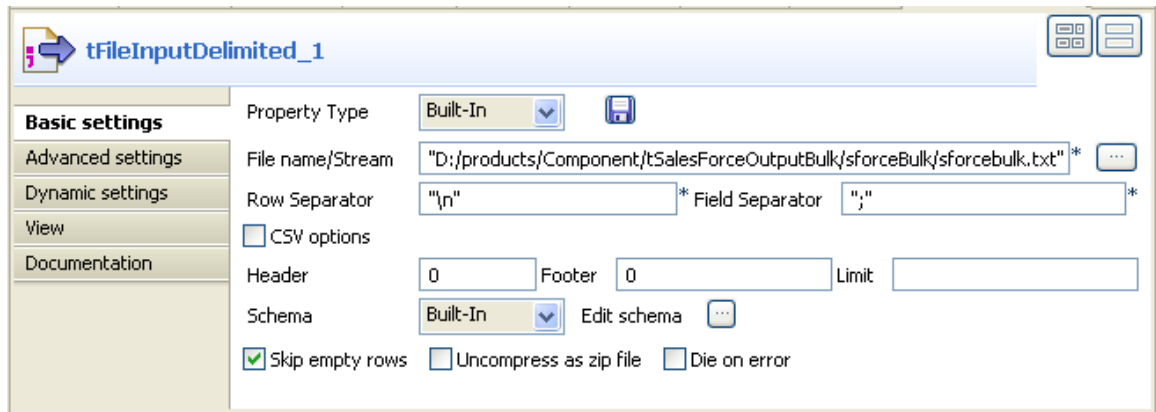

Then to create and execute this Job, operate as follows:

## Setting up the Job

1. Drop **tFileInputDelimited**, **tMap**, **tSalesforceOutputBulk**, **tSalesforceBulkExec** and **tLogRow** from the **Palette** onto the workspace of your studio.
2. Use a **Row > Main** connection to connect **tFileInputDelimited** to **tMap**, and **Row > out1** from **tMap** to **tSalesforceOutputBulk**.
3. Use a **Row > Main** connection and a **Row > Reject** connection to connect **tSalesforceBulkExec** respectively to the two **tLogRow** components.
4. Use a **Trigger > OnSubjobOk** connection to connect **tFileInputDelimited** and **tSalesforceBulkExec**.

## Configuring the input component

1. Double-click **tFileInputDelimited** to display its **Basic settings** view and define the component properties.

- From the **Property Type** list, select **Repository** if you have already stored the connection to the salesforce server in the **Metadata** node of the **Repository** tree view. The property fields that follow are automatically filled in. If you have not defined the server connection locally in the Repository, fill in the details manually after selecting **Built-in** from the **Property Type** list.

For more information about how to create the delimited file metadata, see *Talend Open Studio User Guide*.

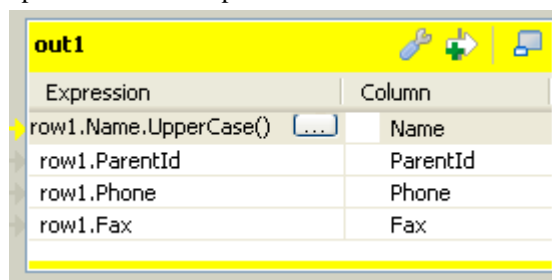

- Next to the **File name/Stream** field, click the [...] button to browse to the input file you prepared for the scenario, for example, *sforcebulk.txt*.
- From the **Schema** list, select **Repository** and then click the three-dot button to open a dialog box where you can select the repository schema you want to use for this component. If you have not defined your schema locally in the metadata, select **Built-in** from the **Schema** list and then click the three-dot button next to the **Edit schema** field to open the dialog box where you can set the schema manually. In this scenario, the schema is made of four columns: *Name*, *ParentId*, *Phone* and *Fax*.

| Column   | Key                      | Type   | <input checked="" type="checkbox"/> | N.. | Date Patt... | Length | Pre... | D... | Co... |
|----------|--------------------------|--------|-------------------------------------|-----|--------------|--------|--------|------|-------|
| Name     | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     |              |        |        |      |       |
| ParentId | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     |              |        |        |      |       |
| Phone    | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     |              |        |        |      |       |
| Fax      | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     |              |        |        |      |       |

- According to your input file to be used by the Job, set the other fields like **Row Separator**, **Field Separator**...

## Setting up the mapping

- Double-click the **tMap** component to open its editor and set the transformation.
- Drop all columns from the input table to the output table.

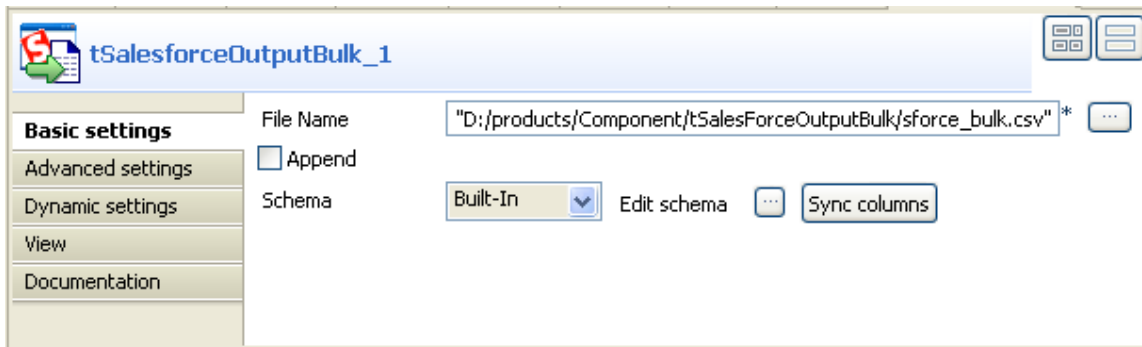

- Add `.toUpperCase()` behind the *Name* column.

4. Click **OK** to validate the transformation.

## Defining the output path

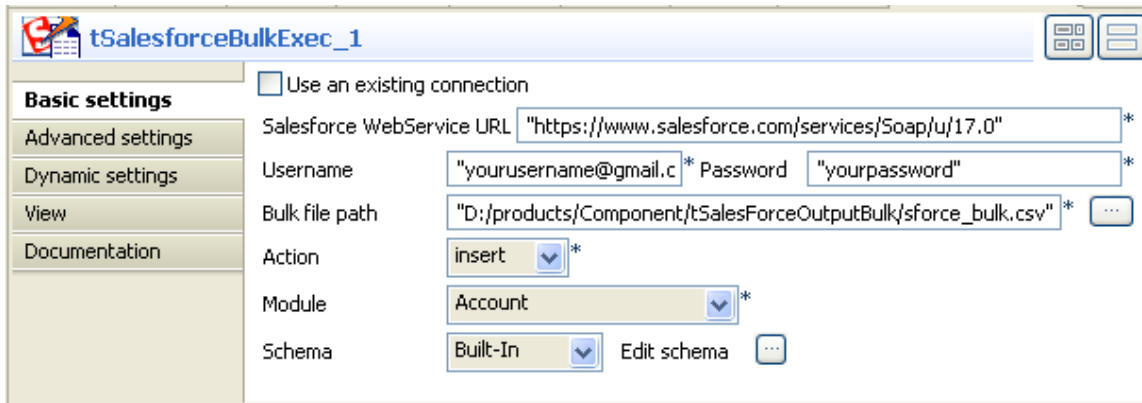

1. Double-click **tSalesforceOutputBulk** to display its **Basic settings** view and define the component properties.

2. In the **File Name** field, type in or browse to the directory where you want to store the generated **.csv** data for bulk processing.
3. Click **Sync columns** to import the schema from its preceding component.

## Setting up the connection to the Salesforce server

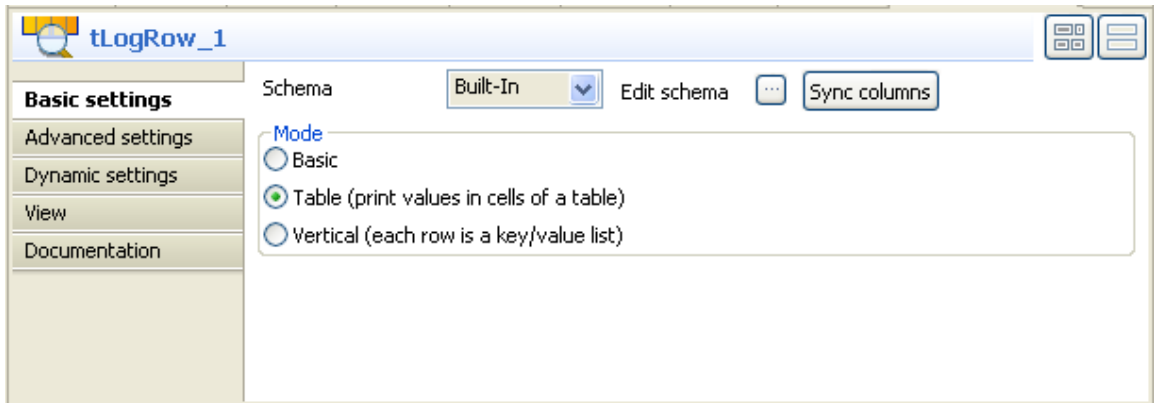

1. Double-click **tSalesforceBulkExec** to display its **Basic settings** view and define the component properties.

2. Use the by-default URL of the Salesforce Web service or enter the URL you want to access.
3. In the **Username** and **Password** fields, enter your username and password for the Web service.
4. In the **Bulk file path** field, browse to the directory where is stored the generated **.csv** file by **tSalesforceOutputBulk**.
5. From the **Action** list, select the action you want to carry out on the prepared bulk data. In this use case, **insert**.
6. From the **Module** list, select the object you want to access, **Account** in this example.
7. From the **Schema** list, select **Repository** and then click the three-dot button to open a dialog box where you can select the repository schema you want to use for this component. If you have not defined your schema locally in the metadata, select **Built-in** from the **Schema** list and then click the three-dot button next to the **Edit schema** field to open the dialog box where you can set the schema manually. In this example, edit it conforming to the schema defined previously.

## Configuring the output component

1. Double-click **tLogRow\_1** to display its **Basic settings** view and define the component properties.

2. Click **Sync columns** to retrieve the schema from the preceding component.
3. Select **Table** mode to display the execution result.
4. Do the same with **tLogRow\_2**.

## Job execution

1. Press **CTRL+S** to save your Job.
2. Press **F6** to execute it.

You can check the execution result on the **Run** console.

```

In the **tLogRow\_1** table, you can read the data inserted into your Salesforce.com.

In the **tLogRow\_2** table, you can read the rejected data due to the incompatibility with the **Account** objects you have accessed.

All the customer names are written in upper case.

# tSalesforceOutputBulkExec

## tSalesforceOutputBulkExec Properties

**tSalesforceOutputBulk** and **tSalesforceBulkExec** components are used together to output the needed file and then execute intended actions on the file for your Salesforce.com. These two steps compose the **tSalesforceOutputBulkExec** component, detailed in a separate section. The interest in having two separate elements lies in the fact that it allows transformations to be carried out before the data loading.

|                          | <i>Module</i>                  | Select the relevant module in the list.<br><br>💡 If you select the <b>Use Custom module</b> option, you display the <b>Custom Module Name</b> field where you can enter the name of the module you want to connect to.                                                                                                                                                                                                                         |
|                          | <i>Schema and Edit Schema</i>  | A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.<br><br>Click <b>Edit Schema</b> to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.<br><br>Click <b>Sync columns</b> to retrieve the schema from the previous component connected in the Job. |
| <b>Advanced settings</b> | <i>Rows to commit</i>          | Specify the number of lines per data batch to be processed.                                                                                                                                                                                                                                                                                                                                                                                    |
|                          | <i>Bytes to commit</i>         | Specify the number of bytes per data batch to be processed.                                                                                                                                                                                                                                                                                                                                                                                    |
|                          | <i>Use Socks Proxy</i>         | Select this check box if you want to use a proxy server. In this case, you should fill in the proxy parameters in the <b>Proxy host</b> , <b>Proxy port</b> , <b>Proxy username</b> and <b>Proxy password</b> fields which appear beneath.                                                                                                                                                                                                     |
|                          | <i>tStatCatcher Statistics</i> | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.                                                                                                                                                                                                                                                                                                                                 |
| <b>Usage</b>             |                                | This component is mainly used when no particular transformation is required on the data to be loaded into Salesforce.com.                                                                                                                                                                                                                                                                                                                      |
| <b>Limitation</b>        |                                | The bulk data to be processed in Salesforce.com should be .csv format.                                                                                                                                                                                                                                                                                                                                                                         |

## Scenario: Inserting bulk data into your Salesforce.com

This scenario describes a four-component Job that submits bulk data into Salesforce.com, executes your intended actions on the data, and ends up with displaying the Job execution results for your reference.

Before starting this scenario, you need to prepare the input file which offers the data to be processed by the Job. In this use case, this file is *sforcebulk.txt*, containing some customer information.

Then to create and execute this Job, operate as follows:

## Setting up the Job

1. Drop **tFileInputDelimited**, **tSalesforceOutputBulkExec**, and **tLogRow** from the **Palette** onto the workspace of your studio.
2. Use **Row > Main** connection to connect **tFileInputDelimited** to **tSalesforceOutputBulkExec**.
3. Use **Row > Main** and **Row > Reject** to connect **tSalesforceOutputBulkExec** respectively to the two **tLogRow** components.

## Setting the input data

1. Double-click **tFileInputDelimited** to display its **Basic settings** view and define the component properties.

The screenshot shows the 'Basic settings' view for the 'tFileInputDelimited\_1' component. The settings are as follows:

- Property Type:** Built-In
- File name/Stream:** "D:/products/Component/tSalesForceOutputBulk/sforceBulk/sforcebulk.txt"\*
- Row Separator:** "\n" \* **Field Separator:** "," \*
- CSV options:**
- Header:** 0 **Footer:** 0 **Limit:** [empty]
- Schema:** Built-In **Edit schema:** [button]
- Checkboxes:**  Skip empty rows,  Uncompress as zip file,  Die on error

2. From the **Property Type** list, select **Repository** if you have already stored the connection to the salesforce server in the **Metadata** node of the **Repository** tree view. The property fields that follow are automatically filled in. If you have not defined the server connection locally in the Repository, fill in the details manually after selecting **Built-in** from the **Property Type** list.

For more information about how to create the delimited file metadata, see *Talend Open Studio User Guide*.

3. Next to the **File name/Stream** field, click the [...] button to browse to the input file you prepared for the scenario, for example, *sforcebulk.txt*.
4. From the **Schema** list, select **Repository** and then click the three-dot button to open a dialog box where you can select the repository schema you want to use for this component. If you have not defined your schema locally in the metadata, select **Built-in** from the **Schema** list and then click the three-dot button next to the **Edit schema** field to open the dialog box where you can set the schema manually. In this scenario, the schema is made of four columns: *Name*, *ParentId*, *Phone* and *Fax*.

| Column   | Key                      | Type   | <input checked="" type="checkbox"/> | N.. | Date Patt... | Length | Pre... | D... | Co... |
|----------|--------------------------|--------|-------------------------------------|-----|--------------|--------|--------|------|-------|
| Name     | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     |              |        |        |      |       |
| ParentId | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     |              |        |        |      |       |
| Phone    | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     |              |        |        |      |       |
| Fax      | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     |              |        |        |      |       |

5. According to your input file to be used by the Job, set the other fields like **Row Separator**, **Field Separator**...

## Setting up the connection to the Salesforce server

1. Double-click **tSalesforceOutputBulkExec** to display its **Basic settings** view and define the component properties.

2. In **Salesforce Webservice URL** field, use the by-default URL of the Salesforce Web service or enter the URL you want to access.
3. In the **Username** and **Password** fields, enter your username and password for the Web service.
4. In the **Bulk file path** field, browse to the directory where you store the bulk **.csv** data to be processed.

The bulk file here to be processed must be in **.csv** format.

5. From the **Action** list, select the action you want to carry out on the prepared bulk data. In this use case, **insert**.
6. From the **Module** list, select the object you want to access, **Account** in this example.
7. From the **Schema** list, select **Repository** and then click the three-dot button to open a dialog box where you can select the repository schema you want to use for this component. If you have not defined your schema locally in the metadata, select **Built-in** from the **Schema** list and then click the three-dot button next to the **Edit schema** field to open the dialog box where you can set the schema manually. In this example, edit it conforming to the schema defined previously.

## Job execution

1. Double-click **tLogRow\_1** to display its **Basic settings** view and define the component properties.

2. Click **Sync columns** to retrieve the schema from the preceding component.
3. Select **Table** mode to display the execution result.

4. Do the same with **tLogRow\_2**.
5. Press **CTRL+S** to save your Job and press **F6** to execute it.

On the console of the **Run** view, you can check the execution result.

```

|statistics| connected
+-----+-----+-----+-----+-----+-----+
| |tLogRow_1|
+-----+-----+-----+-----+-----+-----+
|Name|ParentId|Phone|Fax|salesforce_id|sale:

```

In the **tLogRow\_1** table, you can read the data inserted into your Salesforce.com.

In the **tLogRow\_2** table, you can read the rejected data due to the incompatibility with the **Account** objects you have accessed.

If you want to transform the input data before submitting them, you need to use **tSalesforceOutputBulk** and **tSalesforceBulkExec** in cooperation to achieve this purpose. For further information on the use of the two components, see [the section called “Scenario: Inserting transformed bulk data into your Salesforce.com”](#).

# tSAPBWInput

|                          |                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                      |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Component family</b>  | Business                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                                      |
| <b>Function</b>          | <b>tSAPBWInput</b> reads data from an SAP BW database using a JDBC API connection and extracts fields based on an SQL query.                                                                                          |                                                                                                                                                                                                                                                                                                                                      |
| <b>Purpose</b>           | This component executes an SQL query with a strictly defined order which must correspond to your schema definition. Then it passes on the field list to the next component via a <b>Main</b> > <b>Row</b> connection. |                                                                                                                                                                                                                                                                                                                                      |
| <b>Basic settings</b>    | <i>Property type</i>                                                                                                                                                                                                  | Either <b>Built-in</b> or <b>Repository</b> :                                                                                                                                                                                                                                                                                        |
|                          |                                                                                                                                                                                                                       | <b>Built-in</b> : No property data stored centrally.                                                                                                                                                                                                                                                                                 |
|                          |                                                                                                                                                                                                                       | <b>Repository</b> : Select the repository file where Properties are stored. The fields that come after are pre-filled in using the fetched data.                                                                                                                                                                                     |
|                          | <i>Schema and Edit Schema</i>                                                                                                                                                                                         | A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.<br><br>Click <b>Edit Schema</b> to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in. |
|                          | <i>JDBC URL</i>                                                                                                                                                                                                       | Enter the JDBC URL of the database you want to connect to. For example, enter: <code>jdbc:jdbc4olap://server_address/database_name</code> to connect to an SAP BW database.                                                                                                                                                          |
|                          | <i>Username</i>                                                                                                                                                                                                       | Enter the username for DB access authentication.                                                                                                                                                                                                                                                                                     |
|                          | <i>Password</i>                                                                                                                                                                                                       | Enter the password for DB access authentication.                                                                                                                                                                                                                                                                                     |
|                          | <i>Table Name</i>                                                                                                                                                                                                     | Type in the name of the DB table.                                                                                                                                                                                                                                                                                                    |
|                          | <i>Query Type</i>                                                                                                                                                                                                     | Either <b>Built-in</b> or <b>Repository</b> :                                                                                                                                                                                                                                                                                        |

| <b>Usage</b>      | This component supports SQL queries for SAP BW database using a JDBC connection. |                                                                   |
| <b>Limitation</b> | n/a                                                                              |                                                                   |

## Scenario: Reading data from SAP BW database

This scenario describes a two-component Job that reads data from an SAP BW database. The data is fetched and displayed on the console.

Prior to setting up the Job, make sure the following prerequisites are met:

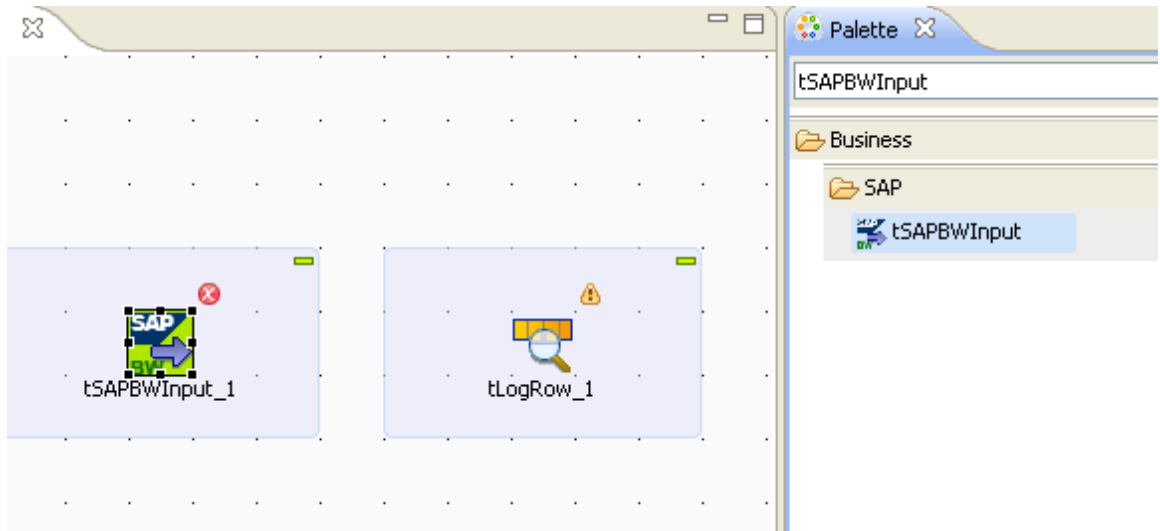

1. Copy the following .jar files which compose the jdbc4olap driver to your class path:
  - activation.jar
  - commons-codec.jar
  - jdbc4olap.jar
  - saaj-api.jar
  - saaj-impl.jar
2. Make sure that you have the latest version of jdbc4olap driver. You can download the latest version of jdbc4olap driver from [jdbc4olap download section](http://sourceforge.net/projects/jdbc4olap/) [http://sourceforge.net/projects/jdbc4olap/]. For further information about the usage of jdbc4olap driver, see [jdbc4olap User Guide](http://cdnetworks-kr-2.dl.sourceforge.net/project/jdbc4olap/Documentation/jdbc4olapUserGuide.pdf) [http://cdnetworks-kr-2.dl.sourceforge.net/project/jdbc4olap/Documentation/jdbc4olapUserGuide.pdf].

The procedure of this scenario requires 4 main steps detailed hereafter:

1. Set up the Job.
2. Set up the jdbc connection to the SAP BW server.
3. Set up a query.
4. Display the fetched data on the console.

### Set up the Job

1. Drop a **tSAPBWInput** component and a **tLogRow** component from the **Palette** onto the workspace.

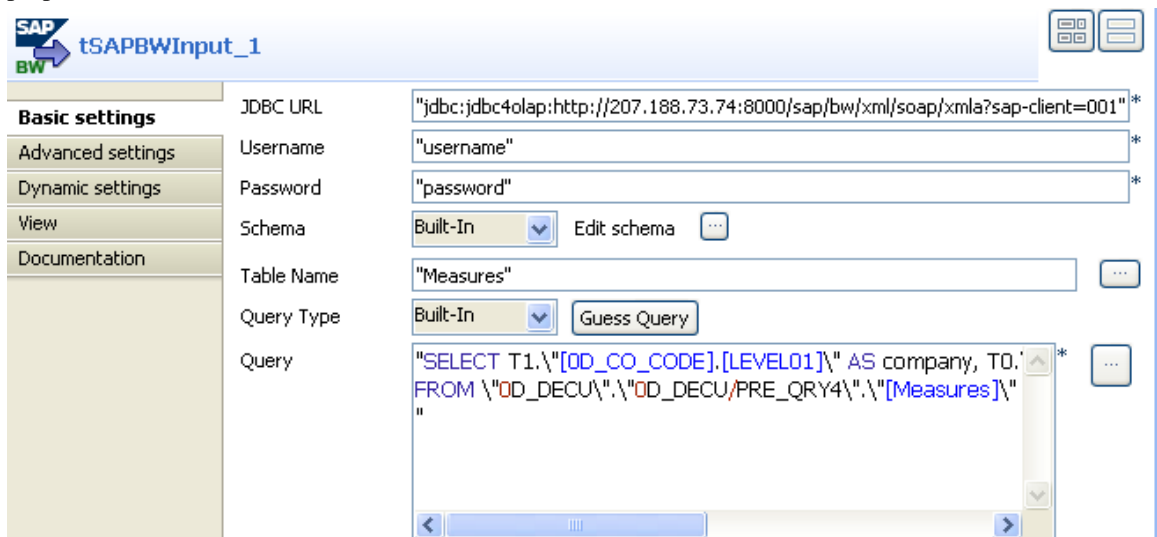

2. Connect the **tSAPBWInput** component and the **tLogRow** component using a **Main > Row** connection.

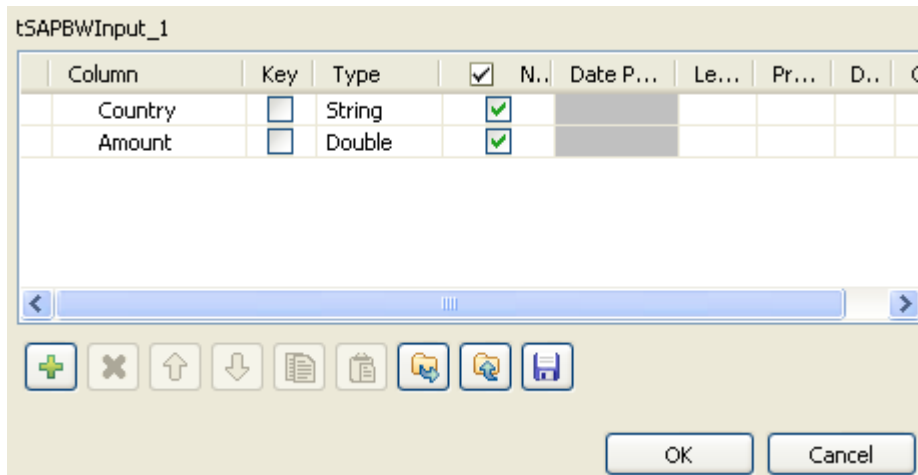

## Set up the jdbc connection to the SAP BW server

1. Double-click the **tSAPBWInput** component to open its **Basic settings** view and define the component properties.

2. Fill the **JDBC URL** field with the URL of your jdbc4olap server.  
Note that the URL displayed above is for demonstration only.
3. Fill the **Username** and **Password** fields with your username and password for the DB access authentication.
4. Click the three-dot button next to **Edit schema** to define the schema to be used.

- Click the plus button to add new columns to the schema and set the data type for each column and click **OK** to save the schema settings.

## Set up a query

- From the **Basic settings** view of **tSAPBWInput**, fill the **Table Name** field with the table name. In this scenario, table name "*Measures*" is for demonstration only.
- Fill the **Query** area with the query script. In this example, we use:

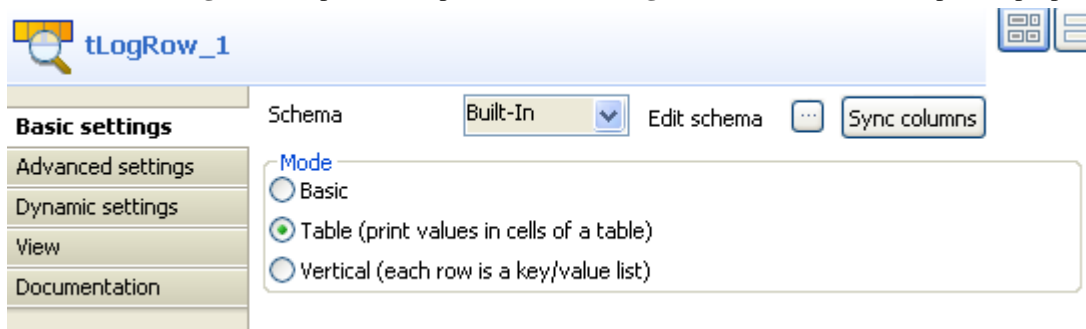

```
"SELECT
T1.\"[0D_CO_CODE].[LEVEL01]\" AS company,
T0.\"[Measures].[D68EEPPGGHUMSZ92PIJARDZ0KA]\" AS amount
FROM
\"0D_DECU\".\"0D_DECU/PRE_QRY4\".\"[Measures]\" T0,
\"0D_DECU\".\"0D_DECU/PRE_QRY4\".\"[0D_CO_CODE]\" T1 "
```

Due to the limitations of the supported SQL queries, the query scripts you use must be based on the grammar defined in the jdbc4olap driver. For further information about this grammar, see [jdbc4olap User Guide](http://cdnetworks-kr-2.dl.sourceforge.net/project/jdbc4olap/Documentation/jdbc4olapUserGuide.pdf) [http://cdnetworks-kr-2.dl.sourceforge.net/project/jdbc4olap/Documentation/jdbc4olapUserGuide.pdf].

## Display the fetched data on the console

- Double-click the **tLogRow** component to open its **Basic settings** view and define the component properties.

- Click **Sync columns** to retrieve the schema defined in the preceding component.

3. Select **Table** in the **Mode** area.
4. Press **Ctrl+S** to save your Job and press **F6** to execute it.

```
[statistics] connecting to socket on port 3762
[statistics] connected
Jan 10, 2012 11:39:36 AM org.jdbc4olap.xmla.XmlaConn
execute
INFO: Query processed by OLAP server in 1199 ms, returning
4533 bytes.
```

| tLogRow_1          |           |
|--------------------|-----------|
| Country            | Amount    |
| IDES               | 976190.0  |
| Century Inc.       | 321678.0  |
| ACE Technology     | 1432954.0 |
| Haitec Enterprise  | 221580.0  |
| Cannon Electronics | 552852.0  |
| #                  | 0.0       |

```
[statistics] disconnected
Job Loop ended at 11:39 10/01/2012. [exit code=0]
```

The data in the table "Measure" is fetched and displayed on the console.

# tSAPCommit

## tSAPCommit Properties

This component is closely related to **tSAPConnection** and **tSAPRollback**. It usually does not make much sense to use these components separately in a transaction.

|                          |                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Usage</b>             | This component is to be used along with SAP components, especially with <b>tSAPConnection</b> and <b>tSAPRollback</b> components.                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Limitation</b>        | n/a                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Related scenario

This component is closely related to **tSAPConnection** and **tSAPRollback**. It usually does not make much sense to use one of these without using a **tSAPConnection** component to open a connection for the current transaction.

For **tSAPCommit** related scenario, see [the section called “Scenario: Inserting data in mother/daughter tables”](#).

# tSAPConnection

## tSAPConnection properties

## Scenario 1: Retrieving metadata from the SAP system

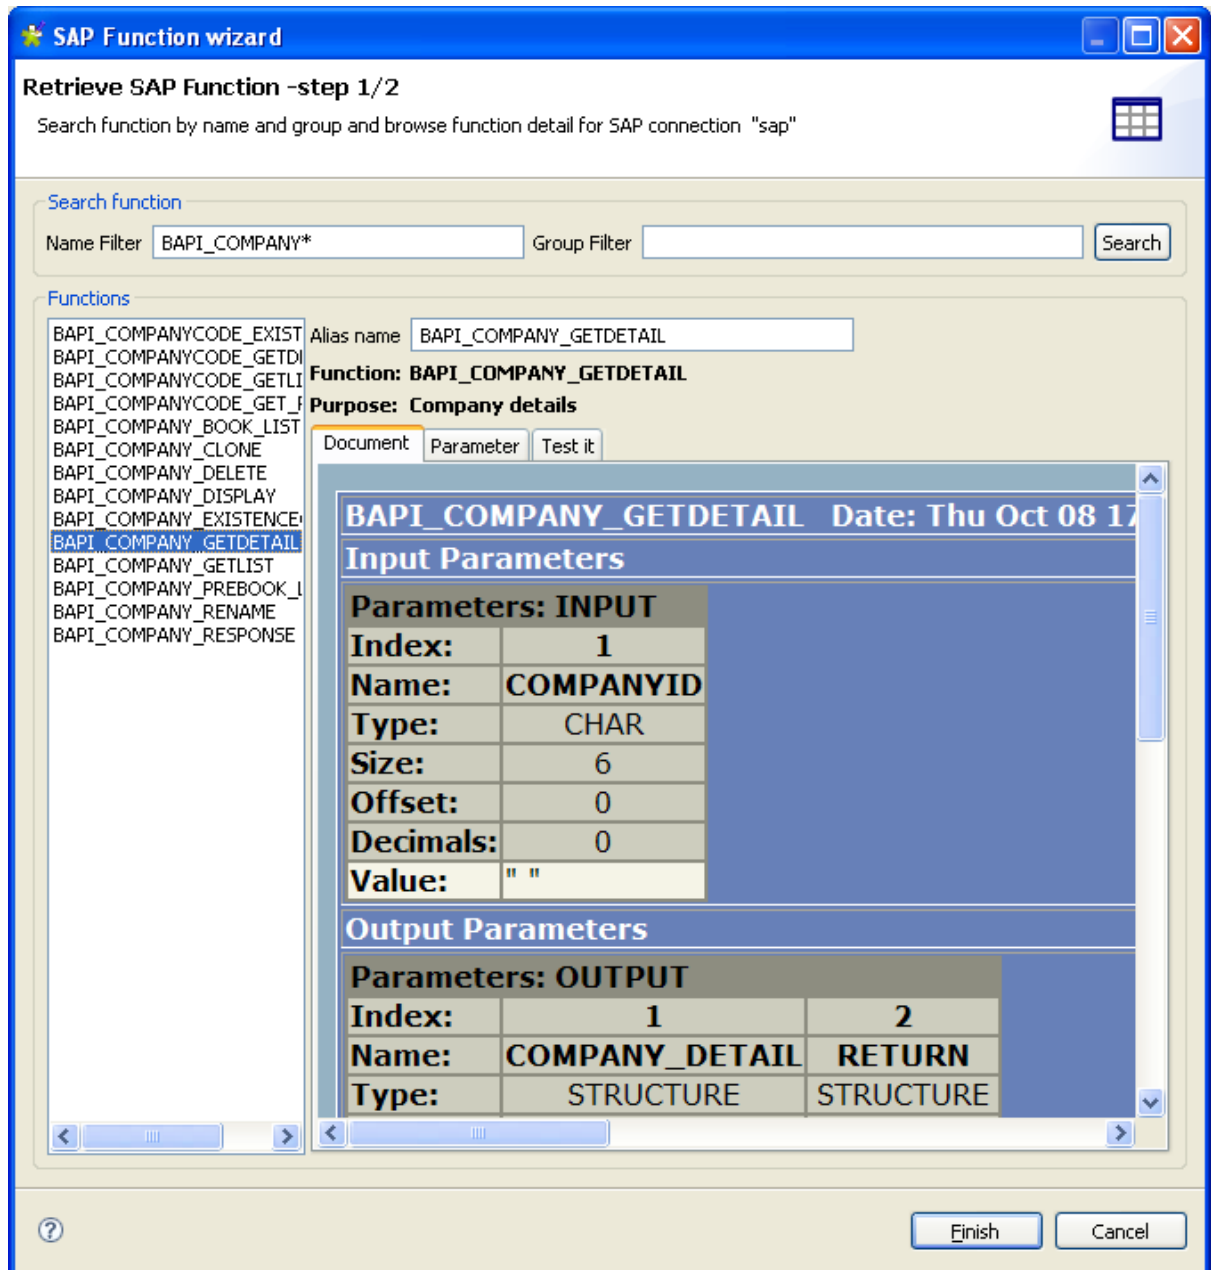

Talend SAP components (**tSAPInput** and **tSAPOutput**) as well as the SAP wizard are based on a library validated and provided by SAP (JCO) that allows the user to call functions and retrieve data from the SAP system at Table, RFC or BAPI, levels.

This scenario uses the SAP wizard that leads a user through dialog steps to create SAP connection and call RFC and BAPI functions. This SAP wizard is available only for **Talend Enterprise** users. If you are a user of **Talend Open Studio** or **Talend Integration Express**, you need to set the basic settings for the **tSAPInput** component manually.

This scenario uses the SAP wizard to first create a connection to the SAP system, and then call a BAPI function to retrieve the details of a company from the SAP system. It finally displays in *Talend Open Studio* the company details stored in the SAP system.

The following figure shows the company detail parameters stored in the SAP system and that we want to read in *Talend Open Studio* using the **tSAPInput** component.

## Setting and configuring the SAP connection using wizard

### Procedure 6. Setting up the connection to the SAP system

1. Create a connection to the SAP system using the SAP connection wizard, in this scenario the SAP connection is called *sap* and is saved in the **Metadata** node.
2. Call the BAPI function *BAPI\_COMPANY\_GETDETAIL* using the SAP wizard to access the BAPI HTML document stored in the SAP system and see the company details.
3. In the **Name filter** field, type in *BAPI\** and click the **Search** button to display all available BAPI functions.
4. Select *BAPI\_COMPANY\_GETDETAIL* to display the schema that describes the company details.

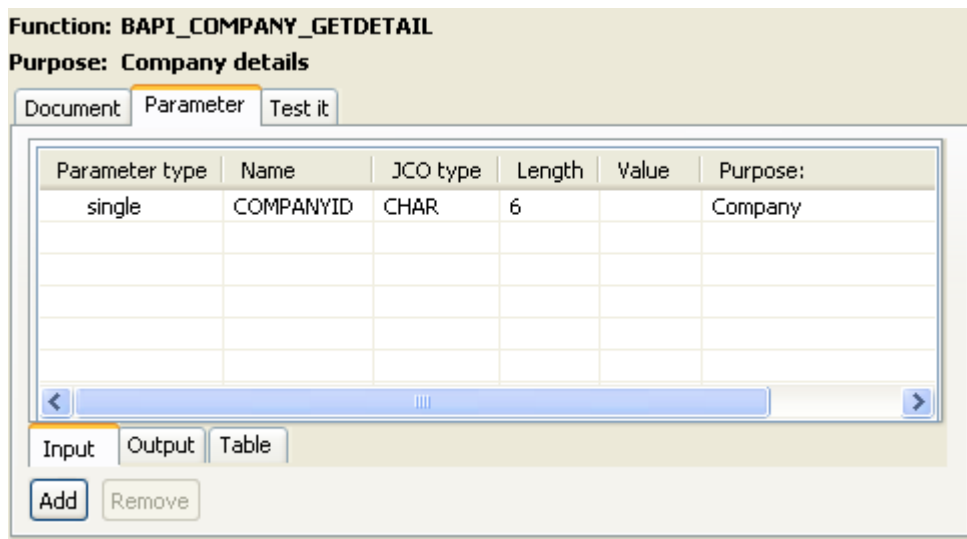

The three-tab view to the right of the wizard displays the metadata of the *BAPI\_COMPANY\_GETDETAIL* function and allows you to set the necessary parameters.

The **Document** view displays the SAP html document about the *BAPI\_COMPANY\_GETDETAIL* function.

The **Parameter** view provides information about the input and output parameters required by the *BAPI\_COMPANY\_GETDETAIL* function to return values.

### Procedure 7. Setting the input and output parameters using the wizard

1. In the **Parameter** view, click the **Input** tab to list the input parameter(s). In this scenario, there is only one input parameter required by *BAPI\_COMPANY\_GETDETAIL* and it is called *COMPANYID*.

2. In the **Parameter** view, click the **Output** tab to list the output parameters returned by *BAPI\_COMPANY\_GETDETAIL*. In this scenario, there are two output parameters: *COMPANY\_DETAIL* and *RETURN*.

**Function: BAPI\_COMPANY\_GETDETAIL**  
**Purpose: Company details**

Document Parameter Test it

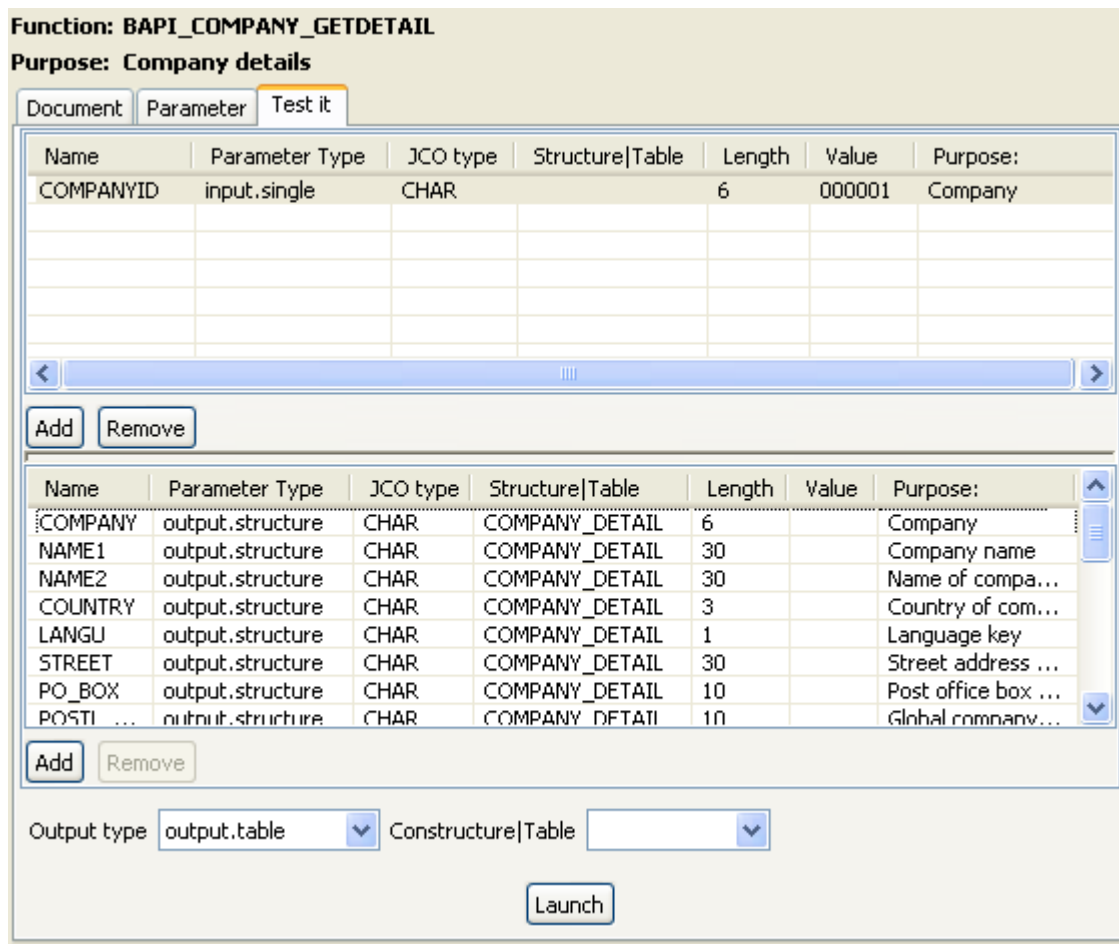

| Parameter type | Name           | JCO type | Length | Value | Purpose:                               |
|----------------|----------------|----------|--------|-------|----------------------------------------|
| [-] structure  | COMPANY_DETAIL |          | 0      |       |                                        |
| single         | COMPANY        | CHAR     | 6      |       | Company                                |
| single         | NAME1          | CHAR     | 30     |       | Company name                           |
| single         | NAME2          | CHAR     | 30     |       | Name of company 2                      |
| single         | COUNTRY        | CHAR     | 3      |       | Country of company                     |
| single         | LANGU          | CHAR     | 1      |       | Language key                           |
| single         | STREET         | CHAR     | 30     |       | Street address of the company          |
| single         | PO_BOX         | CHAR     | 10     |       | Post office box of the company         |
| single         | POSTL_COD1     | CHAR     | 10     |       | Global company zip code                |
| single         | CITY           | CHAR     | 30     |       | City where company is located          |
| single         | CURRENCY       | CHAR     | 5      |       | Local currency                         |
| single         | COUNTRY_ISO    | CHAR     | 2      |       | Country ISO code                       |
| single         | CURRENCY_ISO   | CHAR     | 3      |       | ISO currency code                      |
| single         | LANGU_ISO      | CHAR     | 2      |       | Language according to ISO 639          |
| [-] structure  | RETURN         |          | 0      |       |                                        |
| single         | TYPE           | CHAR     | 1      |       | Message type: S Success, E Error, '... |
| single         | CODE           | CHAR     | 5      |       | Message code                           |
| single         | MESSAGE        | CHAR     | 220    |       | Message text                           |
| single         | LOG_NO         | CHAR     | 20     |       | Application log: log number            |

Input Output Table

Add Remove

Each of these two “structure” parameters consists of numerous “single” parameters.

The **Test it** view allows you to add or delete input parameters according to the called function. In this scenario, we want to retrieve the metadata of the *COMPANY\_DETAIL* “structure” parameter that consists of 14 “single” parameters.

3. In the **Value** column of the **COMPANYID** line in the first table, enter “000001” to send back company data corresponding to the value 000001.
4. In the **Output type** list at the bottom of the wizard, select **output.table**.
5. Click **Launch** at the bottom of the view to display the value of each “single” parameter returned by the *BAPI\_COMPANY\_GETDETAIL* function.
6. Click **Finish** to close the wizard and create the connection.

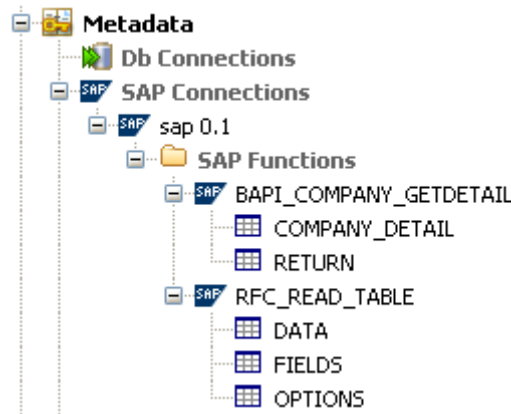

The *sap* connection and the new schema **BAI\_COMPANY\_GETDETAIL** display under the **SAP Connections** node in the **Repository** tree view.

## Retrieving different schemas of the SAP functions

To retrieve the different schemas of the **BAPI\_COMPANY\_GETDETAIL** function, do the following:

1. Right-click **BAPI\_COMPANY\_GETDETAIL** in the **Repository** tree view and select **Retrieve schema** in the contextual menu.
2. In the open dialog box, select the schemas you want to retrieve, **COMPANY\_DETAIL** and **RETURN** in this scenario.
3. Click **Next** to display the two selected schemas and then **Finish** to close the dialog box.

The two schemas display under the **BAPI\_COMPANY\_GETDETAIL** function in the **Repository** tree view.

## Retrieving the company metadata

To retrieve the company metadata that corresponds to the 000001 value and display it in *Talend Open Studio*, do the following:

### Procedure 8. Setting up the Job

1. In the **Repository** tree view, drop the SAP connection you already created to the design workspace to open a dialog box where you can select **tSAPConnection** from the component list and finally click **OK** to close the dialog box. The **tSAPConnection** component holding the SAP connection, *sap* in this example, displays on the design workspace.
2. Double-click **tSAPConnection** to display the **Basic settings** view and define the component properties.

**SAP sap(tSAPConnection\_1)**

(To use this component, you need first to add the SAP Java Connector (sapjco.jar) in the Modules view)

**Basic settings**

Advanced settings  
Dynamic settings  
View  
Documentation

Property Type:  SAP:sap

**Connection configuration**

|               |                  |
|---------------|------------------|
| Client        | "000"            |
| Userid        | "TALEND"         |
| Password      | *****            |
| Language      | "EN"             |
| Host name     | "192.168.80.128" |
| System number | "00"             |

If you store connection details in the **Metadata** node in the **Repository** tree view, the **Repository** mode is selected in the **Property Type** list and the fields that follow are pre-filled. If not, you need to select **Built-in** as “property type” and fill in the connection details manually.

3. In the **Repository** tree-view, expand **Metadata** and **sap** in succession and drop **RFC\_READ\_TABLE** to the design workspace to open a component list.
4. Select **tSAPInput** from the component list and click **OK**.
5. Drop **tFilterColumns** and **tLogRow** from the **Palette** to the design workspace.
6. Connect **tSAPConnection** and **tSAPInput** using a **Trigger > OnSubJobOk** link
7. To connect **tSAPInput** and **tLogRow**, right-click **tSAPInput** and select **Row > row\_COMPANY\_DETAIL\_1** and then click **tLogRow**.

- In the design workspace, double-click **tSAPInput** to display its **Basic settings** view and define the component properties.

The basic setting parameters for the **tSAPInput** component display automatically since the schema is stored in the **Metadata** node and the component is initialized by the SAP wizard.

**Basic settings** (To use this component, you need first to add the SAP Java Connector (sapjco.jar) in the Modules view)

Use an existing connection    Component List: tSAPConnection\_1 - sap

FunName: "BAPI\_COMPANY\_GETDETAIL"\*

Initialize input

| ParameterValue | Type         | TableName(Str... | ParameterName |
|----------------|--------------|------------------|---------------|
| "000001"       | input_single | ""               | "COMPANYID"   |

Outputs

| Schema         | Type(for iterate) | TableName(Str... | Mapping          |
|----------------|-------------------|------------------|------------------|
| row_RETURN_1   | output_structure  | "RETURN"         | "TYPE","CODE",.. |
| row_COMPANY... | output_structure  | "COMPANY_DE...   | "COMPANY","N...  |

- Select the **Use an existing connection** check box and then in the **Component List**, select the relevant **tSAPConnection** component, **sap** in this scenario.

In the **Initialize input** area, we can see the input parameter needed by the **BAPI\_COMPANY\_GETDETAIL** function.

In the **Outputs** area, we can see all different schemas of the **BAPI\_COMPANY\_GETDETAIL** function, in particular, **COMPANY\_DETAIL** that we want to output.

### Procedure 9. Job execution

- In the design workspace, double-click **tLogRow** to display the **Basic settings** view and define the component properties. For more information about this component, see [the section called "LogRow"](#).
- Press **CTRL+S** to save your Job and press **F6** to execute it.

```

Starting job BAPI_SAP at 18:32 07/10/2009.

Job BAPI_SAP ended at 18:32 07/10/2009. [exit code=0]

```

The **tSAPInput** component retrieved from the SAP system the metadata of the *COMPANY\_DETAIL* “structure” parameter and **tLogRow** displayed the information on the console.

## Scenario 2: Reading data in the different schemas of the RFC\_READ\_TABLE function

Talend SAP components (**tSAPInput** and **tSAPOutput**) as well as the SAP wizard are based on a library validated and provided by SAP (JCO) that allows the user to call functions and retrieve data from the SAP system at Table, RFC or BAPI, levels.

This scenario uses the SAP wizard that leads a user through dialog steps to create a SAP connection and call RFC and BAPI functions. This SAP wizard is available only for **Talend Enterprise** users. If you are a user of **Talend Open Studio** or **Talend Integration Express**, you need to set the basic settings for the **tSAPInput** component manually.

This scenario uses the SAP wizard to first create a connection to the SAP system, and then call an RFC function to directly read from the SAP system a table called *SFLIGHT*. It finally displays in *Talend Open Studio* the structure of the *SFLIGHT* table stored in the SAP system.

## Setting and configuring the SAP connection using wizard

### Procedure 10. Setting up the connection to the SAP system

1. Create a connection to the SAP system using the SAP connection wizard, in this scenario the SAP connection is called *sap*.
2. Call the *RFC\_READ\_TABLE* RFC function using the SAP wizard to access the table in the SAP system and see its structure.
3. In the **Name filter** field, type in *RFC\** and click the **Search** button to display all available RFC functions.

4. Select *RFC\_READ\_TABLE* to display the schema that describe the table structure.

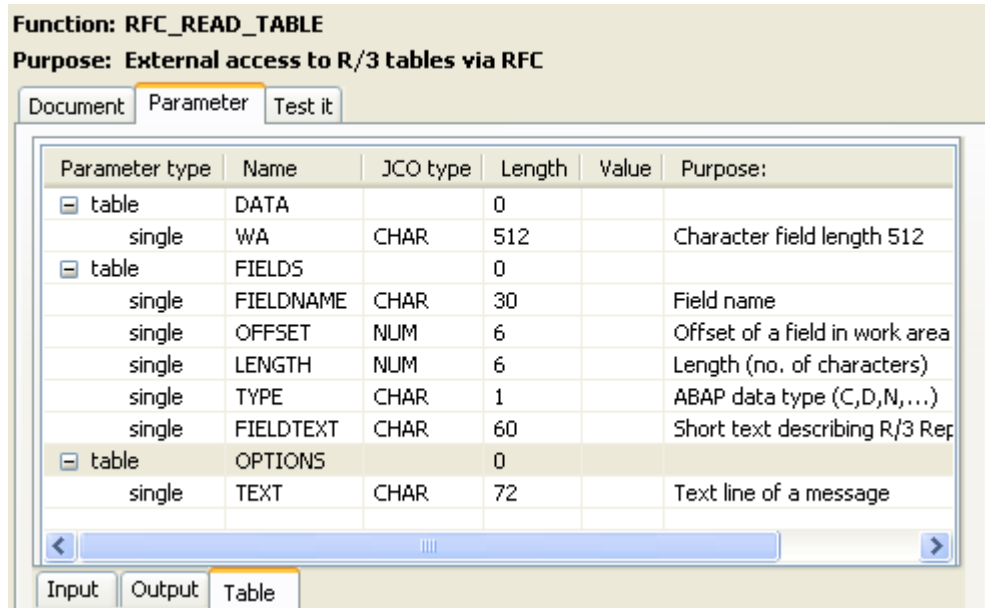

The three-tab view to the right of the wizard displays the metadata of the *RFC\_READ\_TABLE* function and allows you to set the necessary parameters.

The **Document** view displays the SAP html document about the *RFC\_READ\_TABLE* function.

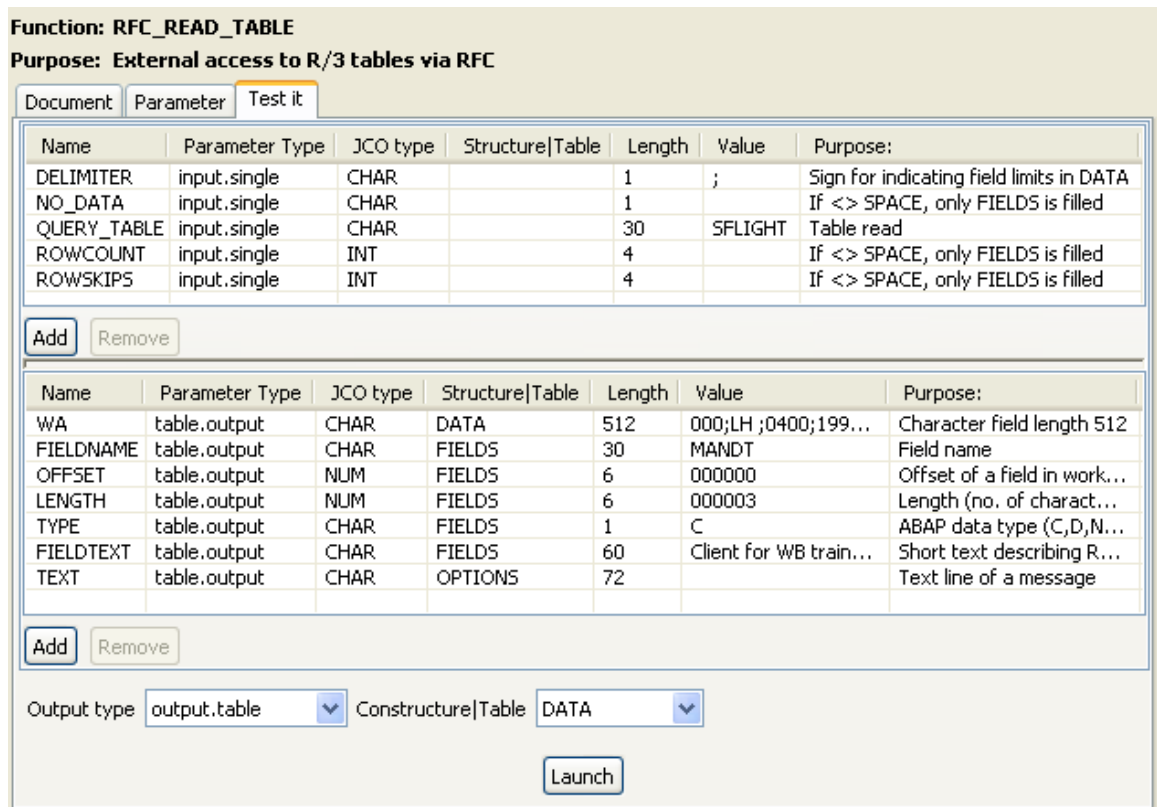

The **Parameter** view provides information about the parameters required by the *RFC\_READ\_TABLE* function to return parameter values.

### Procedure 11. Setting the input and output parameters using the wizard

1. In the **Parameter** view, click the **Table** tab to show a description of the structure of the different tables of the *RFC\_READ\_TABLE* function.

The **Test it** view allows you to add or delete input parameters according to the called function. In this example, we want to retrieve the structure of the *SFLIGHT* table and not any data.

2. In the **Value** column of the **DELIMITER** line, enter “;” as field separator.
3. In the **Value** column of the **QUERY\_TABLE** line, enter *SFLIGHT* as the table to query.
4. In the **Output type** list at the bottom of the view, select **output.table**.
5. In the **Constructure|Table** list, select **DATA**.
6. Click **Launch** at the bottom of the view to display the parameter values returned by the *RFC\_READ\_TABLE* function. In this example, the delimiter is “;” and the table to read is *SFLIGHT*.

7. Click **Finish** to close the wizard and create the connection.

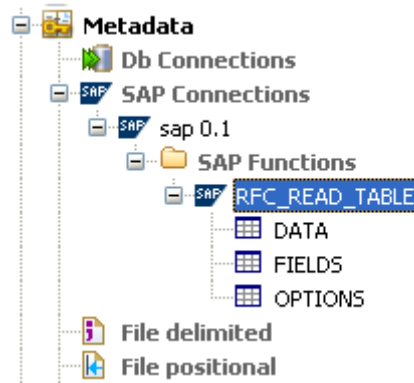

## Procedure 12. Retrieving the different schemas of the RFC\_READ\_TABLE function

The *sap* connection and the **RFC\_READ\_TABLE** function display under the **SAPConnections** node in the **Repository** tree view.

To retrieve the different schemas of the **RFC\_READ\_TABLE** function, do the following:

1. In the **Repository** tree view, right-click **RFC\_READ\_TABLE** and select **Retrieve schema** in the contextual menu. A dialog box displays.
2. Select in the list the schemas you want to retrieve, **DATA**, **FIELDS** and **OPTIONS** in this example.
3. Click **Next** to open a new view on the dialog box and display these different schemas.
4. Click **Finish** to validate your operation and close the dialog box.

The three schemas display under the **RFC\_READ\_TABLE** function in the **Repository** tree view.

## Retrieving the data column names of the SFLIGHT table

In this example, we want to retrieve the data and column names of the **SFLIGHT** table and display them in *Talend Open Studio*. To do that, proceed as the following:

### Procedure 13. Setting up the Job

1. In the **Repository** tree view, drop the **RFC\_READ\_TABLE** function of the *sap* connection to the design workspace to open a dialog box where you can select **tSAPInput** from the component list and then click **OK** to close the dialog box. The **tSAPInput** component displays on the design workspace.
2. Drop two **tLogRow** components from the **Palette** to the design workspace.
3. Right-click **tSAPInput** and select **Row > row\_DATA\_1** and click the first **tLogRow** component.
4. Right-click **tSAPInput** and select **Row > row\_FIELDS\_1** and click the second **tLogRow** components.

In this example, we want to retrieve the **FIELDS** and **DATA** schemas and put them in two different output flows.

5. In the design workspace, double-click **tSAPInput** to open the **Basic settings** view and display the component properties.

(To use this component, you need first to add the SAP Java Connector (sapjco.jar) in the Modules view)

Property Type: Repository | SAP:sap

Use an existing connection

Connection configuration

Client: "000" \*

Userid: "TALEND" \*

Password: "\*\*\*\*\*" \*

Language: "EN" \*

Host name: "192.168.80.128" \*

System number: "00" \*

FunName: "RFC\_READ\_TABLE" \*

Initialize input

| ParameterValue | Type         | TableName(Str... | ParameterName |
|----------------|--------------|------------------|---------------|
| ","            | input_single | ""               | "DELIMITER"   |
| ""             | input_single | ""               | "NO_DATA"     |
| "SFLIGHT"      | input_single | ""               | "QUERY_TABLE" |
| 0              | input_single | ""               | "ROWCOUNT"    |
| 0              | input_single | ""               | "ROWSKIPS"    |

The basic setting parameters for the **tSAPInput** component display automatically since the schema is stored in the **Metadata** node and the component is initialized by the SAP wizard.

In the **Initialize input** area, we can see the input parameters necessary for the **RFC\_READ\_TABLE** function, the field delimiter “,” and the table name “**SFLIGHT**”.

In the **Outputs** area, we can see the different schemas of the **SFLIGHT** table.

Outputs

| Schema        | Type(for iterate) | TableName... | Mapping              |
|---------------|-------------------|--------------|----------------------|
| row_FIELDS_1  | table_output      | "FIELDS"     | "FIELDNAME","OFFSET" |
| row_OPTIONS_1 | table_output      | "OPTIONS"    | "TEXT"               |
| row_DATA_1    | table_output      | "DATA"       | "WA"                 |

### Procedure 14. Job execution

1. In the design workspace, double click each of the two **tLogRow** components to display the **Basic settings** view and define the component properties. For more information on the properties of **tLogRow**, see [the section called "tLogRow"](#).
2. Press **CTRL+S** to save your Job and press **F6** to execute it.

# tSAPRollback

## tSAPRollback properties

This component is closely related to **tSAPCommit** and **tSAPConnection**. It usually does not make much sense to use these components separately in a transaction.

| <b>Component family</b>  | Business/Cloud                                                       |                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Function</b>          | Connects to a Sugar CRM database module via the relevant webservice. |                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Purpose</b>           | Allows you to extract data from a SugarCRM DB based on a query.      |                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Basic settings</b>    | <i>SugarCRM Webservice URL</i>                                       | Type in the webservice URL to connect to the SugarCRM DB.                                                                                                                                                                                                                                                                                                                                                   |
|                          | <i>Username</i> and <i>Password</i>                                  | Type in the Webservice user authentication data.                                                                                                                                                                                                                                                                                                                                                            |
|                          | <i>Module</i>                                                        | Select the relevant module from the list<br><br> To use customized tables, select <b>Use custom module</b> from the list. The <b>Custom module package name</b> and <b>Custom module name</b> fields which appear are automatically filled in with the relevant names.                                                     |
|                          | <i>Schema</i> and <i>Edit Schema</i>                                 | A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.<br><br>Click <b>Edit Schema</b> to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.<br><br>In this component the schema is related to the Module selected. |
|                          | <i>Query condition</i>                                               | Type in the query to select the data to be extracted. Example: account_name= 'Talend'                                                                                                                                                                                                                                                                                                                       |
| <b>Advanced settings</b> | <i>tStat Catcher Statistics</i>                                      | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                                                                                           |
| <b>Usage</b>             | Usually used as a Start component. An output component is required.  |                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Limitation</b>        | n/a                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                             |

## Scenario: Extracting account data from SugarCRM

This scenario describes a two-component Job which extracts account information from a SugarCRM database and writes it to an Excel output file.

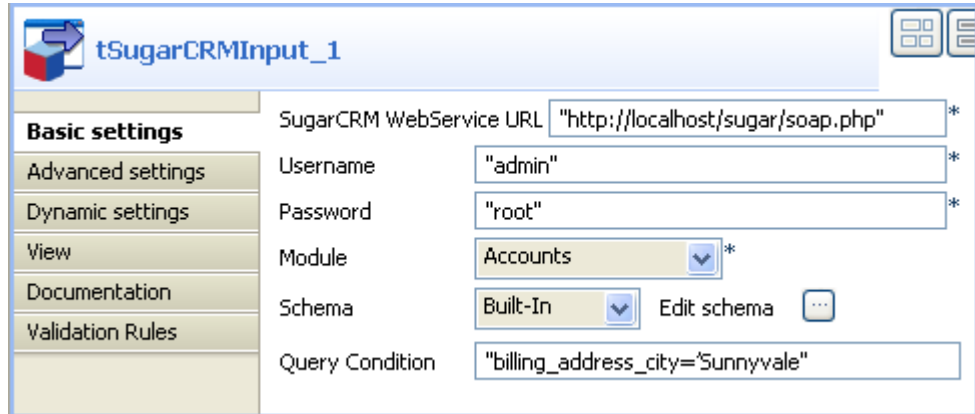

## Setting up the Job

1. Drop a **tSugarCRMInput** and a **tFileOutputExcel** component from the **Palette** onto the workspace.
2. Connect the input component to the output component using a **Row > Main** connection.

## Configuring the input component

1. Double-click **tSugarCRMInput** to define the component properties in its **Basic settings** view.

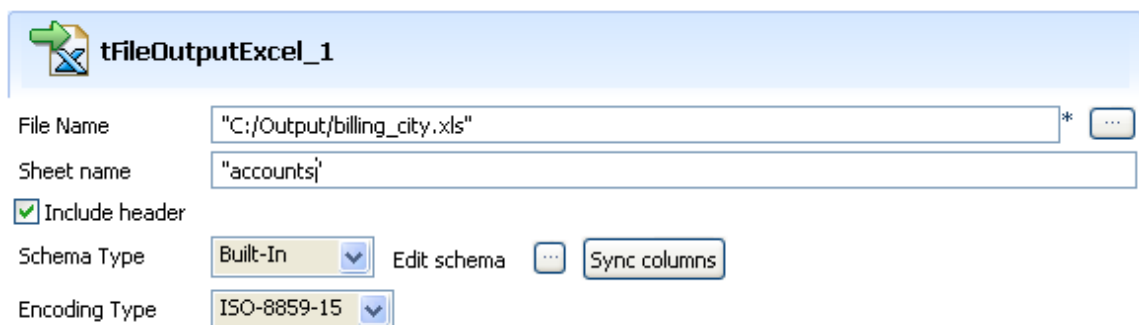

2. Fill the **SugarCRM Webservice URL** field with the connection information, and the **Username** and **Password** fields with the authentication you have.
3. Select the **Module** from the list of modules offered. In this example, *Accounts* is selected.

The **Schema** is then automatically set according to the module selected. But you can change it and remove the columns that you do not require in the output.

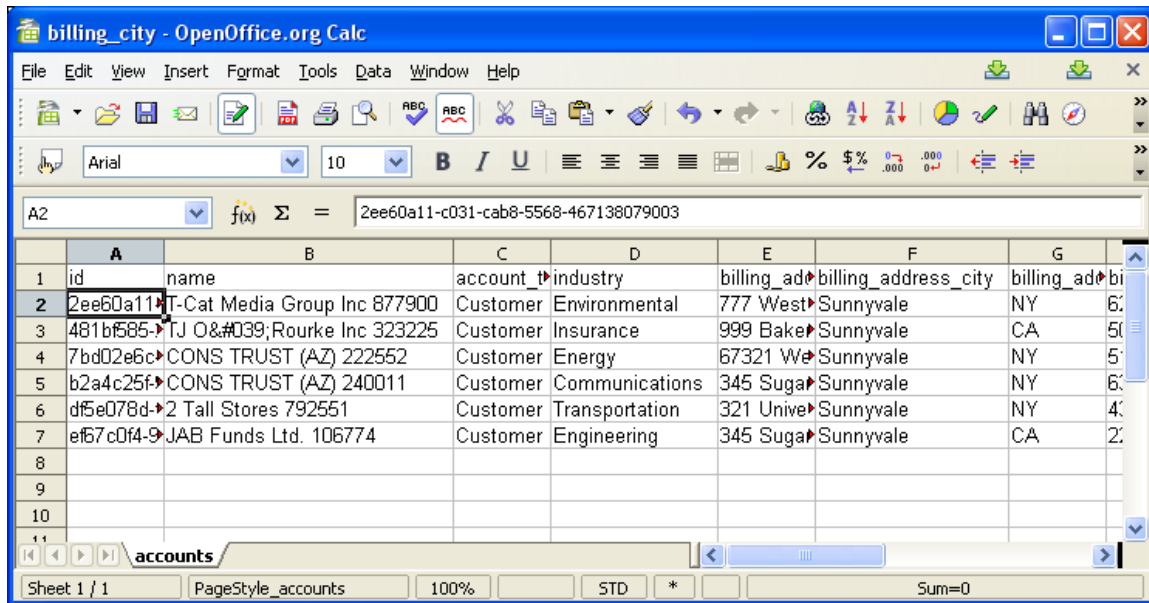

4. In the **Query Condition** field, type in the query you want to extract from the CRM. In this example: "billing\_address\_city='Sunnyvale'".

## Job execution

1. Double-click **tFileOutputExcel** to define the component properties in its **Basic settings** view.

2. Set the destination file name as well as the **Sheet** name and select the **Include header** check box.
3. Press **CTRL+S** to save your Job and press **F6** to execute it.

The filtered data is output in the defined spreadsheet of the specified Excel file.

# tSugarCRMOutput

|                          |                                                              | In this component the schema is related to the Module selected.                                                |
|                          | <i>Die on error</i>                                          | This check box is clear by default to skip the row on error and complete the process for error-free rows.      |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                               | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |
| <b>Usage</b>             | Used as an output component. An Input component is required. |                                                                                                                |
| <b>Limitation</b>        | n/a                                                          |                                                                                                                |

## Related Scenario

No scenario is available for this component yet.

# Business Intelligence components

This chapter details the main components which belong to the **Business Intelligence** family in the *Talend Open Studio Palette*.

The BI family groups connectors that cover needs such as reading or writing multidimensional or OLAP databases, outputting Jasper reports, tracking DB changes in slow changing dimension tables and so on.

|                         |                                                                                                              | <b>Repository:</b> The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                         | <i>Sync columns</i>                                                                                          | Click to synchronize the output file schema with the input file schema. The Sync function only displays once the <b>Row</b> connection is linked with the output component.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                         | <i>Generated image path</i>                                                                                  | Name and path of the output image file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                         | <i>Chart title</i>                                                                                           | Enter the title of the bar chart to be generated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                         | <i>Include legend</i>                                                                                        | Select this check box if you want the bar chart to include a legend, indicating all series in different colors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                         | <i>3Dimensions</i>                                                                                           | Select this check box to create an image with 3D effect. By default, this check box is selected and the bars representing the series of each category will be stacked one over another. If this check box is cleared, a 2D image will be created, with the bars displayed one besides another along the category axis.                                                                                                                                                                                                                                                                                      |
|                         | <i>Image width and Image height</i>                                                                          | Enter the width and height of the image file, in pixels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                         | <i>Category axis name and Value axis name</i>                                                                | Enter the category axis name and value axis name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                         | <i>Foreground alpha</i>                                                                                      | Enter an integer in the range of 0 to 100 to define the transparency of the image. The smaller the number you enter, the more transparent the image will be.                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                          |                                                                                                                      |                                                                                      |
|--------------------------|----------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
|                          | <i>Plot orientation</i>                                                                                              | Select the plot orientation of the bar chart: <b>VERTICAL</b> or <b>HORIZONTAL</b> . |
| <b>Advanced settings</b> | <i>tStat Catcher Statistics</i>                                                                                      | Select this check box to collect log data at the component level.                    |
| <b>Usage</b>             | This component is mainly used as Output component. It requires an Input component and <b>Row</b> main link as input. |                                                                                      |

## Scenario: Creating a bar chart from the input data

This scenario describes a simple Job that reads data from a CSV file and transforms the data into a bar chart. The input file is shown below:

```

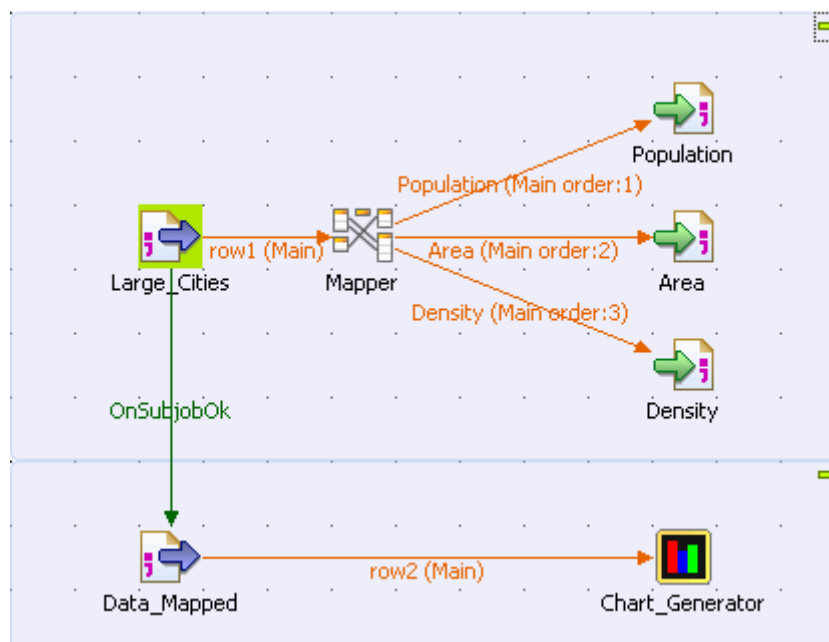

1 City;Population(x1000);LandArea(km2);PopulationDensity(people/km2)
2 Beijing;10233;1418;7620
3 Moscow;10452;1081;9644
4 Seoul;10422;605;17215
5 Tokyo;8731;617;14151
6 Jakarta;8490;664;12738
7 New York;8310;789;10452

```

Because the input file has a different structure than the one required by the **tBarChart** component, this use case uses the **tMap** component to map the data to a three-column CSV file before using the **tBarChart** component to generate a bar chart file.

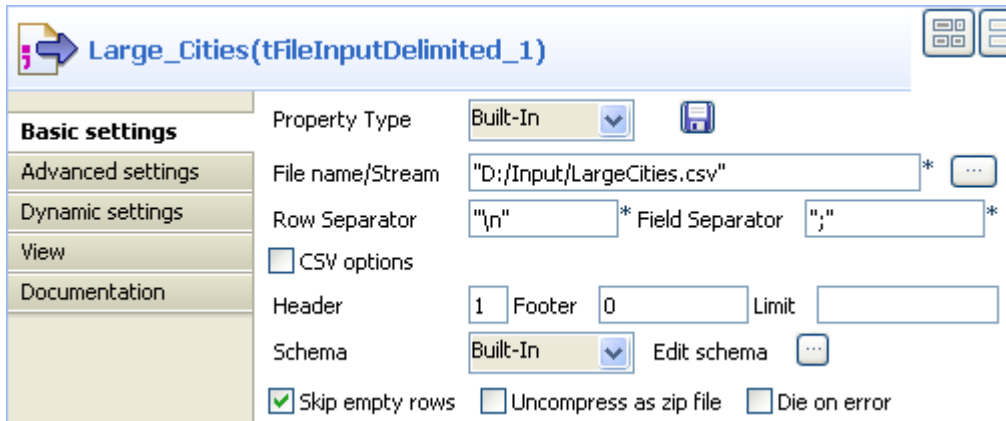

You will usually use the **tMap** component to adjust the input schema in accordance with the schema structure of the **tBarChart** component. For more information about how to use the **tMap** component, see *Talend Open Studio User Guide* and [the section called “tMap”](#).

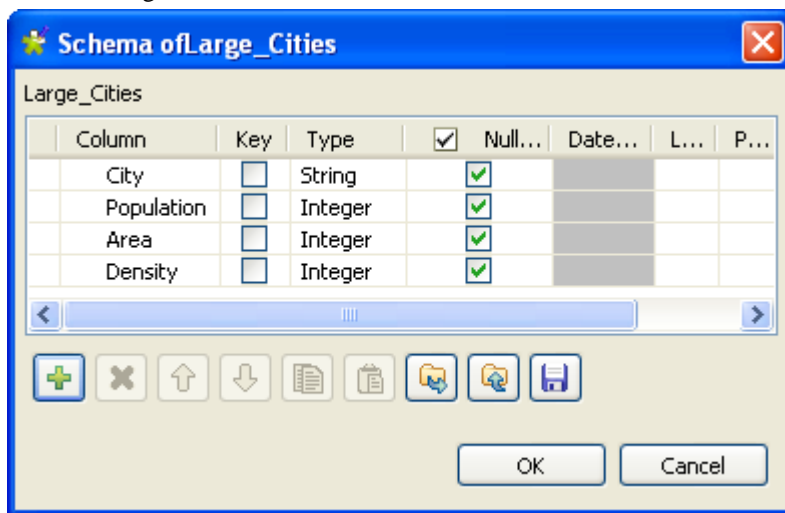

## Setting the input data

- Drop the following components from the **Palette** to the design workspace: two **tFileInputDelimited** components, a **tMap**, three **tFileOutputDelimited** components, and a **tBarChart**. Relabel the components to best describe their functionality.
- Double-click the first **tFileInputDelimited** component to display its **Basic settings** view.

- Fill in the **File name** field by browsing to the input file.
- In the **Header** field, specify the number of header rows. In this use case, you have only one header row.
- Leave the other parameters as they are.
- Click **Edit schema** to describe the data structure of the input file. In this use case, the input schema is made of four columns: *City*, *Population*, *Area*, and *Density*. Upon defining the column names and data types, click **OK** to close the schema dialog box.

## Setting the mapping

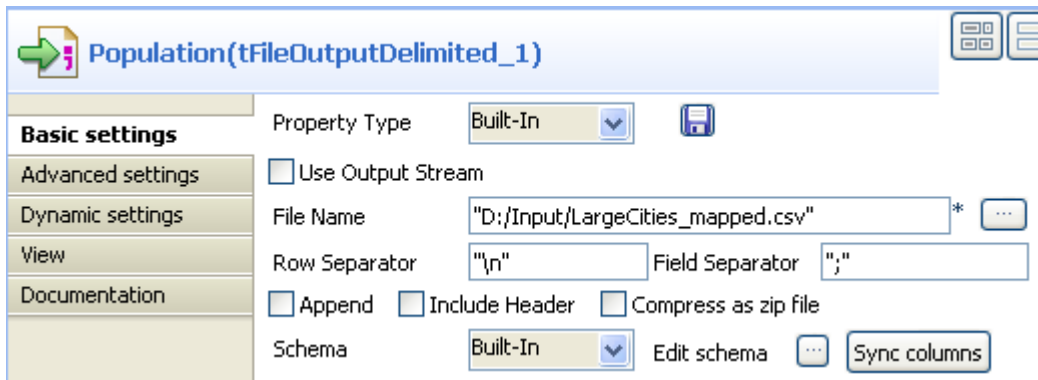

- Connect the **tFileInputDelimited** to the **tMap** using a **Row > Main** connection.
- Double-click the **tMap** to open the **Map Editor**.

3. Click the green plus button on top of the output panel to add three output tables: *Population*, *Area*, and *Density*. These output table names will appear as the labels of the connections linking the **tMap** to the output components on the design workspace.
4. Use the **Schema editor** to add three columns to each output table: *series* (string), *category* (string), and *value* (integer).
5. In the relevant **Expression** field of the output tables, enter the series names, as shown above. These series names will appear in the legend of the bar chart.
6. Drop the *City* column of the input table onto the *category* column of each output table.
7. Drop the *Population* column of the input table onto the *value* column of the *Population* table.
8. Drop the *Area* column of the input table onto the *value* column of the *Area* table.
9. Drop the *Density* column of the input table onto the *value* column of the *Density* table.
10. Click **OK** to save the mappings and close the **Map Editor**.

## Setting the output data

1. Right click the **tMap** component and select **Row > Population** to connect it to the first **tFileOutputDelimited** component.
2. Connect the **tMap** to the other **tFileOutputDelimited** components in the same way but by selecting **Area** and **Density** respectively.
3. Double-click the first **tFileOutputDelimited** component to display its **Basic settings** view.

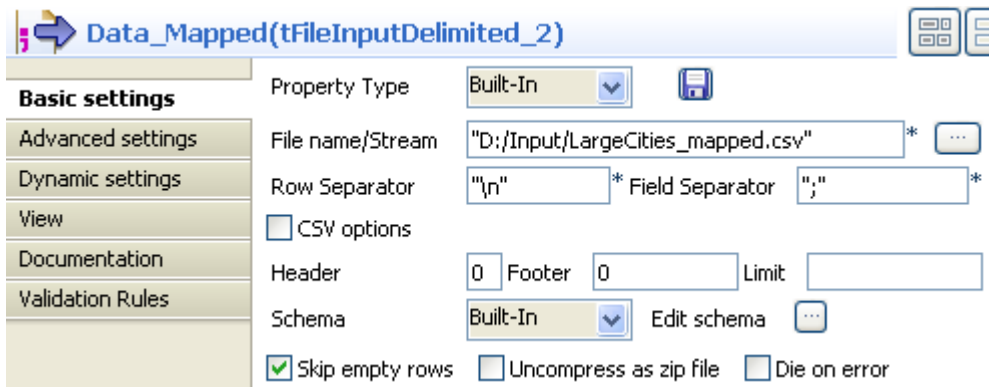

- In the **File Name** field, define a CSV file to send the mapped data flows to. In this use case, we name the output file to be created *LargeCities\_mapped.csv*. This file will be used as the input to the **tBarChart** component. If an existing file name is specified, make sure that the **Append** check box is cleared.
- Leave the other parameters as they are.
- For the other two **tFileOutputDelimited** components, use the same file path as defined for the first **tFileOutputDelimited** component, and select the **Append** check box.

Make sure that the **Append** check box is selected so that all the mapped data flows will go to the same file without overwriting the existing data.

## Setting the input data for tBarChart

- Connect the first **tFileInputDelimited** component to the second **tFileInputDelimited** component using a **Trigger > OnSubjobOK** connection.
- Connect the second **tFileInputDelimited** component to the **tBarChart** using a **Row > Main** connection.
- Double-click the second **tFileInputDelimited** component to display its **Basic settings** view.

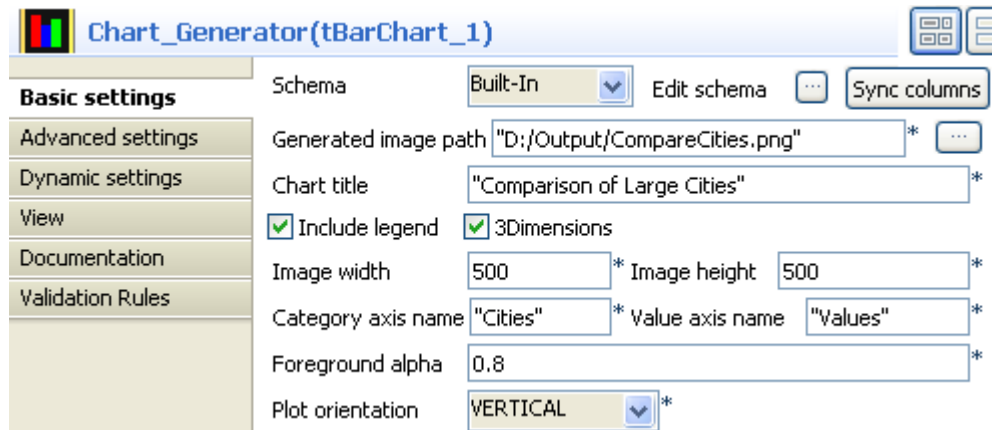

- Fill in the **File name** field with the file path and name defined in the **Basic settings** view of each of the **tFileOutputDelimited** components. In this use case, the input file to the **tBarChart** is *LargeCities\_mapped.csv*.
- Leave the other parameters as they are.

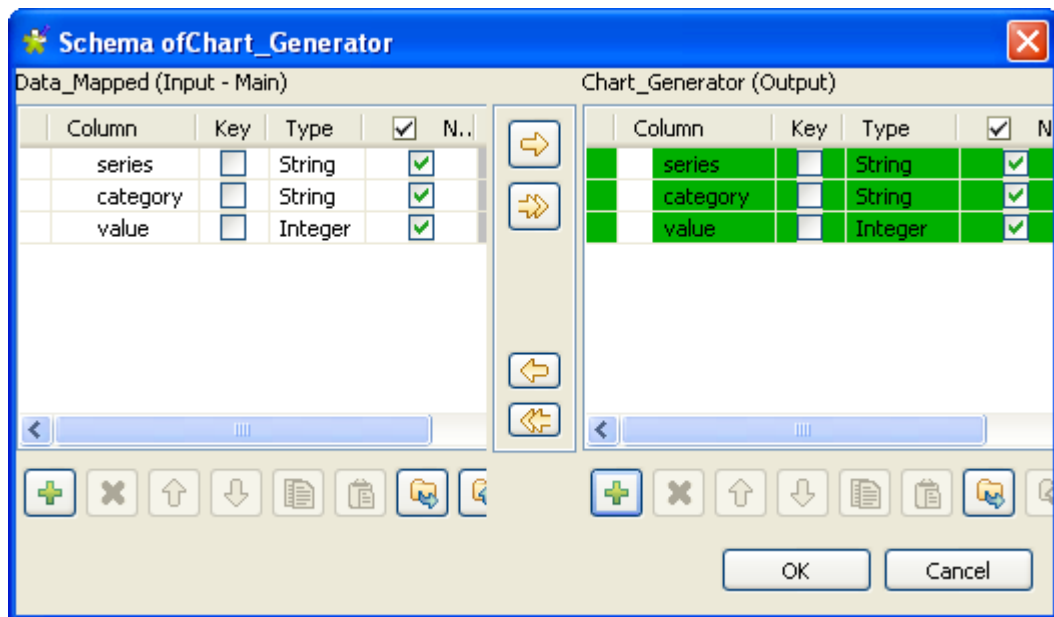

As the input schema needs to have a structure required by the **tBarChart** component, we will copy the structure from the schema of the **tBarChart** component.

## Configuring the tBarChart component

1. Double-click the **tBarChart** component to display its **Basic settings** view.

2. In the **Generated image path** field, define the file path of the image file to be generated.
3. In the **Chart title** field, define a title for the bar chart.
4. Define the category and series axis names.
5. Define the size and transparency degree of the image if needed. In this use case, we simply use the default settings.
6. Click **Edit schema** to open the schema dialog box.

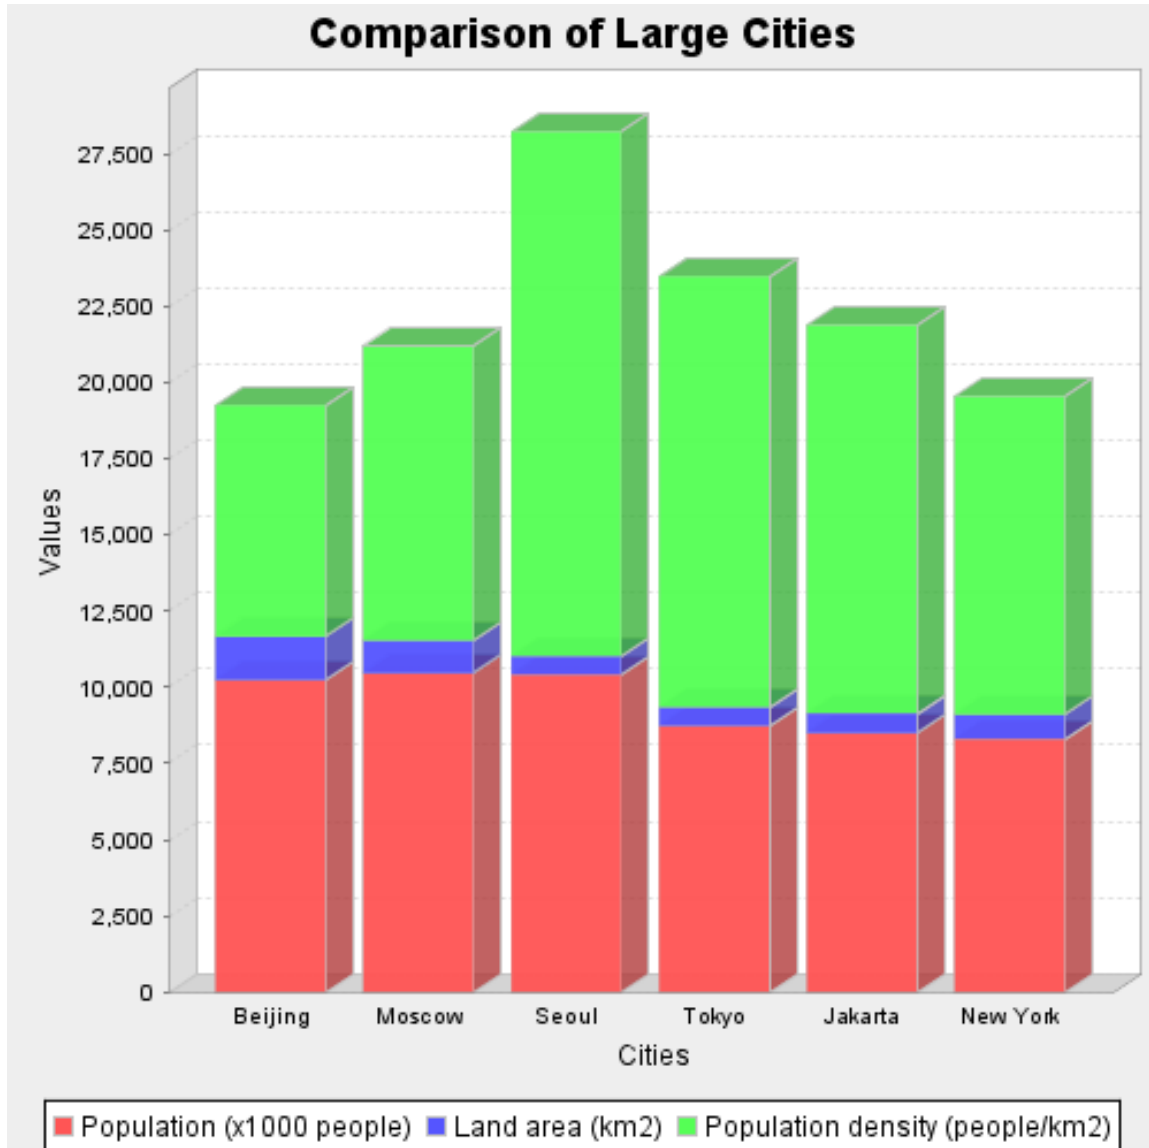

7. Copy all the columns from the output schema to the input schema by clicking the left-pointing double arrow button. Then, click **OK** to close the schema dialog box.

## Job execution

1. Save your Job.
2. Press **F6** to launch it.

A bar chart is generated as defined.

Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|  |                               | <b>Repository:</b> The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|  | <i>Surrogate Key</i>          | Select the surrogate key column from the list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|  | <i>Creation</i>               | <p>Select the method to be used for the surrogate key generation.</p> <p>For more information regarding the creation methods, see <a href="#">the section called “SCD keys”</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|  | <i>Source Keys</i>            | Select one or more columns to be used as keys, to ensure the unicity of incoming data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|  | <i>Use SCD Type 1 fields</i>  | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|  | <i>Use SCD Type 2 fields</i>  | <p>Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.</p> <p><b>Start date:</b> Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.</p> <p><b>End Date:</b> Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select <b>Fixed Year value</b> and fill it in with a fictive year to avoid having a null value in the End Date field.</p> |

|                          |                                                                                                           |                                                                                                                                                                                                                                                                                    |
|--------------------------|-----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                                                                           | <p><b>Log Active Status:</b> Adds a column to your SCD schema to hold the <b>true</b> or <b>false</b> status value. This column helps to easily spot the active record.</p> <p><b>Log versions:</b> Adds a column to your SCD schema to hold the version number of the record.</p> |
| <b>Advanced settings</b> | <i>Debug mode</i>                                                                                         | Select this check box to display each step during processing entries in a database.                                                                                                                                                                                                |
|                          | <i>tStat Catcher Statistics</i>                                                                           | Select this check box to collect log data at the component level.                                                                                                                                                                                                                  |
| <b>Usage</b>             | This component is used as an output component. It requires an input component and Row main link as input. |                                                                                                                                                                                                                                                                                    |

| <b>Usage</b>             | This component is used as Output component. It requires an Input component and Row main link as input. |                                                                                                                                                                                                       |

## Related scenario

For related scenarios, see [the section called “tMySQLSCD”](#).

# tJasperOutput

## tJasperOutput Properties

This component is closely related to Jaspersoft's report designer -- iReport. It reads and processes data from an input flow to create a report against a .jrxml report template defined via iReport.

You can select <b>Custom</b> from the list to enter an encoding method in the field that appears. |
| <b>Usage</b>      | This component is closely related to Jaspersoft's report designer -- iReport. It reads and processes data from an input flow to create a report against a .jrxml report template defined via iReport. |                                                                                                                                           |
| <b>Limitation</b> | n/a                                                                                                                                                                                                   |                                                                                                                                           |

## Scenario: Generating a report against a .jrxml template

The following Job reads data from a .csv file and creates a .pdf report based on an existing .jrxml report template. Note that the template file should be created via Jaspersoft's iReport based on a file that shares the same schema with the source .csv file of this job.

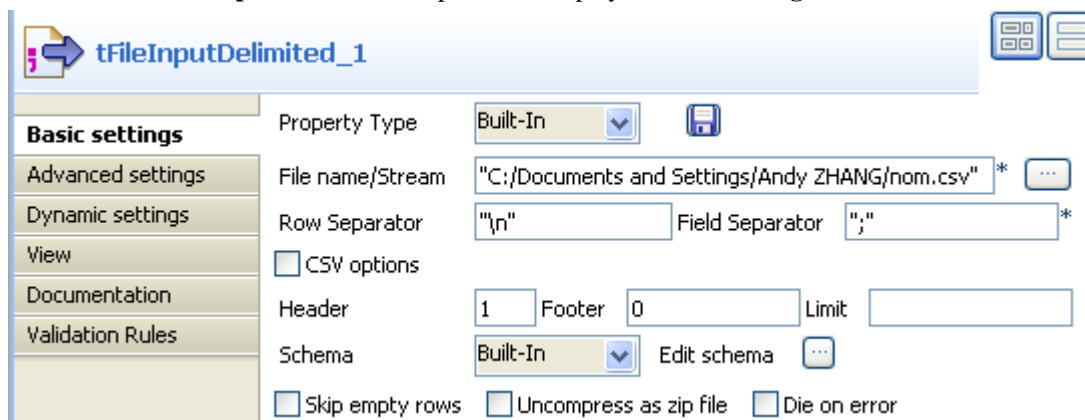

### Setting up the Job

1. Drag and drop the following components from the **Palette** to the workspace: **tFileInputDelimited** and **tJasperOutput**.
2. Connect **tFileInputDelimited** and **tJasperOutput** using a **Row** link.

### Configuring the input component

1. Double-click the **tFileInputDelimited** component to display its **Basic settings** view.

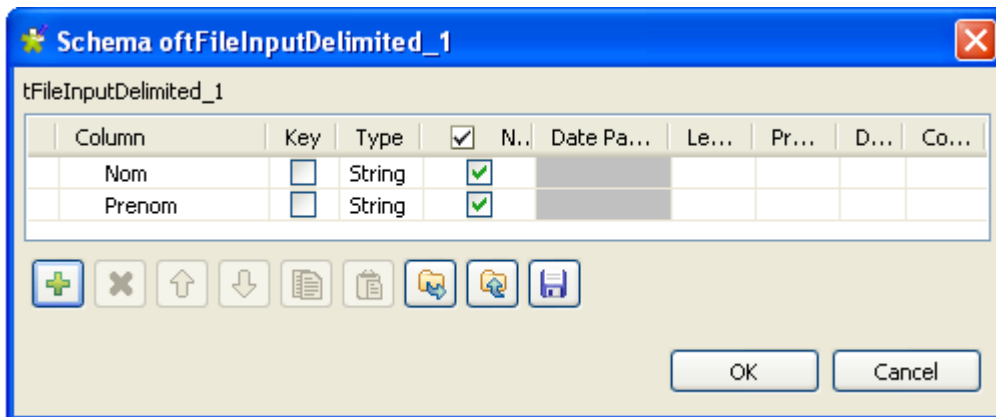

2. Select **Built-In** from the **Property Type** drop-down list.

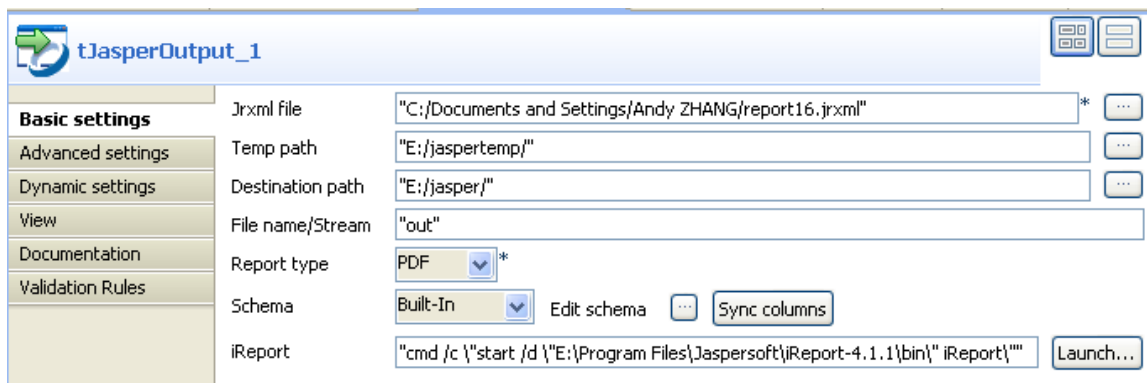

You can select **Repository** from the **Property Type** drop-down list to fill in the relevant fields automatically if the relevant metadata has been stored locally in the **Repository**. For more information about **Metadata**, see the *Talend Open Studio User Guide*.

3. Fill in the **File name/Stream** field to give the path and name of the source file, e.g. "*C:/Documents and Settings/Andy ZHANG/nom.csv*".
4. Keep the default settings for the **Row Separator** and **Field Separator** fields. You can also change them as needed.
5. Set *1* in the **Header** field and *0* in the **Footer** field. Leave the **Limit** field empty. You can also change them as needed.
6. Select **Built-In** from the **Schema** drop-down list and click **Edit schema** to define the data structure of the input file. In this case, the input file has 2 columns: *Nom* and *Prenom*.

## Configuring the output component

1. Double-click **tJasperOutput** to display its **Basic settings** view.

2. Enter the full path of the report template file created via Jaspersoft's iReport in the **Jrxml file** field. You can click the three-dot button to browse.

The schema of the file, which is used to create a .jrxml template file via iReport, should be the same as that of the source file that is used to create the report.

3. Enter the path for the temporary files generated during the job execution in the **Temp path** field. You can click the three-dot button to browse.
4. Enter the path for the final report file generated during the job execution in the **Destination path** field. You can click the three-dot button to browse.

5. Enter the name for the final report file generated during the job execution in the **File name/Stream** field.
6. Select the format for the final report file generated during the job execution in the **Report type** field.
7. Click **Sync columns** to retrieve the schema from the previous component.
8. Enter the path of execution file of Jaspersoft's iReport in the **iReport** field, e.g. replacing `__IREPORT_PATH__\` with `E:\Program Files\Jaspersoft\iReport-4.1.1\bin\`. You can click the **Launch** button to run iReport.

This step is not mandatory. Yet, this helps you conveniently access the iReport software for relevant operations, e.g. creating a report template, etc.

## Job execution

1. Press **CTRL+S** to save your Job.
2. Press **F6** to execute it.

You can find the file *out.pdf* in the folder specified in the **Destination path** field.

# tJasperOutputExec

## tJasperOutputExec Properties

This component is closely related to Jaspersoft's report designer -- iReport. It reads and processes data from a source file to create a report against a .jrxml report template defined via iReport. This component offers a performance gain as it functions as a combination of an input component and a **tJasperOutput** component. The advantage of using two separate components is that data can be transformed before being used to generate a report and the input sources can be various and rich.

| <b>Component family</b> | Business Intelligence/Charts                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Function</b>         | <b>tLineChart</b> reads data from an input flow and transforms the data into a line chart in a PNG image file. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Purpose</b>          | <b>tLineChart</b> generates a line chart from the input data to ease technical analysis.                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Basic settings</b>   | <i>Schema and Edit Schema</i>                                                                                  | <p>A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. The schema is either built-in or remotely stored in the Repository.</p> <p> The schema of <b>tLineChart</b> contains three read-only columns named <b>series</b> (string), <b>x</b> (integer), and <b>y</b> (integer) respectively, in a fixed order. The data in any extra columns will be only passed to the next component, if any, without being presented in the generated line chart.</p> |
|                         |                                                                                                                | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                         |                                                                                                                | <b>Repository:</b> The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                         | <i>Sync columns</i>                                                                                            | Click to synchronize the output file schema with the input file schema. The Sync function only displays once the <b>Row</b> connection is linked with the output component.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                         | <i>Generated image path</i>                                                                                    | Name and path of the output image file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                         | <i>Chart title</i>                                                                                             | Enter the title of the line chart to be generated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                         | <i>Plot orientation</i>                                                                                        | Select the plot orientation of the range axis: <b>Vertical</b> or <b>Horizontal</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                         | <i>Include legend</i>                                                                                          | Select this check box if you want your line chart to include a legend, indicating the lines of different series in different colors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                         | <i>Image width and Image height</i>                                                                            | Enter the width and height of the image, in pixels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                         | <i>Moving average</i>                                                                                          | Select this check box to show a moving average for each series on your line chart. With this check box selected, the <b>Period</b> field appears, letting you define a period of which you want to show the moving average.                                                                                                                                                                                                                                                                                                                                                                                   |

|                          |                                                                                                                      |                                                                         |
|--------------------------|----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
|                          | <i>Lower bound and Upper bound</i>                                                                                   | Define the lowest and highest values to be displayed on the range axis. |
|                          | <i>Chart background and Plot background</i>                                                                          | Select the chart background color and the plot area background color.   |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                                                                       | Select this check box to collect log data at the component level.       |
| <b>Usage</b>             | This component is mainly used as Output component. It requires an Input component and <b>Row</b> main link as input. |                                                                         |

## Scenario: Creating a line chart to ease trend analysis

This scenario describes a simple Job that reads data from a CSV file and transforms the data into a line chart to facilitate trend analysis. The input file records how long (in minutes) per week a person watches different TV channels over ten weeks, as shown below:

|    |                                 |
|----|---------------------------------|
| 1  | Week;Mins_TVÀ;Mins_TVß;Mins_TVÇ |
| 2  | 1;327;286;244                   |
| 3  | 2;326;285;243                   |
| 4  | 3;325;283;245                   |
| 5  | 4;323;282;246                   |
| 6  | 5;322;285;248                   |
| 7  | 6;321;288;247                   |
| 8  | 7;322;291;245                   |
| 9  | 8;321;292;244                   |
| 10 | 9;320;293;243                   |
| 11 | 10;319;294;242                  |

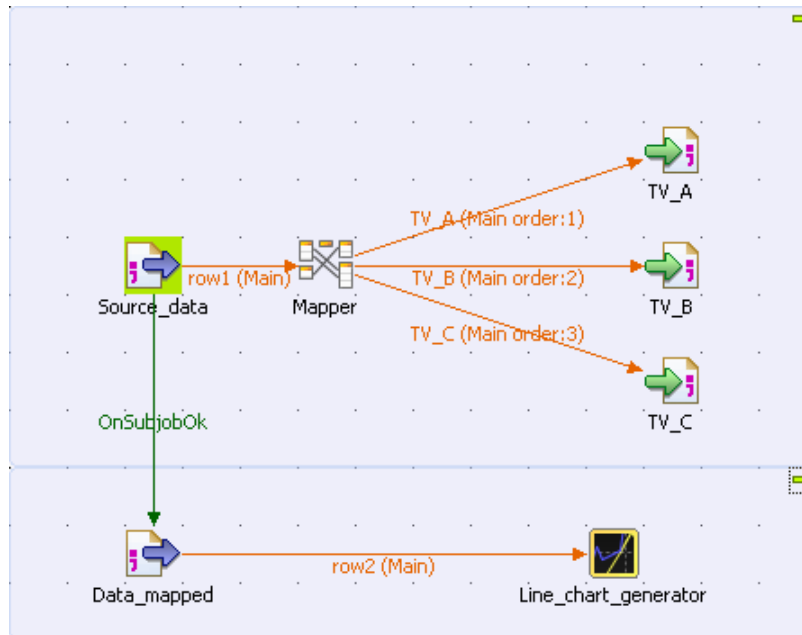

Because the input file has a different structure than required by the **tLineChart** component, this use case uses the **tMap** component to map the data to a CSV file that meets the structure requirement before using the **tLineChart** component to generate a line chart file.

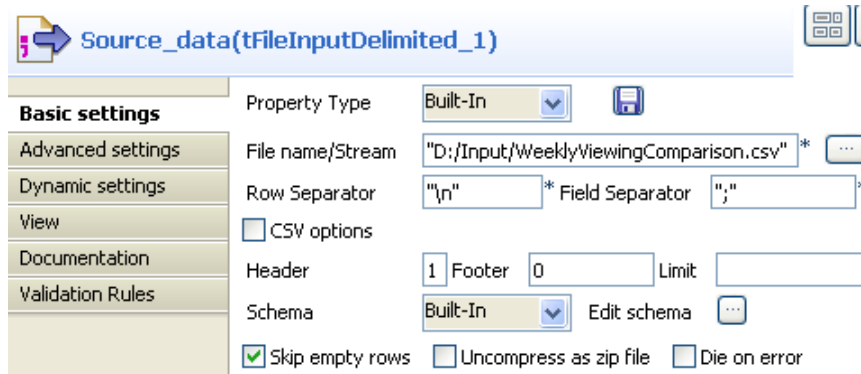

You will usually use the **tMap** component to adjust the input schema in accordance with the schema structure of the **tLineChart** component. For more information about how to use the **tMap** component, see *Talend Open Studio User Guide* and [the section called “tMap”](#).

## Configuring the input component

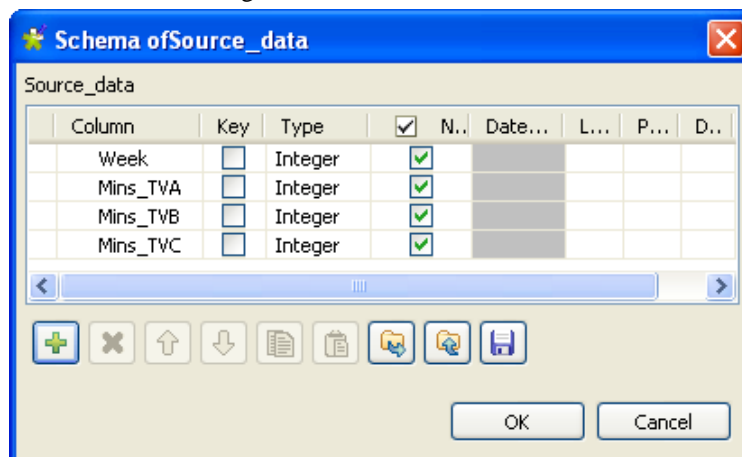

1. Drop the following components from the **Palette** to the design workspace: two **tFileInputDelimited** components, a **tMap**, three **tFileOutputDelimited** components, and a **tLineChart**. Relabel the components to best describe their functionality.

2. Double-click the first **tFileInputDelimited** component to display its **Basic settings** view.

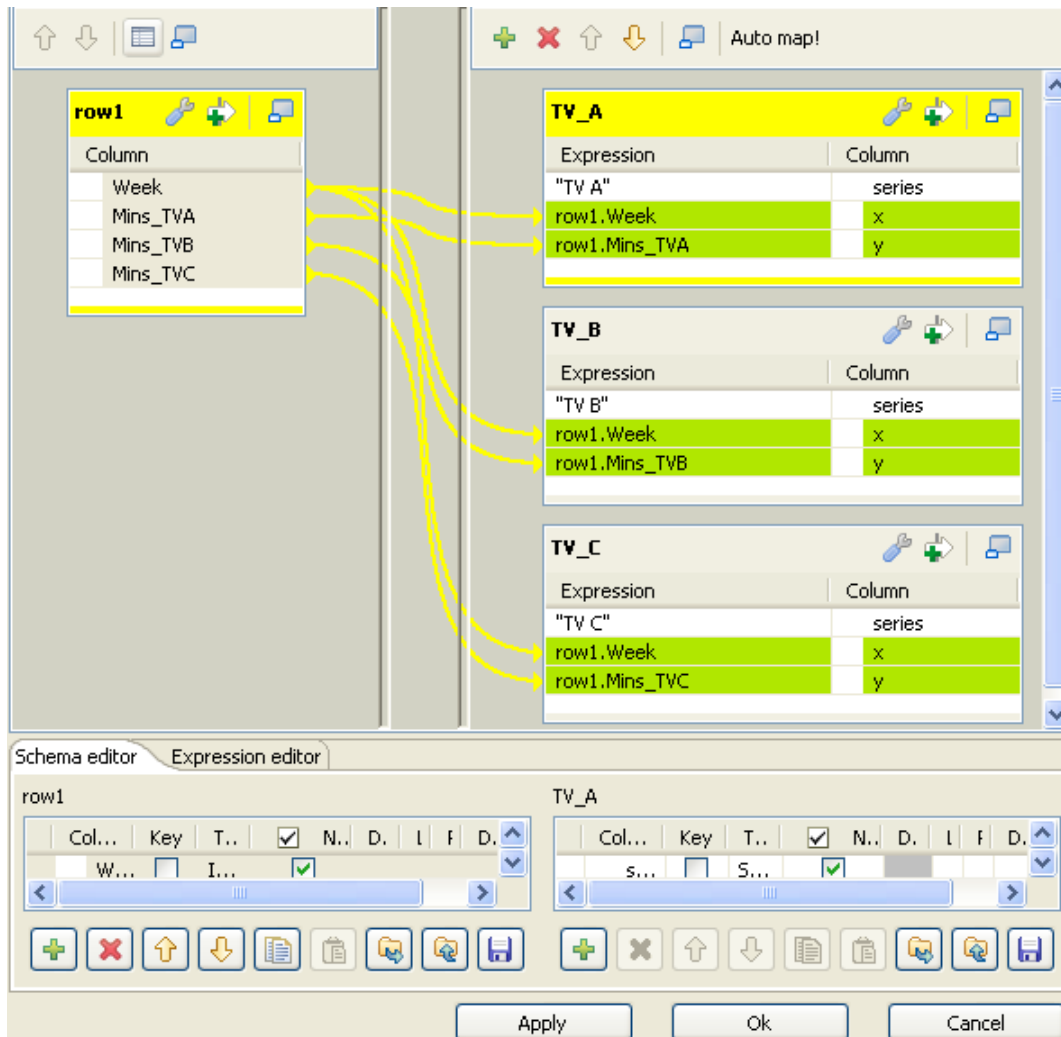

3. Fill in the **File name** field by browsing to the input file.
4. Specify the header row. In this use case, the first row of the input file is the header row. And leave the other parameters as they are.
5. Click **Edit schema** to describe the data structure of the input file. In this use case, the input schema is made of four columns: *Week*, *Mins\_TVA*, *Mins\_TVB*, and *Mins\_TVC*. Upon defining the column names and data type, click **OK** to close the schema dialog box.

## Configuration in the tMap editor

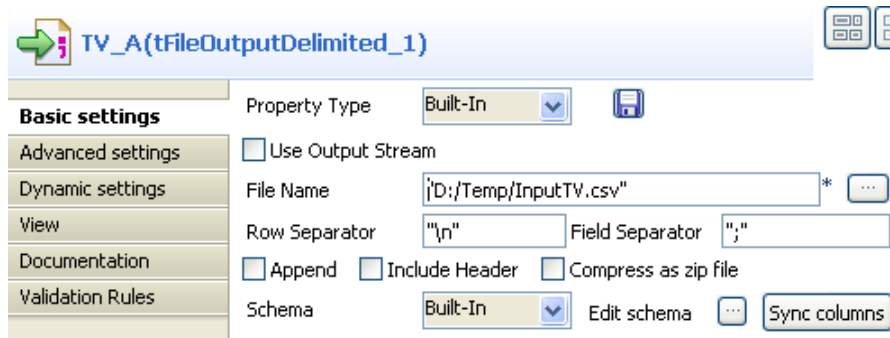

1. Connect the **tFileInputDelimited** to the **tMap** using a **Row > Main** connection.
2. Double-click the **tMap** to open the **Map Editor**.

3. Click the green plus button on top of the output panel to add three output tables: *TV\_A*, *TV\_B*, and *TV\_C*. These output table names will appear as the labels of the connections linking the **tMap** to the output components on the design workspace.
4. Use the **Schema editor** to add three columns to each output table: *series* (string), *x* (integer), and *y* (integer).
5. In the relevant **Expression** field of the output tables, enter the series names, as shown above. These series names will appear in the legend of your line chart.
6. Drop the *Week* column of the input table onto the *x* column of each output table.
7. Drop the *Mins\_TVA* column of the input table onto the *y* column of the *TV\_A* table.
8. Drop the *Mins\_TVB* column of the input table onto the *y* column of the *TV\_B* table.
9. Drop the *Mins\_TVC* column of the input table onto the *y* column of the *TV\_C* table.
10. Click **OK** to save the mappings and close the **Map Editor**.

## Setting up the mapping

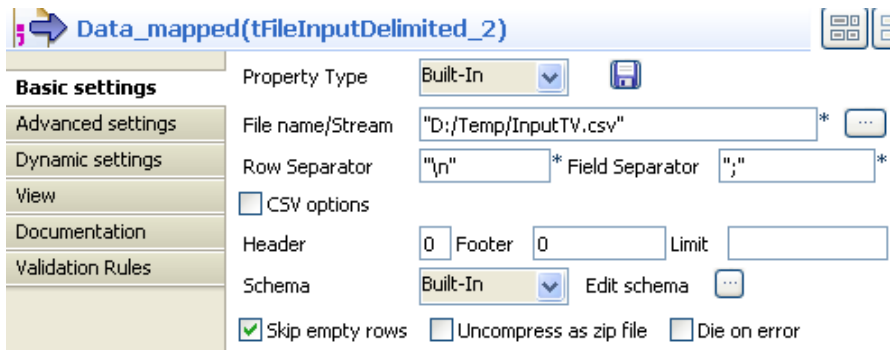

1. Right-click the **tMap** component and select **Row > TV\_A** to connect it to the first **tFileOutputDelimited** component.
2. Connect the **tMap** to the other **tFileOutputDelimited** components in the same way but by selecting **Row > TV\_B** and **Row > TV\_C** respectively
3. Double-click the first **tFileOutputDelimited** component to display its **Basic settings** view.

4. In the **File Name** field, define a CSV file to send the mapped data flows to. In this use case, we name the the output file to be created *InputTV.csv*. This file will be used as the input to the **tLineChart** component. If an existing file name is specified, make sure that the **Append** check box is cleared.
5. Leave the other parameters as they are.
6. For the other **tFileOutputDelimited** components, use the same file path as defined for the first **tFileOutputDelimited** component, and select the **Append** check box.
  -  Make sure that the **Append** check box is selected so that the mapped data flows will go to the same file without overwriting the existing data.
7. Connect the first **tFileInputDelimited** component to the second **tFileInputDelimited** component using a **Trigger > OnSubjobOK** connection.
8. Connect the second **tFileInputDelimited** component to the **tLineChart** using a **Row > Main** connection.

## Configuring the input component for tLineChart

1. Double-click the second **tFileInputDelimited** component to display its **Basic settings** view.

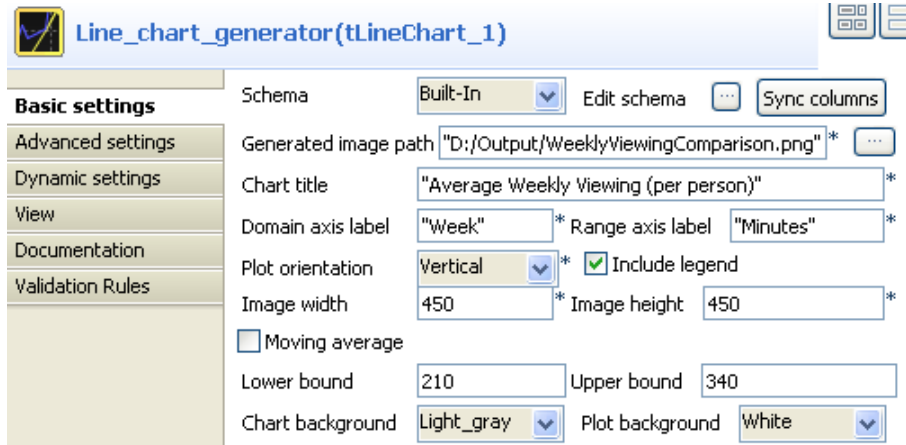

2. Fill in the **File name** field with the file path and name defined in the **Basic settings** view of each of the **tFileOutputDelimited** components. In this use case, the input file to the **tLineChart** is *InputTV.csv*.
3. Leave the other parameters as they are.

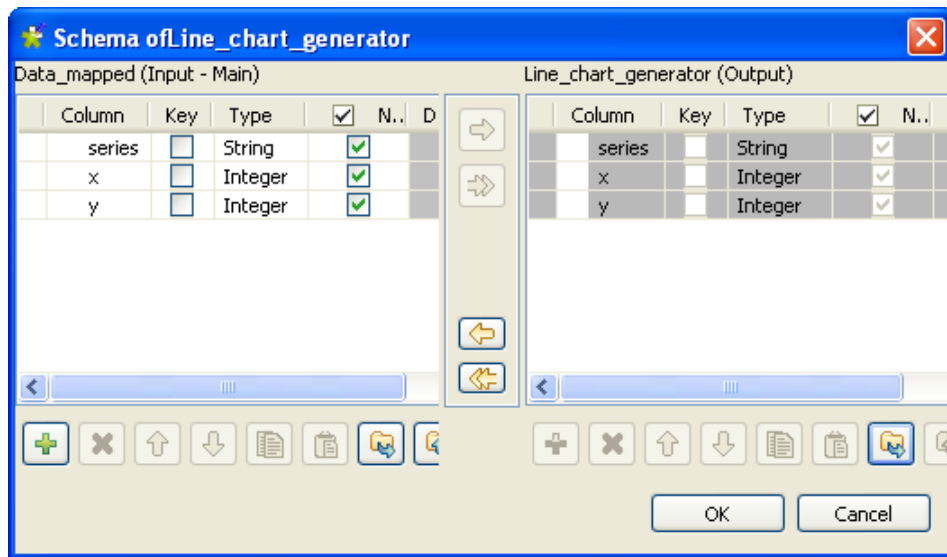

As the input schema needs to have a structure required by the **tLineChart** component, we will copy the structure from the schema of the **tLineChart** component.

## Configuring tLineChart

1. Double-click the **tLineChart** component to display its **Basic settings** view.

2. Click **Edit schema** to open the schema dialog box.

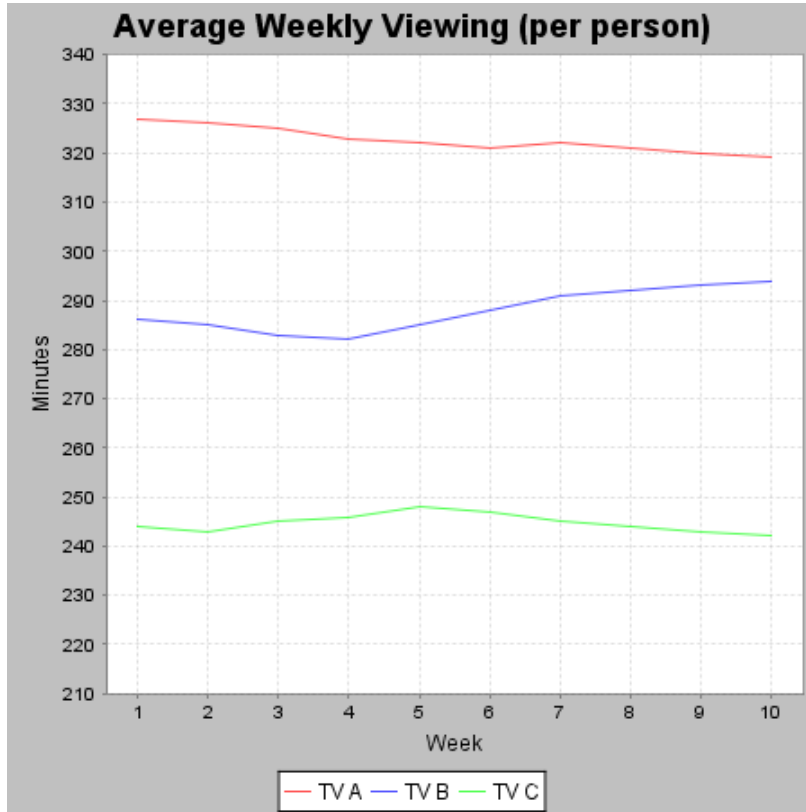

3. Copy all the columns from the output schema to the input schema by clicking the left-pointing double arrow button. Then, click **OK** to close the schema dialog box.
4. In the **Generated image path** field, define the path of the image file to be generated.
5. In the **Chart title** field, define a title for the line chart. In this use case, the chart title is *Average Weekly Viewing (per person)*.
6. Define the domain (X) and range (Y) axis labels. In this use case, the axis labels are *Week* and *Minutes* respectively.
7. Define the image size, the moving average period, the lower and upper bounds, the chart background color, and the background color of the plot area, as you prefer.

In this use case, we set the image size to *450 by 450*, set the lower and upper bounds to *210* and *340* respectively, select *light gray* as the chart background color, and keep the rest settings as they are.

## Job execution

Press **CTRL+S** to save your Job and press **F6** to launch it.

A line chart is generated as defined, showing a comparison of the average weekly viewing time and the viewing trends of different TV channels over the past ten weeks.

| <b>Usage</b>             | This component covers MDX queries for multi-dimensional datasets.                                                                                                                                                                          |                                                                                                                                                                                               |

## Scenario: Cross-join tables

This Job extracts multi-dimensional datasets from relational database tables stored in a MySQL base. The data are retrieved using a multidimensional expression (MDX query). Obviously you need to have to know the structure of your data, or at least have a structure description (catalog) as a reference for the dataset to be retrieved in the various dimensions.

### Setting up the Job

1. Drop **tMondrianInput** and **tLogRow** from the **Palette** to the design workspace.
2. Connect the Mondrian connector to the output component using a **Row Main** connection.

### Setting up the DB connection

1. Double-click the **tMondrianInput** component to display its **Basic settings** view.

2. In **DB type** field, select the relational database you are using with Mondrian.
3. Select the relevant Repository entry as **Property type**, if you store your DB connection details centrally. In this example the properties are built-in.
4. Fill out the details of connection to your DB: **Host**, **Port**, **Database** name, **User Name** and **Password**.
5. Select the relevant **Schema** in the Repository if you store it centrally. In this example, the schema is to be set (built-in).

## Configuring the DB query

1. The relational database we want to query contains five columns: *media*, *drink*, *unit\_sales*, *store\_cost* and *store\_sales*.
2. The query aims at retrieving the *unit\_sales*, *store\_cost* and *store\_sales* figures for various *media* / *drink* using an MDX query such as in the example below:

### CrossJoin Example 1

The current slicer is **1997**.

|                       |                            | Unit Sales | Store Cost | Store Sales |
|-----------------------|----------------------------|------------|------------|-------------|
| <b>Radio</b>          | <b>Alcoholic Beverages</b> | 75         | 70.40      | 168.62      |
|                       | <b>Beverages</b>           | 97         | 75.70      | 186.03      |
|                       | <b>Dairy</b>               | 54         | 36.75      | 89.03       |
| <b>TV</b>             | <b>Alcoholic Beverages</b> | 76         | 70.99      | 182.38      |
|                       | <b>Beverages</b>           | 188        | 167.00     | 419.14      |
|                       | <b>Dairy</b>               | 68         | 45.19      | 119.55      |
| <b>Sunday Paper</b>   | <b>Alcoholic Beverages</b> | 148        | 128.97     | 316.88      |
|                       | <b>Beverages</b>           | 197        | 161.81     | 399.58      |
|                       | <b>Dairy</b>               | 85         | 54.75      | 140.27      |
| <b>Street Handout</b> | <b>Alcoholic Beverages</b> | 158        | 121.14     | 294.55      |
|                       | <b>Beverages</b>           | 270        | 201.28     | 520.55      |
|                       | <b>Dairy</b>               | 84         | 50.26      | 128.32      |

3. Back on the **Basic settings** tab of the **tMondrianInput** component, set the **Catalog** path to the data warehouse. This catalog describes the structure of the warehouse.
4. Then type in the MDX query such as:

```
"select
 {[Measures].[Unit Sales], [Measures].[Store Cost], [Measures].[Store
Sales]} on columns,
 CrossJoin(
 { [Promotion Media].[All Media].[Radio],
 [Promotion Media].[All Media].[TV],
 [Promotion Media].[All Media].[Sunday Paper],
 [Promotion Media].[All Media].[Street Handout] },
```

```
[Product].[All Products].[Drink].children) on rows
from Sales
where ([Time].[1997])"
```

- Eventually, select the **Encoding** type on the list.

## Job execution

- Select the **tLogRow** component and select the **Print header** check box to display the column names on the console.
- Then press **F6** to run the Job.

```
Starting job Mondrian at 15:31 08/01/2008.

This option is not available if you have selected the <b>Use an existing connection</b> check box in the <b>Basic settings</b> .                                                                              |
|                          | <i>tStat Catcher Statistics</i>                                                                        | Select this check box to collect log data at the component level.                                                                                                                                                                                                                              |
|                          | <i>Debug mode</i>                                                                                      | Select this check box to display each step during processing entries in a database.                                                                                                                                                                                                            |
| <b>Usage</b>             | This component is used as Output component. It requires an Input component and Row main link as input. |                                                                                                                                                                                                                                                                                                |

## SCD management methodologies

Slowly Changing Dimensions (SCDs) are dimensions that have data that slowly changes. The SCD editor offers the simplest method of building the data flow for the SCD outputs. In the SCD editor, you can map columns, select surrogate key columns, and set column change attributes through combining SCD types.

The following figure illustrates an example of the SCD editor.

## SCD keys

You must choose one or more source keys columns from the incoming data to ensure its unicity.

You must set one surrogate key column in the dimension table and map it to an input column in the source table. The value of the surrogate key links a record in the source to a record in the dimension table. The editor uses this mapping to locate the record in the dimension table and to determine whether a record is new or changing. The surrogate key is typically the primary key in the source, but it can be an alternate key as long as it uniquely identifies a record and its value does not change.

**Source keys:** Drag one or more columns from the **Unused** panel to the **Source keys** panel to be used as the key(s) that ensure the unicity of the incoming data.

**Surrogate keys:** Set the column where the generated surrogate key will be stored. A surrogate key can be generated based on a method selected on the **Creation** list.

**Creation:** Select any of the below methods to be used for the key generation:

**Auto increment:** auto-incremental key.

**Input field:** key is provided in an input field.

When selected, you can drag the appropriate field from the **Unused** panel to the **complement** field.

**Routine:** from the **complement** field, you can press **Ctrl+ Space** to display the autocompletion list and select the appropriate routine.

**Table max +1:** the maximum value from the SCD table is incremented to create a surrogate key.

**DB Sequence:** from the **complement** field, you can enter the name of the existing database sequence that will automatically increment the column indicated in the **name** field.

This option is only available through the **SCD Editor** of the **tOracleSCD** component.

## Combining SCD types

The Slowly Changing Dimensions support four types of changes: **Type 0** through **Type 3**. You can apply any of the SCD types to any column in a source table by a simple drag-and-drop operation.

**Type 0:** is not used frequently. Some dimension data may be overwritten and other may stay unchanged over time. This is most appropriate when no effort has been made to deal with the changing dimension issues.

**Type 1:** no history is kept in the database. New data overwrites old data. Use this type if tracking changes is not necessary. this is most appropriate when correcting certain typos, for example the spelling of a name.

**Type2:** the whole history is stored in the database. This type tracks historical data by inserting a new record in the dimensional table with a separate key each time a change is made. This is most appropriate to track updates, for example.

SCD **Type 2** principle lies in the fact that a new record is added to the SCD table when changes are detected on the columns defined. Note that although several changes may be made to the same record on various columns defined as SCD **Type 2**, only one additional line tracks these changes in the SCD table.

The SCD schema in this type should include SCD-specific extra columns that hold standard log information such as:

**-start:** adds a column to your SCD schema to hold the start date. You can select one of the input schema columns as a start date in the SCD table.

**-end:** adds a column to your SCD schema to hold the end date value for a record. When the record is currently active, the end date is **NULL** or you can select **Fixed Year Value** and fill in a fictive year to avoid having a null value in the end date field.

**-version:** adds a column to your SCD schema to hold the version number of the record.

**-active:** adds a column to your SCD schema to hold the **true** or **false** status value. this column helps to easily spot the active record.

**Type 3:** only the information about a previous value of a dimension is written into the database. This type tracks changes using separate columns. This is most appropriate to track only the previous value of a changing column.

## Scenario: Tracking changes using Slowly Changing Dimensions (type 0 through type 3)

This five-component Java scenario describes a Job that tracks changes in four of the columns in a source delimited file, writes changes and the history of changes in an SCD table, and displays error information on the **Run** console.

The source delimited file contains various personal details including *firstname*, *lastname*, *address*, *city*, *company*, *age*, and *status*. An *id* column helps ensuring the unicity of the data.

|   | A                                                                      | B | C | D | E | F |
|---|------------------------------------------------------------------------|---|---|---|---|---|
| 1 | id;firstname;lastname;address;city;company;age;status                  |   |   |   |   |   |
| 2 | 1;Janet;Anderson;511 Maple Ave. Apt. 1B;Agoura Hills;Adecco;30;married |   |   |   |   |   |
| 3 | 2;Harold;Smith;662 Lyons Circle;Alameda;Adidas;33;married              |   |   |   |   |   |
| 4 | 3;Adam;Brown;220 Vine Ave.;Albany;Bridgestone;28;single                |   |   |   |   |   |
| 5 | 4;Martin;Clinton;770 Exmoor Rd.;Alhambra;Cutco;25;single               |   |   |   |   |   |
| 6 | 5;Sue;White;1486 Oakwood;Covina;Black&White;35;married                 |   |   |   |   |   |

We want any change in the marital status to overwrite the existing old status record. This type of change is equivalent to an SCD **Type 1**.

We want to insert a new record in the dimensional table with a separate key each time a person changes his/her company. This type of change is equivalent to an SCD **Type 2**.

We want to track only the previous city and previous address of a person. This type of change is equivalent to an SCD **Type 3**.

To realize this kind of scenario, it is better to divide it into three main steps: defining the main flow of the Job, setting up the SCD editor, and finally creating the relevant SCD table in the database.

## Defining the main flow of the Job

1. Drop the following components from the **Palette** onto the design workspace: a **tMySQLConnection**, a **tFileInputDelimited**, a **tMySQLSCD**, a **tMySQLCommit**, and two **tLogRow** components.
2. Connect the **tFileInputDelimited**, the first **tLogRow**, and the **tMySQLSCD** using the **Row Main** link. This is the main flow of your Job.
3. Connect the **tMySQLConnection** to the **tFileInputDelimited** and **tMySQLSCD** to **tMySQLCommit** using the **OnComponentOk** trigger.
4. Connect the **tMySQLSCD** to the second **tLogRow** using the **Row Rejects** link. Two columns, *errorCode* and *errorMessage*, are added to the schema. This connection collects error information.

## Configuring the DB connection and the input component

1. In the design workspace, double-click **tMySQLConnection** to display its **Basic settings** view and set the database connection details manually. The **tMySQLConnection** component should be used to avoid setting several times the same DB connection when multiple DB components are used.

If you have already stored the connection details locally in the **Repository**, drop the needed metadata item to the design workspace and the database connection detail will automatically display in the relevant fields. For more information about Metadata, see *Talend Open Studio User Guide*.

In this scenario, we want to connect to the SCD table where changes in the source delimited file will be tracked down.

| Property Type | Value               |
|---------------|---------------------|
| Repository    | DB (MYSQL):SCDtable |
| Host          | "localhost"         |
| Port          | "3306"              |
| Database      | "talend"            |
| Username      | "root"              |
| Password      | *****               |
| Encoding Type | ISO-8859-15         |

2. In the design workspace, double-click **tFileInputDelimited** to display its **Basic settings** view.

| Property               | Value                               |
|------------------------|-------------------------------------|
| File name/Stream       | "C:/Input/Dataset.csv"              |
| Row Separator          | "\n"                                |
| Field Separator        | ";"                                 |
| Header                 | 1                                   |
| Footer                 | 0                                   |
| Limit                  |                                     |
| Schema                 | Built-In                            |
| Skip empty rows        | <input checked="" type="checkbox"/> |
| Uncompress as zip file | <input type="checkbox"/>            |
| Die on error           | <input type="checkbox"/>            |

3. Click the three-dot button next to the **File Name** field to select the path to the source delimited file, *dataset.csv* in this scenario, that contains the personal details.
4. Define the row and field separators used in the source file.

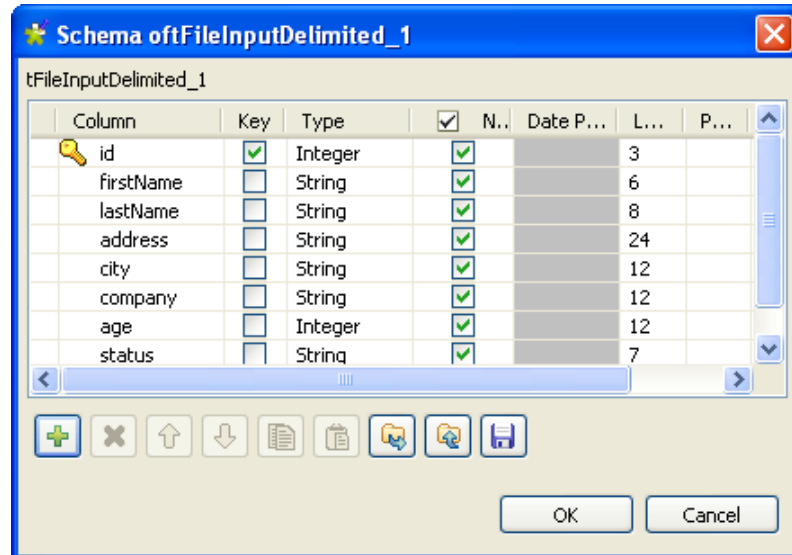

The **File Name**, **Row separator**, and **Field separators** are mandatory.

5. If needed, set **Header**, **Footer**, and **Limit**.

In this scenario, set **Header** to *1*. Footer and limit for the number of processed rows are not set.

6. Click **Edit schema** to describe the data structure of the source delimited file.

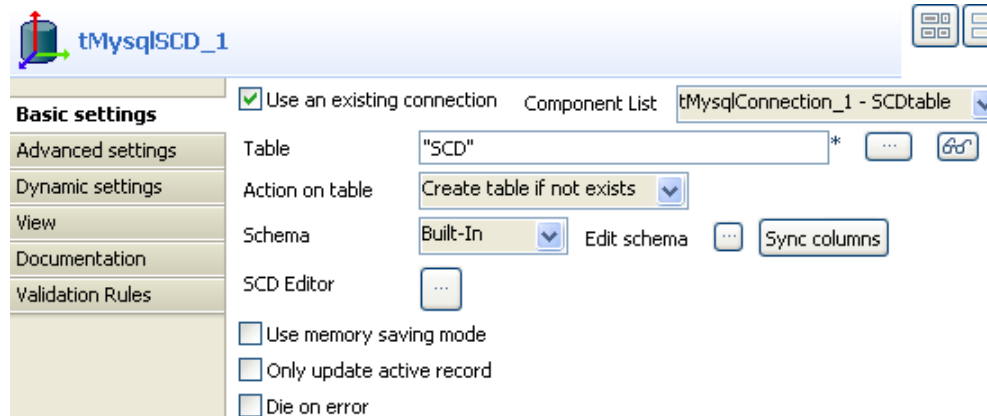

In this scenario, the source schema is made of eight columns: *id*, *firstName*, *lastName*, *address*, *city*, *company*, *age*, and *status*.

7. Define the basic settings for the first **tLogRow** in order to view the content of the source file with varying attributes in cells of a table on the console before being processed through the SCD component.

## Configuring tMysqlSCD and tMysqlCommit

1. In the design workspace, click the **tMysqlSCD** and select the **Component** tab to define its basic settings.

2. In the **Basic settings** view, select the **Use an existing connection** check box to reuse the connection details defined on the **tMysqlConnection** properties.
3. In the **Table** field, enter the table name to be used to track changes.
4. If needed, click **Sync columns** to retrieve the output data structure from the **tFileInputDelimited**.
5. In the design workspace, double-click **tMysqlCommit** to define its basic settings.
6. Select the relevant connection on the **Component list** if more than one connection exists.
7. Define the basic settings of the second **tLogRow** in order to view reject information in cells of a table.

## Setting up the SCD editor

1. Double-click the **tMySQLSCD** component in the design workspace or click the three-dot button next to the **SCD Editor** in the component's **Basic settings** view to open the **SCD editor** and build the data flow for the SCD outputs.

All the columns from the preceding component are displayed in the **Unused** panel of the **SCD editor**. All the other panels in the **SCD editor** are empty.

2. From the **Unused** list, drop the *id* column to the **Source keys** panel to use it as the key to ensure the unicity of the incoming data.
3. In the **Surrogate keys** panel, enter a name for the surrogate key in the **Name** field, *SKI* in this scenario.
4. From the **Creation** list, select the method to be used for the surrogate key generation, **Auto-increment** in this scenario.
5. From the **Unused** list, drop the *firstname* and *lastname* columns to the **Type 0** panel, changes in these two columns do not interest us.
6. Drop the *status* column to the **Type 1** panel. The new value will overwrite the old value.
7. Drop the *company* column to the **Type 2** panel. Each time a person changes his/her company, a new record will be inserted in the dimensional table with a separate key.

In the **Versioning** area:

- Define the **start** and **end** columns of your SCD table that will hold the start and end date values. The end date is null for current records until a change is detected. Then the end date gets filled in and a new record is added with no end date.

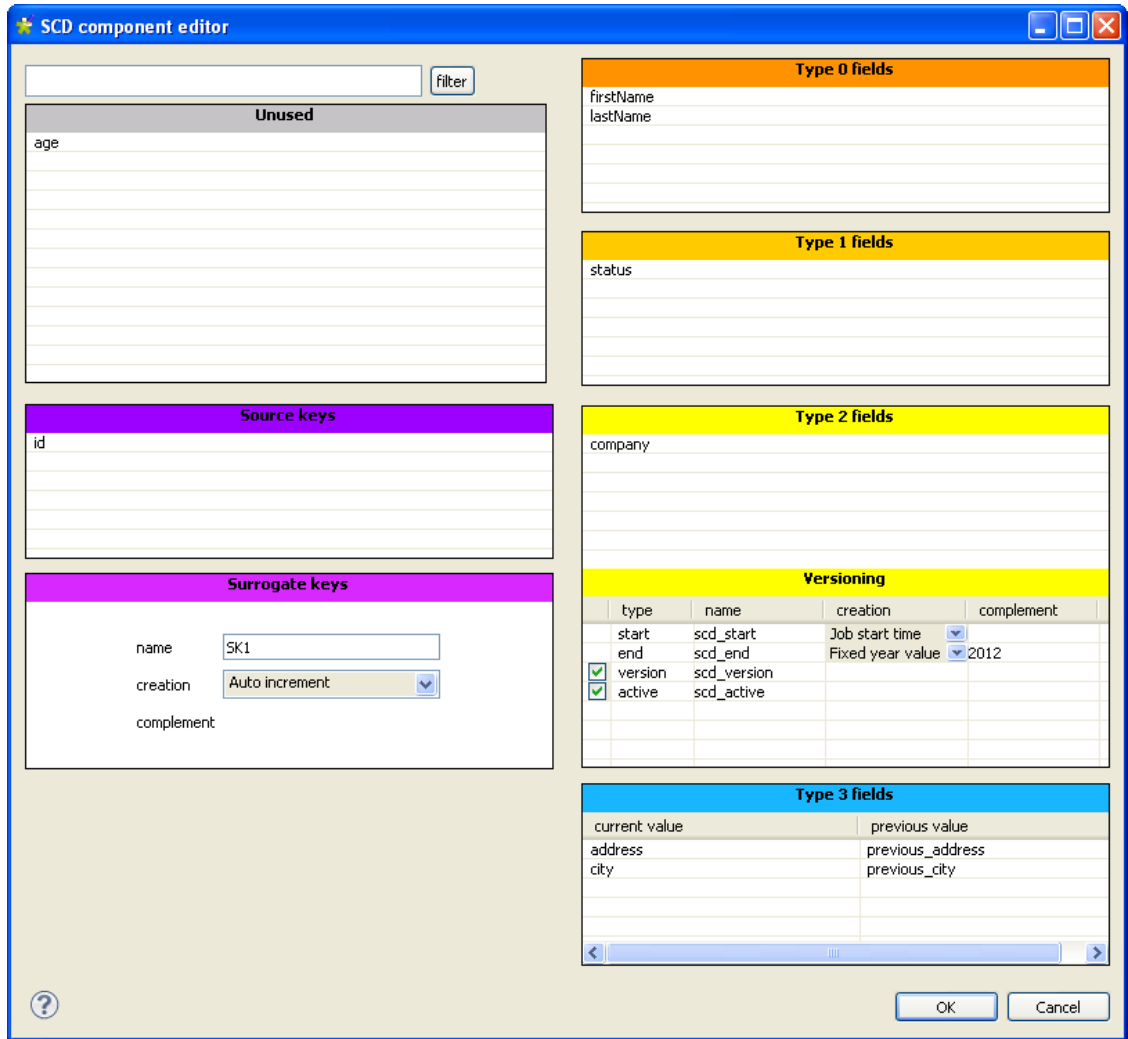

In this scenario, we select **Fixed Year Value** for the **end** column and fill in a fictive year to avoid having a null value in the end date field.

- Select the **version** check box to hold the version number of the record.

- Select the **active** check box to spot the column that will hold the **True** or **False** status. **True** for the current active record and **False** for the modified record.

8. Drop the *address* and *city* columns to the **Type 3** panel to track only the information about the previous value of the address and city.

For more information about SCD types, see [the section called “SCD management methodologies”](#).

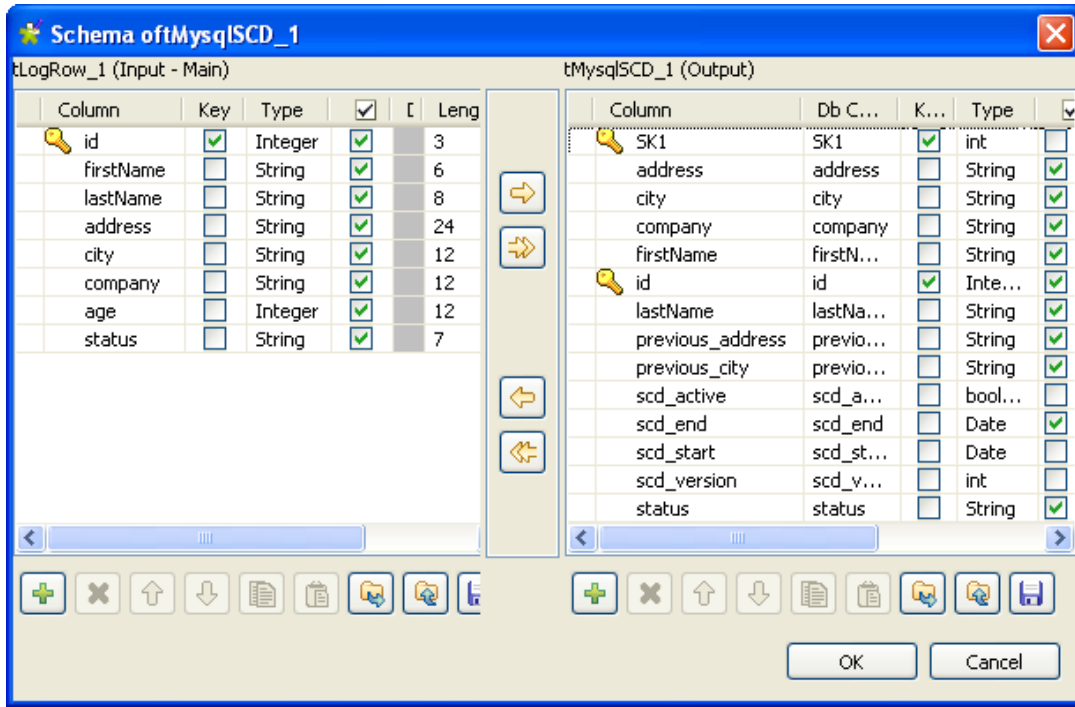

9. Click **OK** to validate your configuration and close the **SCD editor**.

## Creating the SCD table

1. Click **Edit schema** to view the input and output data structures.

The SCD output schema should include the SCD-specific columns defined in the **SCD editor** to hold standard log information.

 If you adjust any of the input schema definitions, you need to check, and reconfigure if necessary, the output flow definitions in the **SCD editor** to ensure that the output data structure is properly updated.

2. In the **Basic settings** view of the **tMysqlSCD** component, select **Create table if not exists** from the **Action on table** list to avoid creating and defining the SCD table manually.

## Job execution

Save your Job and press **F6** to execute it.

The console shows the content of the input delimited file, and your SCD table is created in your database, containing the initial dataset.

| SK1  | address                | city         | company     | firstName | id | lastName | previous_adr | previous_city | scd_ac                   | scd_end  | scd_st | scd_ve | status  |
|------|------------------------|--------------|-------------|-----------|----|----------|--------------|---------------|--------------------------|----------|--------|--------|---------|
| 1    | 511 Maple Ave. Apt. 1B | Agoura Hills | Adecco      | Janet     | 1  | Anderson | (NULL)       | (NULL)        | <input type="checkbox"/> | 2012-01- | 2011-0 | 1      | married |
| 2    | 662 Lyons Circle       | Alameda      | Adidas      | Harold    | 2  | Smith    | (NULL)       | (NULL)        | <input type="checkbox"/> | 2012-01- | 2011-0 | 1      | married |

*Janet gets divorced and moves to Adelanto at 355 Golf Rd. She works at Greenwood.*

*Adam gets married and moves to Belmont at 2505 Alisson ct. He works at Scoop.*

*Martin gets a new job at Phillips and Brothers.*

Update the delimited file with the above information and press **F6** to run your Job.

The console shows the updated personal information and the rejected data, and the SCD table shows the history of valid changes made to the input file along with the status and version number. Because the name of Martin's new company exceeds the length of the column *company* defined in the schema, this change is directed to the reject flow instead of being logged in the SCD table.

Scenario: Tracking changes using Slowly Changing Dimensions (type 0 through type 3)

|  | <i>Table</i>                  | Name of the table to be written. Note that only one table can be written at a time                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|  | <i>Action on table</i>        | <p>Select to perform one of the following operations on the table defined:</p> <p><b>None:</b> No action carried out on the table.</p> <p><b>Drop and create the table:</b> The table is removed and created again</p> <p><b>Create a table:</b> A new table gets created.</p> <p><b>Create a table if not exists:</b> A table gets created if it does not exist.</p> <p><b>Clear a table:</b> The table content is deleted. You have the possibility to rollback the operation.</p> <p><b>Truncate a table:</b> The table content is deleted. You don't have the possibility to rollback the operation.</p> |
|  | <i>Schema and schema Edit</i> | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. The schema is either built-in or remotely stored in the Repository.                                                                                                                                                                                                                                                                                                                                                                                                                |
|  |                               | <b>Built-in:</b> The schema is created and stored locally for this component only. |  | <i>Source table</i>                |                    | Name of the input DB2 SCD table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|  | <i>Table</i>                       |                    | Name of the table to be written. Note that only one table can be written at a time                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|  | <i>Action on table</i>             |                    | <p>Select to perform one of the following operations on the table defined:</p> <p><b>None:</b> No action carried out on the table.</p> <p><b>Drop and create table:</b> The table is removed and created again</p> <p><b>Create table:</b> A new table gets created.</p> <p><b>Create table if not exists:</b> A table gets created if it does not exist.</p> <p><b>Clear table:</b> The table content is deleted. You have the possibility to rollback the operation.</p> <p><b>Truncate table:</b> The table content is deleted. You don not have the possibility to rollback the operation.</p> |
|  | <i>Schema</i><br><i>schema</i>     | and<br><i>Edit</i> | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. The schema is either built-in or remotely stored in the Repository.                                                                                                                                                                                                                                                                                                                                                                                                      |
|  |                                    |                    | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|  |                                    |                    | <b>Repository:</b> The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|  | <i>Surrogate Key</i>               |                    | Select the surrogate key column from the list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|  | <i>Creation</i>                    |                    | <p>Select the method to be used for the surrogate key generation.</p> <p>For more information regarding the creation methods, see <a href="#">the section called “SCD keys”</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                               |
|  | <i>Source Keys</i>                 |                    | Select one or more columns to be used as keys, to ensure the unicity of incoming data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|  | <i>Use SCD Type 1 fields</i>       |                    | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.                                                                                                                                                                                                                                                                                                                                                                                                                   |
|  | <i>Use SCD Type 2 fields</i>       |                    | <p>Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.</p> <p><b>Start date:</b> Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.</p> <p><b>End Date:</b> Adds a column to your SCD schema to hold the end date value for the record. When the record is currently</p>                                                                                                          |

|                          |                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------|-----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                                                                           | <p>active, the End Date column shows a null value, or you can select <b>Fixed Year value</b> and fill it in with a fictive year to avoid having a null value in the End Date field.</p> <p><b>Log Active Status:</b> Adds a column to your SCD schema to hold the <b>true</b> or <b>false</b> status value. This column helps to easily spot the active record.</p> <p><b>Log versions:</b> Adds a column to your SCD schema to hold the version number of the record.</p> |

| <b>Limitation</b>        | The cube creation process does not create dimensions from scratch, so the dimensions to be used in the cube must be created beforehand. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Scenario: Creating a cube in an existing database

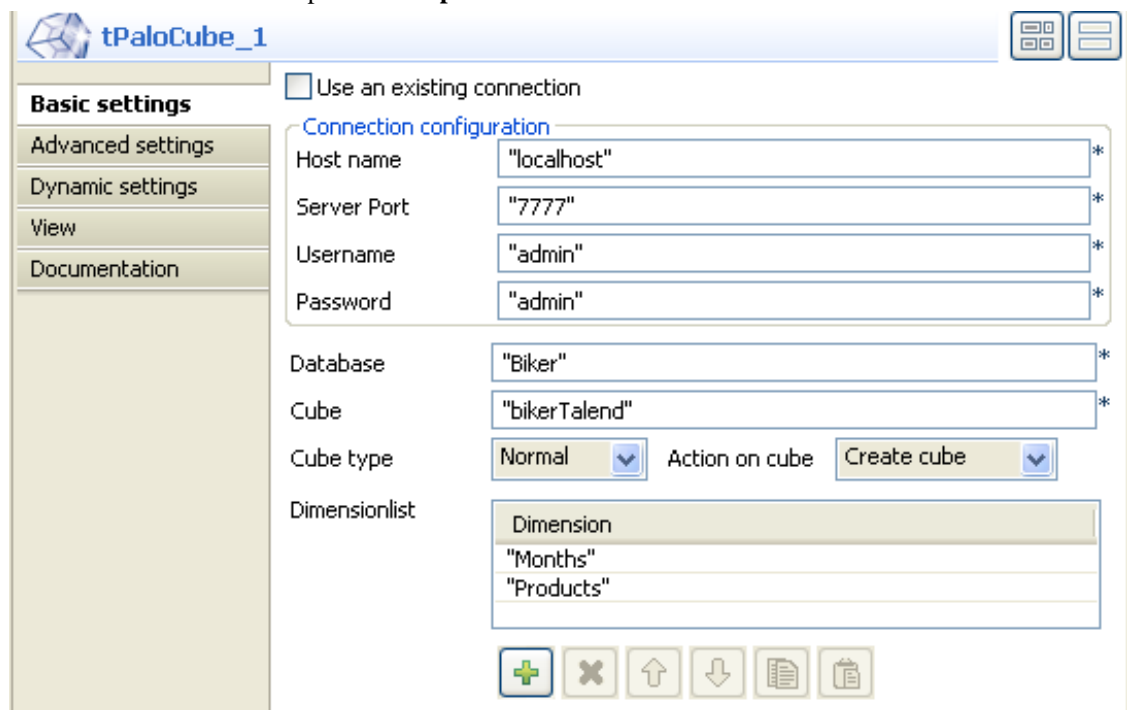

The Job in this scenario creates a new two dimensional cube in the Palo demo database *Biker*.

To replicate this scenario, proceed as follows:

### Configuring the tPaloCube component

1. Drop **tPaloCube** from the **Palette** onto the design workspace.
2. Double-click **tPaloCube** to open its **Component** view.

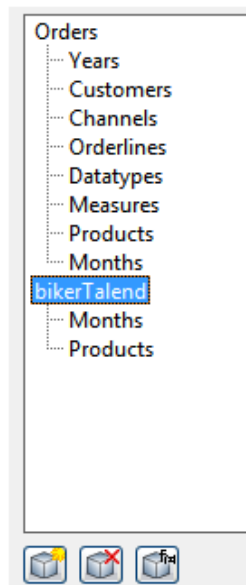

3. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
6. In the **Database** field, type in the database name in which you want to create the cube, *Biker* in this example.
7. In the **Cube** field, type in the name you want to use for the cube to be created, for example, *bikerTalend*.

8. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.
9. In the **Action on cube** field, select the action to be performed. In this scenario, select **Create cube**.
10. Under the **Dimension list** table, click the plus button twice to add two rows into the table.
11. In the **Dimension list** table, type in the name for each newly added row to replace the default row name. In this scenario, type in *Months* for the first row and *Products* for the second. These two dimensions exist already in the Biker database where the new cube will be created.

## Job execution

Press **F6** to run the Job.

A new cube has been created in the *Biker* database and the two dimensions are added into this cube.

# tPaloCubeList

## tPaloCubeList Properties

|                                                                                                                                    |                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Limitation</b>       | The output schema is fixed and read-only.                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Discovering the read-only output schema of tPaloCubeList

The below table presents information related to the read-only schema of the **tPaloCubeList** component.

| Column            | Type   | Description                                 |
|-------------------|--------|---------------------------------------------|
| Cube_id           | int    | Internal id of the cube.                    |
| Cube_name         | string | Name of the cube.                           |
| Cube_dimensions   | int    | Number of dimensions inside the cube.       |
| Cube_cells        | long   | Number of calculated cells inside the cube. |
| Cube_filled_cells | long   | Number of filled cells inside the cube.     |
| Cube_status       | int    | Status of the cube. It may be:              |

| Column    | Type | Description                                                                                                                                             |
|-----------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
|           |      | - <b>0</b> : unloaded<br>- <b>1</b> : loaded<br>- <b>2</b> : changed                                                                                    |
| Cube_type | int  | Type of the cube. It may be:<br>- <b>0</b> : normal<br>- <b>1</b> : system<br>- <b>2</b> : attribute<br>- <b>3</b> : user info<br>- <b>4</b> : gpu type |

## Scenario: Retrieving detailed cube information from a given database

The Job in this scenario retrieves detailed information of the cubes pertaining to the demo Palo database, *Biker*.

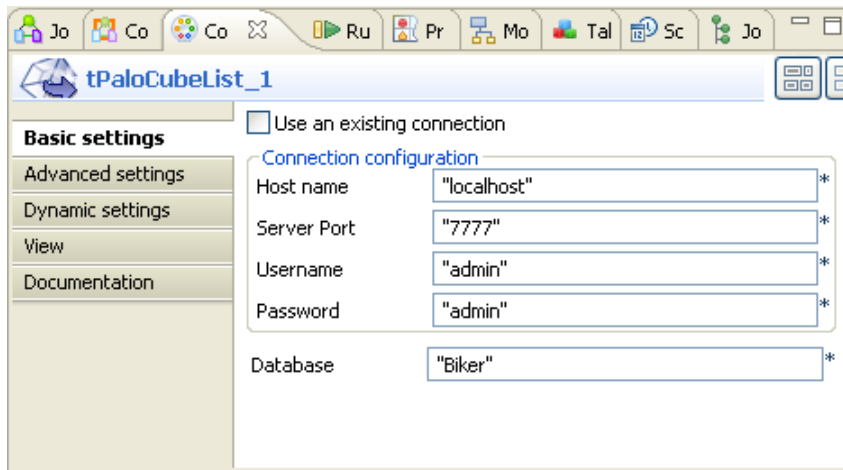

To replicate this scenario, proceed as follows:

### Setting up the Job

1. Drop **tPaloCubeList** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloCubeList** to open the contextual menu.
3. From this menu, select **Row > Main** to link the two components.

### Configuring the tPaloCube component

1. Double-click the **tPaloCube** component to open its **Component** view.

2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
5. In the **Database** field, type in the database name in which you want to create the cube, *Biker* in this example.

## Job execution

Press **F6** to run the Job.

The cube details are retrieved from the *Biker* database and are listed in the console of the **Run** view.

## Scenario: Creating a database

The Job in this scenario creates a new database on a given Palo server.

To replicate this scenario, proceed as follows:

1. Drop **tPaloDatabase** from the component **Palette** onto the design workspace.
2. Double-click the **tPaloDatabase** component to open its **Component** view.

3. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
6. In the **Database** field, type in the database name in which you want to create the cube, *talenddatabase* in this example.
7. In the **Action on database** field, select the action to be performed. In this scenario, select **Create database** as the database to be created does not exist.
8. Press **F6** to run the Job.

A new database is created on the given Palo server.

# tPaloDatabaseList

## tPaloDatabaseList Properties

| <b>Limitation</b>       | The output schema is fixed and read-only. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Discovering the read-only output schema of tPaloDatabaseList

The below table presents information related to the read-only output schema of the **tPaloDatabaseList** component.

| <b>Database</b>     | <b>Type</b> | <b>Description</b>                                                                              |
|---------------------|-------------|-------------------------------------------------------------------------------------------------|
| Database_id         | long        | Internal ID of the database.                                                                    |
| Database_name       | string      | Name of the database.                                                                           |
| Database_dimensions | int         | Number of dimensions inside the database.                                                       |
| Database_cubes      | int         | Number of cubes inside the database.                                                            |
| Database_status     | int         | Status of the database.<br>- <b>0</b> = unloaded<br>- <b>1</b> = loaded<br>- <b>2</b> = changed |

| Database       | Type | Description                                                           |
|----------------|------|-----------------------------------------------------------------------|
| Database_types | int  | Type of the database.<br>- 0 =normal<br>- 1 =system<br>- 3 =user info |

## Scenario: Retrieving detailed database information from a given Palo server

The Job in this scenario retrieves details of all of the databases from a given Palo server.

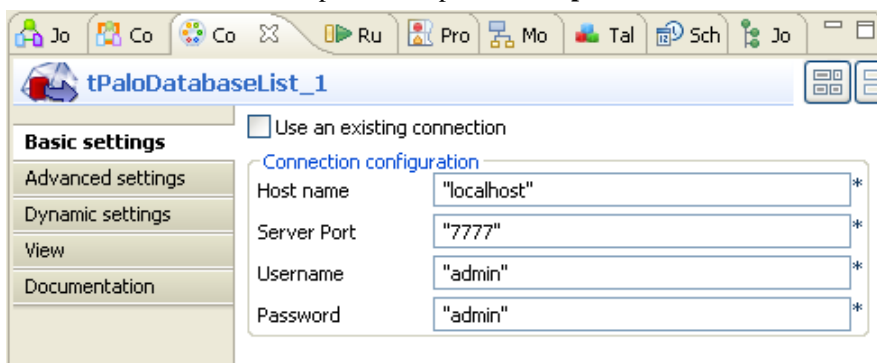

To replicate this scenario, proceed as follows:

### Setting up the Job

1. Drop **tPaloDatabaseList** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloDatabaseList** to open the contextual menu.
3. From this menu, select **Row > Main** to link the two components.

### Configuring the tPaloDatabaseList component

1. Double-click the **tPaloDatabaseList** component to open its **Component** view.

2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

## Job execution

Press **F6** to run the Job.

Details of all of the databases in the Palo server are retrieved and listed in the console of the **Run** view.

```
0|System|7|6|1|1
1|Demo|23|23|1|0
6|Biker|27|28|1|0
9|tx_g|17|17|1|0
25|DBHSE24|13|12|1|0
31|elmCreate|13|12|1|0
32|tPaloOutputMuilt|15|15|1|0
```

For further information about the output schema, see [the section called “Discovering the read-only output schema of tPaloDatabaseList”](#).

# tPaloDimension

## tPaloDimension Properties

|                                                                                                                                    |                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Usage</b>             | This component can be used in standalone or as end component of a process. |                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Global Variables</b>  |                                                                            | <b>Dimensionname</b> : Indicates the name of the dimension processed. This is available as an <b>After</b> variable.<br><br>Returns a String.<br><br>For further information about variables, see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                         |
| <b>Connections</b>       |                                                                            | Outgoing links (from one component to another):<br><br><b>Trigger</b> : Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.<br><br>Incoming links (from one component to another):<br><br><b>Row</b> : Main; Iterate<br><br><b>Trigger</b> : Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.                                                                                 |

|                   |                                                                                                                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | For further information regarding connections, see <i>Talend Open Studio User Guide</i> .                                                                                                       |
| <b>Limitation</b> | Deletion of dimension elements is only possible with the consolidation type <b>None</b> . Only consolidation type <b>Self-Referenced</b> allows the placing of an factor on this consolidation. |

## Scenario: Creating a dimension with elements

The Job in this scenario creates a date dimension with simple element hierarchy composed of three levels: *Year, Month, Date*.

To replicate this scenario, proceed as follows:

### Setting up the Job

1. Drop **tPaloConnection**, **tRowGenerator**, **tMap**, **tPaloDimension** from the component **Palette** onto the design workspace.
2. Right-click **tPaloConnection** to open the contextual menu and select **Trigger > On Subjob Ok** to link it to **tRowGenerator**.
3. Right-click **tRowGenerator** to open the contextual menu and select **Row > Main** to link it to **tMap**.

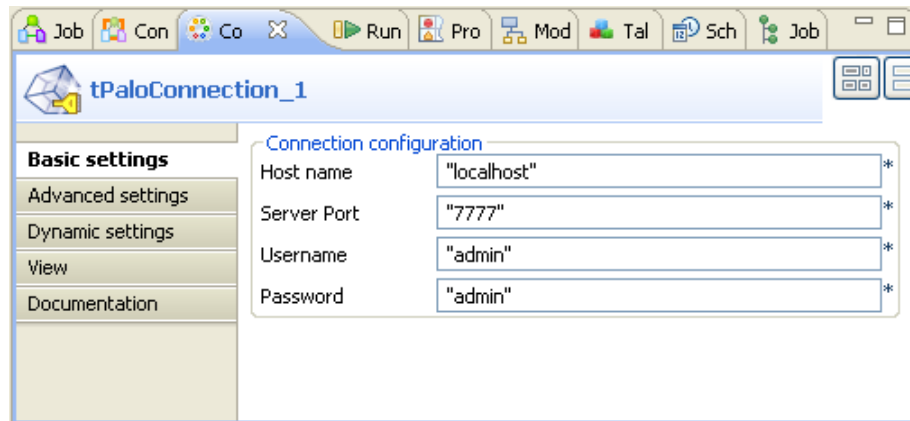

**tRowGenerator** is used to generate rows at random in order to simplify this process. In the real case, you can use one of the other input components to load your actual data.

4. Right-click **tMap** to open the contextual menu and select **Row > New output** to link to **tPaloDimension**, then name it as *out1* in the dialog box that pops up.

### Setting up the DB connection

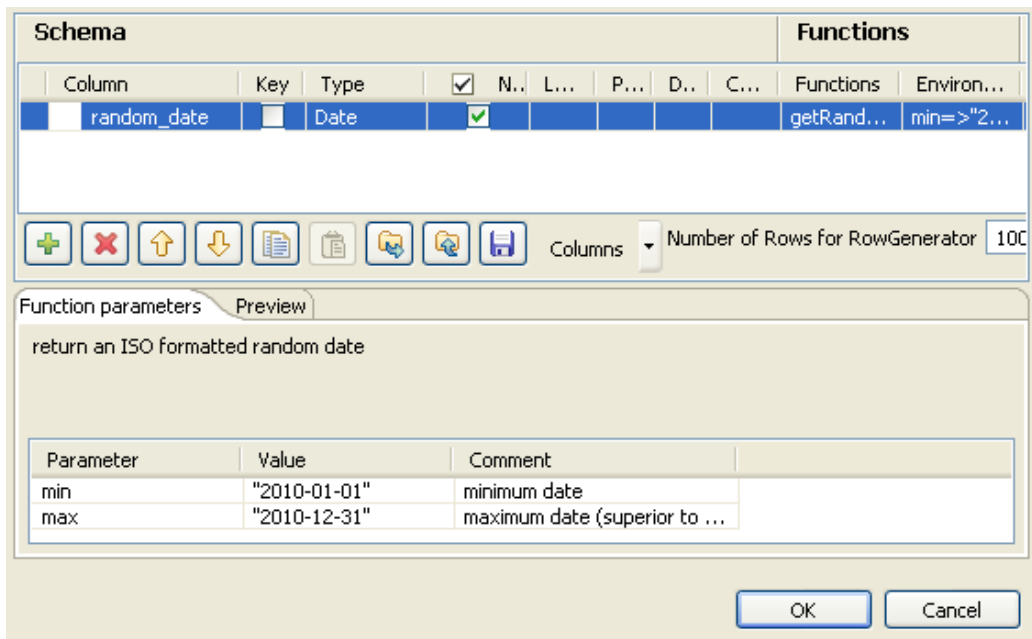

1. Double-click the **tPaloConnection** component to open its **Component** view.

2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

## Configuring the input component

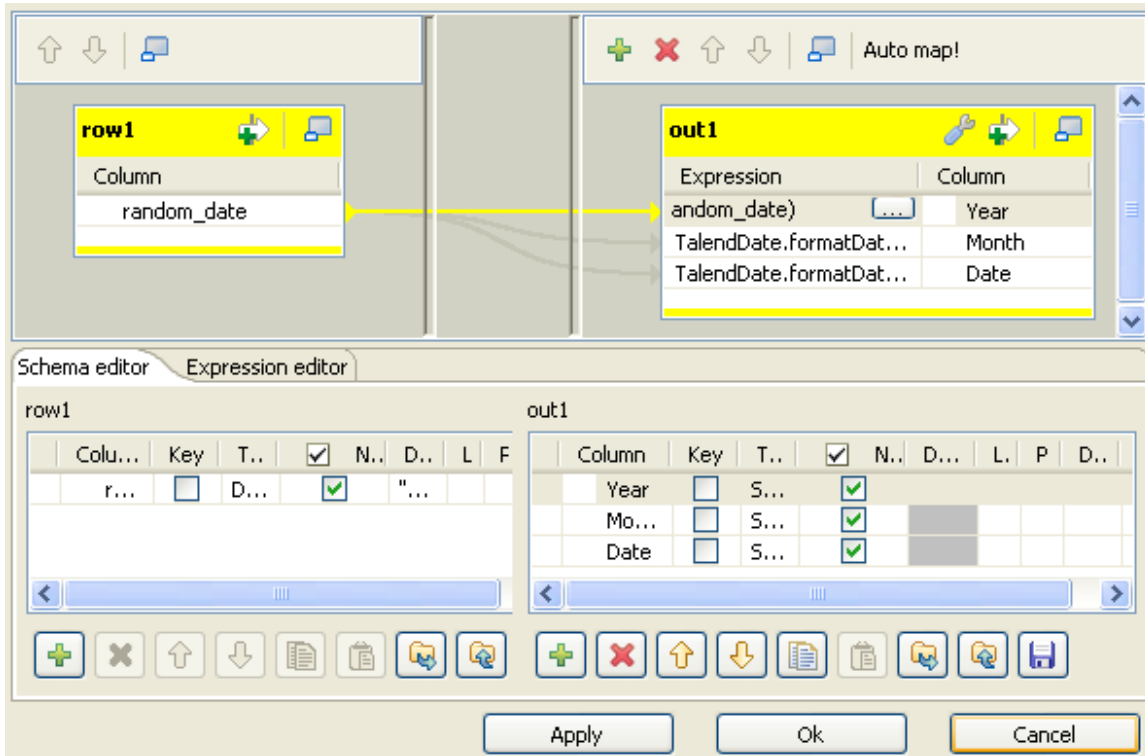

1. Double-click **tRowGenerator** to open its editor.

2. On the upper part of the editor, click the plus button to add one column and rename it as *random\_date* in the **Column** column.
3. In the newly added row, select *Date* in the **Type** column and **getRandomDate** in the **Functions** column.
4. In the **Function parameters** view on the lower part of this editor, type in the new minimum date and maximum date values in the **Value** column. In this example, the minimum is *2010-01-01*, the maximum is *2010-12-31*.
5. Click **OK** to validate your modifications and close the editor.
6. On the dialog box that pops up, click **OK** to propagate your changes.

## Configuration in the tMap editor

1. Double-click **tMap** to open its editor.

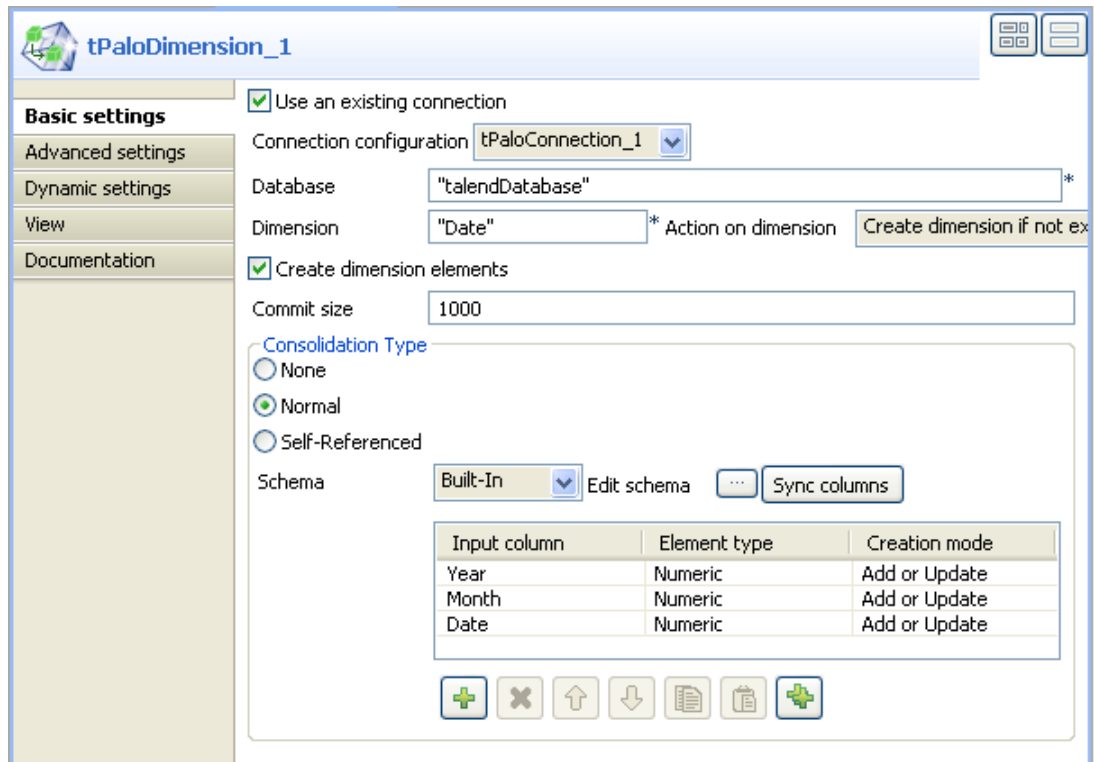

2. On the **Schema editor** view on the lower part of the **tMap** editor, under the **out1** table, click the plus button to add three rows.
3. In the **Column** column of the **out1** table, type in the new names for the three newly added rows. They are *Year*, *Month*, and *Date*. These rows are then added automatically into the **out1** table on the upper part of the **tMap** editor.
4. In the **out1** table on the upper part of the **tMap** editor, click the **Expression** column in the *Year* row to locate the cursor.
5. Press **Ctrl+space** to open the drop-down variable list.
6. Double-click **TalendDate.formatDate** to select it from the list. The expression to get the date displays in the *Year* row under the **Expression** column. The expression is `TalendDate.formatDate("yyyy-MM-dd HH:mm:ss", myDate)`.
7. Replace the default expression with `TalendDate.formatDate("yyyy", row1.random_date)`.
8. Do the same for the *Month* row and the *Date* row to add this default expression and to replace it with `TalendDate.formatDate("MM", row1.random_date)` for the *Month* row and with `TalendDate.formatDate("dd-MM-yyyy", row1.random_date)` for the *Date* row.
9. Click **OK** to validate this modification and accept the propagation by clicking **OK** in the dialog box that pops up.

## Configuring the tPaloDimension component

1. On the workspace, double-click **tPaloDimension** to open its **Component** view.

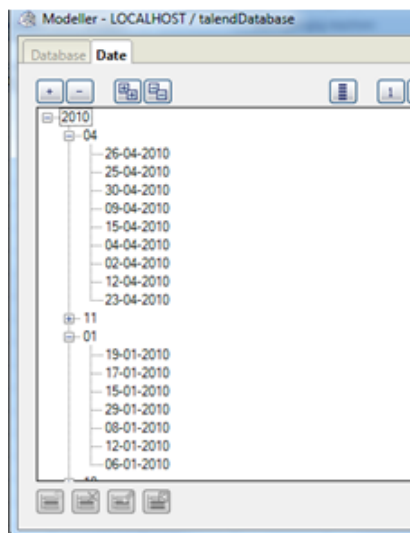

2. Select the **Use an existing connection** check box. Then **tPaloConnection\_1** displays automatically in the **Connection configuration** field.
3. In the **Database** field, type in the database in which the new dimension is created, *talendDatabase* for this scenario.
4. In the **Dimension** field, type in the name you want to use for the dimension to be created, for example, *Date*.
5. In the **Action on dimension** field, select the action to be performed. In this scenario, select **Create dimension if not exist**.
6. Select the **Create dimension elements** check box.
7. In the **Consolidation Type** area, select the **Normal** check box.
8. Under the element hierarchy table in the **Consolidation Type** area, click the plus button to add three rows into the table.
9. In the **Input column** column of the element hierarchy table, select *Year* from the drop-down list for the first row, *Month* for the second and *Date* for the third. This determines levels of elements from different columns of the input schema.

## Job execution

Press **F6** to run the Job.

A new dimension is then created in your Palo database *talendDatabase*.

# tPaloDimensionList

## tPaloDimensionList Properties

|                                                                                                                                    |                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Connections</b>       |                                                                                                                                                                               | <p>Outgoing links (from one component to another):</p> <p><b>Row:</b> Main; Iterate.</p> <p><b>Trigger:</b> Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.</p> <p>Incoming links (from one component to another):</p> <p><b>Row:</b> Iterate</p> <p><b>Trigger:</b> Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.</p> <p>For further information regarding connections, see <i>Talend Open Studio User Guide</i>.</p> |
| <b>Limitation</b>        | The output schema is fixed and read-only.                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Discovering the read-only output schema of tPaloDimensionList

The below table presents information related to the read-only output schema of the **tPaloDimensionList** component.

| Database                 | Type   | Description                                                                                                              |
|--------------------------|--------|--------------------------------------------------------------------------------------------------------------------------|
| Dimension_id             | long   | Internal ID of the dimension.                                                                                            |
| Dimension_name           | string | Name of the dimension.                                                                                                   |
| Dimension_attribute_cube | string | Name of the cube of attributes.                                                                                          |
| Dimension_rights_cube    | string | Name of the cube of rights.                                                                                              |
| Dimension_elements       | int    | Number of the dimension elements                                                                                         |
| Dimension_max_level      | int    | Maximum level of the dimension                                                                                           |
| Dimension_max_indent     | int    | Maximum indent of the dimension                                                                                          |
| Dimension_max_depth      | int    | Maximum depth of the dimension                                                                                           |
| Dimension_type           | int    | Type of the dimension.<br><br>- <b>0</b> =normal<br>- <b>1</b> =system<br>- <b>2</b> =attribute<br>- <b>3</b> =user info |

## Scenario: Retrieving detailed dimension information from a given database

The Job in this scenario retrieves details of all of the dimensions from a given database.

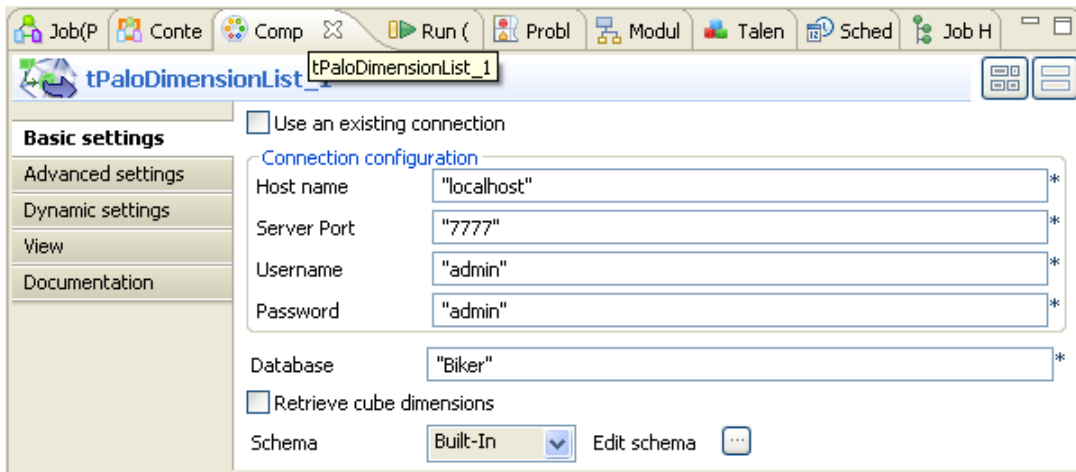

To replicate this scenario, proceed as follows:

### Setting up the Job

1. Drop **tPaloDimensionList** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloDimensionList** to open the contextual menu.
3. From this menu, select **Row > Main** to link the two components.

### Configuring the tPaloDimensionList component

1. Double-click the **tPaloDimensionList** component to open its **Component** view.

2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
5. In the **Database** field, type in the database name where the dimensions of interest reside, *Biker* in this example.

## Job execution

Press **F6** to run the Job.

Details of all the dimensions in the *Biker* database are retrieved and listed in the console of the **Run** view.

|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | For further information regarding connections, see <i>Talend Open Studio User Guide</i> .                                                                                                             |
| <b>Limitation</b> | According to the architecture of OLAP-Systems only one single value (text or numeric) could be retrieved from the cube. The <b>MEASURE</b> column and the <b>TEXT</b> column are fixed and read-only. |

## Scenario: Retrieving dimension elements from a given cube

The Job in this scenario retrieves several dimension elements from a demo Palo cube *Sales*.

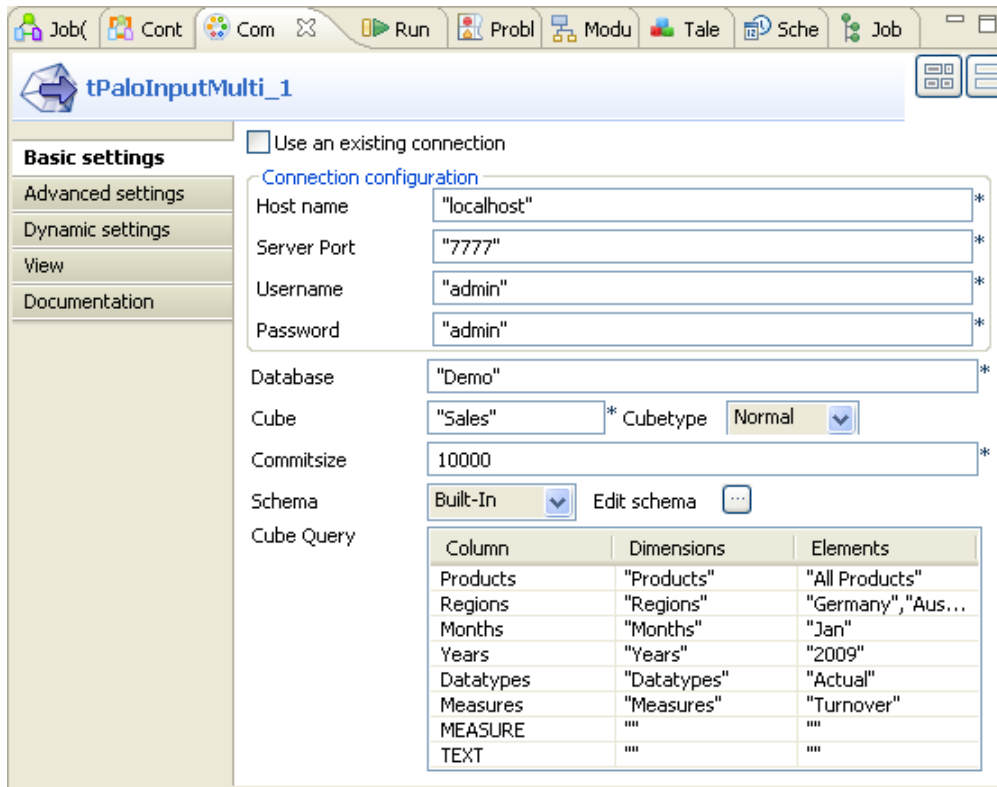

To replicate this scenario, proceed as follows:

### Setting up the Job

1. Drop **tPaloInputMulti** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloInputMulti** to open its contextual menu.
3. In the menu, select **Row > Main** to connect **tPaloInputMulti** to **tLogRow** with a **row** link.

### Setting up the DB connection

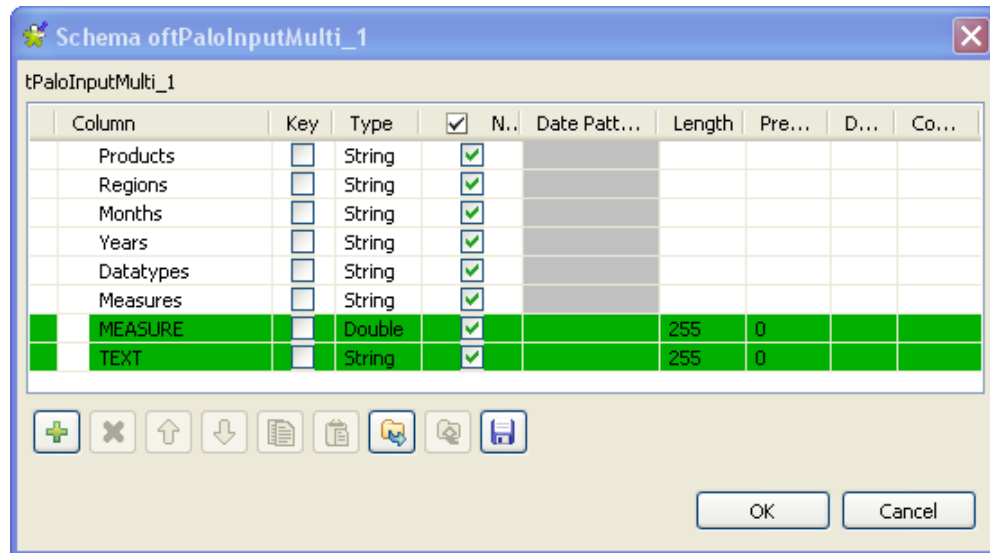

1. Double-click the **tPaloInputMulti** component to open its **Component** view.

2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

## Configuring the Cube Query

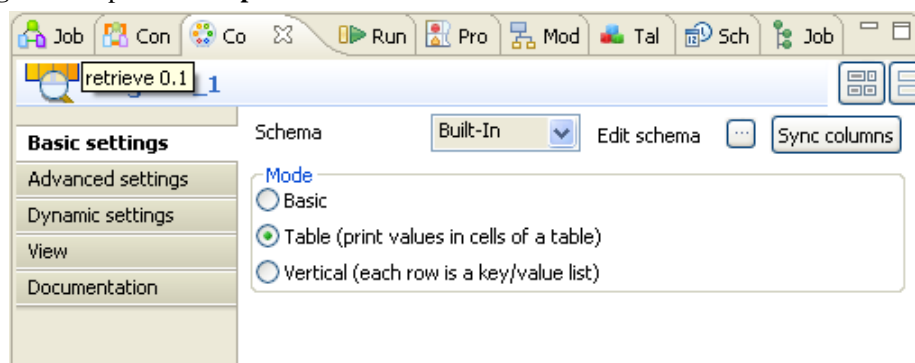

1. In the **Database** field, type in the database name in which the cube to be used is stored.
2. In the **Cube** field, type in the cube name in which the dimensions of interests are stored. In this scenario, it is one of the demo cubes *Sales*.
3. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.
4. Next to the **Edit schema** field, click the three-dot button to open the schema editor.

- In the schema editor, click the plus button to add the rows of the schema to be edited. In this example, add rows corresponding to all of the dimensions stored in the *Sales* cube: *Products*, *Regions*, *Months*, *Years*, *Datatypes*, *Measures*. Type in them in the order given in this cube.
- Click **OK** to validate this editing and accept the propagation of this change to the next component. Then these columns are added automatically into the **Column** column of the **Cube query** table in the **Component** view. If the order is not consistent with the one in the *Sales* cube, adapt it using the up and down arrows under the schema table.
- In the **Dimensions** column of the **Cube query** table, type in each of the dimension names stored in the *Sales* cube regarding to each row in the **Column** column. In the *Sales* cube, the dimension names are: *Products*, *Regions*, *Months*, *Years*, *Datatypes*, *Measures*.
- In the **Elements** columns of the **Cube query** table, type in the dimension elements you want to retrieve regarding to the dimensions they belong to. In this example, the elements to be retrieved are *All Products*, *Germany* and *Austria* (Belonging to the same dimension **Regions**, these two elements are entered in the same row and separated with a coma.), *Jan, 2009*, *Actual*, *Turnover*.

## Job execution

- Click **tLogRow** to open its **Component** view.

- In the **Mode** area, select the **Table (print values in cells of a table)** check box to display the execution result in a table.
- Press **F6** to run the Job.

The dimension elements and the corresponding Measure values display in the **Run** console.

| <b>Limitation</b> | Numeric measures are only be accepted as Double or String type. When the string type is used, write the value to be processed between quotation marks.                                 |

## Scenario 1: Writing data into a given cube

The Job in this scenario writes new values in the *Sales* cube given as demo in the *Demo* database installed with Palo.

To replicate this scenario, proceed as follows:

### Setting up the Job

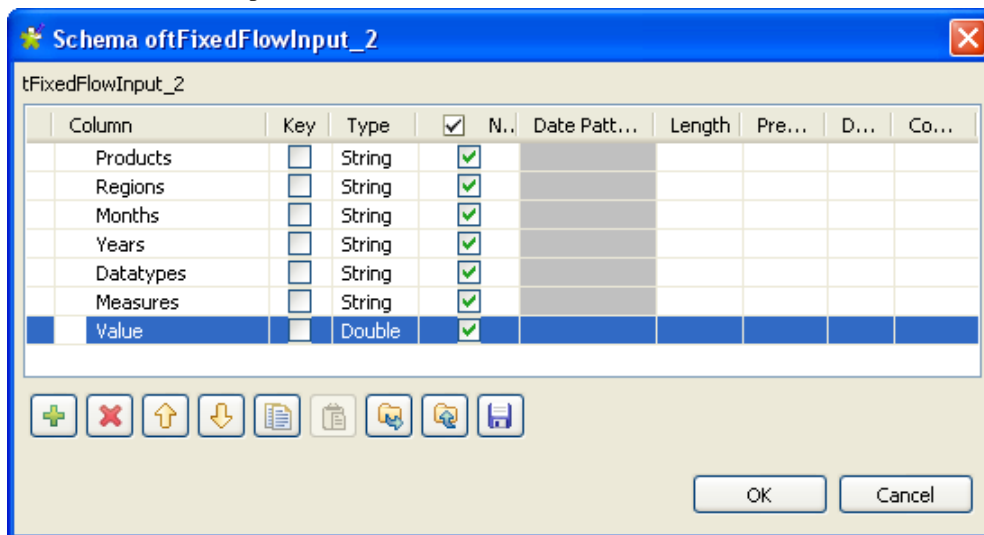

1. Drop **tFixedFlowInput** and **tPaloOutputMulti** from the component **Palette** onto the design workspace.
2. Right-click **tFixedFlowInput** to open its contextual menu.
3. In this menu, select **Row > Main** to connect this component to **tPaloOutputMulti**.

### Configuring the input component

1. Double-click the **tFixedFlowInput** component to open its **Component** view.

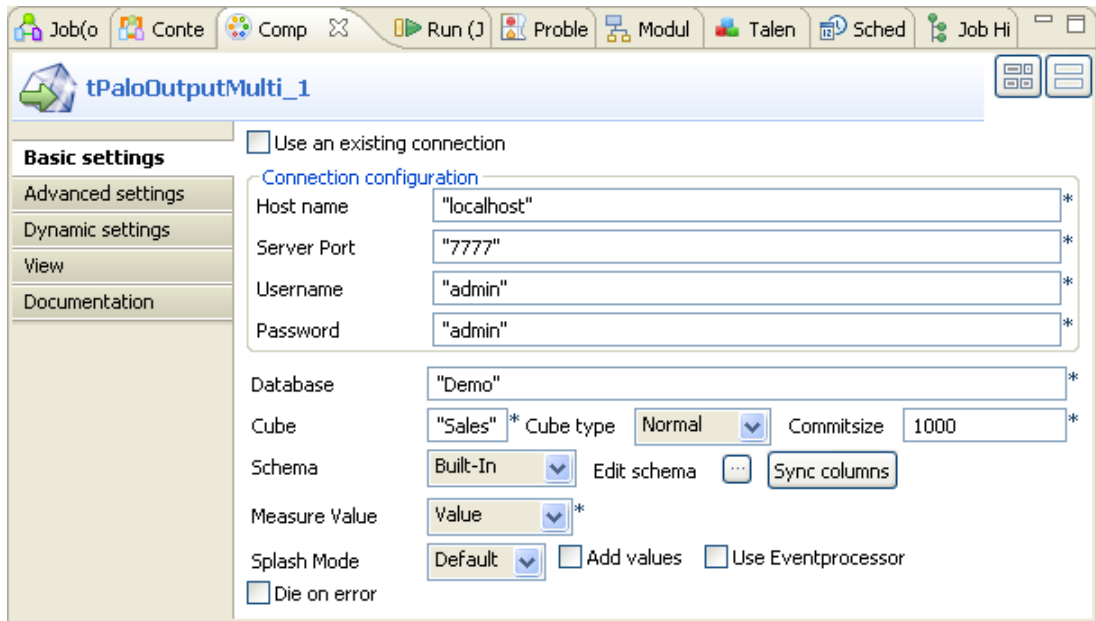

- Click the three-dot button to open the schema editor.

- In the schema editor, click the plus button to add 7 rows and rename them respectively as *Products*, *Regions*, *Months*, *Years*, *Datatypes*, *Measures* and *Values*. The order of these rows must be consistent with that of the corresponding dimensions in the *Sales* cube and the type of the *Value* column where the measure value resides is set to double/Double.
- Click **OK** to validate the editing and accept the propagation prompted by the dialog box that pops up. Then the schema column labels display automatically in the **Value** table under the **Use single table** check box, in the **Mode** area.
- In the **Value** table, type in values for each row in the **Value** column. In this example, these values are: *Desktop L*, *Germany*, *Jan*, *2009*, *Actual*, *Turnover*, *1234.56*.

## Configuring the output component

- Double-click **tPaloOutputMulti** to open its **Component** view.

2. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
3. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
4. In the **Database** field, type in the database name in which you want to create the cube, *Demo* in this example.
5. In the **Cube** field, type in the name of the cube you want to write data in, for example, *Sales*.
6. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.
7. In the **Measure Value** field, select the Measure element. In this scenario, select **Value**.

## Job execution

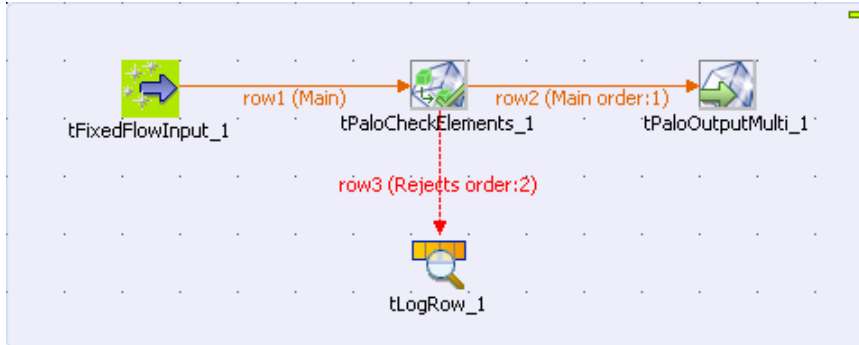

Press **F6** to run the Job.

The inflow data has been written into the *Sales* cube.

|    | A              |
|----|----------------|
| 1  | localhost/Demo |
| 2  | Sales          |
| 3  | Desktop L      |
| 4  | Germany        |
| 5  | Jan            |
| 6  | 2009           |
| 7  | Actual         |
| 8  | Turnover       |
| 9  |                |
| 10 | 1 234,56       |
| 11 |                |

## Scenario 2: Rejecting inflow data when the elements to be written do not exist in a given cube

The Job in this scenario tries to write data into the *Sales* cube but as the elements of interest do not exist in this cube, the inflow data is rejected.

To replicate this scenario, proceed as follows:

### Setting up the Job

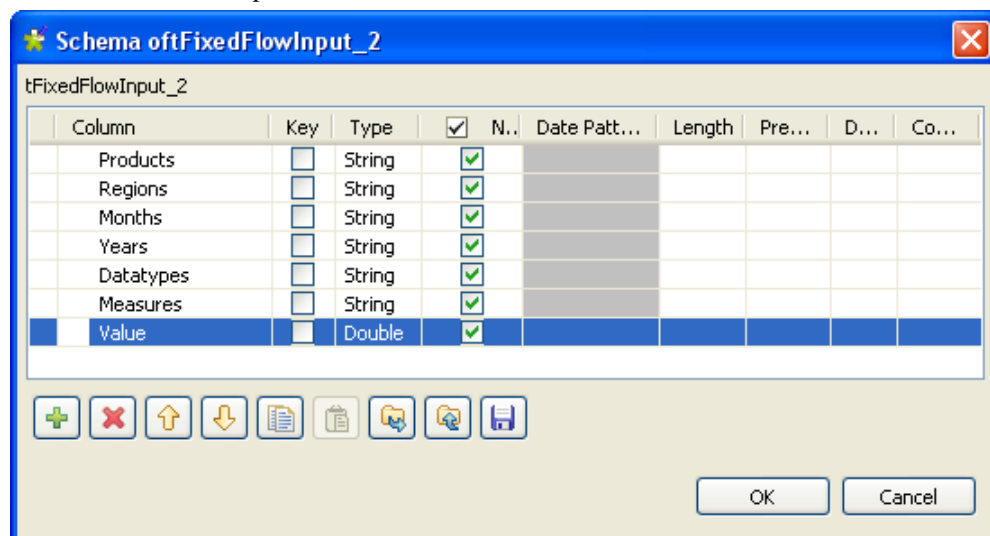

1. Drop **tFixedFlowInput**, **tPaloCheckElements**, **tPaloOutputMulti** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tFixedFlowInput** to open its contextual menu.
3. In this menu, select **Row > Main** to connect this component to **tPaloCheckElements**.
4. Do the same to connect **tPaloOutputMulti** using **row** link.
5. Right-click **tPaloCheckElements** to open its contextual menu.
6. In this menu, select **Row > Reject** to connect this component to **tLogRow**.

### Configuring the input component

1. Double-click the **tFixedFlowInput** component to open its **Component** view.

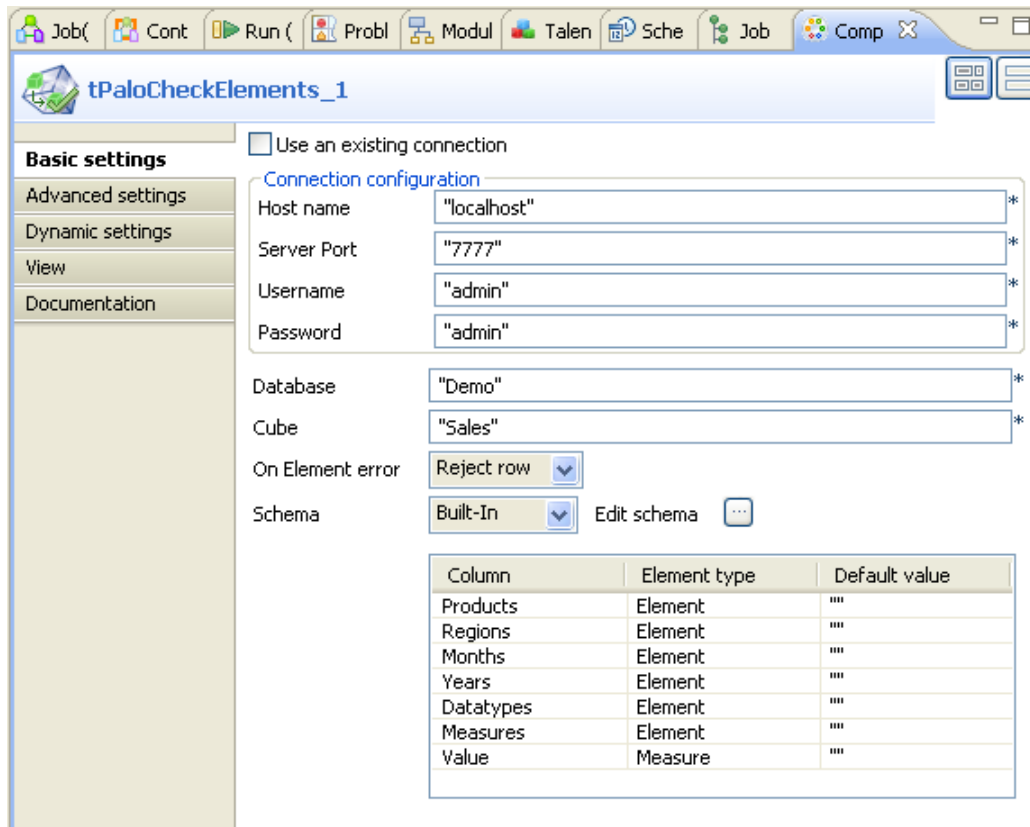

2. Click the three-dot button to open the schema editor.

3. In the schema editor, click the plus button to add 7 rows and rename them respectively as *Products*, *Regions*, *Months*, *Years*, *Datatypes*, *Measures* and *Values*. The order of these rows must be consistent with that of the corresponding dimensions in the *Sales* cube and the type of the *Value* column where the measure value resides is set to double/Double.
4. Click **OK** to validate the editing and accept the propagation prompted by the dialog box that pops up. Then the schema column labels display automatically in the **Value** table under the **Use single table** check box, in the **Mode** area.
5. In the **Value** table, type in values for each row in the **Value** column. In this example, these values are: *Smart Products*, *Germany*, *Jan*, *2009*, *Actual*, *Turnover*, *1234.56*. The *Smart Products* element does not exist in the *Sales* cube.

## Configuring the tPaloCheckElements component

1. Double-click **tPaloCheckElements** to open its **Component** view.

2. In the **Host name** field, type in *localhost*.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
5. In the **Database** field, type in the database name in which you want to create the cube, *Demo* in this example.
6. In the **Cube** field, type in the name of the cube you want to write data in, for example, *Sales*.
7. In the **On Element error** field, select **Reject row** from the drop-down list.
8. In the element table at the bottom of the **Basic settings** view, click the **Element type** column in the *Value* row and select **Measure** from the drop down list.

## Configuring the output component

1. Double-click **tPaloOutputMulti** to open its **Component** view.

2. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.
3. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
4. In the **Database** field, type in the database name in which you want to create the cube, *Demo* in this example.
5. In the **Cube** field, type in the name of the cube you want to write data in, for example, *Sales*.
6. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.
7. In the **Measure Value** field, select the Measure element. In this scenario, select **Value**.

## Job execution

Press **F6** to run the Job.

The data to be written is rejected and displayed in the console of the **Run** view. You can read that the error message is *Smart Products*.

| <b>Usage</b>             | This component can be used in standalone for rule creation, deletion or update.                  |                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Connections</b>       |                                                                                                  | Outgoing links (from one component to another):<br><b>Trigger:</b> Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.<br><br>Incoming links (from one component to another):<br><b>Row:</b> Iterate<br><b>Trigger:</b> Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.<br><br>For further information regarding connections, see <i>Talend Open Studio User Guide</i> . |
| <b>Limitation</b>        | Update or deletion of a rule is available only when this rule has been created with external ID. |                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Scenario: Creating a rule in a given cube

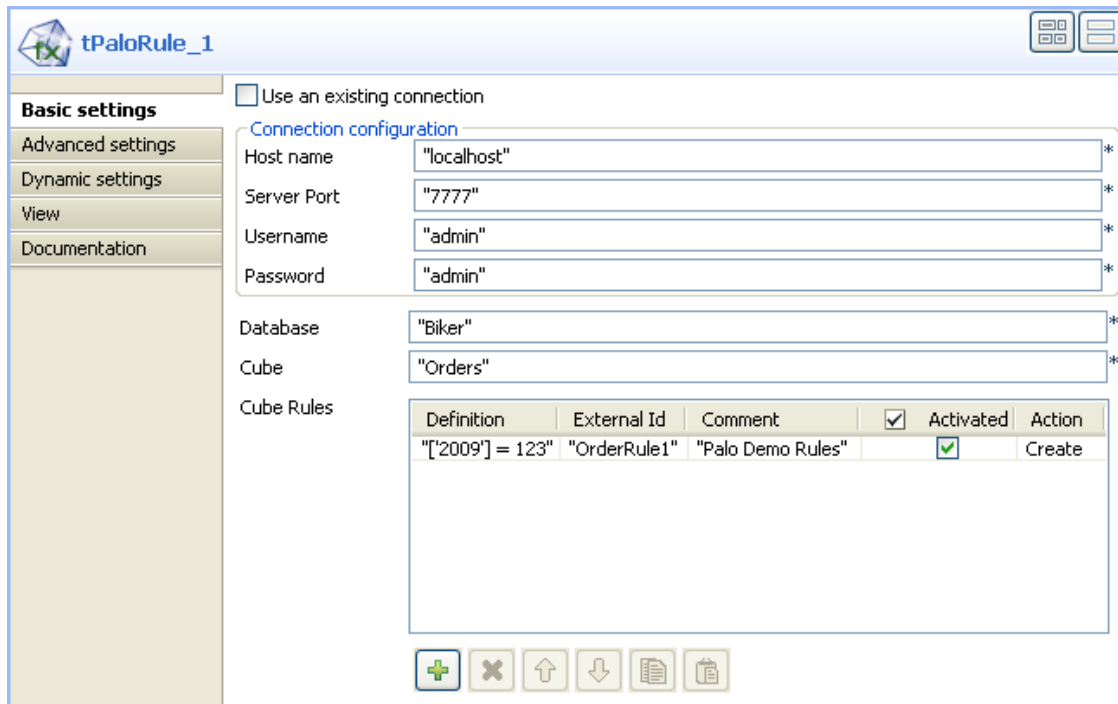

The Job in this scenario creates a rule applied on dimensions of a given cube.

To replicate this scenario, proceed as follows:

## Setting up the DB connection

1. Drop **tPaloRule** from the component **Palette** onto the design workspace.
2. Double-click the **tPaloRule** component to open its **Component** view.

3. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
6. In the **Database** field, type in the database name in which the dimensions applying the created rules reside, *Biker* in this example.
7. In the **Cube** field, type in the name of the cube which the dimensions applying the created rules belong to, for example, *Orders*.

## Setting the Cube rules

1. Under the **Cube rules** table, click the plus button to add a new row.
2. In the **Cube rules** table, type in [ '2009' ] = 123 in the **Definition** column, OrderRule1 in the **External Id** column and Palo Demo Rules in the **Comment** column.
3. In the **Activated** column, select the check box.
4. In the **Action** column, select **Create** from the drop-down list.

## Job execution

Press **F6** to run the Job.

The new rule has been created and the value of every 2009 element is 123.

|    | A               |
|----|-----------------|
| 1  | localhost/Biker |
| 2  | Orders          |
| 3  | All Customers   |
| 4  | All Channels    |
| 5  | All Orders      |
| 6  | All Datatypes   |
| 7  | Units           |
| 8  | All Products    |
| 9  | All Months      |
| 10 | 2009            |
| 11 |                 |
| 12 | 123             |
| 13 |                 |

This is available as an <b>After</b> variable.</p> <p>Returns a Integer.</p> <p><b>External ruleID:</b> Indicates the external IDs of the rules being processed. This is available as a <b>Flow</b> variable.</p> <p>Returns a String</p> <p>For further information about variables, see <i>Talend Open Studio User Guide</i>.</p>                                                                      |
| <b>Connections</b>       |                                                                              | <p>Outgoing links (from one component to another):</p> <p><b>Row:</b> Main; Iterate.</p> <p><b>Trigger:</b> Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.</p> <p>Incoming links (from one component to another):</p> <p><b>Row:</b> Iterate</p> <p><b>Trigger:</b> Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.</p> <p>For further information regarding connections, see <i>Talend Open Studio User Guide</i>.</p> |
| <b>Limitation</b>        | The output schema is fixed and read-only.                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Discovering the read-only output schema of tPaloRuleList

The following table presents information related to the read-only output schema of the **tPaloRuleList** component.

| Database        | Type | Description                                |
|-----------------|------|--------------------------------------------|
| rule_identifier | long | The internal identifier/id for this rule.. |

| Database        | Type    | Description                                                                                    |
|-----------------|---------|------------------------------------------------------------------------------------------------|
| rule_definition | string  | The formula of this rule. For further information about this formula, see the Palo user guide. |
| rule_extern_id  | string  | The user-defined external id.                                                                  |
| rule_comment    | string  | The user-edited comment on this rule.                                                          |
| rule_activated  | boolean | Indicates if this rule had been activated or not.                                              |

## Scenario: Retrieving detailed rule information from a given cube

The Job in this scenario retrieves rule details applied on the dimensions of a given cube.

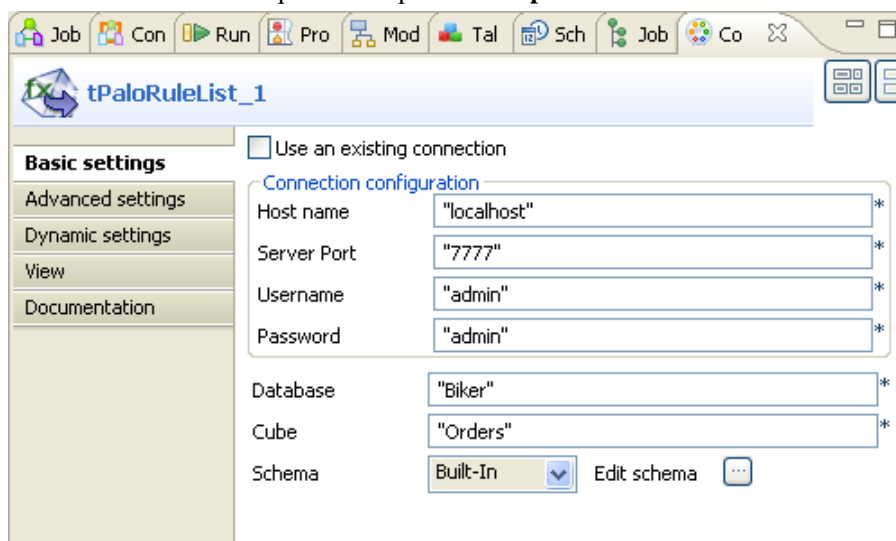

To replicate this scenario, proceed as follows:

### Setting up the Job

1. Drop **tPaloRuleList** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloRuleList** to open the contextual menu.
3. From this menu, select **Row > Main** to link the two components.

### Configuring the tPaloRuleList component

1. Double-click the **tPaloRuleList** component to open its **Component** view.

2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
4. In the **Username** and **Password** fields, type in the authentication information. In this example, both of them are *admin*.
5. In the **Database** field, type in the database name where the dimensions applying the rules of interest reside, *Biker* in this example.
6. In the **Cube** field, type in the name of the cube which the rules of interest belong to.

## Job execution

Press **F6** to run the Job.

Details of all of the rules in the *Orders* cube are retrieved and listed in the console of the **Run** view.

```
Starting job tpalo at 16:34 12/11/2010.
[statistics] connecting to socket on port 3743
[statistics] connected
-----+-----+-----+-----+-----+
| | tLogRow_1 | | | |
|-----+-----+-----+-----+-----+
| rule_identifier | rule_definition | rule_extern_id | rule_comment | rule_activated |
|-----+-----+-----+-----+-----+
| 1 | ['2009'] = 123 | OrderRule1 | Palo Demo Rules | true |
|-----+-----+-----+-----+-----+
[statistics] disconnected
Job tpalo ended at 16:35 12/11/2010. [exit code=0]
```

For further information about the output schema, see [the section called “Discovering the read-only output schema of tPaloRuleList”](#).

| <b>Function</b>         | <b>tPostgresPlusSCD</b> reflects and tracks changes in a dedicated MSSQL SCD table.                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Purpose</b>          | <b>tPostgresPlusSCD</b> addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Basic settings</b>   | <i>Use an existing connection</i>                                                                                                                        | <p>Select this check box and click the relevant DB connection component on the <b>Component list</b> to reuse the connection details you already defined.</p> <p> When a Job contains the parent Job and the child Job, <b>Component list</b> presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, make sure that the available connection components are sharing the intended connection.</p> <p>For more information on how to share a DB connection across Job levels, see <b>Use or register a shared DB connection</b> in any database connection component corresponding to the database you are using, in <a href="#">Database components</a>.</p> <p>Otherwise, you can as well deactivate the connection components and use <b>Dynamic settings</b> of the component to specify the intended connection manually. In this case, make sure the connection name is unique and distinctive all over through the two Job levels. For more information about <b>Dynamic settings</b>, see your studio user guide.</p> |

Note that only one table can be written at a time                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|  | <i>Action on table</i>        | <p>Select to perform one of the following operations on the table defined:</p> <p><b>None:</b> No action carried out on the table.</p> <p><b>Drop and create table:</b> The table is removed and created again</p> <p><b>Create table:</b> A new table gets created.</p> <p><b>Create table if not exists:</b> A table gets created if it does not exist.</p> <p><b>Clear table:</b> The table content is deleted. You have the possibility to rollback the operation.</p> <p><b>Truncate table:</b> The table content is deleted. You don not have the possibility to rollback the operation.</p>                                                                         |
|  | <i>Schema and Edit schema</i> | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. The schema is either built-in or remotely stored in the Repository.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|  |                               | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|  |                               | <b>Repository:</b> The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|  | <i>Surrogate Key</i>          | Select the surrogate key column from the list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|  | <i>Creation</i>               | <p>Select the method to be used for the surrogate key generation.</p> <p>For more information regarding the creation methods, see <a href="#">the section called “SCD keys”</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|  | <i>Source Keys</i>            | Select one or more columns to be used as keys, to ensure the unicity of incoming data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|  | <i>Use SCD Type 1 fields</i>  | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|  | <i>Use SCD Type 2 fields</i>  | <p>Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.</p> <p><b>Start date:</b> Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.</p> <p><b>End Date:</b> Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select <b>Fixed Year value</b> and fill it in with a fictive year to avoid having a null value in the End Date field.</p> |

|                          |                                                                                                           |                                                                                                                                                                                                                                                                                    |
|--------------------------|-----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                                                                           | <p><b>Log Active Status:</b> Adds a column to your SCD schema to hold the <b>true</b> or <b>false</b> status value. This column helps to easily spot the active record.</p> <p><b>Log versions:</b> Adds a column to your SCD schema to hold the version number of the record.</p> |
| <b>Advanced settings</b> | <i>Debug mode</i>                                                                                         | Select this check box to display each step during processing entries in a database.                                                                                                                                                                                                |
|                          | <i>tStat Catcher Statistics</i>                                                                           | Select this check box to collect log data at the component level.                                                                                                                                                                                                                  |
| <b>Usage</b>             | This component is used as an output component. It requires an input component and Row main link as input. |                                                                                                                                                                                                                                                                                    |

| <b>Usage</b>             | This component is used as a start component. It requires an output flow.     |                                                                                                                                                                                                                                       |

## Scenario: Displaying the content of an SPSS .sav file

The following scenario creates a two-component Job, which aims at reading each row of a .sav file and displaying the output on the log console.

### Setting up the Job

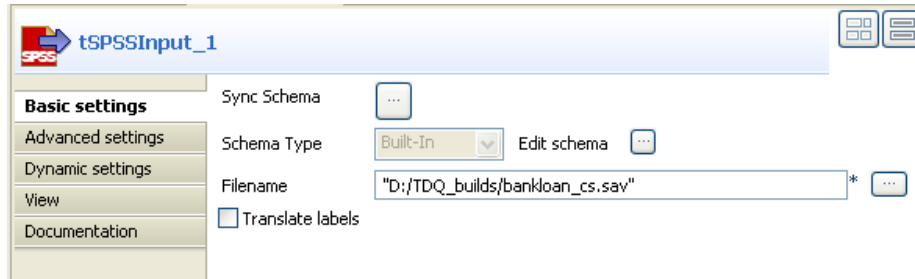

1. Drop a **tSPSSInput** component and a **tLogRow** component from the **Palette** onto the design workspace.

- Right-click on **tSPSSInput** and connect it to **tLogRow** using a **Main Row** link.

## Configuring the input component

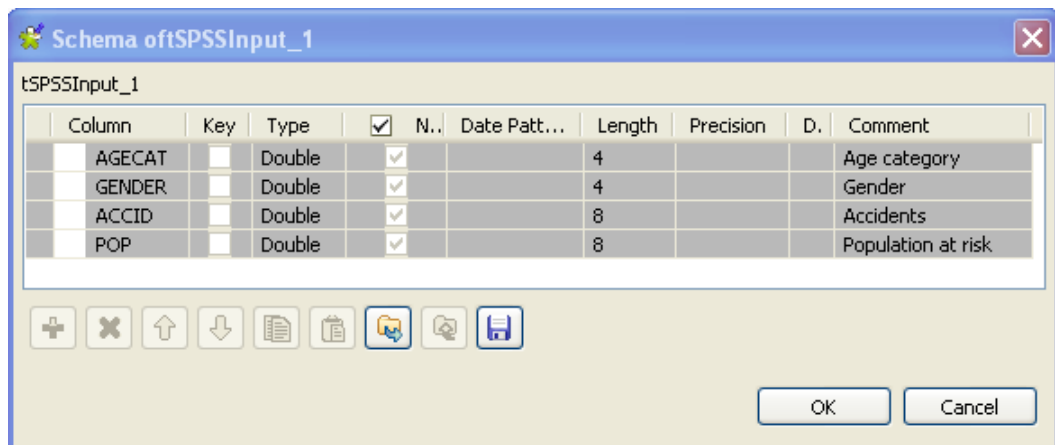

- Click **tSPSSInput** to display its **Basic settings** view and define the component properties.

- Click the three-dot button next to the **Filename** field and browse to the SPSS .sav file you want to read.
- Click the three-dot button next to **Sync schema**. A message opens up prompting you to accept retrieving the schema from the defined SPSS file.

- Click **Yes** to close the message and proceed to the next step.
- If required, click the three-dot button next to **Edit schema** to view the pre-defined data structure of the source SPSS file.

- Click **OK** to close the dialog box.

## Job execution

Save the Job and press **F6** to execute it.

The SPSS file is read row by row and the extracted fields are displayed on the log console.

```
Starting job SPSS at 10:28 20/01/2010.
[statistics] connecting to socket on port 3802
[statistics] connected
1.0|1.0|57997.0|198522.0
2.0|1.0|57113.0|203200.0
3.0|1.0|54123.0|200744.0
1.0|0.0|63936.0|187791.0
2.0|0.0|64835.0|195714.0
3.0|0.0|66804.0|208239.0
[statistics] disconnected
Job SPSS ended at 10:28 20/01/2010. [exit code=0]
```

## Translating the stored values

To translate the stored values, complete the following:

1. In the **Basic settings** view, select the **Translate label** check box.
2. Click **Sync Schema** a second time to retrieve the schema after translation.

A message opens up prompting you to accept retrieving the schema from the defined SPSS file.

3. Click **Yes** to close the message and proceed to the next step.

A second message opens up prompting you to accept propagating the changes.

4. Click **Yes** to close the message and proceed to the next step.
5. Save the Job and press **F6** to execute it.

The SPSS file is read row by row and the extracted fields are displayed on the log console after translating the stored values.

```
Starting job SPSS at 10:32 20/01/2010.
[statistics] connecting to socket on port 3418
[statistics] connected
Under 21|Female|57997.0|198522.0

## Scenario: Writing data in an .sav file

This Java scenario describes a very simple Job that writes data entries in an .sav file.

### Setting up the Job

1. Drop a **tRowGenerator** component and a **tSPSSOutput** component from the **Palette** onto the design workspace.

- Right-click on **tRowGenerator** and connect it to **tSPSSOutput** using a **Main Row** link.

## Configuring the input component

- In the design workspace, double click **tRowGenerator** to display its **Basic Settings** view and open its editor. Here you can define your schema.

| Schema  |                          |        |                                     |     |        |           |         |         | Functions   | Preview    |              |
|---------|--------------------------|--------|-------------------------------------|-----|--------|-----------|---------|---------|-------------|------------|--------------|
| Column  | Key                      | Type   | <input checked="" type="checkbox"/> | N.. | Length | Precision | Default | Comment | Functions   | Environ... | Preview      |
| id      | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     | 6      |           |         |         | getAscii... | length=... | R8Zx50       |
| country | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     | 50     |           |         |         | getUsStr... |            | Burnett Road |

Columns: Number of Rows for RowGenerator: 100

Function parameters: Preview

10 Number of Rows for Preview Preview

|   | id     | country                   |
|---|--------|---------------------------|
| 1 | UTnwds | San Marcos                |
| 2 | ot9fzP | El Camino Real            |
| 3 | 08ydXS | East Calle Primera        |
| 4 | R8Zx50 | Burnett Road              |
| 5 | xMsV5d | French Camp Turnpike Road |

OK Cancel

- Click the plus button to add the columns you want to write in the .sav file.
- Define the schema and set the parameters to the columns.

*Make sure to define the length of your columns. Otherwise, an error message will display when building your Job.*

- Click **OK** to validate your schema and close the editor.

## Configuring the output component

- Click **tSPSSOutput** to display its **Basic settings** view and define the component properties.

tSPSSOutput\_1

Basic settings

Sync Schema ... Schema Type Built-In Edit schema Sync columns

Advanced settings

Filename "C:/Documents and Settings/hmassy/Bureau/out.sav" \*

Dynamic settings

Write Type Write

View

Documentation

2. Click the three-dot button next to the **Filename** field and browse to the SPSS .sav file in which you want to write data.
3. Click the three-dot button next to **Sync columns** to synchronize columns with the previous component. In this example, the schema to be inserted in the .sav file consists of the two columns: *id* and *country*.
4. If required, click **Edit schema** to view/edit the defined schema.
5. From the **Write Type** list, select **Write** or **Append** to simply write the input data in the .sav file or add it to the end of the .sav file.

## Job execution

Save the Job and press **F6** to execute it.

The data generated by the **tRowGenerator** component is written in the defined .sav file.

# tSPSSProperties

In order to benefit from all of the functional objectives of the SPSS components, do the following: -If you have already installed SPSS, add the path to the SPSS directory as the following: `SET PATH=%PATH%;<DR>:\program\SPSS`, or -If you have not installed SPSS, you must copy the SPSS IO "spssio32.dll" lib from the SPSS installation CD and paste it in the **Talend** root directory.

# tSPSSStructure

Before being able to benefit from all functional objectives of the SPSS components, make sure to do the following: -If you have already installed SPSS, add the path to the SPSS directory as the following: `SET PATH=%PATH%;<DR>:\program\SPSS`, or -If you have not installed SPSS, you must copy the SPSS IO "spssio32.dll" lib from the SPSS installation CD and paste it in **Talend** root directory.

## tSPSSStructure properties

|                          |                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

You don not have the possibility to rollback the operation.</p>                                                                         |
|  | <i>Schema and Edit schema</i> | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. The schema is either built-in or remotely stored in the Repository.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|  |                               | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|  |                               | <b>Repository:</b> The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|  | <i>Surrogate Key</i>          | Select the surrogate key column from the list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|  | <i>Creation</i>               | <p>Select the method to be used for the surrogate key generation.</p> <p>For more information regarding the creation methods, see <a href="#">the section called “SCD keys”</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|  | <i>Source Keys</i>            | Select one or more columns to be used as keys, to ensure the unicity of incoming data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|  | <i>Use SCD Type 1 fields</i>  | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|  | <i>Use SCD Type 2 fields</i>  | <p>Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.</p> <p><b>Start date:</b> Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.</p> <p><b>End Date:</b> Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select <b>Fixed Year value</b> and fill it in with a fictive year to avoid having a null value in the End Date field.</p> |

|                          |                                                                                                           |                                                                                                                                                                                                                                                                                    |
|--------------------------|-----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                                                                           | <p><b>Log Active Status:</b> Adds a column to your SCD schema to hold the <b>true</b> or <b>false</b> status value. This column helps to easily spot the active record.</p> <p><b>Log versions:</b> Adds a column to your SCD schema to hold the version number of the record.</p> |
| <b>Advanced settings</b> | <i>Additional parameters</i>                                                                              | <i>JDBC</i>                                                                                                                                                                                                                                                                        |
|                          |                                                                                                           | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <b>Use an existing connection</b> check box in the <b>Basic settings</b> .                                                                  |
|                          | <i>Debug mode</i>                                                                                         | Select this check box to display each step during processing entries in a database.                                                                                                                                                                                                |
|                          | <i>tStatCatcher Statistics</i>                                                                            | Select this check box to collect log data at the component level.                                                                                                                                                                                                                  |
| <b>Usage</b>             | This component is used as an output component. It requires an input component and Row main link as input. |                                                                                                                                                                                                                                                                                    |

## Related Scenario

For related topics, see [the section called “tMysqlSCD”](#) and [the section called “Scenario: Tracking changes using Slowly Changing Dimensions \(type 0 through type 3\)”](#).

# Cloud components

This chapter details the main components which you can find in the **Cloud** family of the *Talend Open Studio Palette*.

Private and public cloud databases, data services and SaaS-based applications (CRM, HR, ERP, etc.) are springing up alongside on-premise applications and databases that have been the mainstay of corporate IT. The resulting hybrid IT environments have more sources, of more diverse types, which require more modes of integration, and more effort on data quality and consistency across sources.

The Cloud family comprises the most popular database connectors adapted to Cloud and SaaS applications and technologies.

# tAmazonMysqlClose

## tAmazonMysqlClose properties

|                          |                                                                                                                                               |                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Function</b>          | tAmazonMysqlClose closes the transaction committed in the connected DB.                                                                       |                                                                                                                             |
| <b>Purpose</b>           | Close a transaction.                                                                                                                          |                                                                                                                             |
| <b>Basic settings</b>    | <i>Component list</i>                                                                                                                         | Select the <b>tAmazonMysqlConnection</b> component in the list if more than one connection are planned for the current Job. |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                                                                                                | Select this check box to collect log data at the component level.                                                           |
| <b>Usage</b>             | This component is to be used along with AmazonMysql components, especially with <b>tAmazonMysqlConnection</b> and <b>tAmazonMysqlCommit</b> . |                                                                                                                             |

## Related scenario

No scenario is available for this component yet.

# tAmazonMysqlCommit

## tAmazonMysqlCommit Properties

This component is closely related to **tAmazonMysqlConnection** and **tAmazonMysqlRollback**. It usually doesn't make much sense to use these components independently in a transaction.

## Related scenario

This component is closely related to **tAmazonMysqlConnection** and **tAmazonMysqlRollback**. It usually doesn't make much sense to use one of these without using a **tAmazonMysqlConnection** component to open a connection for the current transaction.

For **tAmazonMysqlCommit** related scenario, see [the section called “Scenario: Inserting data in mother/daughter tables”](#).

# tAmazonMysqlConnection

## tAmazonMysqlConnection Properties

This component is closely related to **tAmazonMysqlCommit** and **tAmazonMysqlRollback**. It usually doesn't make much sense to use one of these without using a **tAmazonMysqlConnection** component to open a connection for the current transaction.

## Scenario: Inserting data in mother/daughter tables

The following Job is dedicated to advanced database users, who want to carry out multiple table insertions using a parent table id to feed a child table. As a prerequisite to this Job, follow the steps described below to create the relevant tables using an engine such as *innodb*.

### Setting up the Job

1. In a command line editor, connect to your Mysql server. Once connected to the relevant database, type in the following command to create the parent table: create table f1090\_mum(id int not null auto\_increment, name varchar(10), primary key(id)) engine=innodb.
2. Then create the second table: create table baby (id\_baby int not null, years int) engine=innodb.

Back into *Talend Open Studio*, the Job requires seven components including **tAmazonMysqlConnection** and **tAmazonMysqlCommit**.

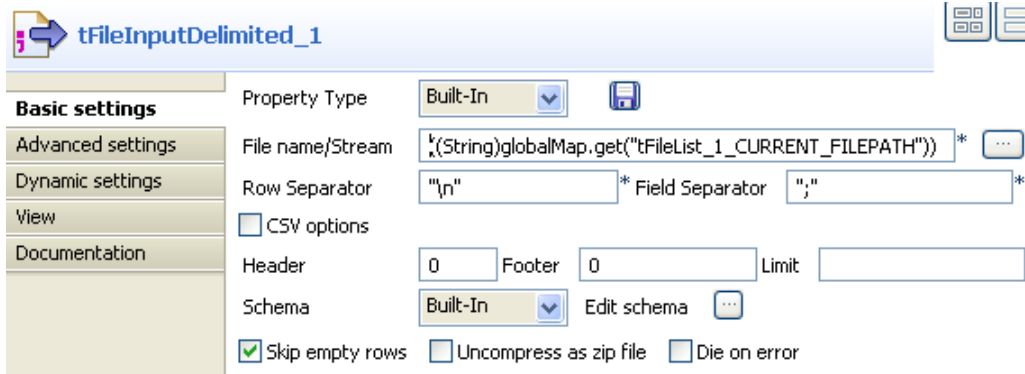

3. Drag and drop the following components from the **Palette**: **tFileList**, **tFileInputDelimited**, **tMap**, **tAmazonMysqlOutput** (x2).
4. Connect the **tFileList** component to the input file component using an **Iterate** link as the name of the file to be processed will be dynamically filled in from the **tFileList** directory using a global variable.
5. Connect the **tFileInputDelimited** component to the **tMap** and dispatch the flow between the two output AmazonMysql DB components. Use a **Row** link for each for these connections representing the main data flow.
6. Set the **tFileList** component properties, such as the directory. name where files will be fetched from.
7. Add a **tAmazonMysqlConnection** component and connect it to the starter component of this job, in this example, the **tFileList** component using an **OnComponentOk** link to define the execution order.

### Setting up the DB connection

In the **tAmazonMysqlConnection** Component view, set the connection details manually or fetch them from the Repository if you centrally stored them as a Metadata DB connection entry. For more information about Metadata, see *Talend Open Studio User Guide*.

## Configuring the input component

1. On the **tFileInputDelimited** component's **Basic settings** panel, press **Ctrl+Space** bar to access the variable list. Set the **File Name** field to the global variable: *tFileList\_1.CURRENT\_FILEPATH*

2. Set the rest of the fields as usual, defining the row and field separators according to your file structure. Then set the schema manually through the **Edit schema** feature or select the schema from the Repository. Make sure the data type is correctly set, in accordance with the nature of the data processed.

## Configuring the tMap component

1. In the **tMap** Output area, add two output tables, one called **mum** for the parent table, the second called **baby**, for the child table.
2. Drag the *Name* column from the **Input** area, and drop it to the **mum** table. Drag the *Years* column from the **Input** area and drop it to the **baby** table.

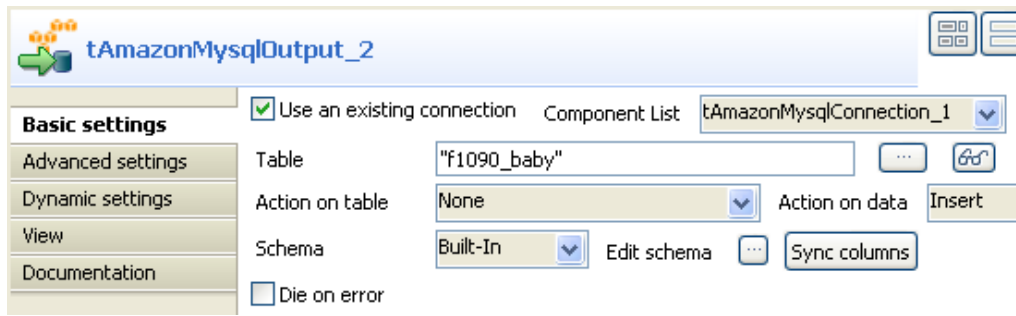

Make sure the **mum** table is on the top of the **baby** table as the order is determining for the flow sequence hence the DB insert to perform correctly.

3. Then connect the output row link to distribute correctly the flow to the relevant DB output component.

## Configuring the output component

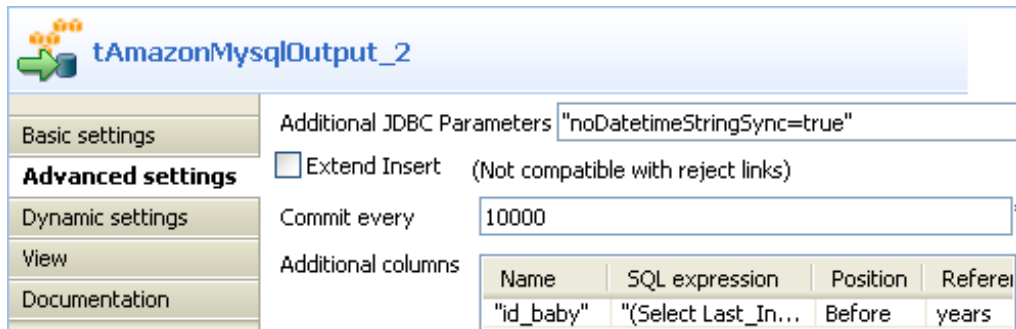

1. In each of the **tAmazonMysqlOutput** components' **Basic settings** panel, select the **Use an existing connection** check box to retrieve the **tAmazonMysqlConnection** details.

2. Set the **Table** name making sure it corresponds to the correct table, in this example either *f1090\_mum* or *f1090\_baby*.

There is no action on the table as they are already created.

3. Select **Insert** as **Action on data** for both output components. Click on **Sync columns** to retrieve the schema set in the **tMap**.
4. Go to the **Advanced settings** panel of each of the **tAmazonMysqlOutput** components. Notice that the **Commit every** field will get overridden by the **tAmazonMysqlCommit**.

5. In the **Additional columns** area of the DB output component corresponding to the child table (*f1090\_baby*), set the `id_baby` column so that it reuses the `id` from the parent table. In the **SQL expression** field type in: `'(Select Last_Insert_id())'`.

The position is *Before* and the **Reference column** is *years*.

## Configuring the tAmazonMysqlCommit component

1. Add the **tAmazonMysqlCommit** component to the design workspace and connect it from the **tFileList** component using a **OnComponentOk** connection in order for the Job to terminate with the transaction commit.
2. On the **tAmazonMysqlCommit Component** view, select in the list the connection to be used.

## Job execution

Save your Job and press **F6** to execute it.

```
mysql> select * from f1090_mum
-> ;
+----+-----+
| id | names |
+----+-----+
6	john
7	bruce
8	beth
9	andrew
10	donald
11	betty
12	john
13	bruce
14	beth
15	andrew
16	donald
17	betty
+----+-----+
12 rows in set (0.00 sec)
```

```
mysql> select * from f1090_baby
-> ;
+-----+-----+
| id_baby | years |
+-----+-----+
6	10
7	23
8	34
9	10
10	23
11	34
12	10
13	23
14	34
15	10
16	23
17	34
+-----+-----+
12 rows in set (0.00 sec)
```

The parent table *id* has been reused to feed the *id\_baby* column.

## Scenario1: Writing columns from a MySQL database to an output file

In this scenario we will read certain columns from a MySQL database, and then write them to a table in a local output file.

### Setting up the Job

1. Drop **tAmazonMysqlInput** and **tFileOutputDelimited** from the **Palette** onto the workspace.

2. Link **tAmazonMysqlInput** to **tFileOutputDelimited** using a **Row > Main** connection.

## Configuring the input component

1. Double-click **tAmazonMysqlInput** to open its **Basic Settings** view in the **Component** tab.

The screenshot shows the 'Basic settings' tab for the 'tAmazonMysqlInput' component. The configuration is as follows:

- Property Type:** Repository (selected)
- DB (MYSQL):mysql** (text field)
- DB Version:** Mysql 5 (dropdown)
- Use an existing connection
- Host:** localhost (text field)
- Port:** 3306 (text field)
- Database:** test (text field)
- Username:** root (text field)
- Password:** \*\*\*\*\* (text field)
- Schema:** Built-In (dropdown) with an 'Edit schema' button
- Table Name:** employees (text field)
- Query Type:** Built-In (dropdown) with 'Guess Query' and 'Guess schema' buttons
- Query:** `select id, first_name, city, salary from employees` (text area)

2. From the **Property Type** list, select **Repository** if you have already stored the connection to database in the **Metadata** node of the **Repository** tree view. The property fields that follow are automatically filled in.

For more information about how to store a database connection, see *Talend Open Studio User Guide*.

3. If you have not defined the database connection locally in the **Repository**, fill in the details manually after selecting **Built-in** from the **Property Type** list.
4. Set the **Schema** as **Built-in** and click **Edit schema** to define the desired schema.

The schema editor opens:

The screenshot shows the 'Schema of tAmazonMysqlInput\_1' dialog box. It contains a table with the following data:

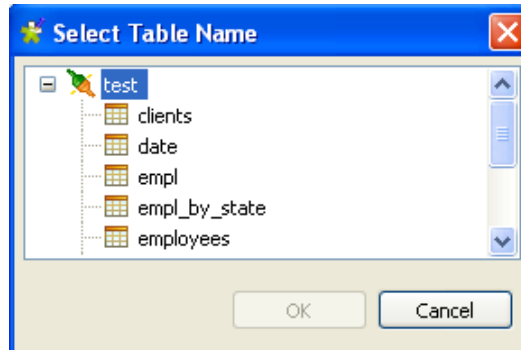

| Column     | Key                                 | Type    | <input type="checkbox"/>            | N.. | Date P... | Le... | Pr... | D.. | C.. |
|------------|-------------------------------------|---------|-------------------------------------|-----|-----------|-------|-------|-----|-----|
| id         | <input checked="" type="checkbox"/> | int     | <input type="checkbox"/>            |     |           | 10    | 0     | "0" |     |
| first_name | <input type="checkbox"/>            | String  | <input checked="" type="checkbox"/> |     |           | 30    | 0     |     |     |
| city       | <input type="checkbox"/>            | String  | <input checked="" type="checkbox"/> |     |           | 30    | 0     |     |     |
| salary     | <input type="checkbox"/>            | Inte... | <input checked="" type="checkbox"/> |     |           | 10    | 0     |     |     |

Below the table are several icons for adding, deleting, and moving rows, and 'OK' and 'Cancel' buttons.

5. Click the **[+]** button to add the rows that you will use to define the schema, four columns in this example *id, first\_name, city* and *salary*.
6. Under **Column**, click in the fields to enter the corresponding column names.
7. Click the field under **Type** to define the type of data. Click **OK** to close the schema editor.

- Next to the **Table Name** field, click the [...] button to select the database table of interest.

A dialog box displays a tree diagram of all the tables in the selected database:

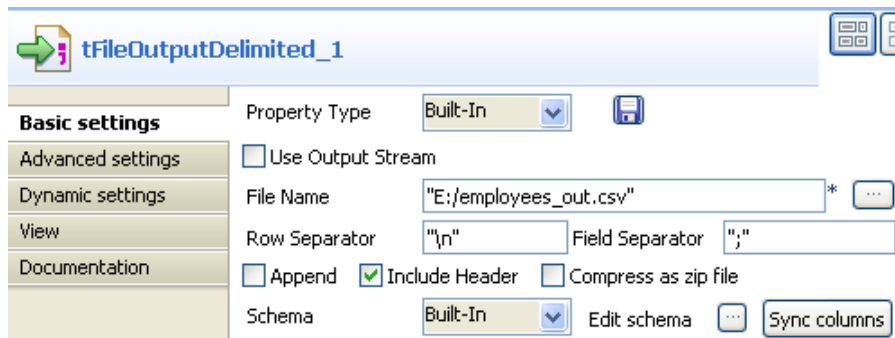

- Click the table of interest and then click **OK** to close the dialog box.
- Set the **Query Type** as **Built-In**. In the **Query** box, enter the query required to retrieve the desired columns from the table.

## Configuring the output component

- Double-click **tFileOutputDelimited** to set its **Basic Settings** in the **Component** tab.

- Next to the **File Name** field, click the [...] button to browse your directory to where you want to save the output file, then enter a name for the file.
- Select the **Include Header** check box to retrieve the column names as well as the data.

## Job execution

Save the Job and press **F6** to run it.

The output file is written with the desired column names and corresponding data, retrieved from the database:

```
1 id;first_name;city;salary
2 1;Martin;Sacramento;9011
3 2;Zachary;Atlanta;8118
4 3;James;Hartford;5087
5 4;Herbert;Charleston;9233
6 5;Herbert;Hartford;6289
7 6;Ulysses;Nashville;6269
```

The Job can also be run in the **Traces Debug** mode, which allows you to view the rows as they are being written to the output file, in the workspace.

# tAmazonMysqlOutput

## tAmazonMysqlOutput properties

|                         |                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|  | <i>Table</i>           | Name of the table to be written. Note that only one table can be written at a time                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|  | <i>Action on table</i> | <p>On the table defined, you can perform one of the following operations:</p> <p><b>None:</b> No operation is carried out.</p> <p><b>Drop and create table:</b> The table is removed and created again.</p> <p><b>Create table:</b> The table does not exist and gets created.</p> <p><b>Create table if not exists:</b> The table is created if it does not exist.</p> <p><b>Drop table if exists and create:</b> The table is removed if it already exists and created again.</p> <p><b>Clear table:</b> The table content is deleted.</p> <p><b>Truncate table:</b> The table content is quickly deleted. However, you will not be able to rollback the operation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|  | <i>Action on data</i>  | <p>On the data of the table defined, you can perform:</p> <p><b>Insert:</b> Add new entries to the table. If duplicates are found, the job stops.</p> <p><b>Update:</b> Make changes to existing entries.</p> <p><b>Insert or update:</b> Add entries or update existing ones.</p> <p><b>Update or insert:</b> Update existing entries or creates them if they do not exist.</p> <p><b>Delete:</b> Remove entries corresponding to the input flow.</p> <p><b>Replace:</b> Add new entries to the table. If an old row in the table has the same value as a new row for a PRIMARY KEY or a UNIQUE index, the old row is deleted before the new row is inserted.</p> <p><b>Insert or update on duplicate key or unique index:</b> Add entries if the inserted value does not exist or update entries if the inserted value already exists and there is a risk of violating a unique index or primary key.</p> <p><b>Insert Ignore:</b> Add only new rows to prevent duplicate key errors.</p> <p> <i>You must specify at least one column as a primary key on which the <b>Update</b> and <b>Delete</b> operations are based. You can do that by clicking <b>Edit Schema</b> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <b>Advanced settings</b> view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the <b>Use field options</b> check box and then in the <b>Key in update</b></i></p> |

|                          |                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                   | <i>column, select the check boxes next to the column name on which you want to base the update operation. Do the same in the <b>Key in delete</b> column for the deletion operation.</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                          | <i>Schema and Edit schema</i>     | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. The schema is either <b>Built-in</b> or stored remotely in the <b>Repository</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                          |                                   | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                          |                                   | <b>Repository:</b> The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                          | <i>Die on error</i>               | This check box is selected by default. Clear the check box to skip the row in error and complete the process for error-free rows. If needed, you can retrieve the rows in error via a <b>Row &gt; Rejects</b> link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Advanced settings</b> | <i>Additional parameters JDBC</i> | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <b>Use an existing connection</b> check box in the <b>Basic settings</b> .<br><br> You can press <b>Ctrl+Space</b> to access a list of predefined global variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                          | <i>Extend Insert</i>              | Select this check box to carry out a bulk insert of a defined set of lines instead of inserting lines one by one. The gain in system performance is considerable.<br><br><b>Number of rows per insert:</b> enter the number of rows to be inserted per operation. Note that the higher the value specified, the lower performance levels shall be due to the increase in memory demands.<br><br> This option is not compatible with the <b>Reject</b> link. You should therefore clear the check box if you are using a <b>Row &gt; Rejects</b> link with this component.<br><br> <i>If you are using this component with <b>tMysqlLastInsertID</b>, ensure that the <b>Extend Insert</b> check box in <b>Advanced Settings</b> is not selected. <b>Extend Insert</b> allows for batch loading, however, if the check box is selected, only the ID of the last line of the last batch will be returned.</i> |
|                          | <i>Use batch size</i>             | Select this check box to activate the batch mode for data processing. In the <b>Batch Size</b> field that appears when this check box is selected, you can type in the number you need to define the batch size to be processed.<br><br> This check box is available only when you have selected, the <b>Update</b> or the <b>Delete</b> option in the <b>Action on data</b> field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|              |                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | <i>Commit every</i>                                                                                                                                                                                                                                                                     | Number of rows to be included in the batch before it is committed to the DB. This option ensures transaction quality (but not rollback) and, above all, a higher performance level.                                                                                                                                                                                                                                                                                                                             |
|              | <i>Additional Columns</i>                                                                                                                                                                                                                                                               | This option is not available if you have just created the DB table (even if you delete it beforehand). This option allows you to call SQL functions to perform actions on columns, provided that these are not insert, update or delete actions, or actions that require pre-processing.                                                                                                                                                                                                                        |
|              |                                                                                                                                                                                                                                                                                         | <b>Name:</b> Type in the name of the schema column to be altered or inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                   |

In this area, parameters are:<br><br>- <b>HINT:</b> specify the hint you need, using the syntax<br><br>/ *+ * / .<br><br>- <b>POSITION:</b> specify where you put the hint in a SQL statement.<br><br>- <b>SQL STMT:</b> select the SQL statement you need to use.                                                                                                                                  |
|              | <i>Enable debug mode</i>                                                                                                                                                                                                                                                                | Select this check box to display each step involved in the process of writing data in the database.                                                                                                                                                                                                                                                                                                                                                                                                             |
|              | <i>Use duplicate key update mode insert</i>                                                                                                                                                                                                                                             | Updates the values of the columns specified, in the event of duplicate primary keys.:<br><br><b>Column:</b> Between double quotation marks, enter the name of the column to be updated.<br><br><b>Value:</b> Enter the action you want to carry out on the column.<br><br> To use this option you must first of all select the <b>Insert</b> mode in the <b>Action on data</b> list found in the <b>Basic Settings</b> view. |
|              | <i>tStatCatcher Statistics</i>                                                                                                                                                                                                                                                          | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Usage</b> | This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.<br><br>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a MySQL database. It also allows you to |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

create a reject flow using a **Row > Rejects** link to filter data in error. For an example of **tAmazonMysqlOutput** in use, see [the section called “Scenario 3: Retrieve data in error with a Reject link”](#).

## Scenario 1: Adding a new column and altering data in a DB table

This Java scenario is a three-component Job that aims at creating random data using a **tRowGenerator**, duplicating a column to be altered using the **tMap** component, and eventually altering the data to be inserted based on an SQL expression using the **tAmazonMysqlOutput** component.

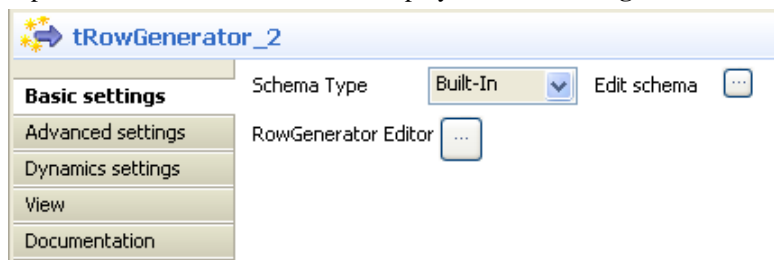

### Setting up the Job

1. Drop the following components from the **Palette** onto the design workspace: **tRowGenerator**, **tMap** and **tAmazonMySQLOutput**.
2. Connect **tRowGenerator**, **tMap**, and **tAmazonMysqlOutput** using the **Row Main** link.

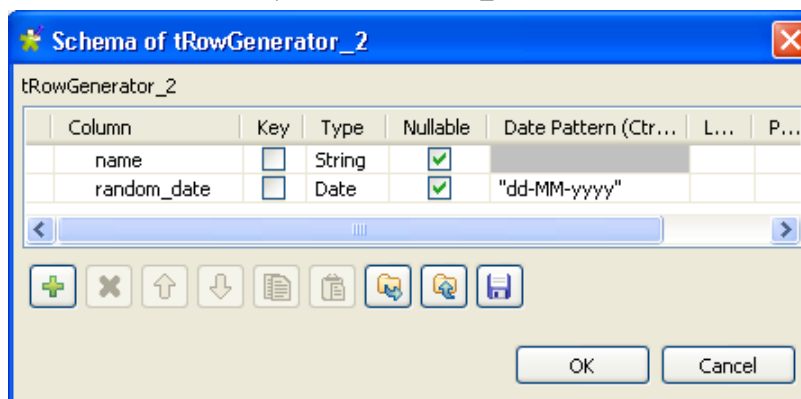

### Configuring the input component

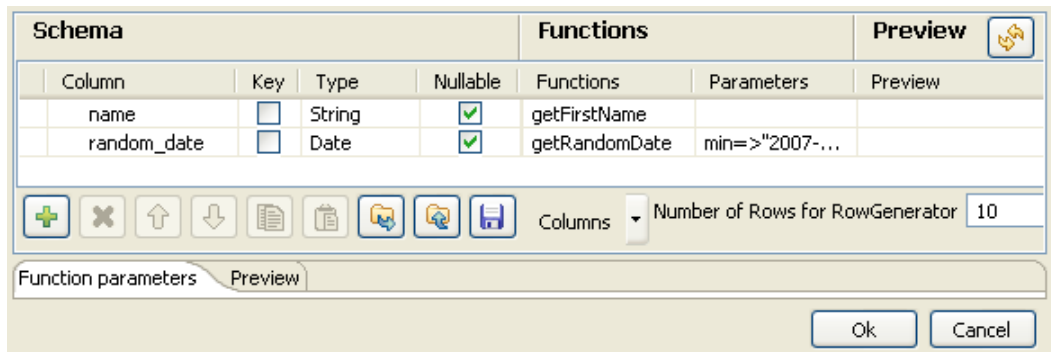

1. In the design workspace, select **tRowGenerator** to display its **Basic settings** view.

2. Set the **Schema** to **Built-In**. Click the **Edit schema** three-dot button to define the data to pass on to the **tMap** component, two columns in this scenario, *name* and *random\_date*.

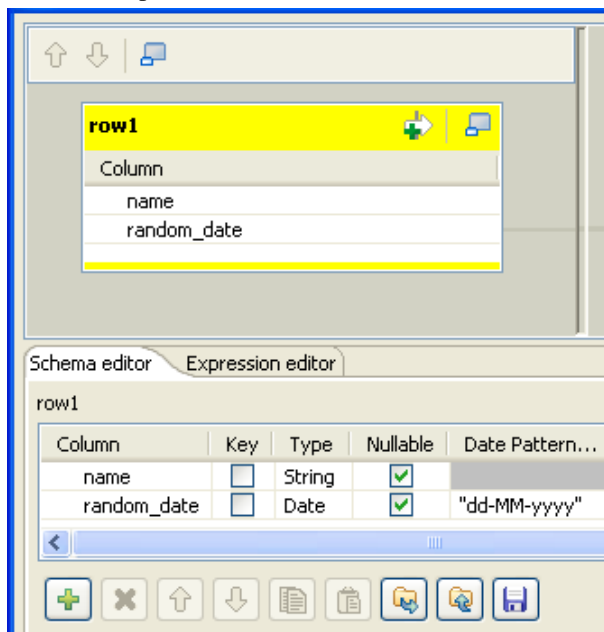

- Click **OK** to close the dialog box.
- Click the **RowGenerator Editor** three-dot button to open the editor and define the data to be generated.

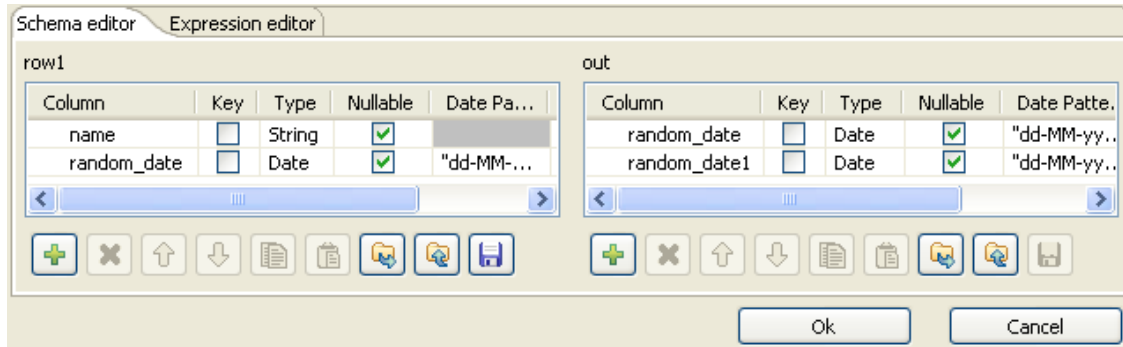

- Click in the corresponding **Functions** fields and select a function for each of the two columns, `getFirstName` for the first column and `getrandomDate` for the second column.
- In the **Number of Rows for Rowgenerator** field, enter 10 to generate ten first name rows and click **Ok** to close the editor.

## Configuring the tMap component

- Double-click the **tMap** component to open the Map editor. The Map editor opens displaying the input metadata of the **tRowGenerator** component.

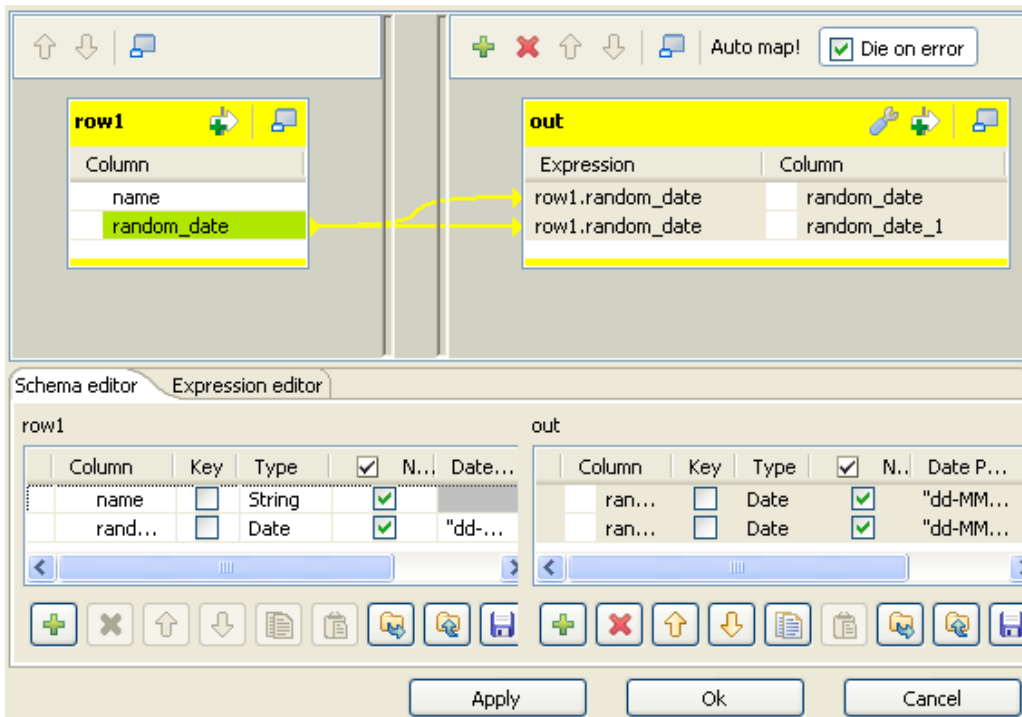

- In the **Schema editor** panel of the Map editor, click the **[+]** button of the output table to add two rows and define the first as `random_date` and the second as `random_date1`.

In this scenario, we want to duplicate the *random\_date* column and adapt the schema in order to alter the data in the output component.

3. In the Map editor, drag the *random\_date* row from the input table to the *random\_date* and *random\_date1* rows in the output table.

4. Click **OK** to close the editor.

## Configuring the output component

1. In the design workspace, double-click the **tAmazonMysqlOutput** component to display its **Basic settings** view and set its parameters.

2. Set **Property Type** to **Repository** and then click the [...] button to open the [**Repository content**] dialog box and select the correct DB connection. The connection details display automatically in the corresponding fields.

If you have not stored the DB connection details in the **Metadata** entry in the **Repository**, select **Built-in** on the property type list and set the connection detail manually.

3. Click the [...] button next to the **Table** field and select the table to be altered, *Dates* in this scenario.
4. On the **Action on table** list, select **Drop table if exists and create**, select *Insert* on the **Action on data** list.
5. If needed, click **Sync columns** to synchronize with the columns coming from the **tMap** component.
6. Click the **Advanced settings** tab to display the corresponding view and set the advanced parameters.

| Name            | SQL expression | Position | Reference column |
|-----------------|----------------|----------|------------------|
| "One_Month_L... | VARCHAR(50)    | Replace  |                  |

7. In the **Additional Columns** area, set the alteration to be performed on columns.

In this scenario, the *One\_month\_later* column replaces *random\_date\_1*. Also, the data itself gets altered using an SQL expression that adds one month to the randomly picked-up date of the *random\_date\_1* column. ex: 2007-08-12 becomes 2007-09-12.

-Enter *One\_Month\_Later* in the **Name** cell.

-In the **SQL expression** cell, enter the relevant addition script to be performed, "adddate(Random\_date, interval 1 month)" in this scenario.

-Select **Replace** on the **Position** list.

-Enter *Random\_date1* on the **Reference column** list.

For this job we duplicated the *random\_date\_1* column in the DB table before replacing one instance of it with the *One\_Month\_Later* column. The aim of this workaround was to be able to view upfront the modification performed.

## Job execution

Save your Job and press **F6** to execute it.

The new *One\_month\_later* column replaces the *random\_date1* column in the DB table and adds one month to each of the randomly generated dates.

| Random_date         | One_Month_Later     |

## Scenario 2: Updating data in a database table

This Java scenario describes a two-component Job that updates data in a MySQL table according to that in a delimited file.

### Setting up the Job

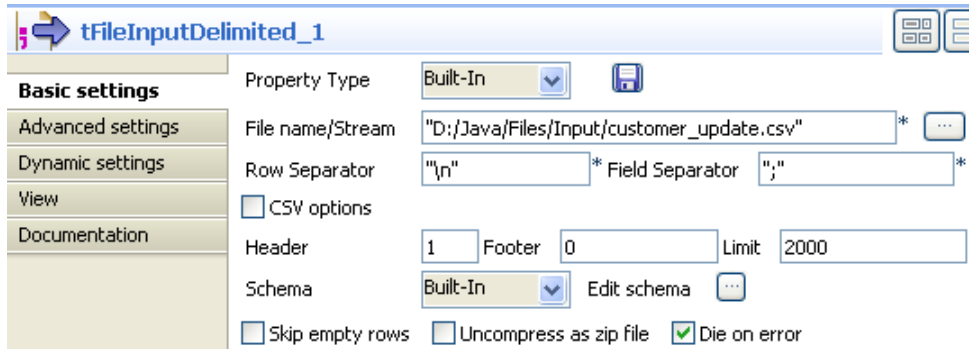

- Drop **tFileInputDelimited** and **tAmazonMysqlOutput** from the **Palette** onto the design workspace. Connect the two components together using a **Row Main** link.

### Configuring the input component

- Double-click **tFileInputDelimited** to display its **Basic settings** view and define the component properties.
- From the **Property Type** list, select **Repository** if you have already stored the metadata of the delimited file in the **Metadata** node in the **Repository** tree view. Otherwise, select **Built-In** to define manually the metadata of the delimited file.

For more information about storing metadata, see *Talend Open Studio User Guide*.

- In the **File Name** field, click the [...] button and browse to the source delimited file that contains the modifications to propagate in the MySQL table.

In this example, we use the *customer\_update* file that holds four columns: *id*, *CustomerName*, *CustomerAddress* and *idState*. Some of the data in these four columns is different from that in the MySQL table.

| id  | CustomerName                   | CustomerAddress        | idState |
|-----|--------------------------------|------------------------|---------|
| 858 | Froggy's Gourmet Catering      | 1831 Beverly Place #9D | 4       |
| 859 | Dependable Plumbing and Sewer  | 1550 Ridge Rd.         | 25      |
| 860 | Lickmen Restoration            | 1235 Easton Rd.        | 40      |
| 861 | Acturial Enterprises Ltd.      | 3148 cottonwood Ct.    | 18      |
| 862 | Rythmics Ltd.                  | 857 Woodbine Rd        | 30      |
| 863 | Acturial Enterprises Ltd.      | 1482 Concorde Circle   | 48      |
| 864 | Crosstracks Car Wash           | 218 Oakridge Ave.      | 39      |
| 865 | Meonits & Mogogni Inc.         | 616 Cobblestone Cir.   | 17      |
| 866 | Foy Aviation                   | 2220 Grant Blvd.       | 50      |
| 867 | Ebert Music Center             | 12 Broadview Lane      | 29      |
| 868 | janice Mann Accounting Service | 1660 Park Ave.         | 9       |
| 869 | Johnson, Erico & Co CPA's      | 2922 Twin Oaks Drive   | 40      |
| 870 | Corbins, Rodriguez, & Savocchi | 115 Pleasent Ave.      | 18      |
| 871 | Nina's Snow Plowing            | 3385 University Ave.   | 20      |
| 872 | Darcy Frame and Matting Servic | 1101 Deerfield Place   | 47      |
| 873 | Marks, Marks, and Kaplan Ltd.  | 1949 Cloverdale Rd.    | 9       |

- Define the row and field separators used in the source file in the corresponding fields. If needed, set **Header**, **Footer** and **Limit**.

In this example, **Header** is set to 1 since the first row holds the names of columns, therefore it should be ignored. Also, the number of processed lines is limited to 2000.

- Select **Built in** from the **Schema** list then click the [...] button next to **Edit Schema** to open a dialog box where you can describe the data structure of the source delimited file that you want to pass to the component that follows.

| Column          | Key                                 | Type    | Nullable                            |
|-----------------|-------------------------------------|---------|-------------------------------------|
| id              | <input checked="" type="checkbox"/> | Integer | <input checked="" type="checkbox"/> |
| CustomerName    | <input type="checkbox"/>            | String  | <input checked="" type="checkbox"/> |
| CustomerAddress | <input type="checkbox"/>            | String  | <input checked="" type="checkbox"/> |
| idState         | <input type="checkbox"/>            | Integer | <input checked="" type="checkbox"/> |

- Select the **Key** check box(es) next to the column name(s) you want to define as key column(s).

It is necessary to define at least one column as a key column for the Job to be executed correctly. Otherwise, the Job is automatically interrupted and an error message displays on the console.

## Configuring the output component

1. In the design workspace, double-click **tAmazonMysqlOutput** to open its **Basic settings** view where you can define its properties.

Property Type: Built-In

Use an existing connection

Host: "localhost" \* Port: "3306" \*

Database: "test" \*

Username: "root" \* Password: "toor" \*

Table: "customers" ...

Action on table: None Action on data: Update

Schema: Built-In Edit schema ... Sync columns

Die on error

2. Click **Sync columns** to retrieve the schema of the preceding component. If needed, click the [...] button next to **Edit schema** to open a dialog box where you can check the retrieved schema.
3. From the **Property Type** list, select **Repository** if you have already stored the connection metadata in the **Metadata** node in the **Repository** tree view. Otherwise, select **Built-In** to define manually the connection information.

For more information about storing metadata, see *Talend Open Studio User Guide*.

4. Fill in the database connection information in the corresponding fields.
5. In the **Table** field, enter the name of the table to update.
6. From the **Action on table** list, select the operation you want to perform, **None** in this example since the table already exists.
7. From the **Action on data** list, select the operation you want to perform on the data, **Update** in this example.

## Job execution

Save your Job and press **F6** to execute it.

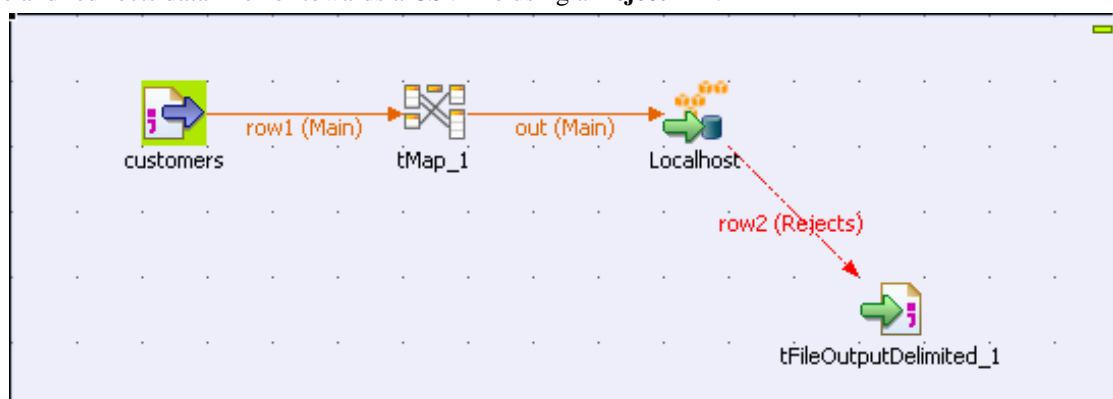

| id  | CustomerName                  | CustomerAddress        | idState |
|-----|-------------------------------|------------------------|---------|
| 858 | Froggy's Gourmet Catering     | 1831 Beverly Place #9D | 4       |
| 859 | Dependable Plumbing and Sewer | 1550 Ridge Rd.         | 25      |
| 860 | Lickmen Restoration           | 1235 Easton Rd.        | 40      |
| 861 | Acturial Enterprises Ltd.     | 3148 Cottonwood Ct.    | 18      |
| 862 | Rythmics Ltd.                 | 857 Woodbine Rd        | 30      |
| 863 | Acturial Enterprises Ltd.     | 1482 Concorde Circle   | 48      |
| 864 | Crosstracks Car Wash          | 218 Oakridge Ave.      | 39      |
| 865 | Meonits & Mogogni Inc.        | 616 Cobblestone Cir.   | 17      |
| 866 | Foy Aviation                  | 2220 Grant Blvd.       | 50      |
| 867 | Ebert Music Center            | 12 Broadview Lane      | 29      |
| 868 | janice Mann Accounting Serv   | 1660 Park Ave.         | 9       |
| 869 | Johnson, Erico & Co CPA's     | 2922 Twin Oaks Drive   | 40      |
| 870 | Corbins, Rodriguez, & Savocch | 115 Pleasant Ave.      | 18      |
| 871 | Nina's Snow Plowing           | 3385 University Ave.   | 20      |
| 872 | Darcy Frame and Matting Serv  | 1101 Deerfield Place   | 47      |
| 873 | Marks, Marks, and Kaplan Ltd. | 1949 Cloverdale Rd.    | 9       |

Using your DB browser, you can verify if the MySQL table, *customers*, has been modified according to the delimited file.

In the above example, the database table has always the four columns *id*, *CustomerName*, *CustomerAddress* and *idState*, but certain fields have been modified according to the data in the delimited file used.

## Scenario 3: Retrieve data in error with a Reject link

This scenario describes a four-component Job that carries out migration from a customer file to a MySQL database table and redirects data in error towards a CSV file using a **Reject** link.

### Setting up the Job

1. In the **Repository**, select the customer file metadata that you want to migrate and drop it onto the workspace. In the **[Components]** dialog box, select **tFileInputDelimited** and click **OK**. The component properties will be filled in automatically.

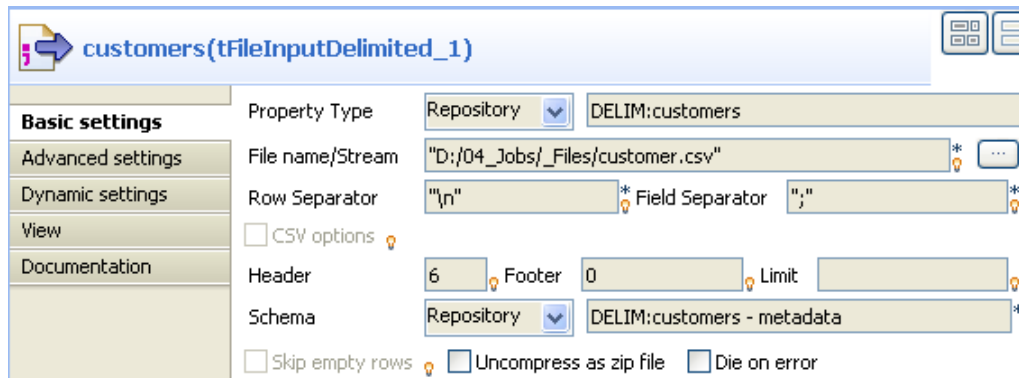

- If you have not stored the information about your customer file under the **Metadata** node in the **Repository**. Drop a **tFileInputDelimited** component from the family **File > Input**, in the **Palette**, and fill in its properties manually in the **Component** tab.
- From the **Palette**, drop a **tMap** from the **Processing** family onto the workspace.
- In the **Repository**, expand the **Metadata** node, followed by the **Db Connections** node and select the connection required to migrate your data to the appropriate database. Drop it onto the workspace. In the **[Components]** dialog box, select **tAmazonMysqlOutput** and click **OK**. The database connection properties will be automatically filled in.
- If you have not stored the database connection details under the **Db Connections** node in the **Repository**, drop a **tAmazonMysqlOutput** from the **Databases** family in the **Palette** and fill in its properties manually in the **Component** tab.

or more information, see *Talend Open Studio User Guide*.

- From the **Palette**, select a **tFileOutputDelimited** from the **File > Output** family, and drop it onto the workspace.
- Link the **customers** component to the **tMap** component, and the **tMap** and **Localhost** with a **Row Main** link. Name this second link *out*.
- Link the **Localhost** to the **tFileOutputDelimited** using a **Row > Reject** link.

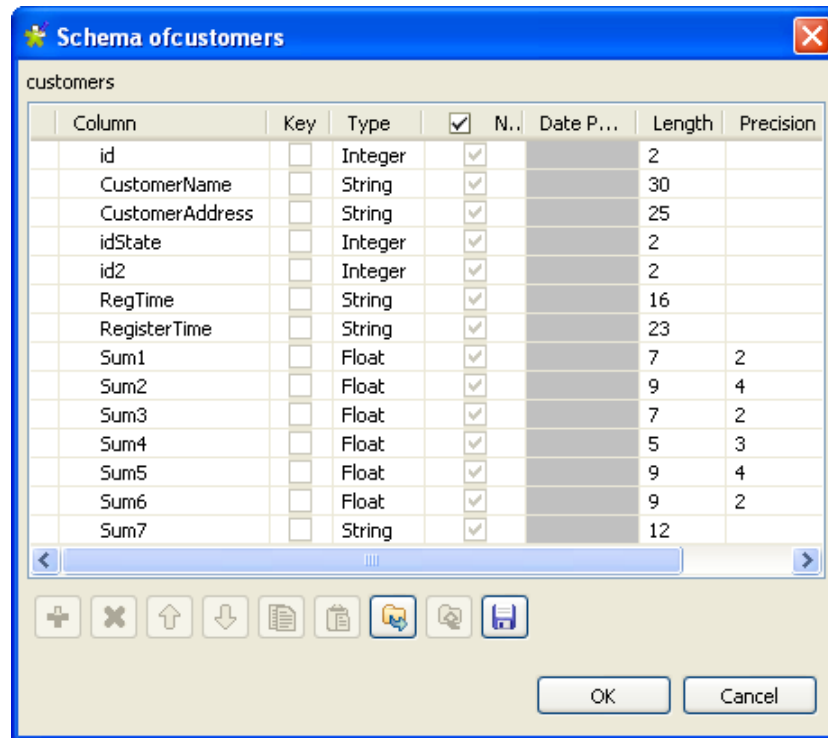

## Configuring the input component

- Double-click the **customers** component to display the **Component** view.

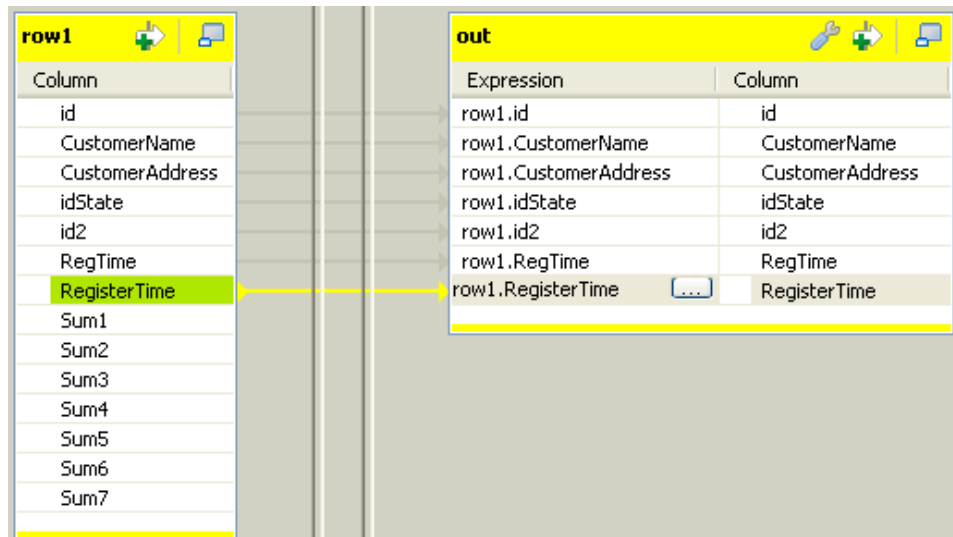

- In the **Property Type** list, select **Repository** and click the **[...]** button in order to select the metadata containing the connection to your file. You can also select the **Built-in** mode and fill in the fields manually.
- Click the **[...]** button next to the **File Name** field, and fill in the path and the name of the file you want to use.
- In the **Row** and **Field Separator** fields, type in between inverted commas the row and field separator used in the file.
- In the **Header**, **Footer** and **Limit** fields, type in the number of headers and footers to ignore, and the number of rows to which processing should be limited.
- In the **Schema** list, select **Repository** and click the **[...]** button in order to select the schema of your file, if it is stored under the **Metadata** node in the **Repository**. You can also click the **[...]** button next to the **Edit schema** field, and set the schema manually.

The schema is as follows:

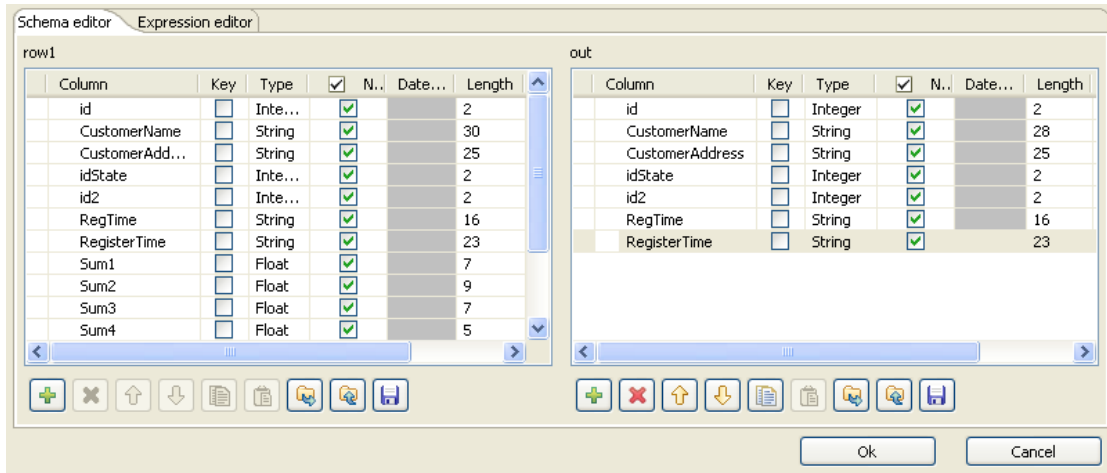

## Configuring the tMap component

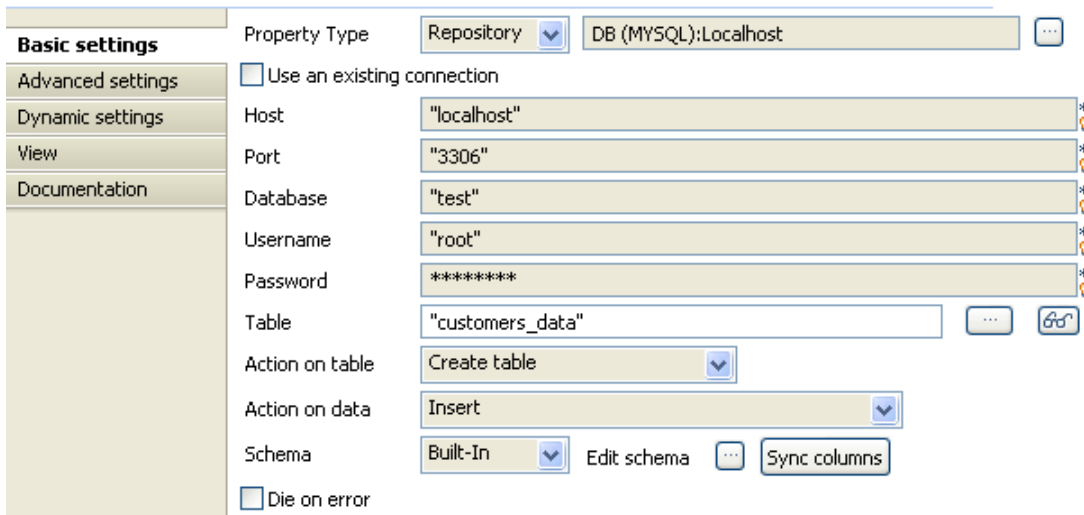

1. Double-click the **tMap** component to open its editor.

2. Select the *id*, *CustomerName*, *CustomerAddress*, *idSate*, *id2*, *RegTime* and *RegisterTime* columns on the table on the left and drop them on the **out** table, on the right.

3. In the **Schema editor** area, at the bottom of the **tMap** editor, in the right table, change the length of the **CustomerName** column to 28 to create an error. Thus, any data for which the length is greater than 28 will create errors, retrieved with the **Reject** link.
4. Click **OK**. In the workspace, double-click the output **Localhost** component to display its **Component** view.

5. In the **Property Type** list, select **Repository** and click the [...] button to select the connection to the database metadata. The connection details will be automatically filled in. You can also select the **Built-in** mode and set the fields manually.
6. In the **Table** field, type in the name of the table to be created. In this scenario, we call it *customers\_data*. In the **Action on data** list, select the **Create table** option. Click the **Sync columns** button to retrieve the schema from the previous component.

Make sure the **Die on error** check box isn't selected, so that the Job can be executed despite the error you just created.

7. Click the **Advanced settings** tab of the **Component** view to set the advanced parameters of the component.

Basic settings

Additional JDBC Parameters `"noDatetimeStringSync=true"`

Extend Insert (Not compatible with reject links)

Dynamic settings

Commit every `10000`\*

View

Additional columns

| Name | SQL expression | Position | Reference column |
|------|----------------|----------|------------------|
|------|----------------|----------|------------------|

Use field options  
 Use Hint Options  
 Enable debug mode  
 Use duplicate key update mode insert  
 tStatCatcher Statistics  
 Enable parallel execution

8. Deselect the **Extend Insert** check box which enables you to insert rows in batch, because this option is not compatible with the **Reject** link.

## Configuring the output component

1. Double-click the **tFileOutputDelimited** component to set its properties in the **Component** view.

tFileOutputDelimited\_1

Property Type `Built-In`

Use Output Stream

File Name `"D:/TDQ_EE_MPX-All_r33000-V3.2.2/workspace/out.csv"`\*

Row Separator `"\n"` Field Separator `","`

Append  Include Header  Compress as zip file

Schema `Built-In` Edit schema `...` `Sync columns`

2. Click the `[...]` button next to the **File Name** field to fill in the path and name of the output file. Click the **Sync columns** button to retrieve the schema of the previous component.

## Job execution

Save your Job and press **F6** to execute it.

The data in error are sent to the delimited file, as well as the error type met. Here, we have: **Data truncation**.

# tAmazonMysqlRollback

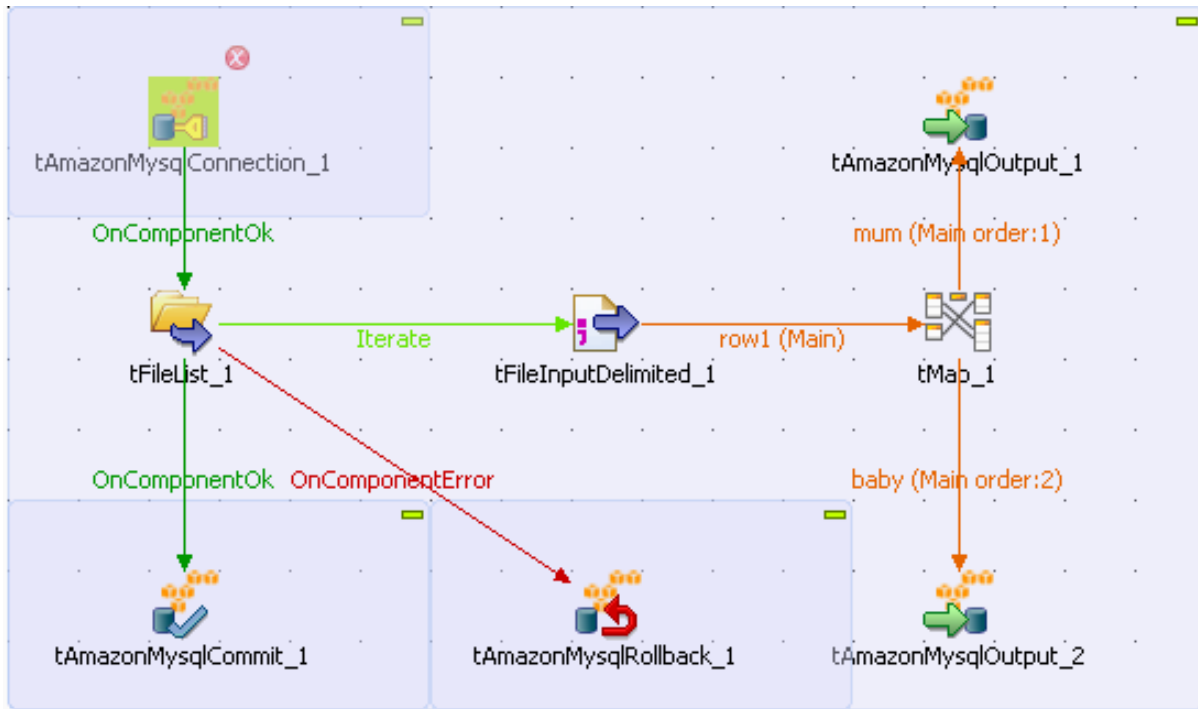

## tAmazonMysqlRollback properties

This component is closely related to **tAmazonMysqlCommit** and **tAmazonMysqlConnection**. It usually does not make much sense to use these components independently in a transaction.

|                          |                                                                                                                                                         |                                                                                                                             |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Component family</b>  | Cloud/AmazonRDS/<br>Mysql                                                                                                                               |                                                                                                                             |
| <b>Function</b>          | Cancel the transaction commit in the connected DB.                                                                                                      |                                                                                                                             |
| <b>Purpose</b>           | Avoids to commit part of a transaction involuntarily.                                                                                                   |                                                                                                                             |
| <b>Basic settings</b>    | <i>Component list</i>                                                                                                                                   | Select the <b>tAmazonMysqlConnection</b> component in the list if more than one connection are planned for the current job. |
|                          | <i>Close Connection</i>                                                                                                                                 | Clear this check box to continue to use the selected connection once the component has performed its task.                  |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                                                                                                          | Select this check box to collect log data at the component level.                                                           |
| <b>Usage</b>             | This component is to be used along with AmazonMysql components, especially with <b>tAmazonMysqlConnection</b> and <b>tAmazonMysqlCommit</b> components. |                                                                                                                             |
| <b>Limitation</b>        | n/a                                                                                                                                                     |                                                                                                                             |

## Scenario: Rollback from inserting data in mother/daughter tables

Based on [the section called “Scenario: Inserting data in mother/daughter tables”](#), insert a rollback function in order to prevent unwanted commit.

1. Drag and drop a **tAmazonMysqlRollback** to the design workspace and connect it to the Start component.
2. Set the Rollback unique field on the relevant DB connection.

This complementary element to the Job ensures that the transaction will not be partly committed.

# tAmazonMysqlRow

## tAmazonMysqlRow properties

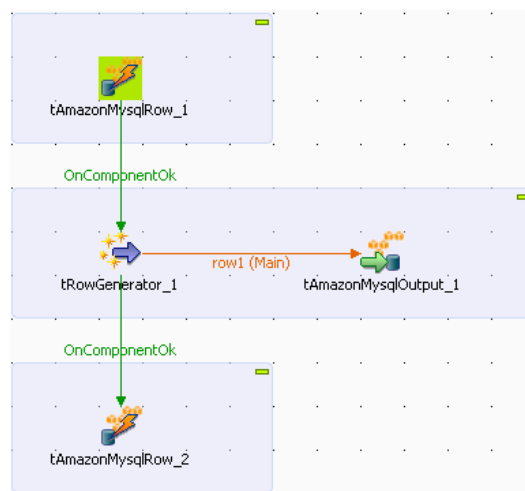

|                         |                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Function</b>         | tAmazonMysqlRow is the specific component for this database query. It executes the SQL query stated in the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Purpose</b>          | Depending on the nature of the query and the database, tAmazonMysqlRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|              | <i>tStatCatcher Statistics</i>                                                             | Select this check box to collect log data at the component level.                      |
| <b>Usage</b> | This component offers the flexibility of the DB query and covers all possible SQL queries. |                                                                                        |

## Scenario 1: Removing and regenerating a MySQL table index

This scenario describes a four-component job that removes a table index, applies a select insert action onto a table then regenerates the index.

### Setting up the Job

1. Select and drop the following components onto the design workspace: **tAmazonMysqlRow** (x2), **tRowGenerator**, and **tAmazonMysqlOutput**.
2. Connect **tRowGenerator** to **tAmazonMysqlOutput**.
3. Using a **OnComponentOk** connections, link the first **tAmazonMysqlRow** to **tRowGenerator** and **tRowGenerator** to the second **tAmazonMysqlRow**.

### Configuring the tAmazonMysqlRow component

1. Select the **tAmazonMysqlRow** to fill in the **DB Basic settings**.
2. In **Property type** as well in **Schema**, select the relevant DB entry in the list.  
The DB connection details and the table schema are accordingly filled in.
3. Propagate the properties and schema details onto the other components of the job.
4. The query being stored in the **Metadata** area of the **Repository**, you can also select **Repository** in the **Query type** field and the relevant query entry.

5. If you didn't store your query in the **Repository**, type in the following SQL statement to alter the database entries: drop index <index\_name> on <table\_name>
6. Select the second **tAmazonMySQLRow** component, check the DB properties and schema.
7. Type in the SQL statement to recreate an index on the table using the following statement: create index <index\_name> on <table\_name> (<column\_name>)

The **tRowGenerator** component is used to generate automatically the columns to be added to the DB output table defined.

## Configuring the output component

1. Select the **tAmazonMySQLOutput** component and fill in the DB connection properties either from the Repository or manually the DB connection details are specific for this use only. The table to be fed is named: *comprehensive*.
2. The schema should be automatically inherited from the data flow coming from the **tRowGenerator**. Edit the schema to check its structure and check that it corresponds to the schema expected on the DB table specified.
3. The **Action on table** is *None* and the **Action on data** is *Insert*.

## Job execution

Press **F6** to run the job.

If you manage to watch the action on DB data, you can notice that the index is dropped at the start of the job and recreated at the end of the insert action.

Related topics: [the section called "tDBSQLRow properties"](#).

## Scenario 2: Using PreparedStatement objects to query data

This scenario describes a four component job which allows you to link a table column with a client file. The MySQL table contains a list of all the American States along with the State ID, while the file contains the customer information including the ID of the State in which they live. We want to retrieve the name of the State for each client, using an SQL query. In order to process a large volume of data quickly, we use a PreparedStatement object which means that the query is executed only once rather than against each row in turn. Then each row is sent as a parameter.

For this scenario, we use a file and a database for which we have already stored the connection and properties in the Repository metadata. For further information concerning the creation of metadata in delimited files, the creation of database connection metadata and the usage of metadata, see *Talend Open Studio User Guide*.

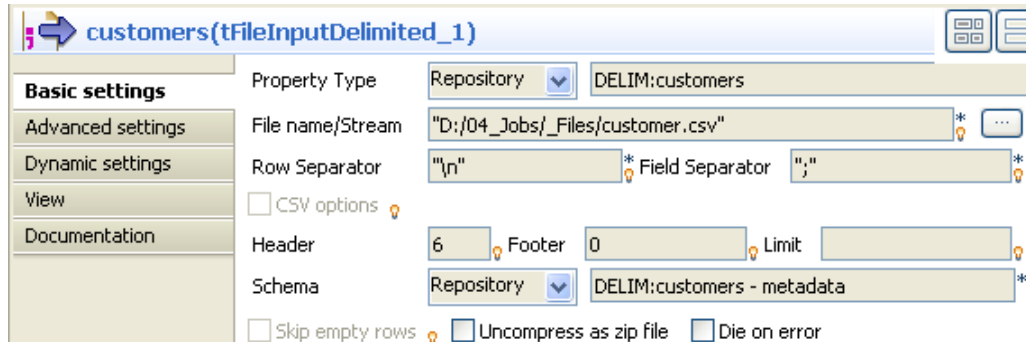

## Configuring the input component

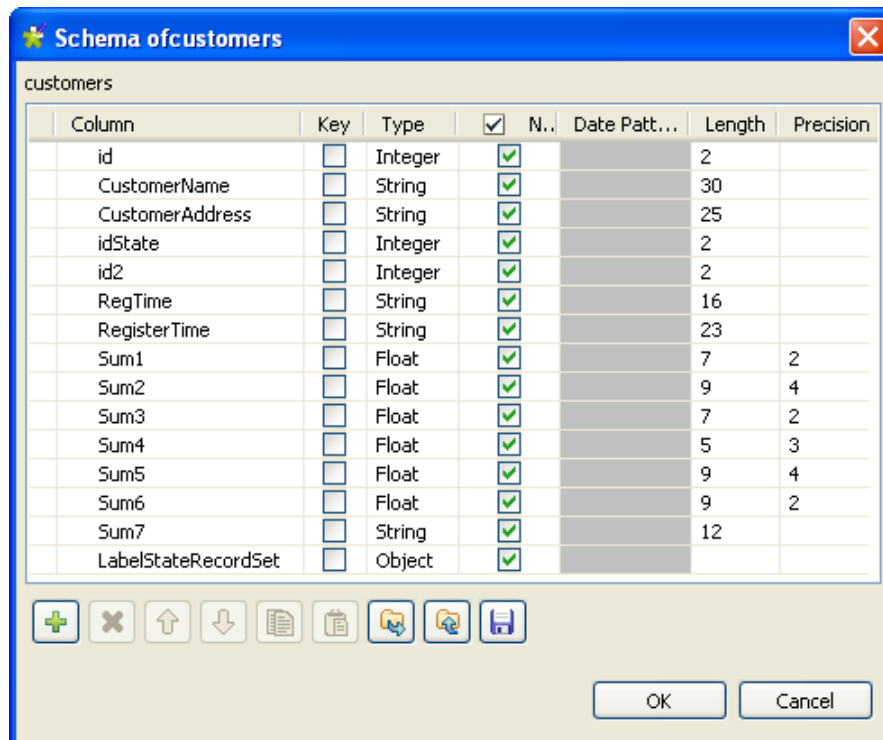

1. In the **Repository**, expand the **Metadata** and **File delimited** nodes. Select the metadata which corresponds to the client file you want to use in the Job.

Here, we are using the *customers* metadata.

2. Slide the metadata onto the workspace and double-click **tFileInputDelimited** in the **Components** dialog box so that the **tFileInputDelimited** component is created with the parameters already set.

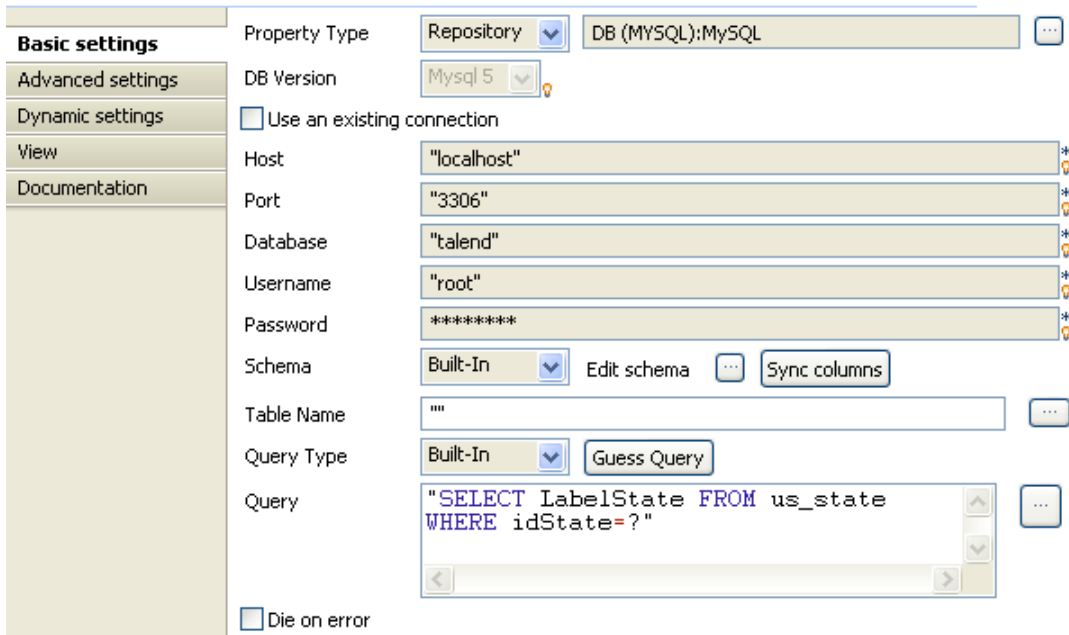

3. In the **Schema** list, select **Built-in** so that you can modify the component's schema. Then click on [...] next to the **Edit schema** field to add a column into which the name of the State will be inserted.

4. Click on the [+] button to add a column to the schema. Rename this column *LabelStateRecordSet* and select **Object** from the **Type** list. Click **OK** to save your modifications.
5. From the **Palette**, select the **tAmazonMySQLRow**, **tParseRecordSet** and **tFileOutputDelimited** components and drop them onto the workspace. Connect the four components using **Row > Main** type links.

## Setting up the DB connection

1. Double-click **tAmazonMySQLRow** to set its properties in the **Basic settings** tab of the **Component** view.

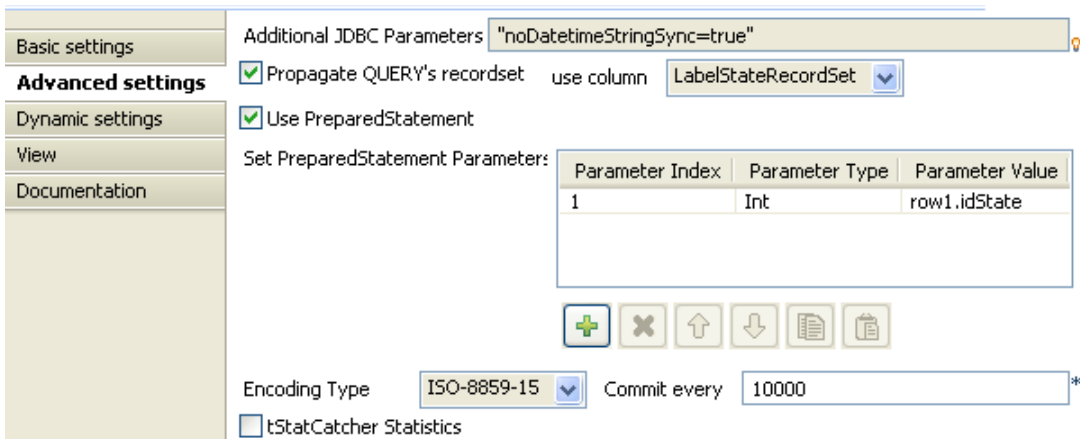

2. In the **Property Type** list, select **Repository** and click on the [...] button to select a database connection from the metadata in the Repository. The **DB Version**, **Host**, **Port**, **Database**, **Username** and **Password** fields are completed automatically. If you are using the **Built-in** mode, complete these fields manually.
3. From the **Schema** list, select **Built-in** to set the schema properties manually and add the *LabelStateRecordSet* column, or click directly on the **Sync columns** button to retrieve the schema from the preceding component.
4. In the **Query** field, enter the SQL query you want to use. Here, we want to retrieve the names of the American States from the *LabelState* column of the MySQL table, *us\_state*:

```
"SELECT LabelState
FROM us_state WHERE idState=?"
```

The question mark, “?”, represents the parameter to be set in the **Advanced settings** tab.

## Configuring the Advanced settings of tAmazonMysqlRow

1. Click **Advanced settings** to set the component's advanced properties.

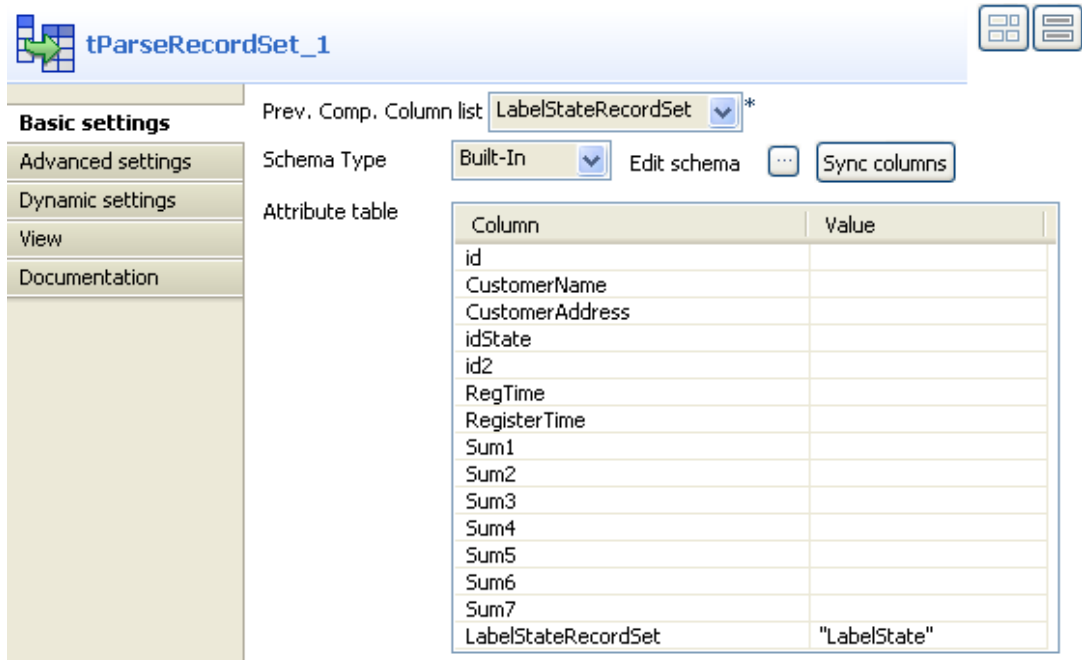

2. Select the **Propagate QUERY's recordset** check box and select the *LabelStateRecordSet* column from the **use column** list to insert the query results in that column.

3. Select the **Use PreparedStatement** check box and define the parameter used in the query in the **Set PreparedStatement Parameters** table. Click on the [+] button to add a parameter.
4. In the **Parameter Index** cell, enter the parameter position in the SQL instruction. Enter "1" as we are only using one parameter in this example.
5. In the **Parameter Type** cell, enter the type of parameter. Here, the parameter is a whole number, hence, select **Int** from the list.
6. In the **Parameter Value** cell, enter the parameter value. Here, we want to retrieve the name of the State based on the State ID for every client in the input file. Hence, enter "row1 . idState" .

## Configuring the tParseRecordSet component

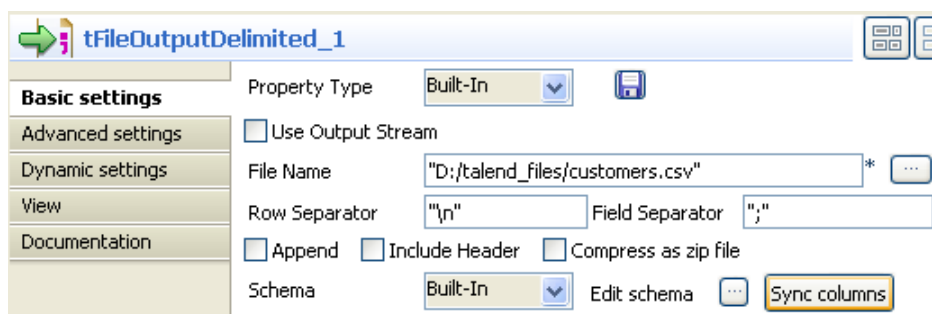

1. Double-click **tParseRecordSet** to set its properties in the **Basic settings** tab of the **Component** view.

2. From the **Prev. Comp. Column list**, select the preceding components column for analysis. In this example, select *LabelStateRecordSet*.
3. Click on the **Sync columns** button to retrieve the schema from the preceding component. The **Attribute table** is automatically completed with the schema columns.
4. In the **Attribute table**, in the **Value** field which corresponds to the *LabelStateRecordSet*, enter the name of the column containing the State names to be retrieved and matched with each client, within double quotation marks. In this example, enter "LabelState".

## Configuring the output component

1. Double-click **tFileOutputDelimited** to set its properties in the **Basic settings** tab of the **Component** view.

- In the **File Name** field, enter the access path and name of the output file. Click **Sync columns** to retrieve the schema from the preceding component.

## Job execution

Save your Job and press **F6** to run it.

## Related scenario

This component is closely related to **tAmazonOracleConnection** and **tAmazonOracleRollback**. It usually doesn't make much sense to use one of these without using a **tAmazonOracleConnection** component to open a connection for the current transaction.

For **tAmazonOracleCommit** related scenario, see [the section called "tMysqlConnection"](#)

# tAmazonOracleConnection

## tAmazonOracleConnection Properties

This component is closely related to **tAmazonOracleCommit** and **tAmazonOracleRollback**. It usually doesn't make much sense to use one of these without using a **tAmazonOracleConnection** component to open a connection for the current transaction.

## Related scenario

This component is closely related to **tAmazonOracleCommit** and **tAmazonOracleRollback**. It usually doesn't make much sense to use one of these without using a **tAmazonOracleConnection** component to open a connection for the current transaction.

For **tAmazonOracleConnection** related scenario, see [the section called "tMysqlConnection"](#)

| <b>Function</b>         | <b>tAmazonOracleInput</b> reads a database and extracts fields based on a query.                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Purpose</b>          | <b>tAmazonOracleInput</b> executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|  | <i>Oracle schema</i>                 | Name of the Oracle schema.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|  | <i>Table</i>                         | Name of the table to be written. Note that only one table can be written at a time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|  | <i>Action on table</i>               | <p>On the table defined, you can perform one of the following operations:</p> <p><b>None:</b> No operation is carried out.</p> <p><b>Drop and create a table:</b> The table is removed and created again.</p> <p><b>Create a table:</b> The table does not exist and gets created.</p> <p><b>Create a table if not exists:</b> The table is created if it does not exist.</p> <p><b>Drop a table if exists and create:</b> The table is removed if it already exists and created again.</p> <p><b>Clear a table:</b> The table content is deleted.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|  | <i>Action on data</i>                | <p>On the data of the table defined, you can perform:</p> <p><b>Insert:</b> Add new entries to the table. If duplicates are found, job stops.</p> <p><b>Update:</b> Make changes to existing entries</p> <p><b>Insert or update:</b> Add entries or update existing ones.</p> <p><b>Update or insert:</b> Update existing entries or create it if non existing</p> <p><b>Delete:</b> Remove entries corresponding to the input flow.</p> <p> <i>It is necessary to specify at least one column as a primary key on which the <b>Update</b> and <b>Delete</b> operations are based. You can do that by clicking <b>Edit Schema</b> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <b>Advanced settings</b> view where you can simultaneously define primary keys for the <b>Update</b> and <b>Delete</b> operations. To do that: Select the <b>Use field options</b> check box and then in the <b>Key in update column</b>, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the <b>Key in delete column</b> for the Delete operation.</i></p> |
|  | <i>Schema</i> and <i>Edit schema</i> | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                          |                                                            |                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                            | component. The schema is either <b>Built-in</b> or stored remotely in the <b>Repository</b> .                                                                                                                                                                                                                                                                                               |
|                          |                                                            | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                                |
|                          |                                                            | <b>Repository:</b> The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                                                                                                                                                |
|                          | <i>Die on error</i>                                        | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <b>Row &gt; Rejects</b> link.                                                                                                                                                                         |
| <b>Advanced settings</b> | <i>Additional parameters</i> <i>JDBC</i>                   | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <b>Use an existing connection</b> check box in the <b>Basic settings</b> .<br><br> You can press <b>Ctrl+Space</b> to access a list of predefined global variables. |
|                          | <i>Override any existing NLS_LANG environment variable</i> | Select this check box to override variables already set for a NLS language environment.                                                                                                                                                                                                                                                                                                     |
|                          | <i>Commit every</i>                                        | Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.                                                                                                                                                                                |
|                          | <i>tStatCatcher Statistics</i>                             | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                                                                           |
|                          | <i>Additional Columns</i>                                  | This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.                                                                                                                              |
|                          |                                                            | <b>Name:</b> Type in the name of the schema column to be altered or inserted as new column.                                                                                                                                                                                                                                                                                                 |
|                          |                                                            | <b>SQL expression:</b> Type in the SQL statement to be executed in order to alter or insert the relevant column data.                                                                                                                                                                                                                                                                       |
|                          |                                                            | <b>Position:</b> Select <b>Before</b> , <b>Replace</b> or <b>After</b> following the action to be performed on the reference column.                                                                                                                                                                                                                                                        |
|                          |                                                            | <b>Reference column:</b> Type in a column of reference that the <b>tDBOutput</b> can use to place or replace the new or altered column.                                                                                                                                                                                                                                                     |
|                          | <i>Use field options</i>                                   | Select this check box to customize a request, especially when there is double action on data.                                                                                                                                                                                                                                                                                               |
|                          | <i>Use Hint Options</i>                                    | Select this check box to activate the hint configuration area which helps you optimize a query's execution. In this area, parameters are:<br><br>- <b>HINT:</b> specify the hint you need, using the syntax<br><br><code>/*+ */.</code>                                                                                                                                                     |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                             |

# tAmazonOracleRollback

## tAmazonOracleRollback properties

This component is closely related to **tAmazonOracleCommit** and **tAmazonOracleConnection**. It usually doesn't make much sense to use these components independently in a transaction.

|                          |                                                                                                                                                            |                                                                                                                              |

|                          | <i>Close Connection</i>                                                                                                                                    | Clear this check box to continue to use the selected connection once the component has performed its task.                   |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                                                                                                             | Select this check box to collect log data at the component level.                                                            |
| <b>Usage</b>             | This component is to be used along with AmazonOracle components, especially with <b>tAmazonOracleConnection</b> and <b>tAmazonOracleCommit</b> components. |                                                                                                                              |
| <b>Limitation</b>        | n/a                                                                                                                                                        |                                                                                                                              |

## Related scenario

This component is closely related to **tAmazonOracleConnection** and **tAmazonOracleCommit**. It usually doesn't make much sense to use one of these without using a **tAmazonOracleConnection** component to open a connection for the current transaction.

For **tAmazonOracleRollback** related scenario, see [the section called "tMysqlRollback"](#).

# tAmazonOracleRow

## tAmazonOracleRow properties

|                         |                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Component family</b> | Cloud/AmazonRDS/<br>Oracle                                                                                                                                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Function</b>         | <b>tAmazonOracleRow</b> is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Purpose</b>          | Depending on the nature of the query and the database, <b>tAmazonOracleRow</b> acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

The Query field gets accordingly filled in.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                          | <i>Query</i>                       |                | Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                          | <i>Die on error</i>                |                | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <b>Row &gt; Rejects</b> link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Advanced settings</b> | <i>Propagate recordset</i>         | <i>QUERY's</i> | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the <b>use column</b> list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                          | <i>Use PreparedStatement</i>       |                | Select this checkbox if you want to query the database using a PreparedStatement. In the <b>Set PreparedStatement Parameter</b> table, define the parameters represented by “?” in the SQL instruction of the <b>Query</b> field in the <b>Basic Settings</b> tab.<br><br><b>Parameter Index:</b> Enter the parameter position in the SQL instruction.<br><br><b>Parameter Type:</b> Enter the parameter type.<br><br><b>Parameter Value:</b> Enter the parameter value.<br><br> This option is very useful if you need to execute the same query several times. Performance levels are increased |
|                          | <i>Commit every</i>                |                | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                          | <i>tStatCatcher Statistics</i>     |                | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Usage</b>             |                                    |                | This component offers the flexibility of the DB query and covers all possible SQL queries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

# Custom Code components

This chapter details the major components which belong to the **Custom Code** family in the *Talend Open Studio Palette*.

The **Custom Code** components enable you to create codes for specific needs, quickly and efficiently.

# tGroovy

## tGroovy properties

|                          |                                                                                                                                |                                                                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Component Family</b>  | Custom Code                                                                                                                    |                                                                                                                                            |
| <b>Function</b>          | <b>tGroovy</b> allows you to enter customized code which you can integrate in the Talend programme. The code is run only once. |                                                                                                                                            |
| <b>Purpose</b>           | <b>tGroovy</b> broadens the functionality if the Talend Job, using the Groovy language which is a simplified Java syntax.      |                                                                                                                                            |
| <b>Basic settings</b>    | <i>Groovy Script</i>                                                                                                           | Enter the Groovy code youou want to run.                                                                                                   |
|                          | <i>Variables</i>                                                                                                               | This table has two columns.<br><b>Name:</b> Name of the variable called in the code..<br><b>Value:</b> Value associated with the variable. |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                                                                                 | Select this check box to collect the log data at component level.                                                                          |
| <b>Usage</b>             | This component can be used alone or as a subjob along with one other component.                                                |                                                                                                                                            |
| <b>Limitation</b>        | Knowledge of the Groovy language is required.                                                                                  |                                                                                                                                            |

## Related Scenarios

| <b>Limitation</b>        | Knowledge of the Groovy language is required.                                                                             |                                                                                                                                                 |

## Scenario: Calling a file which contains Groovy code

This scenario uses **tGroovyFile**, on its own. The Job calls a file containing Groovy code in order to display the file information in the **Console**. Below, is an example of the information displayed:

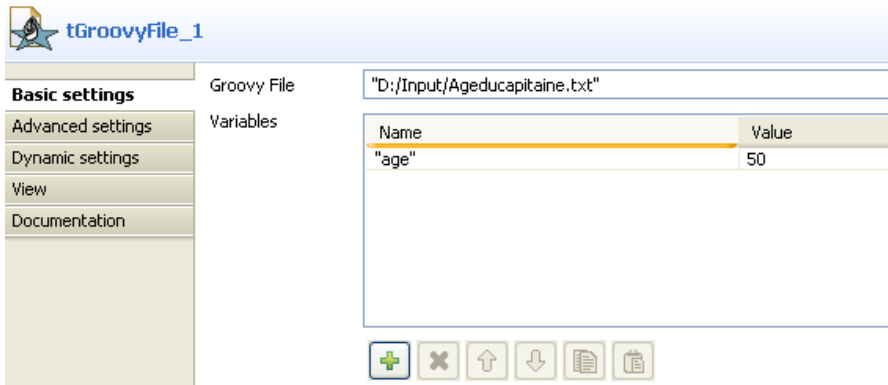

## Setting up the Job

Open the **Custom\_Code** folder in the **Palette** and drop a **tGroovyFile** component onto the workspace.

## Configuring the tGroovyFile component

1. Double-click the component to display the **Component** view.
2. In the **Groovy File** field, enter the path to the file containing the Groovy code, or browse to the file in your directory.

3. In the **Variables** table, add a line by clicking the [+] button.
4. In the **Name** column, enter “age”, then in the Value column, enter 50, as in the screenshot.

## Job execution

Press **F6** to save and run the Job.

The **Console** displays the information contained in the input file, to which the variable result is added.

```
Starting job tGroovyFile at 09:49 17/02/2010.
[statistics] connecting to socket on port 4016
[statistics] connected
The captain is 50 years old
[statistics] disconnected
Job tGroovyFile ended at 09:49 17/02/2010. [exit code=0]
```

# tJava

|                          | <i>tStatCatcher Statistics</i>                                                                                                              | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.                                                                                                                                                                                                                                                                                        |
| <b>Usage</b>             | This component is generally used as a one-component subjob.                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Limitation</b>        | You should know Java language.                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                       |

## Scenario: Printing out a variable content

The following scenario is a simple demo of the extended application of the **tJava** component. The Job aims at printing out the number of lines being processed using a Java command and the global variable provided in *Talend Open Studio*.

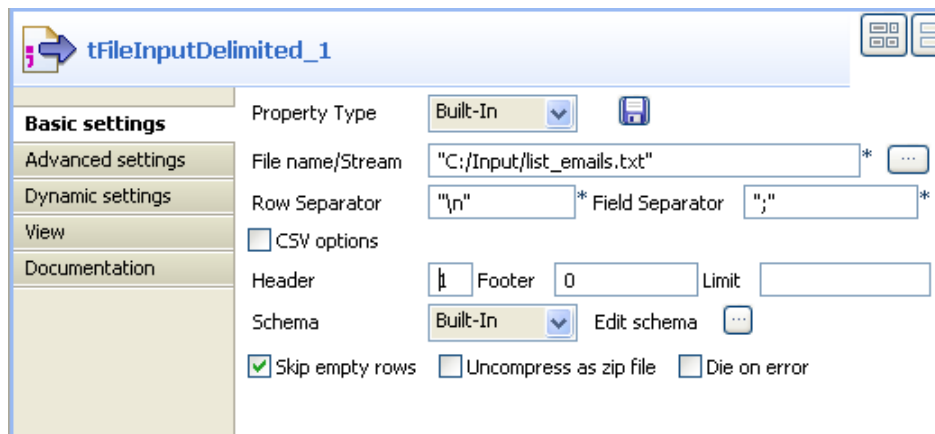

## Setting up the Job

1. Select and drop the following components from the **Palette** onto the design workspace: **tFileInputDelimited**, **tFileOutputExcel**, **tJava**.
2. Connect the **tFileInputDelimited** to the **tFileOutputExcel** using a **Row Main** connection. The content from a delimited txt file will be passed on through the connection to an xls-type of file without further transformation.
3. Then connect the **tFileInputDelimited** component to the **tJava** component using a **Then Run** link. This link sets a sequence ordering **tJava** to be executed at the end of the main process.

## Configuring the input component

1. Set the **Basic settings** of the **tFileInputDelimited** component. The input file used in this example is a simple text file made of two columns: *Names* and their respective *Emails*.

2. The schema has not been stored in the repository for this use case, therefore you need to set manually the two-column schema
3. Click the **Edit Schema** button.

| Column | Key                                 | Type   | Nullable                            | Date P... | Le... | Pr... | D... | C... |
|--------|-------------------------------------|--------|-------------------------------------|-----------|-------|-------|------|------|
| Names  | <input checked="" type="checkbox"/> | String | <input checked="" type="checkbox"/> |           | 255   |       |      |      |
| Emails | <input type="checkbox"/>            | String | <input checked="" type="checkbox"/> |           | 255   |       |      |      |

4. When prompted, click **OK** to accept the propagation, so that the **tFileOutputExcel** component gets automatically set with the input schema. Therefore no need to set the schema again.

## Configuring the output component

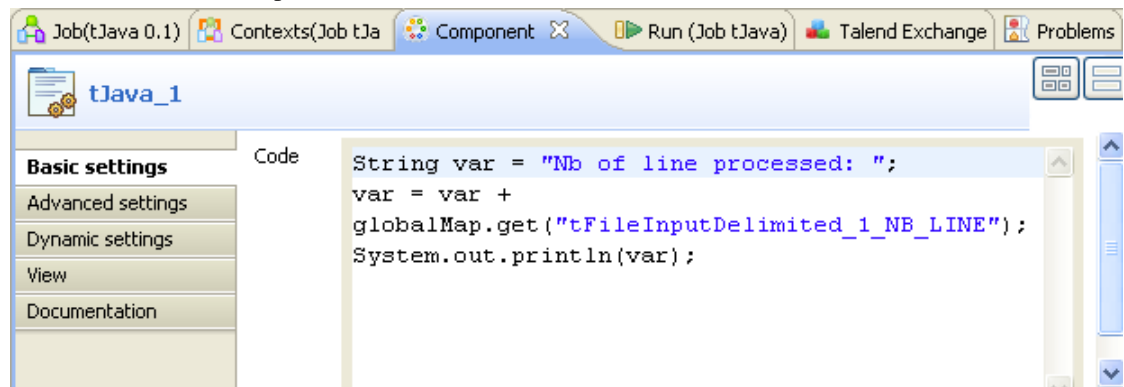

Set the output file to receive the input content without changes. If the file does not exist already, it will get created.

In this example, the **Sheet name** is *Email* and the **Include Header** box is selected.

## Configuring the tJava component

1. Then select the **tJava** component to set the Java command to execute.

2. In the **Code** area, type in the following command:

```
String var = "Nb of line processed: ";
var = var + globalMap.get("tFileInputDelimited_1_NB_LINE");
System.out.println(var);
```

In this use case, we use the *NB\_Line* variable. To access the global variable list, press Ctrl + Space bar on your keyboard and select the relevant global parameter.

## Job execution

Save your Job and press **F6** to execute it.

```
Starting job JavaDb at 13:53 20/08/2007.
Nb of line processed: 4
Job JavaDb ended at 13:53 20/08/2007. [exit code=0]
```

The content gets passed on to the Excel file defined and the Number of lines processed are displayed on the **Run** console.

# tJavaFlex

|                          | <i>tStatCatcher Statistics</i>                                                                                                                                                                                                                                            | Select this check box to gather the Job processing metadata at a job level as well as at each component level.                                                                                                                                                                                                                                                                                                                                              |
| <b>Usage</b>             | You can use this component as a start, intermediate or output component. You can as well use it as a one-component subjob.                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Limitation</b>        | You should know the Java language.                                                                                                                                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Scenario 1: Generating data flow

This scenario describes a two-components Job that generates a three-line data flow describing different personal titles (Miss, Mrs, and Mr) and displaying them on the console.

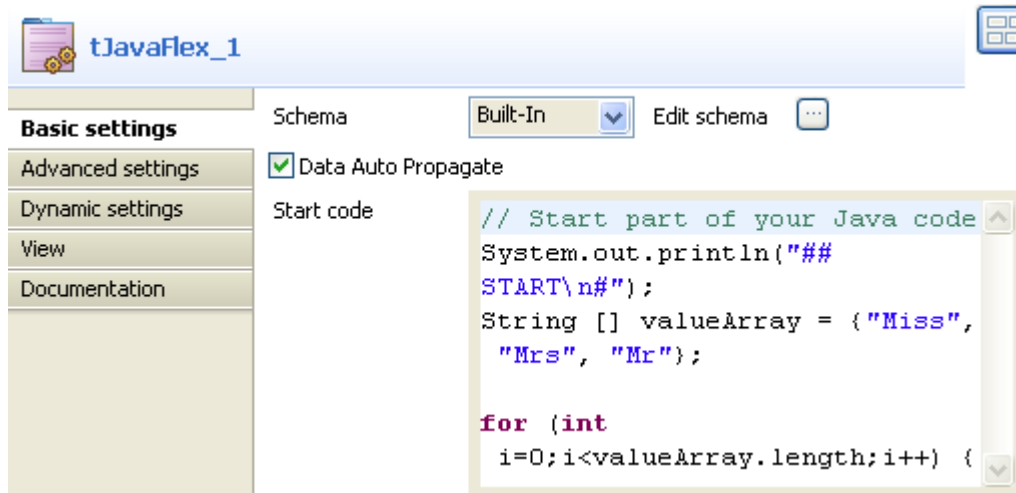

### Setting up the Job

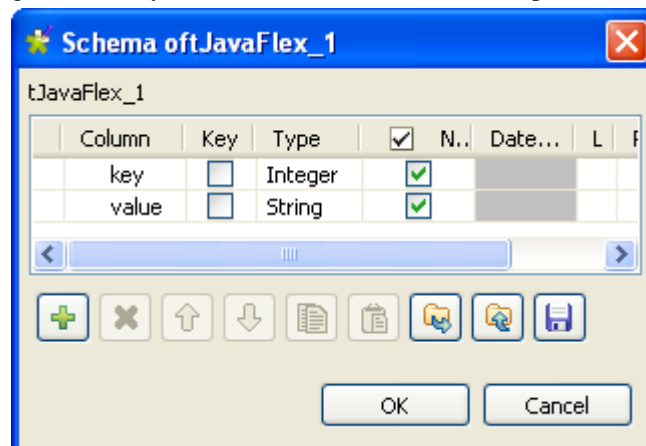

1. Drop **tJavaFlex** and **tLogRow** from the **Palette** onto the design workspace.
2. Connect the components together using a **Row Main** link.

### Configuring the tJavaFlex component

1. Double-click **tJavaFlex** to display its **Basic settings** view and define its properties.

2. From the **Schema Type** list, select **Built-in** and then click the three-dot button next to **Edit schema** to open the corresponding dialog box where you can define the data structure to pass to the component that follows.

- Click the [+] button to add two columns: *key* and *value* and then set their types to **Integer** and **String** respectively.
- Click **OK** to validate your changes and close the dialog box.
- In the **Basic settings** view of **tJavaFlex**, select the **Data Auto Propagate** check box to automatically propagate data to the component that follows.

In this example, we do not want to do any transformation on the retrieved data.

- In the **Start code** field, enter the code to be executed in the initialization phase.

In this example, the code indicates the initialization of **tJavaFlex** by displaying the START message and sets up the loop and the variables to be used afterwards in the Java code:

```
System.out.println("## START\n#");
String [] valueArray = {"Miss", "Mrs", "Mr"};

for (int i=0;i<valueArray.length;i++) {
```

- In the **Main code** field, enter the code you want to apply on each of the data rows.

In this example, we want to display each key with its value:

```
row1.key = i;
row1.value = valueArray[i];
```

Main code

```
// Main part of your Java code
(loop)

row1.key = i;
row1.value = valueArray[i];
```

*In the **Main code** field, "row1" corresponds to the name of the link that comes out of **tJavaFlex**. If you rename this link, you have to modify the code of this field accordingly.*

- In the **End code** field, enter the code that will be executed in the closing phase.

In this example, the brace (curly bracket) closes the loop and the code indicates the end of the execution of **tJavaFlex** by displaying the END message:

```
}
System.out.println("#\n## END");
```

End code

```
// End part of your Java code
}
System.out.println("#\n##
END");
```

9. If needed, double-click **tLogRow** and in its **Basic settings** view, click the [...] button next to **Edit schema** to make sure that the schema has been correctly propagated.

## Saving and executing the Job

1. Save your Job by pressing **Ctrl+S**.
2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

*Starting job tJavaFlex\_scenario1 at 14:49 02/09/2009.*

```
START
#
0 | Miss
1 | Mrs
2 | Mr
#
END
Job tJavaFlex_scenario1 ended at 14:49 02/09/2009. [exit code=0]
```

The three personal titles are displayed on the console along with their corresponding keys.

## Scenario 2: Processing rows of data with tJavaFlex

This scenario describes a two-component Job that generates random data and then collects that data and does some transformation on it line by line using Java code through the **tJavaFlex** component.

### Setting up the Job

1. Drop **tRowGenerator** and **tJavaFlex** from the **Palette** onto the design workspace.
2. Connect the components together using a **Row Main** link.

### Configuring the input component

1. Double-click **tRowGenerator** to display its **Basic settings** view and the **[RowGenerator Editor]** dialog box where you can define the component properties.

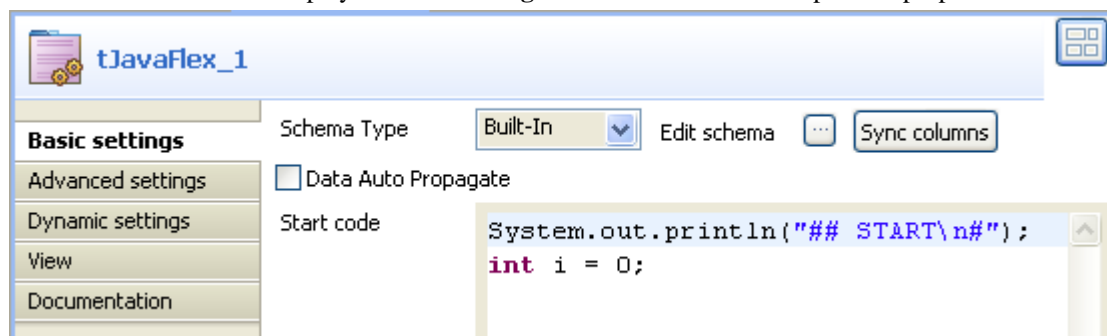

2. Click the plus button to add four columns: *number*, *txt*, *date* and *flag*.
3. Define the schema and set the parameters to the four columns according to the above capture.
4. In the **Functions** column, select the three-dot function [...] for each of the defined columns.
5. In the **Parameters** column, enter 10 different parameters for each of the defined columns. These 10 parameters corresponds to the data that will be randomly generated when executing **tRowGenerator**.
6. Click **OK** to validate your changes and close the editor.

## Configuring the tJavaFlex component

1. Double-click **tJavaFlex** to display its **Basic settings** view and define the components properties.

2. Click **Sync columns** to retrieve the schema from the preceding component.
3. In the **Start code** field, enter the code to be executed in the initialization phase.

In this example, the code indicates the initialization of the **tJavaFlex** component by displaying the START message and defining the variable to be used afterwards in the Java code:

```
System.out.println("## START\\n#");
```

```
int i = 0;
```

4. In the **Main code** field, enter the code to be applied on each line of data.

In this example, we want to show the number of each line starting from 0 and then the number and the random text transformed to upper case and finally the random date set in the editor of **tRowGenerator**. Then, we create a condition to show if the status is **true** or **false** and we increment the number of the line:

```
System.out.print(" row" + i + ":");
System.out.print("# number:" + row1.number);
System.out.print (" | txt:" + row1.txt.toUpperCase());
System.out.print(" | date:" + row1.date);
if(row1.flag) System.out.println(" | flag: true");
else System.out.println(" | flag: false");

i++;
```

Main code

```
System.out.print(" row" + i + ":");
System.out.print("# number:" +
 row1.number);
System.out.print (" | txt:" +
 row1.txt.toUpperCase());
System.out.print(" | date:" +
 row1.date);
if(row1.flag) System.out.println(" |
flag: true");
else System.out.println(" | flag:
false");

i++;
```

*In the **Main code** field, "row1" corresponds to the name of the link that connects to **tJavaFlex**. If you rename this link, you have to modify the code.*

5. In the **End code** field, enter the code that will be executed in the closing phase.

In this example, the code indicates the end of the execution of **tJavaFlex** by displaying the END message:

```
System.out.println("#\n## END");
```

End code

```
System.out.println("#\n## END");
```

## Saving and executing the Job

1. Save your Job by pressing **Ctrl+S**.

- Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

*Starting job tJavaFlex\_scenario2 at 18:35 02/09/2009.*

```
START
#
row0:# number:10 | txt:TEXT5 | date:2006-05-25 | flag: false
row1:# number:7 | txt:TEXT7 | date:2006-06-26 | flag: true
row2:# number:5 | txt:TEXT2 | date:2006-05-25 | flag: false
row3:# number:6 | txt:TEXT1 | date:2005-08-28 | flag: true
row4:# number:8 | txt:TEXT9 | date:2006-05-25 | flag: false
row5:# number:9 | txt:TEXT1 | date:2007-01-21 | flag: false
row6:# number:7 | txt:TEXT5 | date:2004-11-21 | flag: true

| <b>Usage</b>             | This component is used as an intermediary between two other components. It must be linked to both an input and an output component.                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Limitation</b>        | Knowledge of Java language is necessary.                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Scenario: Transforming data line by line using tJavaRow

In this scenario, the information of a few cities read from an input delimited file is transformed using Java code through the **tJavaRow** component and printed on the console.

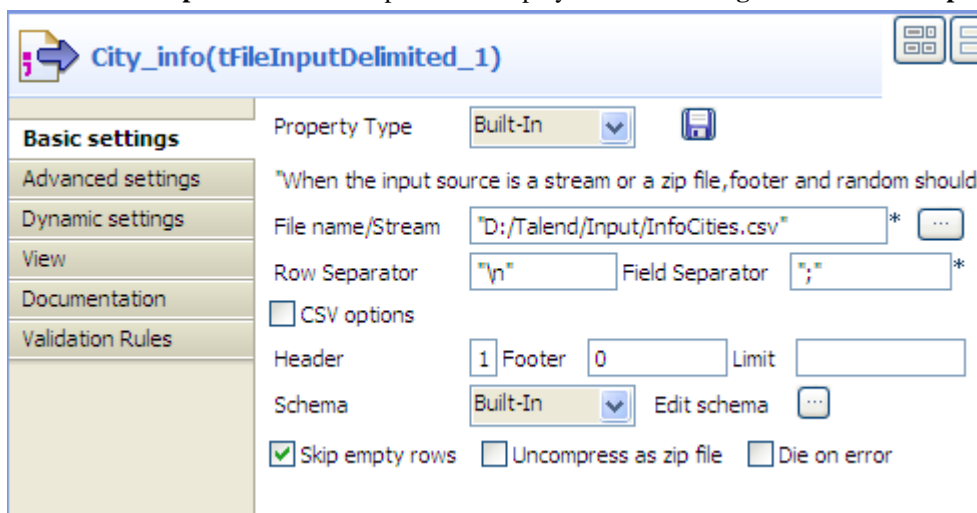

## Setting up the Job

1. Drop a **tFileInputDelimited** component and a **tJavaRow** component from the **Palette** onto the design workspace, and label them to better identify their roles in the Job.
2. Connect the two components using a **Row > Main** connection.

## Configuring the components

1. Double-click the **tFileInputDelimited** component to display its **Basic settings** view in the **Component** tab.

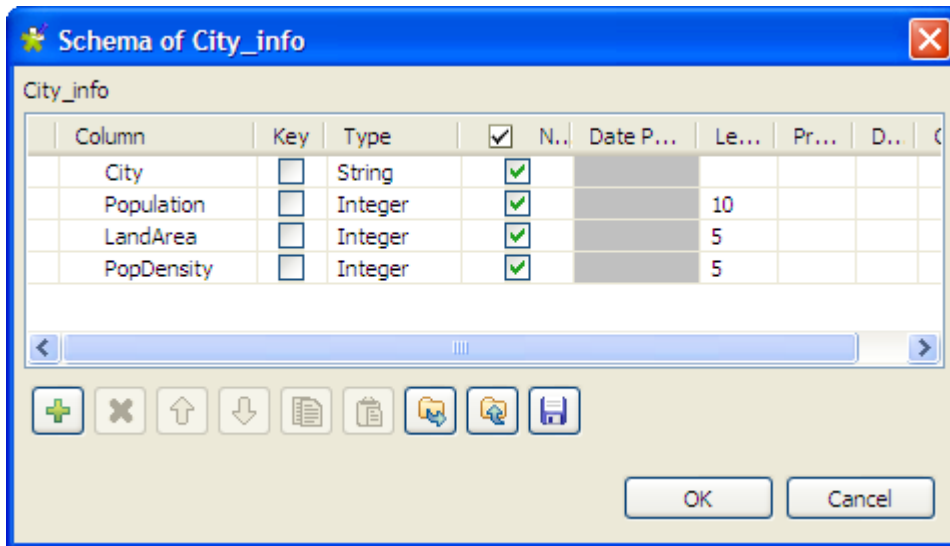

2. In the **File name/Stream** field, type in the path to the input file in double quotation marks, or browse to the path by clicking the [...] button, and define the first line of the file as the header.

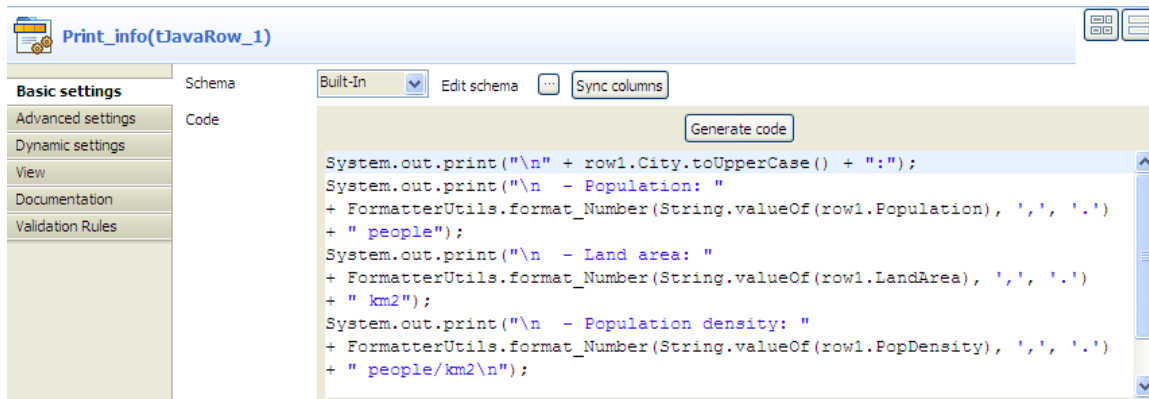

In this example, the input file has the following content:

```
City;Population;LandArea;PopDensity
Beijing;10233000;1418;7620
Moscow;10452000;1081;9644
Seoul;10422000;605;17215
Tokyo;8731000;617;14151
New York;8310000;789;10452
```

3. Click the [...] button next to Edit schema to open the **[Schema]** dialog box, and define the data structure of the input file. Then, click **OK** to validate the schema setting and close the dialog box.

4. Double-click the **tJavaRow** component to display its **Basic settings** view in the **Component** tab.

5. Click **Sync columns** to make sure that the schema is correctly retrieved from the preceding component.
6. In the **Code** field, enter the code to be applied on each line of data based on the defined schema columns.

In this example, we want to transform the city names to upper case, group digits of numbers larger than 1000 using the thousands separator for ease of reading, and print the data on the console:

```
System.out.print("\n" + row1.City.toUpperCase() + ":");
System.out.print("\n - Population: "
+ FormatterUtils.format_Number(String.valueOf(row1.Population), ',', '.')
+ " people");
System.out.print("\n - Land area: "
+ FormatterUtils.format_Number(String.valueOf(row1.LandArea), ',', '.')
+ " km2");
System.out.print("\n - Population density: "
+ FormatterUtils.format_Number(String.valueOf(row1.PopDensity), ',', '.')
+ " people/km2\n");
```

 In the **Code** field, "row1" refers to the name of the link that connects to **tJavaRow**. If you rename the link, you have to modify the code.

## Saving and executing the Job

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the **Run** tab to execute the Job.

The city information is transformed by the Java code set through **tJavaRow** and displayed on the console.

# tLibraryLoad

## tLibraryLoad properties

|                             |                                                                                           |                                                                                                                                                |
|-----------------------------|-------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Famille de composant</b> | Custom Code                                                                               |                                                                                                                                                |
| <b>Function</b>             | <b>tLibraryLoad</b> allows you to import a library.                                       |                                                                                                                                                |
| <b>Purpose</b>              | <b>tLibraryLoad</b> allows you to load useable Java libraries in a Job.                   |                                                                                                                                                |
| <b>Basic settings</b>       | <i>Library</i>                                                                            | Select the library you want to import from the list, or click on the [...] button to browse to the library in your directory.                  |
| <b>Advanced settings</b>    | <i>Dynamic Libs</i>                                                                       | <b>Lib Paths:</b> Enter the access path to your library, between double quotation marks.                                                       |
|                             | <i>Import</i>                                                                             | Enter the Java code required to import, if required, the external library used in the <b>Main code</b> field of the <b>Basic settings</b> tab. |
|                             | <i>tStatCatcher Statistics</i>                                                            | Select this check box to collect the log data at component level.                                                                              |
| <b>Usage</b>                | This component may be used alone, although it is more logical to use it as part of a Job. |                                                                                                                                                |
| <b>Limitation</b>           | n/a                                                                                       |                                                                                                                                                |

## Scenario: Checking the format of an e-mail address!

This scenario uses two components, a **tLibraryLoad** and a **tJava**. The goal of this scenario is to check the format of an e-mail address and verify whether the format is valid or not.

## Setting up the Job

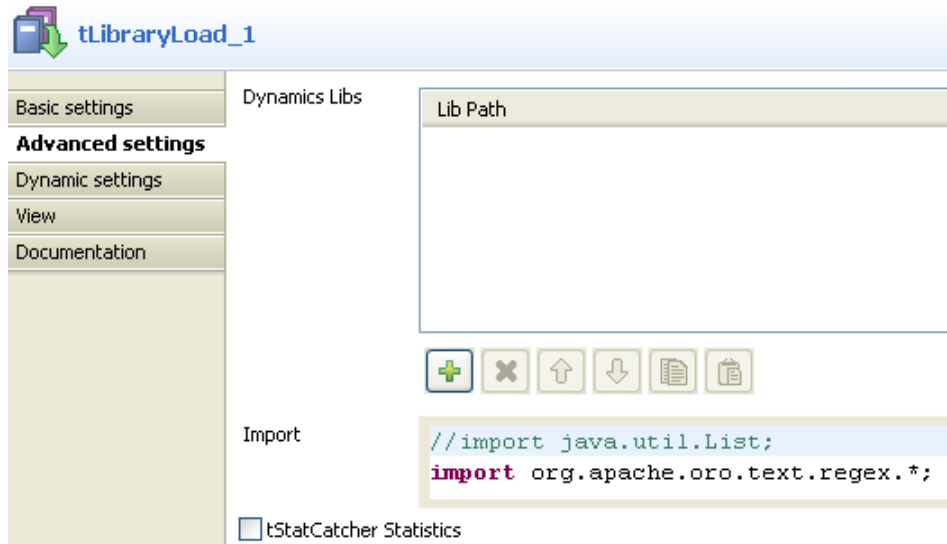

1. In the **Palette**, open the **Custom\_Code** folder, and slide a **tLibraryLoad** and **tJava** component onto the workspace.

2. Connect **tLibraryLoad** to **tJava** using a **Trigger > OnSubjobOk** link.

## Configuring the tLibraryLoad component

1. Double-click on **tLibraryLoad** to display its **Basic settings**. From the **Library** list, select *jakarta-oro-2.0.8.jar*.
2. In the **Import** field of the **Advanced settings** tab, type *import org.apache.oro.text.regex.\*;*

## Configuring the tJava component

1. Double-click on **tJava** to display its **Component** view.
2. In the **Basic settings** tab, enter your code, as in the screenshot below. The code allows you to check whether the character string pertains to an e-mail address, based on the regular expression: `"^[\\w_.-]+@[\\w_.-]+\\. [\\w]+$. "`.

## Job execution

Press **F6** to save and run the Job.

```
Starting job LibraryLoad at 16:51 18/02/2010.
[statistics] connecting to socket on port 3979
[statistics] connected
ma@cocom : false
[statistics] disconnected
Job LibraryLoad ended at 16:51 18/02/2010. [exit code=0]
```

The **Console** displays the boolean *false*. Hence, the e-mail address is not valid as the format is incorrect.

# tSetGlobalVar

## tSetGlobalVar properties

|                          |                                                                            |                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Component family</b>  | Custom Code                                                                |                                                                                                                                                          |
| <b>Function</b>          | <b>tSetGlobalVar</b> allows you to define and set global variables in GUI. |                                                                                                                                                          |
| <b>Purpose</b>           | <b>tSetGlobalVar</b> facilitates the process of defining global variables. |                                                                                                                                                          |
| <b>Basic settings</b>    | <i>Variables</i>                                                           | This table contains two columns.<br><br><b>Key:</b> Name of the variable to be called in the code.<br><br><b>Value:</b> Value assigned to this variable. |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                             | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.                                           |
| <b>Usage</b>             | This component is generally used as a one-component subjob.                |                                                                                                                                                          |
| <b>Limitation</b>        | Knowledge of Java language is required.                                    |                                                                                                                                                          |

## Scenario: Printing out the content of a global variable

This scenario is a simple Job that prints out the value of a global variable defined in the **tSetGlobalVar** component.

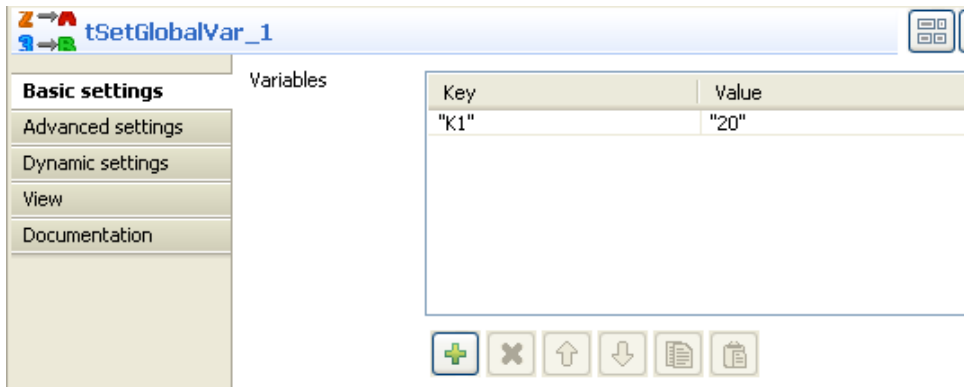

### Setting up the Job

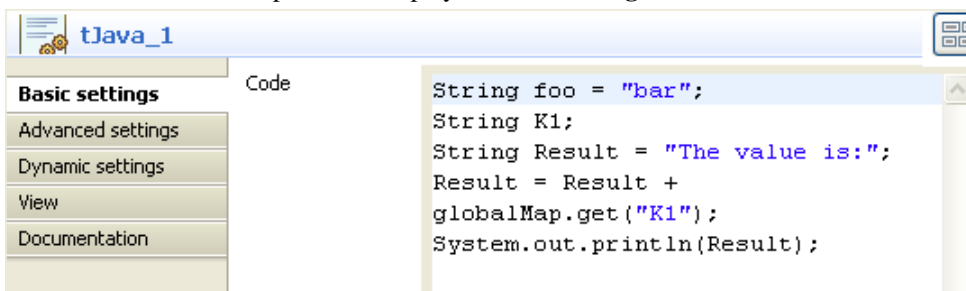

1. Drop the following components from the **Palette** onto the design workspace: **tSetGlobalVar** and **tJava**.
2. Connect the **tSetGlobalVar** component to the **tJava** component using a **Trigger** > **OnSubjobOk** connection.

### Configuring the tSetGlobalVar component

1. Double-click the **tSetGlobalVar** component to display its **Basic settings** view.

- Click the plus button to add a line in the **Variables** table, and fill the **Key** and **Value** fields with *K1* and *20* respectively.
- Then double-click the **tJava** component to display its **Basic settings** view.

- In the **Code** area, type in the following lines:

```
String foo = "bar";
String K1;
String Result = "The value is:";

Result = Result + globalMap.get("K1");

System.out.println(Result);
```

In this use case, we use the *Result* variable. To access the global variable list, press **Ctrl + Space** bar on your keyboard and select the relevant global parameter.

## Job execution

Save your Job and press **F6** to execute it.

The content of global variable *K1* is displayed on the console.

```
Starting job SetGlobalVar at 16:22 25/02/2011.
[statistics] connecting to socket on port 3489
[statistics] connected
The value is:20
[statistics] disconnected
Job SetGlobalVar ended at 16:22 25/02/2011.
[exit code=0]
```

# Data Quality components

This chapter details the main components that you can find in the **Data Quality** family of the *Talend Open Studio Palette*.

The Data Quality family comprises dedicated components that help you improve the quality of your data. These components covers various needs such as narrow down filtering the unique row, calculating CRC, finding data based on fuzzy matching, and so on.

# tAddCRCRow

## tAddCRCRow properties

|                          |                                                                                                                 |                                                                                                                                                                                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Component family</b>  | Data Quality                                                                                                    |                                                                                                                                                                                                                                                         |
| <b>Function</b>          | <b>tAddCRCRow</b> calculates a surrogate key based on one or several columns and adds it to the defined schema. |                                                                                                                                                                                                                                                         |
| <b>Purpose</b>           | Providing a unique ID helps improving the quality of processed data.                                            |                                                                                                                                                                                                                                                         |
| <b>Basic settings</b>    | <i>Schema and Edit Schema</i>                                                                                   | A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository. In this component, a new CRC column is automatically added. |
|                          |                                                                                                                 | <b>Built-in:</b> The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio User Guide</i> .                                                                                                       |
|                          |                                                                                                                 | <b>Repository:</b> The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see <i>Talend Open Studio User Guide</i> .                                                        |
|                          | <i>Implication</i>                                                                                              | Select the check box facing the relevant columns to be used for the surrogate key checksum.                                                                                                                                                             |
| <b>Advanced Settings</b> | <i>CRC type</i>                                                                                                 | Select a CRC type in the list. The longer the CRC, the least overlap you will have.                                                                                                                                                                     |
|                          | <i>tStatCatcher Statistics</i>                                                                                  | Select this check box to collect log data at the component level.                                                                                                                                                                                       |
| <b>Usage</b>             | This component is an intermediary step. It requires an input flow as well as an output.                         |                                                                                                                                                                                                                                                         |
| <b>Limitation</b>        | n/a                                                                                                             |                                                                                                                                                                                                                                                         |

## Scenario: Adding a surrogate key to a file

This scenario describes a Job adding a surrogate key to a delimited file schema.

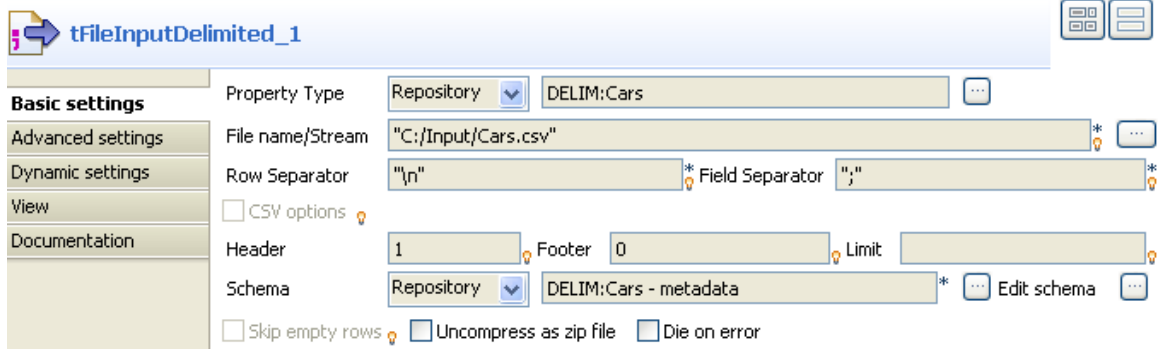

## Setting up the Job

1. Drop the following components: **tFileInputDelimited**, **tAddCRCRow** and **tLogRow**.

2. Connect them using a **Main row** connection.

## Configuring the input component

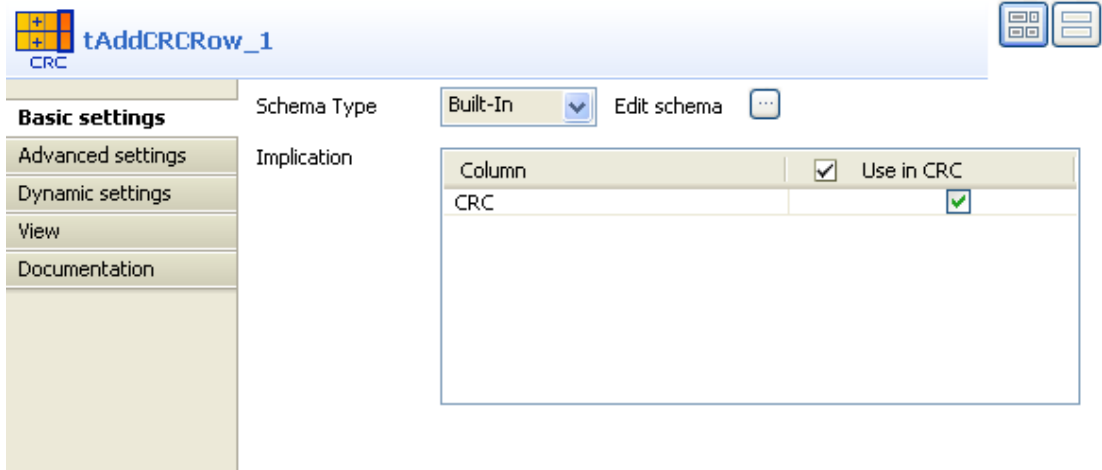

1. In the **tFileInputDelimited Component** view, set the **File Name** path and all related properties in case these are not stored in the **Repository**.

2. Create the schema through the **Edit Schema** button, if the schema is not stored already in the **Repository**. Remember to set the data type column and for more information on the Date pattern to be filled in, visit <http://docs.oracle.com/javase/6/docs/api/index.html>.

## Configuring the tAddCRCRow component

1. In the **tAddCRCRow Component** view, select the check boxes of the input flow columns to be used to calculate the CRC.

Notice that a CRC column (read-only) has been added at the end of the schema.

2. Select **CRC32** as **CRC Type** to get a longer surrogate key.

3. In the **Basic settings** view of **tLogRow**, select the **Print values in cells of a table** option to display the output data in a table on the Console.

## Job execution

Then save your Job and press **F6** to execute it.

Starting job addcrc at 11:51 06/07/2007.

| tLogRow_1 |            |            |        |             |             |  |

An additional CRC Column has been added to the schema calculated on all previously selected columns (in this case all columns of the schema).

# tChangeFileEncoding

**tChangeFileEncoding** component belongs to two component families: Data Quality and File. For more information about **tChangeFileEncoding**, see [the section called “tChangeFileEncoding”](#).

# tExtractRegexFields

**tExtractRegexFields** belongs to two component families: Data Quality and Processing. For more information on **tExtractRegexFields**, see [the section called “tExtractRegexFields”](#).

# tFuzzyMatch

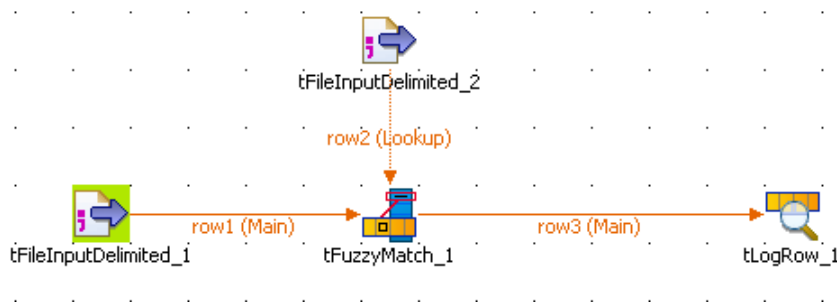

## tFuzzyMatch properties

|              |                                                                                                                  |                                                                                                                                                     |
|--------------|------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
|              | <i>Unique matching</i>                                                                                           | Select this check box if you want to get the best match possible, in case several matches are available.                                            |
|              | <i>Matching separator</i>                                                                                        | In case several matches are available, all of them are displayed unless the unique match box is selected. Define the delimiter between all matches. |
| <b>Usage</b> | This component is not startable (green background) and it requires two input components and an output component. |                                                                                                                                                     |

## Scenario 1: Levenshtein distance of 0 in first names

This scenario describes a four-component Job aiming at checking the edit distance between the *First Name* column of an input file with the data of the reference input file. The output of this Levenshtein type check is displayed along with the content of the main flow on a table

- Drag and drop the following components from the **Palette** to the design workspace: **tFileInputDelimited** (x2), **tFuzzyMatch**, **tFileOutputDelimited**.
- Define the first **tFileInputDelimited** Basic settings. Browse the system to the input file to be analyzed and most importantly set the schema to be used for the flow to be checked.
- In the schema, set the **Type** of data in the Java version, especially if you are in **Built-in** mode.
- Link the defined input to the **tFuzzyMatch** using a **Main** row link.
- Define the second **tFileInputDelimited** component the same way.

*Make sure the reference column is set as key column in the schema of the lookup flow.*

| Column       | Key                                 | Type   | Nullable                            | Length | Precision | Comment |
|--------------|-------------------------------------|--------|-------------------------------------|--------|-----------|---------|
| 01_firstname | <input checked="" type="checkbox"/> | String | <input checked="" type="checkbox"/> | 13     |           |         |
| 02_gender    | <input type="checkbox"/>            | String | <input checked="" type="checkbox"/> | 3      |           |         |

- Then connect the second input component to the **tFuzzyMatch** using a main row (which displays as a **Lookup** row on the design workspace).
- Select the **tFuzzyMatch** Basic settings.
- The **Schema** should match the **Main** input flow schema in order for the main flow to be checked against the reference.

| Column       | Key | Type   | Nullable                            | Length | Precis... | Com... |
|--------------|-----|--------|-------------------------------------|--------|-----------|--------|
| O1_firstname |     | String | <input checked="" type="checkbox"/> | 13     |           |        |
| VALUE        |     | String | <input checked="" type="checkbox"/> | 255    |           |        |
| MATCHING     |     | String | <input checked="" type="checkbox"/> | 255    |           |        |

- Note that two columns, **Value** and **Matching**, are added to the output schema. These are standard matching information and are read-only.
- Select the method to be used to check the incoming data. In this scenario, *Levenshtein* is the **Matching type** to be used.
- Then set the distance. In this method, the distance is the number of char changes (insertion, deletion or substitution) that needs to be carried out in order for the entry to fully match the reference.

- In this use case, we want the distance be of 0 for the min. or for the max. This means only the exact matches will be output.
- Also, clear the **Case sensitive** check box.
- And select the column of the main flow schema that will be selected. In this example, the first name.
- No need to select the **Unique matching** check box nor hence the separator.
- Link the **tFuzzyMatch** to the standard output **tLogRow**. No other parameters than the display delimiter is to be set for this scenario.
- Save the Job and press **F6** to execute the Job.

```

august {2}||
augusta|
auguste|0|auguste
augustijn|
augustin|0|augustin
augustine||
augusto||
augusts||
augustus||
aukusti|

```

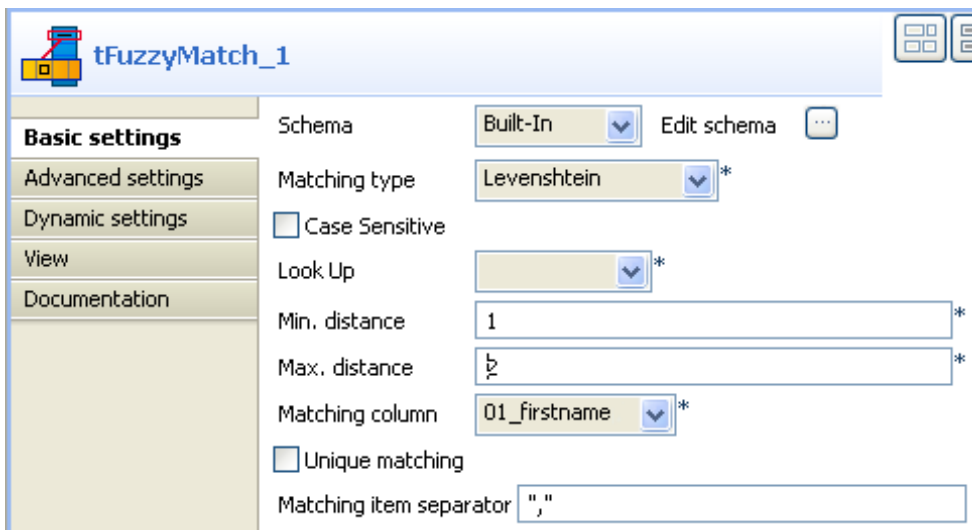

As the edit distance has been set to 0 (min and max), the output shows the result of a regular join between the main flow and the lookup (reference) flow, hence only full matches with Value of 0 are displayed.

A more obvious example is with a minimum distance of 1 and a max. distance of 2, see [the section called “Scenario 2: Levenshtein distance of 1 or 2 in first names”](#)

## Scenario 2: Levenshtein distance of 1 or 2 in first names

This scenario is based on the scenario 1 described above. Only the min and max distance settings in **tFuzzyMatch** component get modified, which will change the output displayed.

- In the **Component** view of the **tFuzzyMatch**, change the min distance from 0 to 1. This excludes straight away the exact matches (which would show a distance of 0).
- Change also the max distance to 2 as the max distance cannot be lower than the min distance. The output will provide all matching entries showing a discrepancy of 2 characters at most.

- No other change of the setting is required.
- Make sure the **Matching item separator** is defined, as several references might be matching the main flow entry.
- Save the new Job and press **F6** to run it.

```

augusts|1|auguste
augustus|2|auguste,augustin
aokusti|2|auguste,augustin
auly||
aulus|2|jules

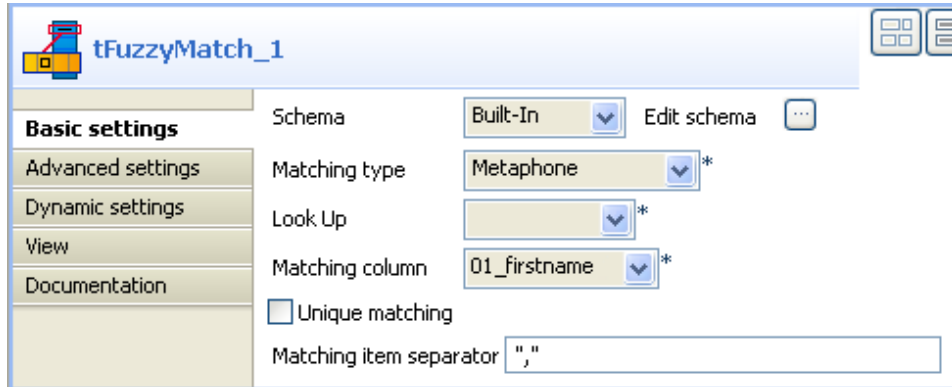

```

As the edit distance has been set to 2, some entries of the main flow match several reference entries.

You can also use another method, the metaphone, to assess the distance between the main flow and the reference,

## Scenario 3: Metaphonic distance in first name

This scenario is based on the scenario 1 described above.

- Change the **Matching type** to **Metaphone**. There is no min nor max distance to set as the matching method is based on the discrepancies with the phonetics of the reference.
- Save the Job and press **F6**. The phonetics value is displayed along with the possible matches.

| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                                                                                                                                              | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                    |
| <b>Usage</b>             | This component handles flow of data therefore it requires input and output, hence is defined as an intermediary step.                                                                       |                                                                                                                                                                                                                                                                                                                                      |
| <b>Limitation</b>        | n/a                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                      |

## Scenario: Identifying Ip country

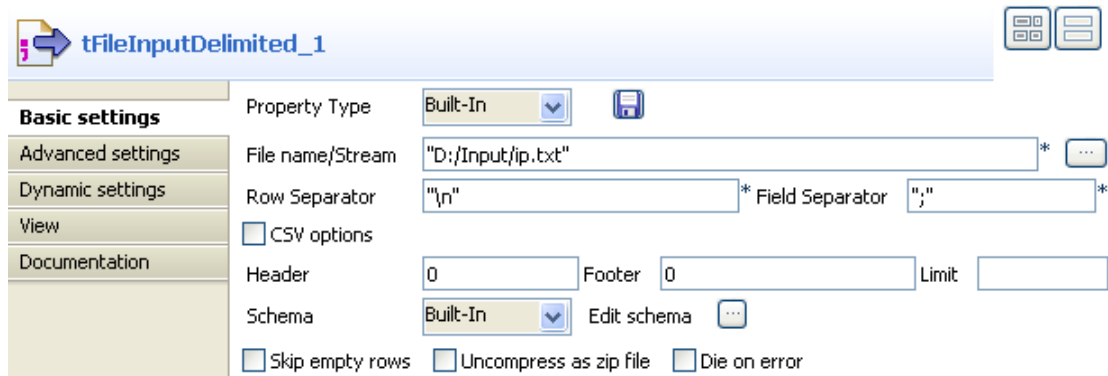

In this Job, an incoming main flow provides 2 columns: *Documents* and *IP* dummy values. A second file used as lookup flow in Java contains a list of sorted IP ranges and their corresponding country. This Job aims at retrieving each document's country from their IP value, in other words, creating a Join between the main flow and the lookup flow.

The Job requires one extra **tFileInputDelimited**, a **tIntervalMatch** and a **tLogRow**.

- Drop the components onto the design workspace.
- Set the basic settings of the **tFileInputDelimited** component.

- The schema is made of two columns, respectively *Document* and *IP*
- Set the **Type** column on **String** for the *Document* column and **Integer** for the *IP* column.
- Set now the second **tFileInputDelimited** properties.

| Column  | Key                      | Type    | Nullable                            | Date Patt... | Len... | Pre... | D... | Co... |
|---------|--------------------------|---------|-------------------------------------|--------------|--------|--------|------|-------|
| min     | <input type="checkbox"/> | Integer | <input checked="" type="checkbox"/> |              | 4      |        |      |       |
| max     | <input type="checkbox"/> | Integer | <input checked="" type="checkbox"/> |              | 4      |        |      |       |
| country | <input type="checkbox"/> | String  | <input checked="" type="checkbox"/> |              | 11     |        |      |       |

- Don't forget to define the **Type** of data.
- Propagate the schema from the incoming main flow to the **tIntervalMatch** component.

| Column   | Key                      | Type    | Nullable                            | Dat... | L..  | P.. |
|----------|--------------------------|---------|-------------------------------------|--------|------|-----|
| document | <input type="checkbox"/> | String  | <input checked="" type="checkbox"/> |        | 9    |     |
| ip       | <input type="checkbox"/> | Inte... | <input checked="" type="checkbox"/> |        | 4    |     |
| LOOKUP   | <input type="checkbox"/> | String  | <input checked="" type="checkbox"/> |        | 2... |     |

- Note that the output schema from the **tIntervalMatch** component is read-only and is made of the input schema plus an extra Lookup column which will output the requested lookup data.
- Set the other properties of the **tIntervalMatch** component.

Schema: Built-In (dropdown) Edit schema (button) Sync columns (button)

File Name: 'D:/Input/rangeip.txt' (text field) \*

Row Separator: "\n" (text field) Field Separator: ';' (text field)

Lookup column index: 0 (text field) \* Search column: ip (dropdown) \*

- Set the tIntervalMatch other properties such as the min and max column corresponding to the range bounds.

Schema: Built-In (dropdown) Edit schema (button)

Search Column: ip (dropdown) \* Column (LOOKUP): row2.country (dropdown) \*

Lookup Column (min): row2.min (dropdown) \*  bounds strictly (min)

Lookup Column (max): row2.max (dropdown) \*  bounds strictly (max)

- In the **Column Lookup** field, select the column where are the values to be returned.
- In the **Search column** field, select the main flow column containing the values to be matched to the range values.
- The **tLogRow** component does not require any specific setting for this Job.

Following result is displayed:

```
Starting job intervalMatch at 17:05 01/02/2008.
document1 | 1200 | DEUTSCHLAND
document2 | 4500 |
document3 | 500 | FRANCE
document1 | 2201 | ITALIA
Job intervalMatch ended at 17:05 01/02/2008. [exit c
```

Only requested values (country) are included in the output.

# tReplaceList

## tReplaceList Properties

|                         |                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Usage</b>             | <b>tReplaceList</b> is an intermediary component. It requires an input flow and an output component. |                                                                   |

## Scenario: Replacement from a reference file

The following Job searches and replaces a list of countries with their corresponding codes. The relevant codes are taken from a reference file placed as lookup flow in the Job. The main flow is replicated and both outputs are displayed on the console, in order to show the main flow before and after replacement.

- Drop the following components from the **Palette** to the design workspace: **tMySQLInput**, **tFileInputDelimited**, **tReplicate**, **tReplaceList** and **tLogRow** (x2). Note that if your input schemas are stored in the Repository, you can simply drag and drop the relevant node from the Repository’s Metadata Manager onto the design workspace to retrieve automatically the input components’ setting. For more information, see *Talend Open Studio User Guide*.
- Connect the components using **Main Row** connections via a right-click on each component. Notice that the main row coming from the reference flow (**tFileInputDelimited**) is called a lookup row.
- Select the **tMySQLInput** component and set the input flow parameters.

Property Type:  Repository: \*

Use an existing connection

Host:  Port:  Database: \*

Username: \* Password: \*

Schema:  \*  ...

Table Name:  ...

Query Type:

Query: \*

Encoding Type:

- The input schema is made of two columns: *Names*, *States*. The column *States* gathered the name of the United States of America which are to be replaced by their respective code.
- In the **Query** field, make sure the *State* column is included in the *Select* statement. In this use case, all columns are selected.

- Check the **tReplicate** component setting. The schema is simply duplicated into two identical flows, but no change to the schema can be made.
- Then double-click on the **tFileInputDelimited** component, to set the reference file.

- The file includes two columns: *Postal*, *State* where *Postal* provides the zipcode corresponding to the name given in the respective row of the *State* column.
- The fields are delimited by semicolons and rows are separated by carriage returns.
- Edit the lookup flow schema.

| Column           | Key                                 | Type   | Nullable                            | Length | Precision | Comment |
|------------------|-------------------------------------|--------|-------------------------------------|--------|-----------|---------|
| Postal           | <input type="checkbox"/>            | String | <input checked="" type="checkbox"/> | 10     |           |         |
| State            | <input checked="" type="checkbox"/> | String | <input checked="" type="checkbox"/> | 255    |           |         |
| Capital          | <input type="checkbox"/>            | String | <input checked="" type="checkbox"/> | 255    |           |         |
| MostPopulousCity | <input type="checkbox"/>            | String | <input checked="" type="checkbox"/> | 255    |           |         |

- Make sure the lookup search column (in this use case: *State*) is a key, in order to ensure the uniqueness of the values being searched.
- Select the **tReplaceList** and set the operation to carry out.
- The schema is retrieved from the previous component of the main flow.

Schema Type: Built-In Edit schema Sync columns

Lookup search index: 1

Lookup replacement index: 0

| Column | Replace                             |
|--------|-------------------------------------|
| Name   | <input type="checkbox"/>            |
| States | <input checked="" type="checkbox"/> |

- In **Lookup search index** field, type in the position index of the column being searched. In this use case, *State* is the second column of the lookup input file, therefore type in **1** in this field.
- In **Lookup replacement index** field, fill in the position number of the column containing the replacement values, in this example: *Postal* for the *State* codes.

- In the **Column options** table, select the *States* column as in this use case, the State names are to be replaced with their corresponding code.
- In both **tLogRow** components, select the **Print values in table cells** check box for a better readability of the outputs.
- Save the Job and press **F6** to execute it.

*Starting job ReplaceList at 15:06 22/10/2007.*

| tLogRow_3          |               |
|--------------------|---------------|
| Name               | States        |
| William Grant      | Iowa          |
| William Hoover     | New York      |
| Grover Lincoln     | North Dakota  |
| Lyndon Jefferson   | Ohio          |
| Gerald Hayes       | Washington    |
| Benjamin Grant     | Maine         |
| George Pierce      | Connecticut   |
| Jimmy Reagan       | Alaska        |
| Martin Hayes       | Washington    |
| Franklin Jefferson | Iowa          |
| Andrew Nixon       | New Hampshire |

| tLogRow_2          |        |
|--------------------|--------|
| Name               | States |
| William Grant      | IA     |
| William Hoover     | NY     |
| Grover Lincoln     | ND     |
| Lyndon Jefferson   | OH     |
| Gerald Hayes       | WA     |
| Benjamin Grant     | ME     |
| George Pierce      | CT     |
| Jimmy Reagan       | AK     |
| Martin Hayes       | WA     |
| Franklin Jefferson | IA     |
| Andrew Nixon       | NH     |

*Job ReplaceList ended at 15:06 22/10/2007. [exit code=0]*

The first flow output shows the States column with full state names as it comes from the main input flow.

The second flow output shows the States column after the State column names have been replaced with their respective codes.
