| <b>Usage</b>      | <b>tUniservBTGeneric</b> sends data to <i>DQ Batch Suite</i> and starts the specified <i>DQ Batch Suite</i> job. When the execution is finished, the output data of the job is returned to <i>Data Quality Service Hub Studio</i> for further processing.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Limitation</b> | <p>To use <b>tUniservBTGeneric</b>, the Uniserv software <i>DQ Batch Suite</i> must be installed.</p> <p> Please note the following:</p> <ul style="list-style-type: none"> <li>• The job must be configured and executable in the <i>DQ Batch Suite</i>.</li> <li>• The user must have the authority to execute the <i>DQ Batch Suite</i> job.</li> <li>• The <i>DQ Batch Suite</i> job may only have one line.</li> <li>• The files defined in the functions <b>Input</b> and <b>Output</b> must possess the record format delimiter.</li> <li>• Input and output data must be provided in the UTF-8 character set.</li> </ul> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Scenario: Execution of a Job in the

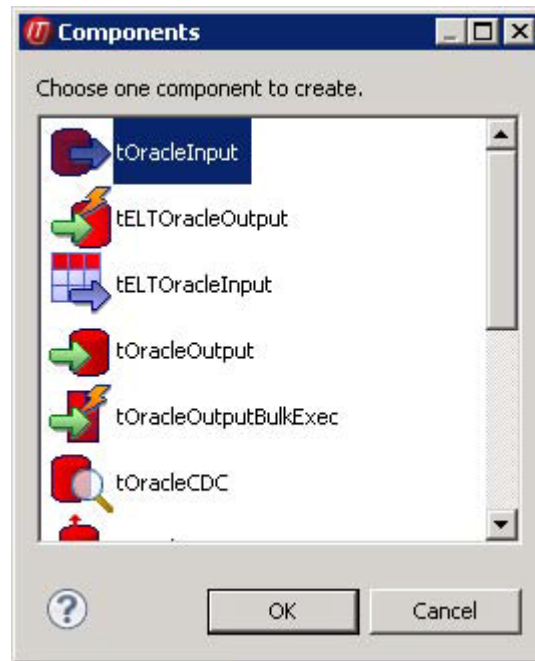

This scenario describes a *DQ Batch Suite* job which execution results are processed in the *Data Quality Service Hub Studio*. The input source for the job is provided by the *Data Quality Service Hub Studio*.

The job was completely defined in the *DQ Batch Suite* and saved under the name "*BTGeneric\_Sample*". In the function **Input**, the file "*btinput.csv*" was specified as the input file saved in the job directory and all fields were assigned. The file is not yet existent physically as it will only be provided by the *Data Quality Service Hub Studio*, so that the job cannot yet run.

In the *Data Quality Service Hub Studio*, the input source (here a table from an Oracle database) for this scenario was already saved in the **Repository**, so that all schema metadata is available.

1. In the **Repository** view, expand the **Metadata** node and the directory in which you saved the source. Then drag this source into the design workspace.

The dialog box below appears.

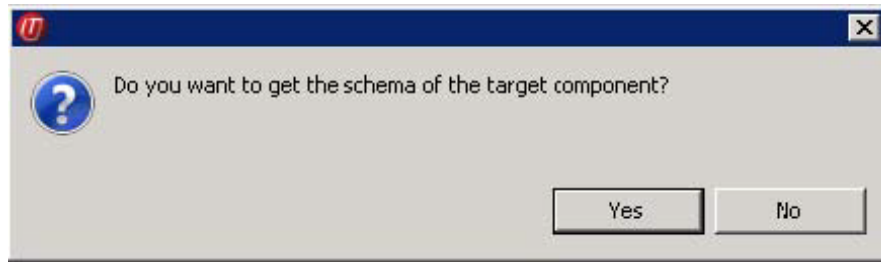

2. Select **tOracleInput** and then click **OK** to close the dialog box.

The component is displayed in the workspace. The table used in this scenario is called *LOCATIONS*.

3. Drag the following components from the **Palette** into the design workspace: two **tMap** components, **tOracleOutput** and **tUniservBTGeneric**.
4. Connect the components via **Row > Main**.

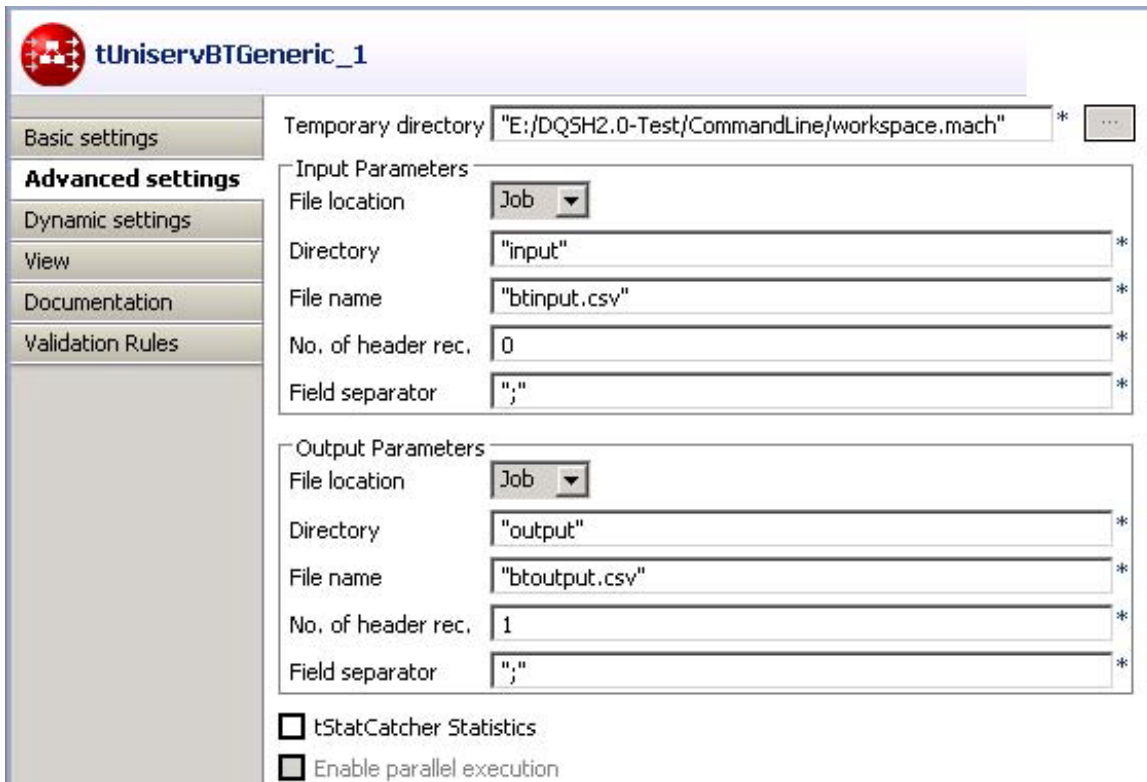

During the process, accept the schema from **tUniservBTGeneric** by clicking **Yes** in the validation window.

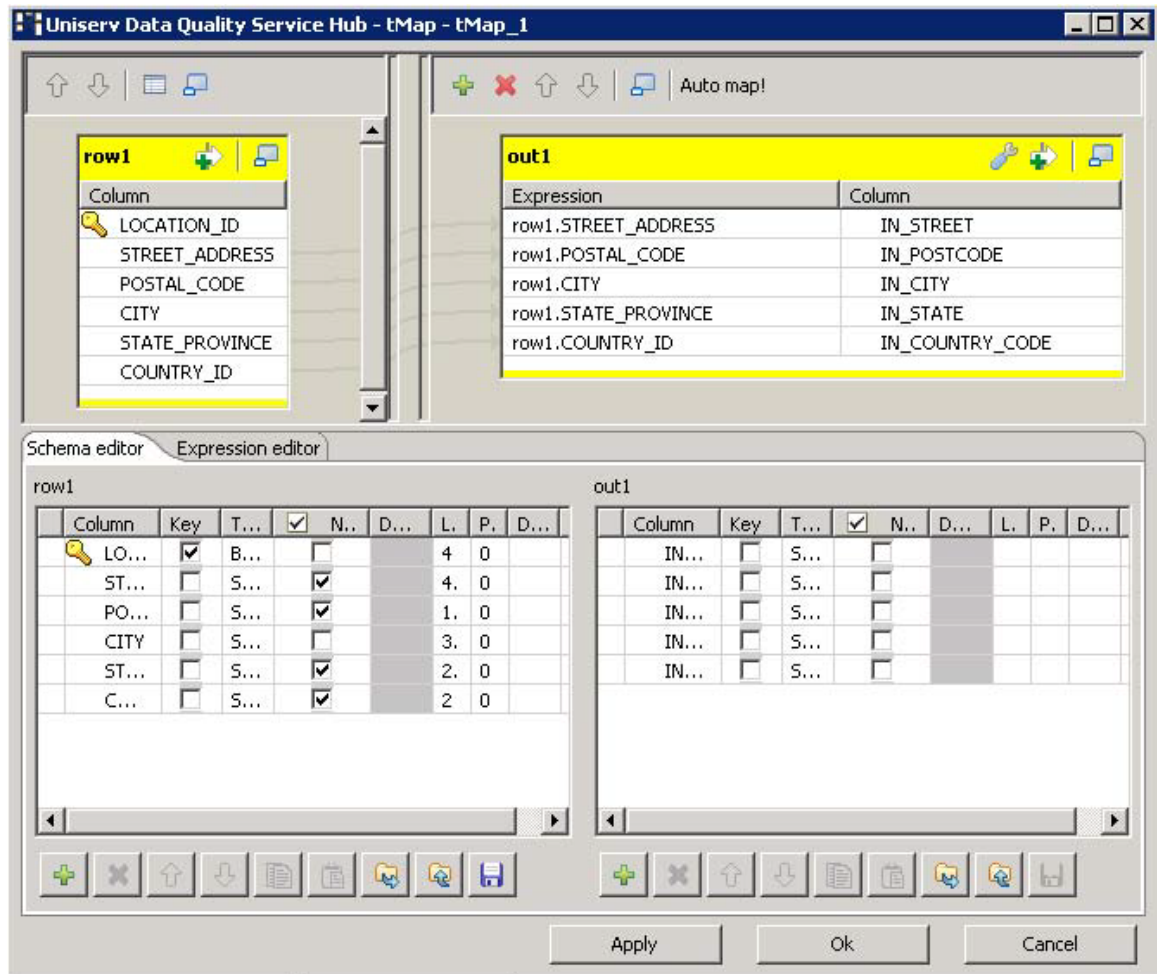

5. Double-click **tUniservBTGeneric** to open its **Basic Settings** view.

6. Enter the connection data for the *DQ Batch Suite* job. Note that the absolute path must be entered in the field **Job File Path**.
7. Click **Retrieve Schema** to automatically create a schema for **tUniservBTGeneric** from the input and output definitions of the *DQ Batch Suite* job and automatically fill in the fields in the **Advanced Settings**.
8. Check the details in the **Advanced Settings** view. The definitions for input and output must be defined exactly the same as the *DQ Batch Suite* job. If necessary, adapt the path for the temporary files.

9. Double-click **tMap\_1** to open the schema mapping window. On the left is the structure of the input source, on the right is the schema of **tUniservBTGeneric** (and thus the input for the *DQ Batch Suite* job). At the bottom is the **Schema Editor**, where you can find the attributes of the individual columns and edit them.
10. Assign the columns of the input source to the respective columns of **tUniservBTGeneric**. For this purpose, select a column of the input source and drag it onto the appropriate column on the right side.

Click **OK** to close the dialog box.

11. Then define how to process the execution results of the job, including which components will be used.
12. Before starting the job, make sure that all path details are correct, the server of the *DQ Batch Suite* is running and that you are able to access the job.

# tUniservRTConvertName

This component will be available in the **Palette** of the studio on the condition that you have subscribed to the relevant edition of Data Quality Service Hub Studio.

## tUniservRTConvertName properties

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Limitation</b>        | To use <b>tUniservRTConvertName</b> , the Uniserv software <i>convert-name</i> must be installed.                                                                            |                                                                                                                                                                                                                                                                                                                                                                              |

## Scenario: Analysis of a name line and assignment of the salutation

This scenario describes a batch job that analyzes the person names in a file and assigns them a salutation.

The input file for this scenario is already saved in the **Repository**, so that all schema metadata is available.

Please observe that the data from the input source must all be related to the same country.

1. In the **Repository** view, expand the **Metadata** node and the directory in which the file is saved. Then drag this file into the design workspace.

The dialog box below appears.

2. Select **tFileInputDelimited** and then click **OK** to close the dialog box.

The component is displayed in the workspace. The file used in this scenario is called *SampleAddresses..*

3. Drag the following components from the **Palette** into the design workspace: two **tMap** components, **tUniservRTConvertName**, and **tFileOutputDelimited..**
4. Connect the components via **Row > Main**.

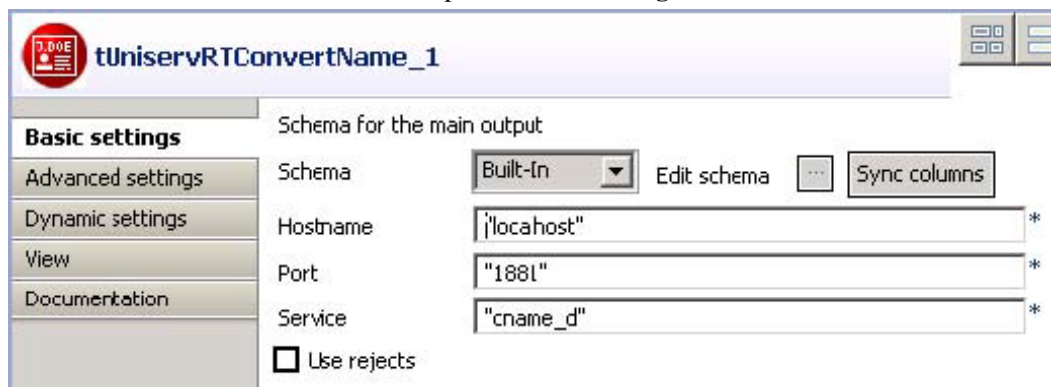

During the process, accept the schema from **tUniservRTConvertName** by clicking **Yes** in the validation window.

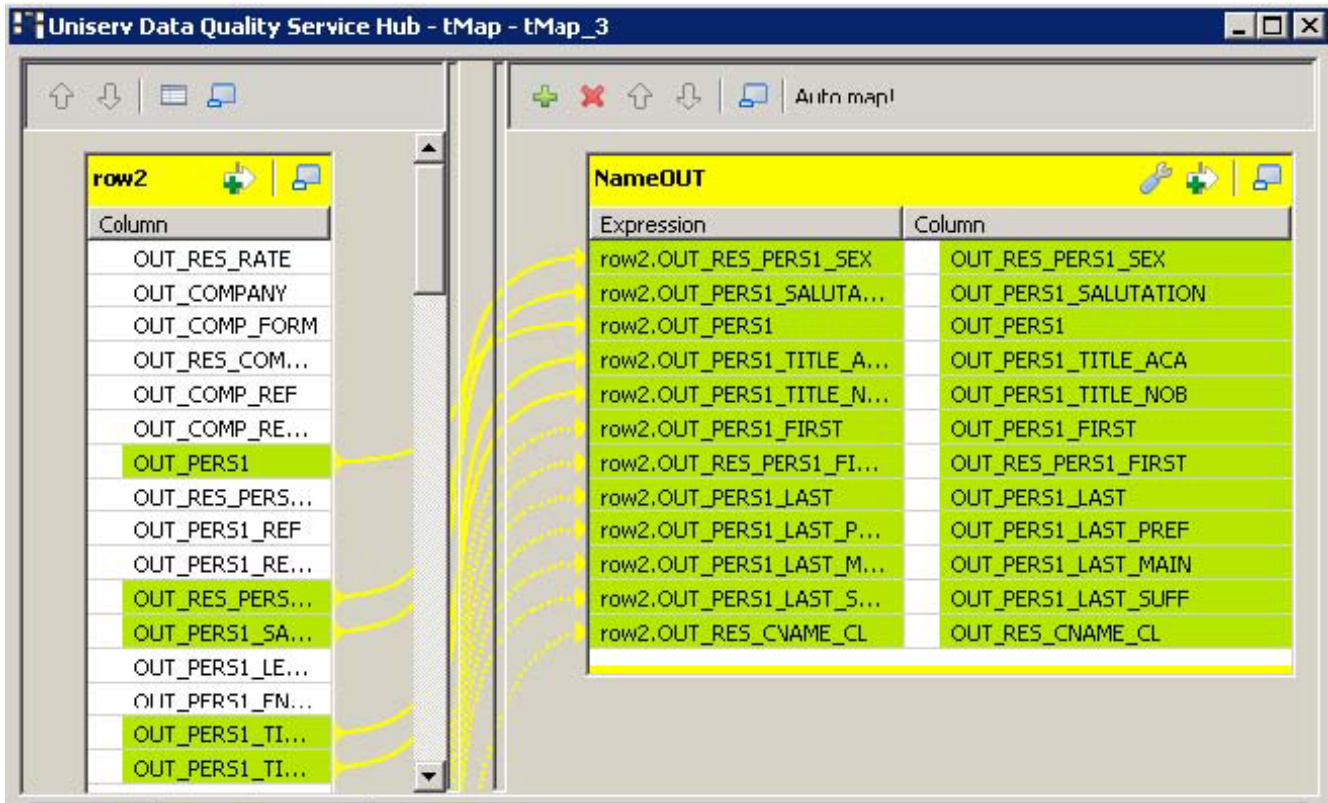

5. Double-click **tMap\_1** to open the schema mapping window. On the left is the structure of the input file, on the right is the schema of **tUniservRTConvertName**. At the bottom lies the **Schema Editor**, where you can find the attributes of the individual columns and edit them.

6. Assign the columns of the input source to the respective columns of **tUniservRTConvertName**. For this purpose, select a column of the input source and drag it onto the appropriate column on the right side. If fields from the input file are to be passed on to the output file, like the address fields or IDs, you have to define additional fields.
7. Click **OK** to close the dialog box.
8. Double-click **tUniservRTConvertName** to open its **Basic Settings** view.

9. Fill in the server information and specify the country-specific service.
10. Double-click **tMap\_3** to open the mapping window. On the left is the schema of **tUniservRTConvertName** and on the right is the schema of the output file.

11. Click **OK** to close the window.
12. Double-click **tFileOutputDelimited** and enter the details for the output file.

# tUniservRTMailBulk

This component will be available in the **Palette** of the studio on the condition that you have subscribed to the relevant edition of Data Quality Service Hub Studio.

## Scenario: Creating an index pool

This scenario describes a batch job that loads the address list of an SQL database into the index pool.

The database for this scenario is already saved in the **Repository**, so that all schema metadata is available.

1. In the **Repository** view, expand the **Metadata** node and the directory in which the database is saved. Then drag this database into the design workspace.

The dialog box below appears.

2. Select **tMysqlInput** and then click **OK** to close the dialog box.

The component is then displayed in the workspace.

3. Drag the following components from the **Palette** into the design workspace: **tMap** and **tUniservRTMailBulk**.
4. Connect the components via **Row** > **Main**.

During the process, accept the schema from **tUniservRTMailBulk** by clicking **Yes** in the validation window.

5. Double-click **tMap\_1** to open the schema mapping window. On the left is the schema of the database file and on the right is the schema of **tUniservRTMailBulk**. At the bottom is displayed the **Schema Editor**, where you can find the attributes of the individual columns and edit them.

6. Assign the columns of the input source to the respective columns of **tUniservRTMailBulk**. For this purpose, select a column of the input source and drag it onto the appropriate column on the right side. The meaning of the individual arguments is described in the Uniserv user manual *mailRetrieval*.
7. Click **OK** to close the window.
8. Double-click **tUniservRTMailBulk** to open its **Basic Settings** view.

9. Fill in the server information and specify the service.
10. Select **Advanced Settings** to adapt the server parameters.

|                          | <i>tStatCatcher Statistics</i> | Select this check box to collect log data at the Job and the component levels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Usage</b>             | <b>tUniservRTMailOutput</b>    | updates the index pool and passes the input set on. The output is amended by the status of the operation. If the operation fails, an error message will be displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Limitation**

To use **tUniservRTMailOutput**, the Uniserv software *mailRetrieval* must be installed.

Before the first use of **tUniservRTMailOutput**, an index pool must be created. You can create the index pool with **tUniservRTMailBulk**.

## Related scenarios

For a related scenario, see [the section called “Scenario: Adding contacts to the mailRetrieval index pool”](#).

# tUniservRTMailSearch

This component will be available in the **Palette** of the studio on the condition that you have subscribed to the relevant edition of Data Quality Service Hub Studio.

|                          |                 | Before the first use of <b>tUniservRTMailSearch</b> , an index pool must be created. You can create the index pool with <b>tUniservRTMailBulk</b> .                                                                                                         |

## Scenario: Adding contacts to the mailRetrieval index pool

This scenario describes a batch job that adds contacts to the index pool of *mailRetrieval*. Before the addition, it must be checked whether these contacts already exist.

The input file for this scenario is already saved in the **Repository**, so that all schema metadata is available.

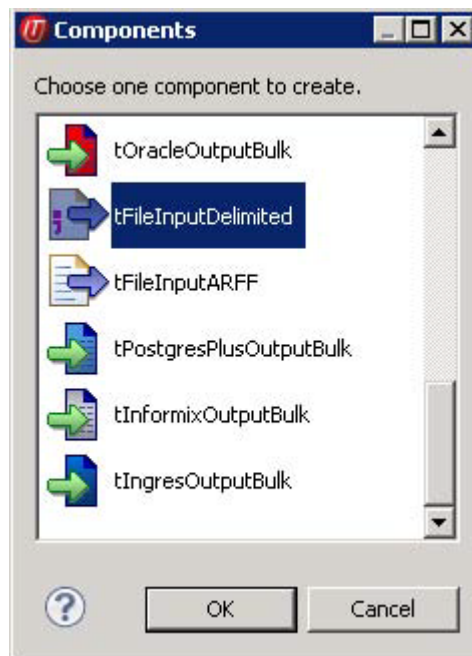

Please note that the data from the input source must be related to the same country.

### Dropping and connecting the components

1. In the **Repository** view, expand the **Metadata** node and the directory in which the file is saved. Then drag this file into the design workspace.

The dialog box below appears.

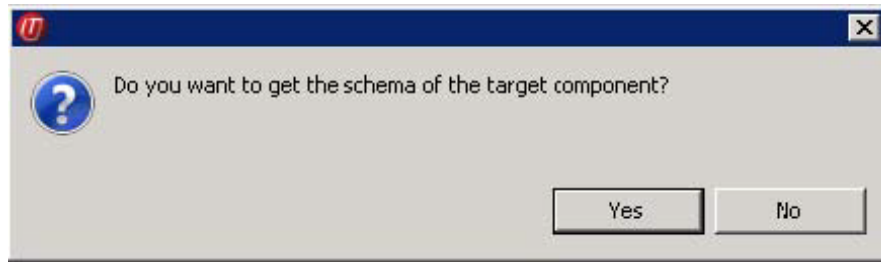

2. Select **tFileInputDelimited** and then click **OK** to close the dialog box.

The component is displayed in the workspace.

3. Drag the following components from the **Palette** into the design workspace: two **tMap** components, **tUniservRTMailSearch** and **tUniservRTMailOutput**.
4. Connect the components via **Row > Main**.

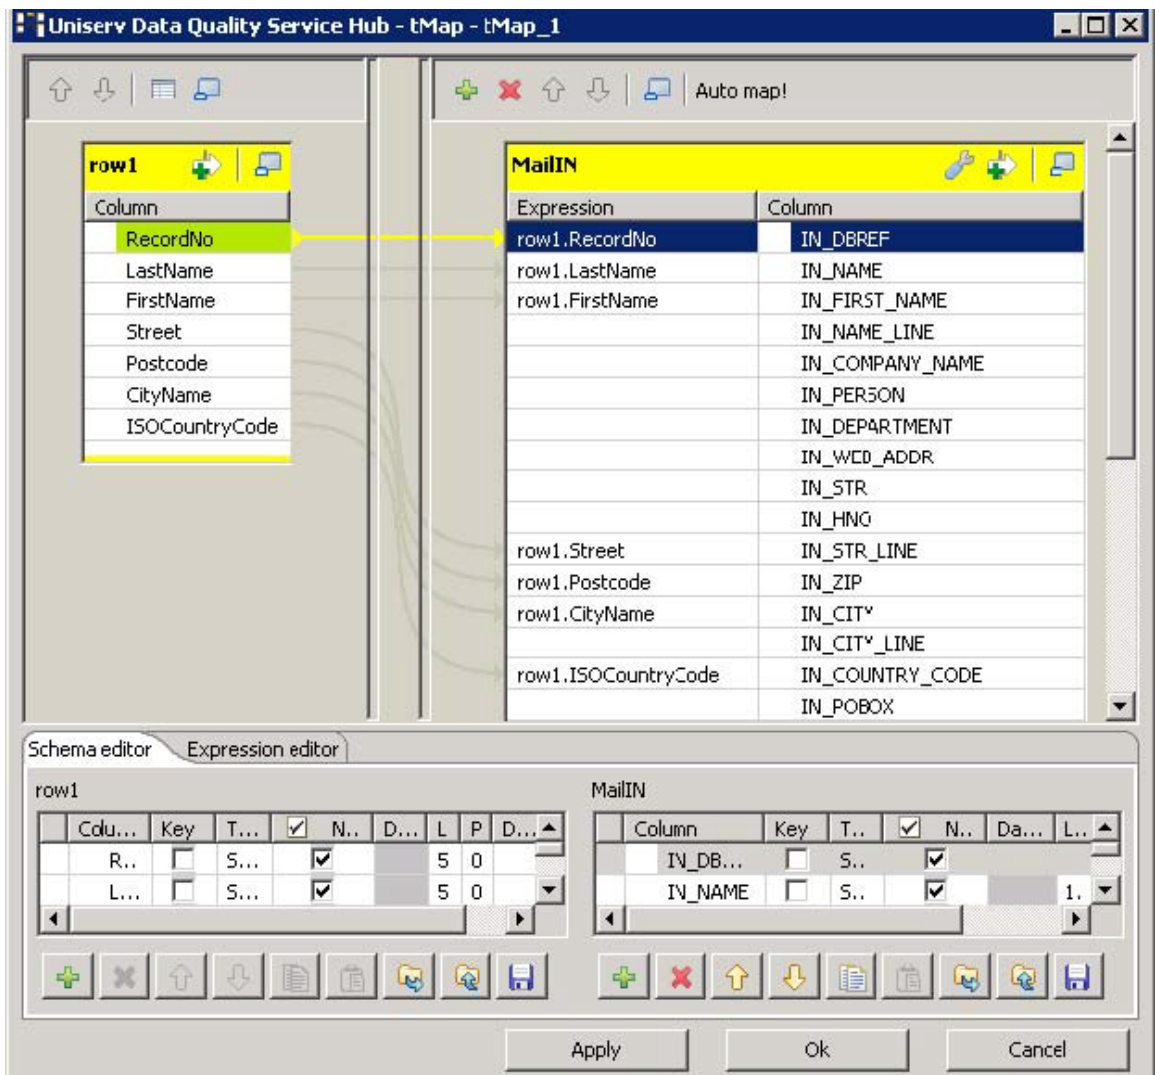

During the process, accept the schema from **tUniservRTMailSearch** by clicking **Yes** in the validation window.

## Configuring the components

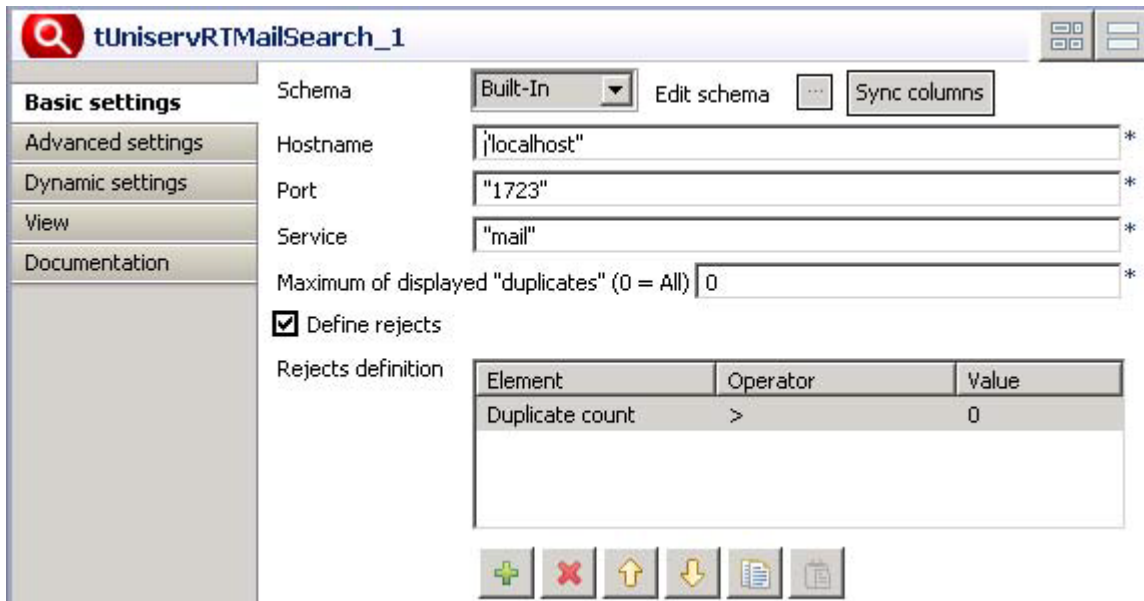

1. Double-click **tMap\_1** to open the schema mapping window. On the left is the structure of the input file and on the right is the schema of **tUniservRTMailSearch**. At the bottom lies the **Schema Editor**, where you can find the attributes of the individual columns and edit them.

2. Assign the columns of the input file to the respective columns of **tUniservRTMailSearch**. For this purpose, select a column of the input source and drag it onto the appropriate column on the right side.
3. When your input list contains a reference ID, you should adopt it. In order to do so, create a new column **IN\_DBREF** in the **Schema Editor** and connect it with your reference ID.

Click **OK** to close the window.

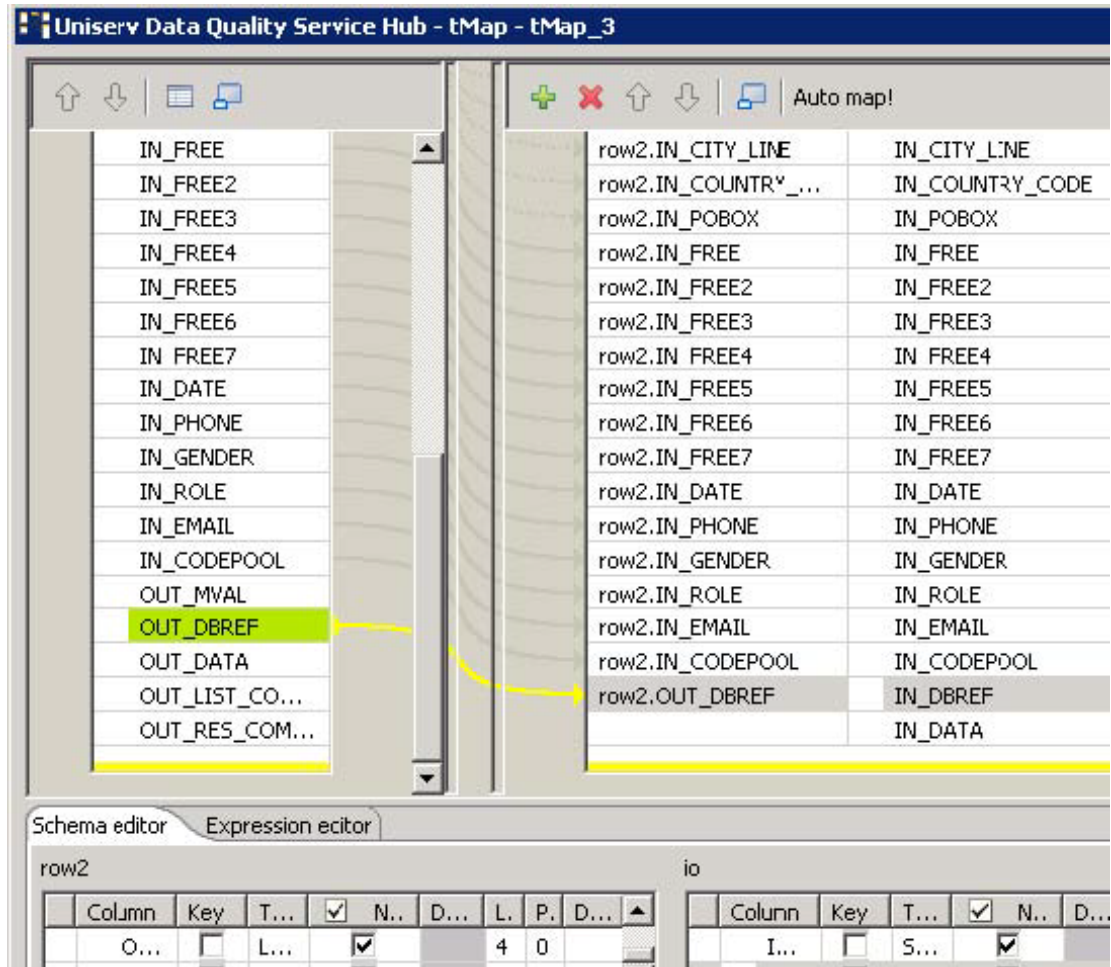

4. Double-click **tUniservRTMailSearch** to open its **Basic settings** view.

5. Under **Maximum of displayed "duplicates"**, enter *0* to display all the duplicates.

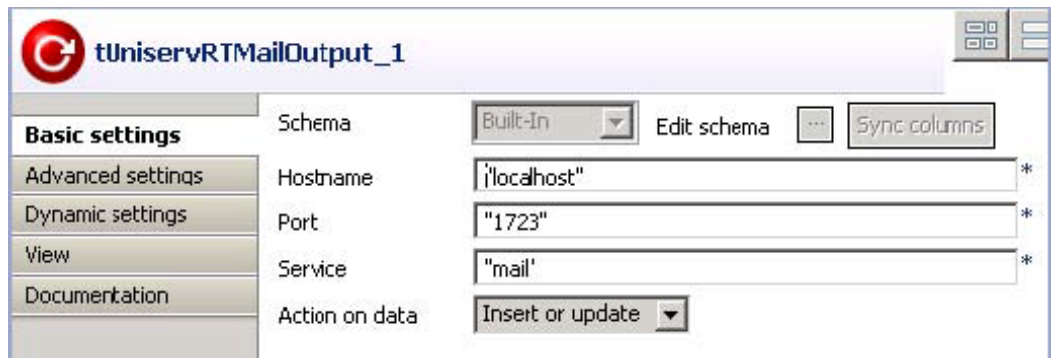

Select **Define rejects** to open the rejects definition window.

6. Click the [+] button to insert a new line in the window. Select *Duplicate count* under the element column, > under the operator column, and *0* under the value column. So all the existing contacts are disqualified and only the new contact will be added to the index pool.
7. Enter the **Advanced settings** view and check the parameters. Reasonable parameters are preset. Detailed information can be found in the manual *mailRetrieval*.
8. Double-click **tMap\_3** to open schema mapping window. On the left is the schema of **tUniservRTMailSearch** and on the right is the schema of **tUniservRTMailOutput**.
9. Click **Auto map!** to assign the fields automatically.
10. The only field that must be assigned manually is the reference ID. In order to do so, drag *OUT-DBREF* from the left side onto the field *IN\_DBREF* on the right side.

Click **OK** to close the dialog box.

- Double-click **tUniservRTMailOutput** to open the **Basic settings** view.

From the **Action on Data** list, select *Insert or update*. This way, all new contacts are added to the index pool.

# tUniservRTPost

This component will be available in the **Palette** of the studio on the condition that you have subscribed to the relevant edition of Data Quality Service Hub Studio.

For detailed information, please refer to the Uniserv user manual <i>International Postal Framework</i> .                                                                                                |
|                          | <i>tStatCatcher Statistics</i>                                                                                                                                                                                                                                                                                                                                                            | Select this check box to collect log data at the Job and the component levels.                                                                                                                                                                                         |
|                          | <i>“Full address” selection list</i>                                                                                                                                                                                                                                                                                                                                                      | Select the check box <b>Display</b> to show all the columns. Or, select the check box next to a particular column to show it alone.<br><br>This option controls the content of the file for ambiguous addresses. Only selected columns would be written into the file. |
| <b>Usage</b>             | <b>tUniservRTPost</b> requires an input set. Its postal validation will then be checked. In case of an unambiguous result, the corrected set will be output via the <b>Main</b> connection. If the address is ambiguous, the potential candidates will be output via the <b>Ambiguity</b> connection. If an address was not found, it will be passed on via the <b>Reject</b> connection. |                                                                                                                                                                                                                                                                        |
| <b>Limitation</b>        | To use <b>tUniservRTPost</b> , the Uniserv software <i>International Postal Framework</i> and the required post servers must be installed.                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                        |

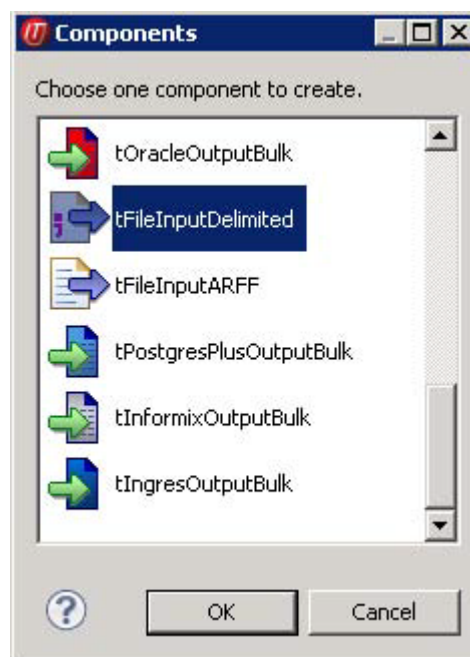

## Scenario 1: Checking and correcting the postal code, city and street

This scenario describes a batch job that checks and corrects the addresses and postal codes from a file.

The input file for this scenario is already saved in the **Repository**, so that all schema metadata is available.

1. In the **Repository** view, expand the **Metadata** node and the directory in which the file is saved. Then drag this file into the design workspace.

The dialog box below appears.

2. Select **tFileInputDelimited** and click **OK** to close the dialog box.

The component is displayed in the workspace. The file used in this scenario is called *SampleAddresses*. It contains address data that comes with a country code. The street and house number are saved together in the street field, while postal code and city are respectively saved in separate fields.

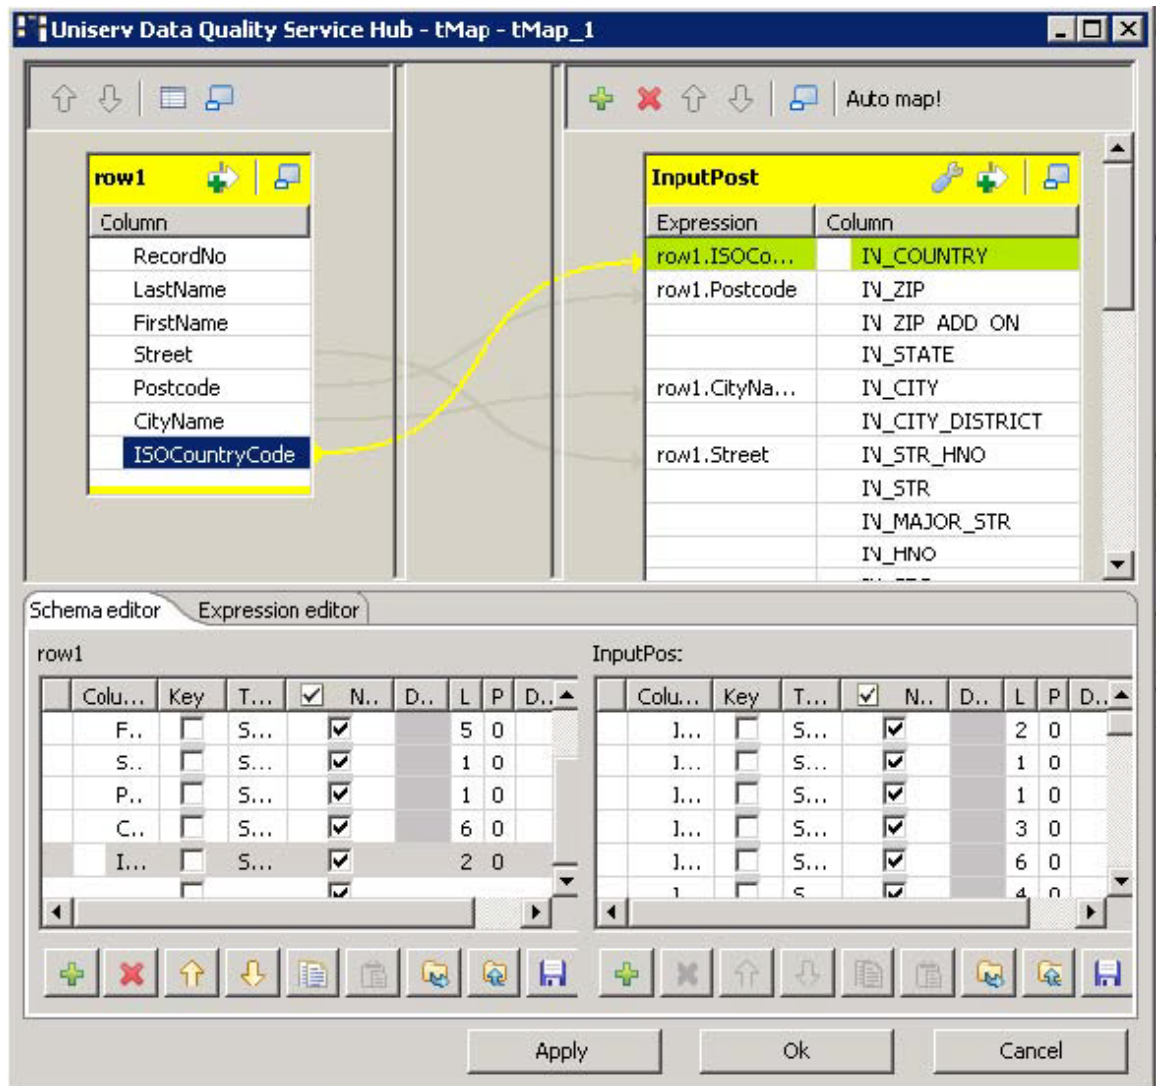

3. Drag the following components from the **Palette** into the design workspace: two **tMap** components, **tUniservRTPost** and **tFileOutputDelimited**.
4. Connect the components via **Row > Main**.

5. During the process, accept the schema from **tUniservRTPost** by clicking **Yes** in the validation window.

6. Double-click **tMap\_1** to open the schema mapping window. On the left is the structure of the input file and on the right is the schema of **tUniservRTPost**. At the bottom is displayed the **Schema Editor**, where you can find the attributes of the individual columns and edit them.

7. Assign the columns of the input file to the respective columns of **tUniservRTPost**. For this purpose, select a column of the input source and drag it onto the appropriate column on the right side. If fields from the input file are to be passed on to the output file, e.g. the names or the IDs, additional fields must be defined.

When assigning the fields, note that street and house number can either be saved together in the street column or respectively in separate fields. If your data list does not have a country code but the addresses are from the same country, the relevant ISO-country code should be manually entered between double quotation marks in the column *IN\_COUNTRY*. If you have an international data list without country code, just leave the column *IN\_COUNTRY* empty. For detailed information, please refer to the Uniserv user manual *International Postal Framework*.

8. Click **OK** to close the window.
9. Double-click **tUniservRTPost** and enter its **Advanced settings** view.

The screenshot shows the configuration interface for the **tUniservRTPost\_1** component. The left sidebar contains navigation options: Basic settings, **Advanced settings**, Dynamic settings, View, and Documentation. The main area is titled "Uniserv parameters" and includes several sections:

- Configuring Character Sets and Case
- Setting Field lengths, Abbreviations and Languages

Parameters for field lengths and abbreviations are set as follows:

- par\_language: English
- par\_client\_codepage: iso-8859-1
- par\_len\_out\_line: 99
- par\_city\_len: 40
- par\_str\_len: 40
- par\_city\_abbrev: UNI\_IT\_BEST
- par\_str\_abbrev: UNI\_IT\_BEST
- par\_alternative\_city: UNI\_LIKE\_INPUT
- par\_alternative\_str: UNI\_IKE\_INPUT

Other options include:

- Control over Address Elements
- Hints to Address Analysis Processing
- Miscellaneous
- Configuring ambiguity lists
- tStatCatcher Statistics

The "Full address" selection list table is shown below:

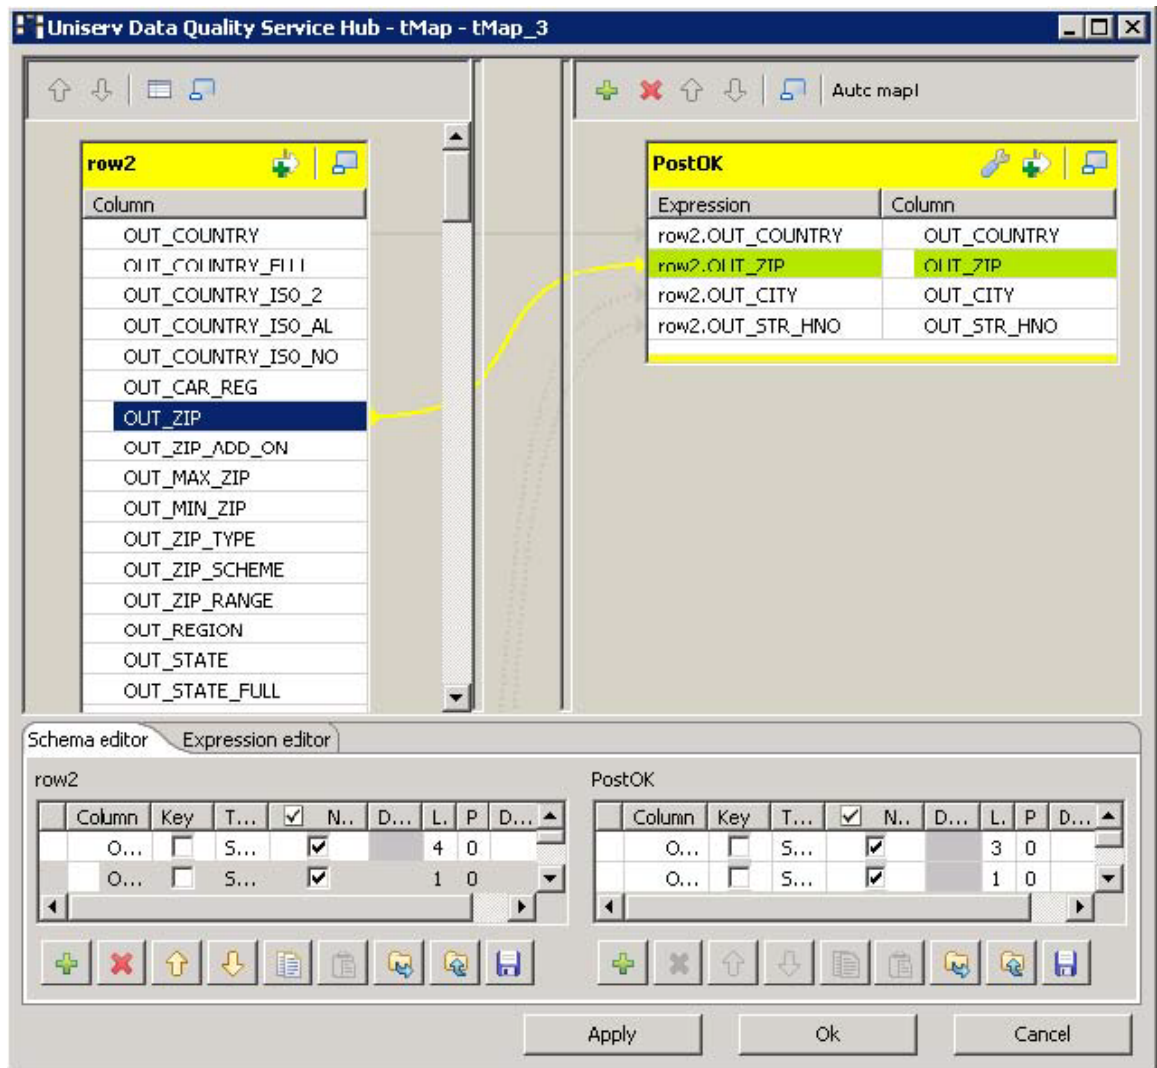

| Column            | Display                             |
|-------------------|-------------------------------------|
| OUT_BUILDING_NAME | <input checked="" type="checkbox"/> |
| OUT_CITY          | <input checked="" type="checkbox"/> |
| OUT_CITY_ABBREV   | <input checked="" type="checkbox"/> |
| OUT_CITY_DETAIL   | <input checked="" type="checkbox"/> |

10. Change the parameters and field lengths if necessary and select the output fields.

Make sure sufficient field length is defined. For detailed information, please refer to the Uniserv user manual *International Postal Framework*.

11. Double-click **tMap\_3** to open schema mapping window. On the left is the schema of **tUniservRTPost** and on the right is the schema of the output file.

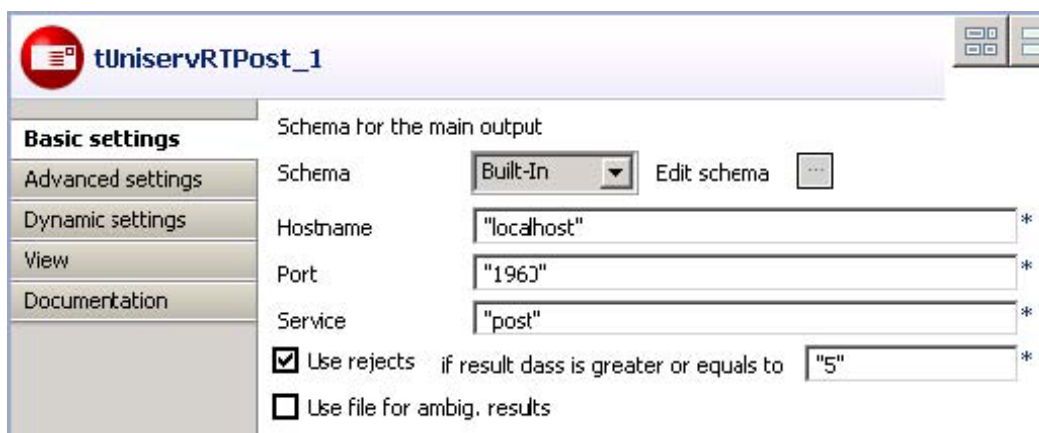

12. Click **OK** to close the dialog box.
13. Double-click **tFileOutputDelimited** to enter the details for the output file.

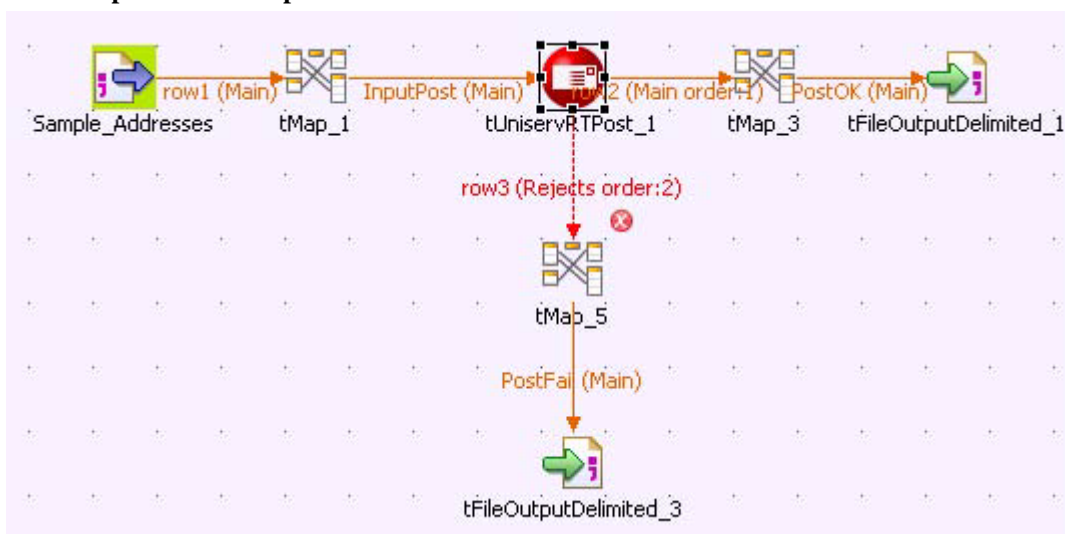

## Scenario 2: Checking and correcting the postal code, city and street, as well as rejecting the unfeasible

This scenario is closely related to the one above. But the difference is that, the addresses that cannot be assigned are written into a separate file for manual checking. Additionally, to write ambiguous addresses in a separate file, the procedure is the same as described here.

1. Create a job as described in the previous scenario.
2. Drag the following additional components from the **Palette** into the design workspace: **tMap** and **tFileOutputDelimited**.
3. Double-click **tUniservRTPost** to open its **Basic settings** view.
4. Select the **Use rejects** check box and enter "5" in the field **if result class greater or equals to**. This is the result class from the check of postal codes in addresses, which contain too few or unfeasible data.

- 5. Connect **tUniservRTPost** with **tMap\_5** via **Row > Rejects**.
- 6. Connect **tMap** with **tFileOutputDelimited** via **Row > Main**.

- 7. Define the fields for the output file in the mapping window.

## Databases - traditional components

This chapter describes connectors for the most popular and traditional databases. These connectors cover various needs, including: opening connections, reading and writing tables, committing transactions as a whole, as well as performing rollback for error handling. Over 40 RDBMS are supported. These components can be found in the **Databases** family in **Palette** of *Talend Open Studio for Big Data*.

Other types of database connectors, such as connectors for Appliance/DW databases and database management, are documented in [Databases - appliance/datawarehouse components](#) and [Databases - other components](#).

For *Talend Open Studio for Big Data*, the **Property type**, **Schema** and **Query Type** of components are always **Built-in**. For how to edit a Built-in schema, see *Talend Open Studio for Big Data User Guide*.

# tAccessBulkExec

## tAccessBulkExec properties

The **tAccessOutputBulk** and **tAccessBulkExec** components are generally used together to output data to a delimited file and then to perform various actions on the file in an Access database, in a two step process. These two steps are fused together in the **tAccessOutputBulkExec** component, detailed in a separate section. The advantage of using a two step process is that it makes it possible to carry out transformations on the data before loading it in the database.

- [the section called “Scenario: Inserting data in MySQL database”](#)

# tAccessCommit

## tAccessCommit Properties

This component is closely related to **tAccessConnection** and **tAccessRollback**. It usually doesn't make much sense to use these components independently in a transaction.

|                          |                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Related scenario

This component is closely related to **tAccessConnection** and **tAccessRollback**. It usually does not make much sense to use one of these without using a **tAccessConnection** component to open a connection for the current transaction.

For **tAccessCommit** related scenario, see [the section called "tMysqlConnection"](#)

# tAccessConnection

## tAccessConnection Properties

This component is closely related to **tAccessCommit**, **tAccessInput** and **tAccessOutput**. It usually does not make much sense to use one of these without using a **tAccessConnection** component to open a connection for the current transaction.

| <b>Usage</b>             | This component is to be used along with Access components, especially with <b>tAccessCommit</b> and <b>tAccessOutput</b> components.          |                                                                                                                                                                                                                                                                                                                                                  |
| <b>Limitation</b>        | n/a                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                  |

## Scenario: Inserting data in parent/child tables

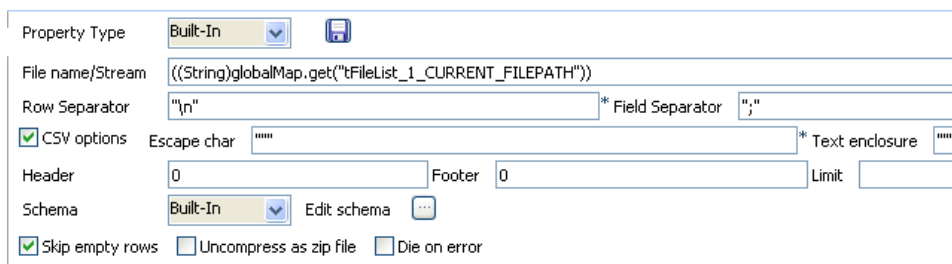

The following Job is dedicated to advanced database users, who want to carry out multiple table insertions using a parent table *Table1* to generate two child tables: *Name* and *Birthday*.

- In Access 2007, create an Access database named *Database1*.
- Once the Access database is created, create a table named *Table1* with two column headings: *Name* and *Birthday*.

Back into *Talend Open Studio for Big Data*, the Job requires twelve components including **tAccessConnection**, **tAccessCommit**, **tAccessInput**, **tAccessOutput** and **tAccessClose**.

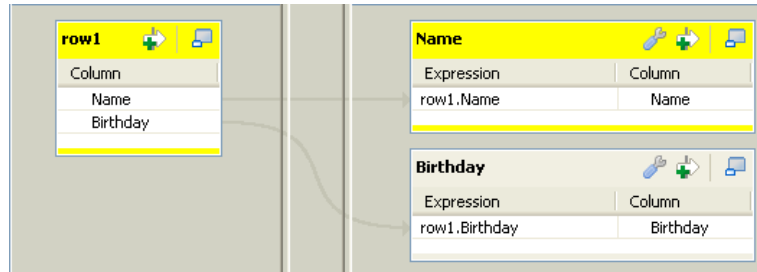

- Drop the following components from the **Palette** to the design workspace: **tFileList**, **tFileInputDelimited**, **tMap**, **tAccessOutput** (x2), **tAccessInput** (x2), **tAccessCommit**, **tAccessClose** and **tLogRow** (x2).
- Connect the **tFileList** component to the input file component using an **Iterate** link. Thus, the name of the file to be processed will be dynamically filled in from the **tFileList** directory using a global variable.
- Connect the **tFileInputDelimited** component to the **tMap** component and dispatch the flow between the two output Access components. Use a **Row** link for each of these connections representing the main data flow.
- Set the **tFileList** component properties, such as the directory where files will be fetched from.
- Add a **tAccessConnection** component and connect it to the starter component of this Job. In this example, the **tFileList** component uses an **OnComponentOk** link to define the execution order.
- In the **tAccessConnection** Component view, set the connection details.
- In the **tFileInputDelimited** component's **Basic settings** view, press **Ctrl+Space** bar to access the variable list. Set the **File Name** field to the global variable: `tFileList_1.CURRENT_FILEPATH`. For more information about using variables, see *Talend Open Studio for Big Data User Guide*.

- Set the rest of the fields as usual, defining the row and field separators according to your file structure.
- Then set the schema manually through the **Edit schema** dialog box. Make sure the data type is correctly set, in accordance with the nature of the data processed.

- In the **tMap** Output area, add two output tables, one called *Name* for the *Name* table, the second called *Birthday*, for the *Birthday* table. For more information about the **tMap** component, see *Talend Open Studio for Big Data User Guide*.
- Drag the *Name* column from the **Input** area, and drop it to the *Name* table.
- Drag the *Birthday* column from the **Input** area, and drop it to the *Birthday* table.

- Then connect the output row links to distribute the flow correctly to the relevant DB output components.
- In each of the **tAccessOutput** components' **Basic settings** view, select the **Use an existing connection** check box to retrieve the **tAccessConnection** details.

- Set the **Table** name making sure it corresponds to the correct table, in this example either *Name* or *Birthday*.
- There is no action on the table as they are already created.
- Select **Insert** as **Action on data** for both output components.
- Click on **Sync columns** to retrieve the schema set in the **tMap**.
- Then connect the first **tAccessOutput** component to the first **tAccessInput** component using an **OnComponentOk** link.
- In each of the **tAccessInput** components' **Basic settings** view, select the **Use an existing connection** check box to retrieve the distributed data flow. Then set the schema manually through **Edit schema** dialog box.
- Then set the **Table Name** accordingly. In **tAccessInput\_1**, this will be *Name*.
- Click on the **Guess Query**.
- Connect each **tAccessInput** component to **tLogRow** component with a **Row > Main** link. In each of the **tLogRow** components' **basic settings** view, select **Table** in the **Mode** field.
- Add the **tAccessCommit** component below the **tFileList** component in the design workspace and connect them together using an **OnComponentOk** link in order to terminate the Job with the transaction commit.
- In the **basic settings** view of **tAccessCommit** component and from the **Component list**, select the connection to be used, **tAccessConnection\_1** in this scenario.
- Save your Job and press **F6** to execute it.

```
Starting job Access at 18:02 28/12/2010.
[statistics] connecting to socket on port 3938
[statistics] connected

tLogRow_1
Name

| <b>Function</b>         | <b>tAccessInput</b> reads a database and extracts fields based on a query.                                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Purpose</b>          | <b>tAccessInput</b> executes a DB query with a strictly defined statement which must correspond to the schema definition. Then it passes on the field list to the next component via a <b>Row &gt; Main</b> connection. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                          | <i>Action on data</i>             | <p>On the data of the table defined, you can perform:</p> <p><b>Insert:</b> Add new entries to the table. If duplicates are found, Job stops.</p> <p><b>Update:</b> Make changes to existing entries.</p> <p><b>Insert or update:</b> Add entries or update existing ones.</p> <p><b>Update or insert:</b> Update existing entries or create it if non existing.</p> <p><b>Delete:</b> Remove entries corresponding to the input flow.</p> <p> <i>You must specify at least one column as a primary key on which the <b>Update</b> and <b>Delete</b> operations are based. You can do that by clicking <b>Edit Schema</b> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <b>Advanced settings</b> view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the <b>Use field options</b> check box and then in the <b>Key in update</b> column, select the check boxes next to the column name on which you want to base the update operation. Do the same in the <b>Key in delete</b> column for the deletion operation.</i></p> |
|                          | <i>Schema and Edit schema</i>     | <p>A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i>, the schema is always <b>Built-in</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing. |
|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <b>Name:</b> Type in the name of the schema column to be altered or inserted as new column                                                                                                                                                                     |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |  Make sure the Nullable check box is selected for the corresponding columns in the schema.                                                                                  |
| <b>Usage</b> | <p>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.</p> <p>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Access database. It also allows you to create a reject flow using a <b>Row &gt; Rejects</b> link to filSchemaSchemater data in error. For an example of <b>tMySQLOutput</b> in use, see <a href="#">the section called "Scenario 3: Retrieve data in error with a Reject link"</a>.</p> |                                                                                                                                                                                                                                                                |

# tAccessOutputBulk

## tAccessOutputBulk properties

The **tAccessOutputBulk** and **tAccessBulkExec** components are generally used together to output data to a delimited file and then to perform various actions on the file in an Access database, in a two step process. These two steps are fused together in the **tAccessOutputBulkExec** component, detailed in a separate section. The advantage of using a two step process is that it makes it possible to carry out transformations on the data before loading it in the database.

# tAccessOutputBulkExec

## tAccessOutputBulkExec properties

The **tAccessOutputBulk** and **tAccessBulkExec** components are generally used together to output data to a delimited file and then to perform various actions on the file in an Access database, in a two step process. These two steps are fused together in **tAccessOutputBulkExec**.

# tAccessRollback

## tAccessRollback properties

This component is closely related to **tAccessConnection** and **tAccessCommit** components. It usually does not make much sense to use these components independently in a transaction.

| <b>Function</b>         | <b>tAccessRow</b> is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Purpose</b>          | Depending on the nature of the query and the database, <b>tAccessRow</b> acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Limitation</b>        | n/a                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Related scenario

This component is closely related to **tAS400Connection** and **tAS400Rollback**. It usually does not make much sense to use one of these without using a **tAS400Connection** component to open a connection for the current transaction.

For **tAS400Commit** related scenario, see [the section called “tMysqlConnection”](#)

# tAS400Connection

## tAS400Connection Properties

This component is closely related to **tAS400Commit** and **tAS400Rollback**. It usually does not make much sense to use one of the components without using a **tAS400Connection** component to open a connection for the current transaction.

| <b>Usage</b>             | This component is to be used along with AS400components, especially with <b>tAS400Commit</b> and <b>tAS400Rollback</b> components.            |                                                                                                                                                                                                                                                                                                                                                  |
| <b>Limitation</b>        | n/a                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                  |

## Related scenario

This component is closely related to **tAS400Commit** and **tAS400Rollback**. It usually does not make much sense to use one of these without using a **tAS400Connection** component to open a connection for the current transaction.

For **tAS400Connection** related scenario, see [the section called “tMysqlConnection”](#)

| <b>Function</b>         | <b>tAS400Input</b> reads a database and extracts fields based on a query.                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Purpose</b>          | <b>tAS400SInput</b> executes a DB query with a strictly defined statement which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Basic settings</b>   | <i>Use an existing connection</i>                                                                                                                                                                     | <p>Select this check box and click the relevant <b>tAS400Connection</b> component on the Component list to reuse the connection details you already defined.</p> <p> When a Job contains the parent Job and the child Job, <b>Component list</b> presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, make sure that the available connection components are sharing the intended connection.</p> <p>For more information on how to share a DB connection across Job levels, see <b>Use or register a shared DB connection</b> in any database connection component corresponding to the database you are using.</p> <p>Otherwise, you can as well deactivate the connection components and use <b>Dynamic settings</b> of the component to specify the intended connection manually. In this case, make sure the connection name is unique and distinctive all over through the two Job levels. For more information about <b>Dynamic settings</b>, see <i>Talend Open Studio for Big Data User Guide</i>.</p> |

|                          | <i>Action on data</i>         | <p>On the data of the table defined, you can perform:</p> <p><b>Insert:</b> Add new entries to the table. If duplicates are found, Job stops.</p> <p><b>Update:</b> Make changes to existing entries</p> <p><b>Insert or update:</b> Add entries or update existing ones.</p> <p><b>Update or insert:</b> Update existing entries or create it if non existing</p> <p><b>Delete:</b> Remove entries corresponding to the input flow.</p> <p> <i>It is necessary to specify at least one column as a primary key on which the <b>Update</b> and <b>Delete</b> operations are based. You can do that by clicking <b>Edit Schema</b> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <b>Advanced settings</b> view where you can simultaneously define primary keys for the <b>Update</b> and <b>Delete</b> operations. To do that: Select the <b>Use field options</b> check box and then in the <b>Key in update column</b>, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the <b>Key in delete column</b> for the Delete operation.</i></p> |
|                          | <i>Schema and Edit schema</i> | <p>A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i>, the schema is always <b>Built-in</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <p><b>Usage</b></p> | <p>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.</p> <p>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a AS400 database. It also allows you to create a reject flow using a <b>Row &gt; Rejects</b> link to filter data in error. For an example of <b>tMySQLOutput</b> in use, see <a href="#">the section called “Scenario 3: Retrieve data in error with a Reject link”</a>.</p> |                                                                                                                                                                                                                                                                                                                                                                                                   |

# tAS400Rollback

## tAS400Rollback properties

This component is closely related to **tAS400Commit** and **tAS400Connection**. It usually does not make much sense to use these components independently in a transaction.

| <b>Function</b>         | <b>tAS400Row</b> is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Purpose</b>          | Depending on the nature of the query and the database, <b>tAS400Row</b> acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Basic settings</b>   | <i>Use an existing connection</i>                                                                                                                                                                                                            | <p>Select this check box and click the relevant <b>tAS400Connection</b> component on the Component list to reuse the connection details you already defined.</p> <p> When a Job contains the parent Job and the child Job, <b>Component list</b> presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, make sure that the available connection components are sharing the intended connection.</p> <p>For more information on how to share a DB connection across Job levels, see <b>Use or register a shared DB connection</b> in any database connection component corresponding to the database you are using.</p> <p>Otherwise, you can as well deactivate the connection components and use <b>Dynamic settings</b> of the component to specify the intended connection manually. In this case, make sure the connection name is unique and distinctive all over through the two Job levels. For more information about <b>Dynamic settings</b>, see <i>Talend Open Studio for Big Data User Guide</i>.</p> |

# tDB2Commit

## tDB2Commit Properties

This component is closely related to **tDB2Connection** and **tDB2Rollback**. It usually doesn't make much sense to use these components independently in a transaction.

## Related scenario

This component is closely related to **tDB2Connection** and **tDB2Rollback**. It usually doesn't make much sense to use one of these without using a **tDB2Connection** component to open a connection for the current transaction.

For **tDB2Commit** related scenario, see [the section called "tMysqlConnection"](#)

# tDB2Connection

## tDB2Connection properties

This component is closely related to **tDB2Commit** and **tDB2Rollback**. It usually does not make much sense to use one of these without using a **tDB2Connection** to open a connection for the current transaction.

| <b>Usage</b>             | This component is to be used along with DB2 components, especially with <b>tDB2Commit</b> and <b>tDB2Rollback</b> .                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                  |
| <b>Limitation</b>        | Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> . |                                                                                                                                                                                                                                                                                                                                                  |

## Related scenarios

This component is closely related to **tDB2Commit** and **tDB2Rollback**. It usually does not make much sense to use one of these without using a **tDB2Connection** component to open a connection for the current transaction.

For **tDB2Connection** related scenario, see [the section called “tMySQLConnection”](#)

| <b>Function</b>         | <b>tDB2Input</b> reads a database and extracts fields based on a query.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Purpose</b>          | <p><b>tDB2Input</b> executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a <b>Main</b> row link.</p> <p> If double quotes exist in the column names of a table, the double quotation marks cannot be retrieved when retrieving the column. Therefore, it is recommended not to use double quotes in column names in a DB2 database table.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

# tDB2Rollback

## tDB2Rollback properties

This component is closely related to **tDB2Commit** and **tDB2Connection**. It usually does not make much sense to use these components independently in a transaction.

|                          |                                                                                                                       |                                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Component family</b>  | Databases/DB2                                                                                                         |                                                                                                                     |
| <b>Function</b>          | <b>tDB2Rollback</b> cancels the transaction committed in the connected DB.                                            |                                                                                                                     |
| <b>Purpose</b>           | Avoids to commit part of a transaction involuntarily.                                                                 |                                                                                                                     |
| <b>Basic settings</b>    | <i>Component list</i>                                                                                                 | Select the <b>tDB2Connection</b> component in the list if more than one connection are planned for the current Job. |
|                          | <i>Close Connection</i>                                                                                               | Clear this check box to continue to use the selected connection once the component has performed its task.          |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                                                                        | Select this check box to collect log data at the component level.                                                   |
| <b>Usage</b>             | This component is to be used along with DB2 components, especially with <b>tDB2Connection</b> and <b>tDB2Commit</b> . |                                                                                                                     |

| <b>Function</b>         | <b>tDB2Row</b> is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Purpose</b>          | Depending on the nature of the query and the database, <b>tDB2Row</b> acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Basic settings</b>   | <i>Use an existing connection</i>                                                                                                                                                                                                          | <p>Select this check box and click the relevant <b>tDB2Connection</b> component on the <b>Component list</b> to reuse the connection details you already defined.</p> <p> When a Job contains the parent Job and the child Job, <b>Component list</b> presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, make sure that the available connection components are sharing the intended connection.</p> <p>For more information on how to share a DB connection across Job levels, see <b>Use or register a shared DB connection</b> in any database connection component corresponding to the database you are using.</p> <p>Otherwise, you can as well deactivate the connection components and use <b>Dynamic settings</b> of the component to specify the intended connection manually. In this case, make sure the connection name is unique and distinctive all over through the two Job levels. For more information about <b>Dynamic settings</b>, see your studio user guide.</p> |

| <b>Usage</b>             | This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Limitation</b>        | The Stored Procedures syntax should match the Database syntax.<br><br>Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> . |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Related scenarios

For related topic, see [the section called "Scenario: Executing a stored procedure in the MDM Hub"](#).

Check [the section called "tPostgresqlCommit"](#) as well if you want to analyze a set of records from a database table or DB query and return single records.

# tInformixBulkExec

## tInformixBulkExec Properties

**tInformixOutputBulk** and **tInformixBulkExec** are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the **tInformixOutputBulkExec** component, detailed in another section. The advantage of using two components is that data can be transformed before it is loaded in the database.

| <b>Usage</b>             | This component is generally used as an input component. It requires an output component. |                                                                                                        |
| <b>Limitation</b>        | n/a                                                                                      |                                                                                                        |

## Related scenario

This component is for use with **tInformixConnection** and **tInformixRollback**. They are generally used along with **tInformixConnection** as the latter allows you to open a connection for the transaction which is underway.

To see a scenario in which **tInformixClose** might be used, see [the section called “tMysqlConnection”](#).

# tInformixCommit

## tInformixCommit properties

This component is closely related to **tInformixConnection** and **tInformixRollback**. They are generally used to execute transactions together.

## Related Scenario

This component is for use with **tInformixConnection** and **tInformixRollback**. They are generally used along with **tInformixConnection** as the latter allows you to open a connection for the transaction which is underway

To see a scenario in which **tInformixCommit** might be used, see [the section called “tMysqlConnection”](#).

# tInformixConnection

## tInformixConnection properties

This component is closely related to **tInformixCommit** and **tInformixRollback**. They are generally used along with **tInformixConnection**, with **tInformixConnection** opening the connection for the transaction.

| <b>Function</b>         | <b>tInformixInput</b> reads a database and extracts fields based on a query.                                                                                                                                                                                                                                                                                          |                                                                                                                                                                                                              |
| <b>Purpose</b>          | <b>tInformixInput</b> executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.                                                                                                                                                                   |                                                                                                                                                                                                              |

|--------------------------|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                   | <p><b>Update or insert:</b> Update existing entries or create it if non existing</p> <p><b>Delete:</b> Remove entries corresponding to the input flow.</p> <p> <i>It is necessary to specify at least one column as a primary key on which the <b>Update</b> and <b>Delete</b> operations are based. You can do that by clicking <b>Edit Schema</b> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <b>Advanced settings</b> view where you can simultaneously define primary keys for the <b>Update</b> and <b>Delete</b> operations. To do that: Select the <b>Use field options</b> check box and then in the <b>Key in update column</b>, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the <b>Key in delete column</b> for the Delete operation.</i></p> |
|                          | <i>Schema and Edit schema</i>     | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                          |                                   | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                          | <i>Die on error</i>               | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <b>Row &gt; Rejects</b> link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Advanced settings</b> | <i>Additional parameters JDBC</i> | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <b>Use an existing connection</b> check box in the <b>Basic settings</b> .<br><br> You can press <b>Ctrl+Space</b> to access a list of predefined global variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                          | <i>Commit every</i>               | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at executions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                          | <i>Additional Columns</i>         | This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                          |                                   | <b>Name:</b> Type in the name of the schema column to be altered or inserted as new column                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                          |                                   | <b>SQL expression:</b> Type in the SQL statement to be executed in order to alter or insert the relevant column data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                   | <i>tStatCatcher Statistics</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Select this check box to collect log data at the component level.                                                                       |
| <b>Usage</b>      | <p>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.</p> <p>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Informix database. It also allows you to create a reject flow using a <b>Row &gt; Rejects</b> link to filter data in error. For an example of <b>tMySQLOutput</b> in use, see <a href="#">the section called “Scenario 3: Retrieve data in error with a Reject link”</a>.</p> |                                                                                                                                         |
| <b>Limitation</b> | <p>Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i>.</p>                                                                                                                                                        |                                                                                                                                         |

## Related scenarios

For **tInformixOutput** related topics, see:

- [the section called “Scenario: Writing a row to a table in the MySQL database via an ODBC connection”](#).
- [the section called “Scenario 1: Adding a new column and altering data in a DB table”](#).

# tInformixOutputBulk

## tInformixOutputBulk properties

**tInformixOutputBulk** and **tInformixBulkExec** are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the **tInformixOutputBulkExec** component, detailed in another section. The advantage of using two components is that data can be transformed before it is loaded in the database.

|                          | <i>Field separator</i>                                                                           | Character, string or regular expression used to separate fields                                                                                                                                              |
|                          | <i>Set DBMONEY</i>                                                                               | Select this box if you want to define the decimal separator in the corresponding field.                                                                                                                      |
|                          | <i>Set DBDATE</i>                                                                                | Select the date format that you want to apply.                                                                                                                                                               |
|                          | <i>Create directory if not exists</i>                                                            | This check box is selected automatically. The option allows you to create a folder for the output file if it doesn't already exist.                                                                          |
|                          | <i>Custom the flush buffer size</i>                                                              | Select this box in order to customize the memory size used to store the data temporarily. In the <b>Row number</b> field enter the number of rows at which point the memory should be freed.                 |
|                          | <i>Encoding</i>                                                                                  | Select the encoding from the list or select <b>Custom</b> and define it manually. This field is compulsory for DB data handling.                                                                             |

|                   |                                                                                                                                                                                                                                                                                                                                                                       |                                                                   |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
|                   | <i>tStatCatcher</i> Statistics                                                                                                                                                                                                                                                                                                                                        | Select this check box to collect log data at the component level. |
| <b>Usage</b>      | This component is generally used along with <b>tInformixBulkExec</b> . Together, they improve performance levels when adding data to an Informix database.                                                                                                                                                                                                            |                                                                   |
| <b>Limitation</b> | Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> . |                                                                   |

## Related scenario

For a scenario in which **tInformixOutputBulk** might be used, see:

- [the section called “Scenario: Inserting transformed data in MySQL database”](#).
- [the section called “Scenario: Inserting data in MySQL database”](#).

# tInformixOutputBulkExec

## tInformixOutputBulkExec properties

**tInformixOutputBulk** and **tInformixBulkExec** are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the **tInformixOutputBulkExec** component.

| <b>Function</b>         | <b>tInformixRow</b> is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Purpose</b>          | Depending on the nature of the query and the database, <b>tInformixRow</b> acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

In this case, only the entry parameters are authorized.                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Limitation</b>        | The stored procedure syntax must correspond to that of the database.<br><br>Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> . |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Related scenario

For a scenario in which **tInformixSP** may be used, see:

- [the section called “Scenario: Executing a stored procedure in the MDM Hub”](#).

- [the section called “Scenario: Checking number format using a stored procedure”](#).

Also, see [the section called “tPostgresqlCommit”](#) if you want to analyse a set of records in a table or SQL query.

# tMSSqlBulkExec

## tMSSqlBulkExec properties

The **tMSSqlOutputBulk** and **tMSSqlBulkExec** components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the **tMSSqlOutputBulkExec** component, detailed in a separate section. The advantage of using a two step process is that the data can be transformed before it is loaded in the database.

## Related scenarios

This component is closely related to **tMSSqlConnection** and **tMSSqlRollback**. It usually does not make much sense to use one of these without using a **tMSSqlConnection** component to open a connection for the current transaction.

For a **tMSSqlCommit** related scenario, see [the section called “Scenario: Inserting data in mother/daughter tables”](#).

# tMSSqlConnection

## tMSSqlConnection properties

This component is closely related to **tMSSqlCommit** and **tMSSqlRollback**. Both components are usually used with a **tMSSqlConnection** component to open a connection for the current transaction.

|                          | <i>tStatCatcher Statistics</i>                                                                                                                                                                                                                                                                                                                                        | Select this check box to gather the job processing metadata at a Job level as well as at each component level.                                                                                                                                                                                                                                   |
| <b>Usage</b>             | This component is to be used along with MSSql components, especially with <b>tMSSqlCommit</b> and <b>tMSSqlRollback</b> .                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                  |
| <b>Limitation</b>        | Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> . |                                                                                                                                                                                                                                                                                                                                                  |

## Related scenarios

This component is closely related to **tMSSqlCommit** and **tMSSqlRollback**. It usually does not make much sense to use one if these without using a **tMSSqlConnection** component to open a connection for the current transaction.

For **tMSSqlConnection** related scenario, see [the section called “Scenario: Inserting data in mother/daughter tables”](#).

# tMSSqlInput

## tMSSqlInput properties

|                         |                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Function</b>         | <b>tMSSqlInput</b> reads a database and extracts fields based on a query.                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Purpose</b>          | <b>tMSSqlInput</b> executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|  | <i>Action on table</i>         | <p>On the table defined, you can perform one of the following operations:</p> <p><b>Default:</b> No operation is carried out.</p> <p><b>Drop and create a table:</b> The table is removed and created again.</p> <p><b>Create a table:</b> The table does not exist and gets created.</p> <p><b>Create a table if not exists:</b> The table is created if it does not exist.</p> <p><b>Drop a table if exists and create:</b> The table is removed if it already exists and created again.</p> <p><b>Clear a table:</b> The table content is deleted.</p> <p><b>Truncate table:</b> The table content is deleted. You do not have the possibility to rollback the operation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|  | <i>Turn on identity insert</i> | <p>Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|  | <i>Action on data</i>          | <p>On the data of the table defined, you can perform:</p> <p><b>Insert:</b> Add new entries to the table. If duplicates are found, job stops.</p> <p><b>Single Insert Query:</b> Add entries to the table in a batch</p> <p><b>Update:</b> Make changes to existing entries</p> <p><b>Insert or update:</b> Add entries or update existing ones.</p> <p><b>Update or insert:</b> Update existing entries or create it if non existing</p> <p><b>Delete:</b> Remove entries corresponding to the input flow.</p> <p><b>Insert if not exist :</b> Add new entries to the table if they do not exist.</p> <p> <i>It is necessary to specify at least one column as a primary key on which the <b>Update</b> and <b>Delete</b> operations are based. You can do that by clicking <b>Edit Schema</b> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <b>Advanced settings</b> view where you can simultaneously define primary keys for the <b>Update</b> and <b>Delete</b> operations. To do that: Select the <b>Use field options</b> check box and then in the <b>Key in update column</b>, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the <b>Key in delete column</b> for the Delete operation.</i></p> |
|  | <i>Specify identity field</i>  | <p>Select this check box to specify the identity field, which is made up of an automatically incrementing identification</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                          |                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                          | <p>number. When this check box is selected, three other fields display:</p> <p><b>Identity field:</b> select the column you want to define as the identity field from the list.</p> <p><b>Start value:</b> type in a start value, used for the very first row loaded into the table.</p> <p><b>Step:</b> type in an incremental value, added to the value of the previous row that was loaded.</p> <p> You can also specify the identity field from the schema of the component. To do so, set the <b>DB Type</b> of the relevant column to <b>INT IDENTITY</b>.</p> <p> When the <b>Specify identity field</b> check box is selected, the <b>INT IDENTITY DB Type</b> in the schema is ignored.</p> |
|                          | <i>Schema and Edit schema</i>            | <p>A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i>, the schema is always <b>Built-in</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                          |                                          | <p><b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                          | <i>Die on error</i>                      | <p>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <b>Row &gt; Rejects</b> link.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Advanced settings</b> | <i>Additional parameters</i> <i>JDBC</i> | <p>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <b>Use an existing connection</b> check box in the <b>Basic settings</b>.</p> <p> You can press <b>Ctrl+Space</b> to access a list of predefined global variables.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                          | <i>Commit every</i>                      | <p>Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                          | <i>Additional Columns</i>                | <p>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Usage</b>      | <p>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.</p> <p>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a MSSql database. It also allows you to create a reject flow using a <b>Row &gt; Rejects</b> link to filter data in error. For an example of <b>tMySQLOutput</b> in use, see <a href="#">the section called “Scenario 3: Retrieve data in error with a Reject link”</a>.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Limitation</b> | <p>Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i>. For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i>.</p>                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Related scenarios

For **tMSSqlOutput** related topics, see:

- [the section called “Scenario: Writing a row to a table in the MySQL database via an ODBC connection”](#).
- [the section called “Scenario 1: Adding a new column and altering data in a DB table”](#).

# tMSSqlOutputBulk

## tMSSqlOutputBulk properties

The **tMSSqlOutputBulk** and **tMSSqlBulkExec** components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the **tMSSqlOutputBulkExec** component, detailed in a separate section. The advantage of using a two step process is that the data can be transformed before it is loaded in the database.

This field is compulsory for DB data handling.                                                                             |
|                          | <i>tStatcher statistics</i>                                                                                                                            | Select this check box to collect log data at the component level.                                                                                                                                            |
| <b>Usage</b>             | This component is to be used along with <b>tMSSqlBulkExec</b> component. Used together they offer gains in performance while feeding a MSSql database. |                                                                                                                                                                                                              |

## Related scenarios

For use cases in relation with **tMSSqlOutputBulk**, see the following scenarios:

- [the section called “Scenario: Inserting transformed data in MySQL database”](#).
- [the section called “Scenario: Inserting data in MySQL database”](#).

# tMSSqlOutputBulkExec

## tMSSqlOutputBulkExec properties

The **tMSSqlOutputBulk** and **tMSSqlBulkExec** components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the **tMSSqlOutputBulkExec** component.

|                   | <i>Encoding</i>                                                                                                         | Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling. |
|                   | <i>tStaCatcher statistics</i>                                                                                           | Select this check box to collect log data at the component level.                                                         |
| <b>Usage</b>      | This component is mainly used when no particular transformation is required on the data to be loaded onto the database. |                                                                                                                           |
| <b>Limitation</b> | n/a                                                                                                                     |                                                                                                                           |

## Related scenarios

For use cases in relation with **tMSSqlOutputBulkExec**, see the following scenarios:

- [the section called “Scenario: Inserting transformed data in MySQL database”](#)
- [the section called “Scenario: Inserting data in MySQL database”](#)

# tMSSqlRollback

## tMSSqlRollback properties

This component is closely related to **tMSSqlCommit** and **tMSSqlConnection**. It usually doesn't make much sense to use these components independently in a transaction.

| <b>Function</b>         | <b>tMSSqlRow</b> is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Purpose</b>          | Depending on the nature of the query and the database, <b>tMSSqlRow</b> acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                          | <i>Guess Query</i>              |                | Click the <b>Guess Query</b> button to generate the query which corresponds to your table schema in the <b>Query</b> field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                          | <i>Query</i>                    |                | Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                          | <i>Die on error</i>             |                | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <b>Row &gt; Rejects</b> link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Advanced settings</b> | <i>Additional parameters</i>    | <i>JDBC</i>    | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <b>Use an existing connection</b> check box in the <b>Basic settings</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                          | <i>Propagate recordset</i>      | <i>QUERY's</i> | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the <b>use column</b> list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                          | <i>Use PreparedStatement</i>    |                | Select this checkbox if you want to query the database using a PreparedStatement. In the <b>Set PreparedStatement Parameter</b> table, define the parameters represented by “?” in the SQL instruction of the <b>Query</b> field in the <b>Basic Settings</b> tab.<br><br><b>Parameter Index:</b> Enter the parameter position in the SQL instruction.<br><br><b>Parameter Type:</b> Enter the parameter type.<br><br><b>Parameter Value:</b> Enter the parameter value.<br><br> This option is very useful if you need to execute the same query several times. Performance levels are increased |
|                          | <i>Commit every</i>             |                | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                          | <i>tStat Catcher Statistics</i> |                | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

---

|                   |                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage</b>      | This component offers the flexibility of the DB query and covers all possible SQL queries.                                                                                                                                                                                                                                                                            |
| <b>Limitation</b> | Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> . |

## tMSSqlTableList Properties

|                          |                                                                                                     |                                                                                                                       |
|--------------------------|-----------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>Component family</b>  | Databases/MS SQL                                                                                    |                                                                                                                       |
| <b>Function</b>          | Iterates on a set of table names through a defined MS SQL connection.                               |                                                                                                                       |
| <b>Purpose</b>           | Lists the names of a given set of MSSql tables using a select statement based on a Where clause.    |                                                                                                                       |
| <b>Basic settings</b>    | <i>Component list</i>                                                                               | Select the <b>tMSSqlConnection</b> component in the list if more than one connection are planned for the current job. |
|                          | Where clause for table name selection                                                               | Enter the Where clause to identify the tables to iterate on.                                                          |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                                                      | Select this check box to collect log data at the component level.                                                     |
| <b>Usage</b>             | This component is to be used along with MSSql components, especially with <b>tMSSqlConnection</b> . |                                                                                                                       |
| <b>Limitation</b>        | n/a                                                                                                 |                                                                                                                       |

## Related scenario

For **tMSSqlTableList** related scenario, see [the section called “Scenario: Iterating on a DB table and listing its column names”](#).

# tMysqlBulkExec

## tMysqlBulkExec properties

The **tMysqlOutputBulk** and **tMysqlBulkExec** components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the **tMysqlOutputBulkExec** component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

|                         |                                                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Scenario: Iterating on a DB table and listing its column names

The following Java scenario creates a five-component job that iterates on a given table name from a Mysql database using a Where clause and lists all column names present in the table.

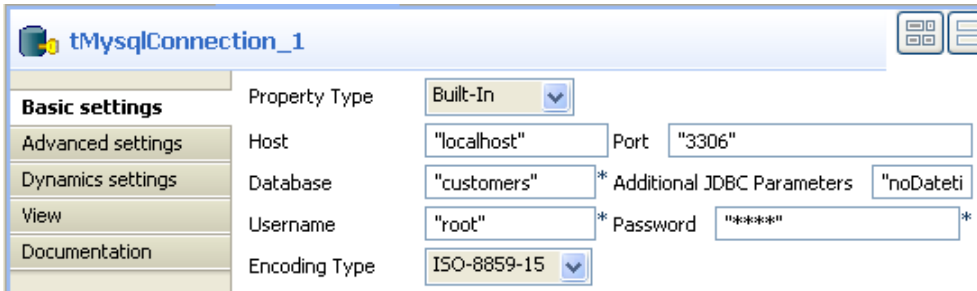

- Drop the following components from the **Palette** onto the design workspace: **tMysqlConnection**, **tMysqlTableList**, **tMysqlColumnList**, **tFixedFlowInput**, and **tLogRow**.
- Connect **tMysqlConnection** to **tMysqlTableList** using an **OnSubjobOk** link.
- Connect **tMysqlTableList**, **tMysqlColumnList**, and **tFixedFlowInput** using **Iterate** links.
- Connect **tFixedFlowInput** to **tLogRow** using a **Row Main** link.

- In the design workspace, select **tMysqlConnection** and click the **Component** tab to define its basic settings.

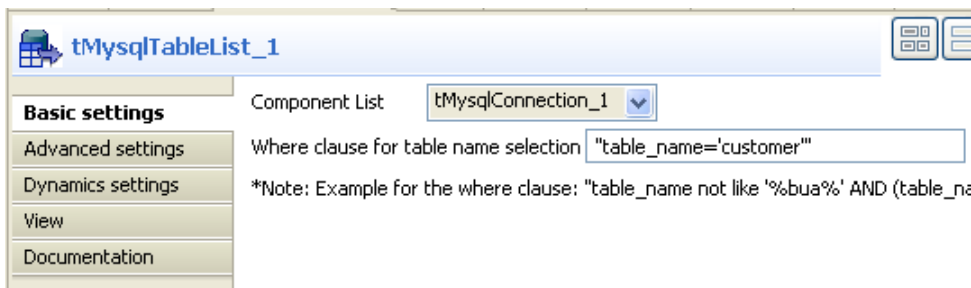

- In the **Basic settings** view, set the database connection details manually or select them from the context variable list, through a **Ctrl+Space** click in the corresponding field if you have stored them locally as Metadata DB connection entries.

For more information about Metadata, see *Talend Open Studio for Big Data User Guide*.

In this example, we want to connect to a Mysql database called *customers*.

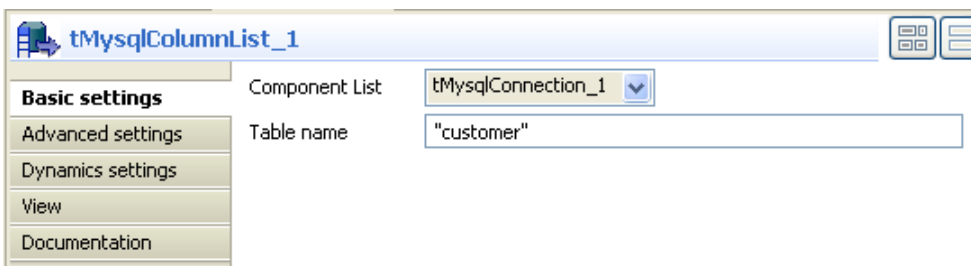

- In the design workspace, select **tMysqlTableList** and click the **Component** tab to define its basic settings.

- On the **Component list**, select the relevant Mysql connection component if more than one connection is used.
- Enter a Where clause using the right syntax in the corresponding field to iterate on the table name(s) you want to list on the console.

In this scenario, the table we want to iterate on is called *customer*.

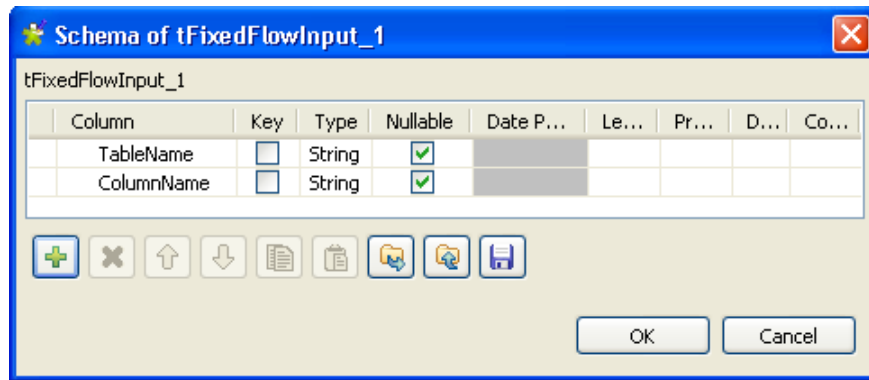

- In the design workspace, select **tMysqlColumnList** and click the **Component** tab to define its basic settings.

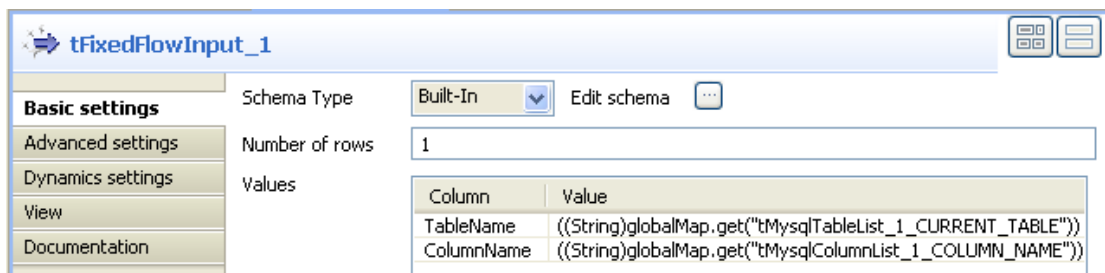

- On the **Component list**, select the relevant Mysql connection component if more than one connection is used.
- In the **Table name** field, enter the name of the DB table you want to list its column names.

In this scenario, we want to list the columns present in the DB table called *customer*.

- In the design workspace, select **tFixedFlowInput** and click the **Component** tab to define its basic settings.
- Set the **Schema to Built-In** and click the three-dot [...] button next to **Edit Schema** to define the data you want to use as input. In this scenario, the schema is made of two columns, the first for the table name and the second for the column name.

- Click **OK** to close the dialog box, and accept propagating the changes when prompted by the system. The defined columns display in the **Values** panel of the **Basic settings** view.
- Click in the **Value** cell for each of the two defined columns and press **Ctrl+Space** to access the global variable list.
- From the global variable list, select `((String)globalMap.get("tMysqlTableList_1_CURRENT_TABLE"))` and `((String)globalMap.get("tMysqlColumnList_1_COLUMN_NAME"))` for the *TableName* and *ColumnName* respectively.

- In the design workspace, select **tLogRow**.
- Click the **Component** tab and define the basic settings for **tLogRow** as needed.
- Save your job and press **F6** to execute it.

```
Starting job Column_Table_List at 00:55 17/11/2008.
customer|id
customer|First_Name
customer|Last_Name
customer|Address
customer|id_State
Job Column_Table_List ended at 00:55 17/11/2008. [exit code=0]
```

The name of the DB table is displayed on the console along with all its column names.

# tMysqlCommit

## tMysqlCommit Properties

This component is closely related to **tMysqlConnection** and **tMysqlRollback**. It usually doesn't make much sense to use these components independently in a transaction.

## Related scenario

This component is closely related to **tMysqlConnection** and **tMysqlRollback**. It usually doesn't make much sense to use one of these without using a **tMysqlConnection** component to open a connection for the current transaction.

For **tMysqlCommit** related scenario, see [the section called "Scenario: Inserting data in mother/daughter tables"](#).

# tMysqlConnection

## tMysqlConnection Properties

This component is closely related to **tMysqlCommit** and **tMysqlRollback**. It usually doesn't make much sense to use one of these without using a **tMysqlConnection** component to open a connection for the current transaction.

|                         |                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Component family</b> | Databases/MySQL                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                  |
| <b>Function</b>         | Opens a connection to the database for a current transaction.                                                                                 |                                                                                                                                                                                                                                                                                                                                                  |
| <b>Purpose</b>          | This component allows you to commit all of the Job data to an output database in just a single transaction, once the data has been validated. |                                                                                                                                                                                                                                                                                                                                                  |
| <b>Basic settings</b>   | <i>Property type</i>                                                                                                                          | In <i>Talend Open Studio for Big Data</i> , the Property type is always <b>Built-in</b> .                                                                                                                                                                                                                                                        |
|                         |                                                                                                                                               | <b>Built-in:</b> No property data stored centrally.                                                                                                                                                                                                                                                                                              |

|                         | <i>Use or register a shared DB Connection</i>                                                                                                 | Select this check box to share your connection or fetch a connection shared by a parent or child Job. This allows you to share one single DB connection among several DB connection components from different Job levels that can be either parent or child.<br><br><b>Shared DB Connection Name:</b> set or type in the shared connection name. |
| <b>Usage</b>            | This component is to be used along with Mysql components, especially with <b>tMysqlCommit</b> and <b>tMysqlRollback</b> components.           |                                                                                                                                                                                                                                                                                                                                                  |
| <b>Limitation</b>       | n/a                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                  |

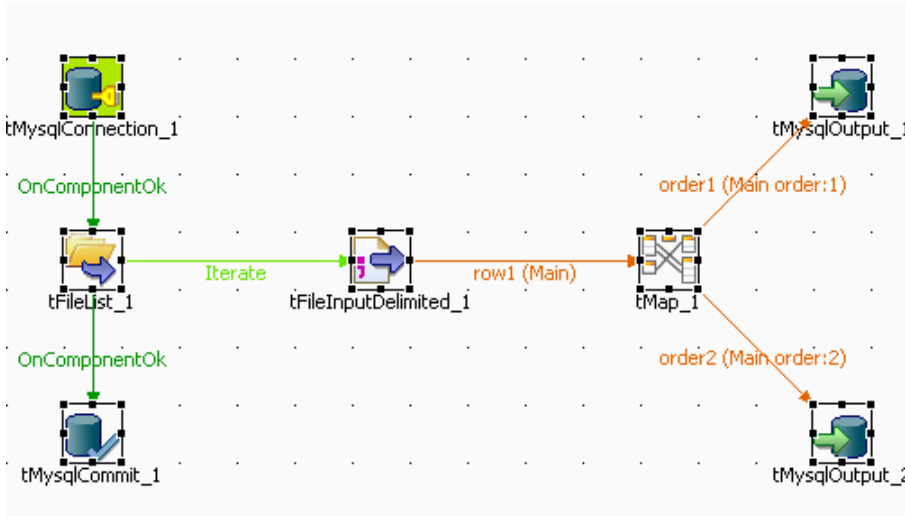

## Scenario: Inserting data in mother/daughter tables

The following Job is dedicated to advanced database users, who want to carry out multiple table insertions using a parent table id to feed a child table. As a prerequisite to this Job, follow the steps described below to create the relevant tables using an engine such as *innodb*.

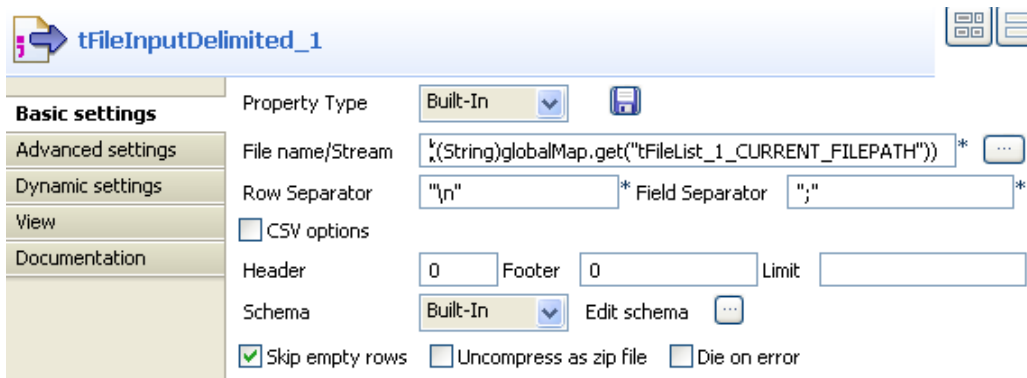

- In a command line editor, connect to your Mysql server.
- Once connected to the relevant database, type in the following command to create the parent table: create table f1090\_mum(id int not null auto\_increment, name varchar(10), primary key(id)) engine=innodb;

- Then create the second table: create table baby (id\_baby int not null, years int) engine=innodb;

Back in *Talend Open Studio for Big Data*, the Job requires seven components including **tMysqlConnection** and **tMysqlCommit**.

- Drag and drop the following components from the **Palette**: **tFileList**, **tFileInputDelimited**, **tMap**, **tMysqlOutput** (x2).
- Connect the **tFileList** component to the input file component using an **Iterate** link as the name of the file to be processed will be dynamically filled in from the **tFileList** directory using a global variable.
- Connect the **tFileInputDelimited** component to the **tMap** and dispatch the flow between the two output Mysql DB components. Use a **Row** link for each for these connections representing the main data flow.
- Set the **tFileList** component properties, such as the directory. name where files will be fetched from.
- Add a **tMysqlConnection** component and connect it to the starter component of this job, in this example, the **tFileList** component using an **OnComponentOk** link to define the execution order.
- In the **tMysqlConnection** Component view, set the connection details.
- On the **tFileInputDelimited** component's **Basic settings** panel, press **Ctrl+Space** bar to access the variable list. Set the **File Name** field to the global variable: `tFileList_1.CURRENT_FILEPATH`

- Set the rest of the fields as usual, defining the row and field separators according to your file structure.
- Then set the schema manually through the **Edit schema** feature or select the schema from the Repository. In Java version, make sure the data type is correctly set, in accordance with the nature of the data processed.
- In the **tMap** Output area, add two output tables, one called mum for the parent table, the second called baby, for the child table.

- Drag the *Name* column from the **Input** area, and drop it to the mum table.
- Drag the *Years* column from the **Input** area and drop it to the baby table.

- Make sure the mum table is on the top of the baby table as the order is determining for the flow sequence hence the DB insert to perform correctly.
- Then connect the output row link to distribute correctly the flow to the relevant DB output component.
- In each of the **tMySQLOutput** components' **Basic settings** panel, select the **Use an existing connection** check box to retrieve the **tMySQLConnection** details.

**tMySQLOutput\_2**

Property Type: Built-In

Use an existing connection    Component List: tMySQLConnection\_1

Table: 'f1090\_baby'

Action on table: None    Action on data: Insert

Schema Type: Built-In    Edit schema    Sync columns

Encoding Type: ISO-8859-15

Additional columns

| Name      | SQL expression           | Position | Reference column |
|-----------|--------------------------|----------|------------------|
| 'id_baby' | '(Select Last_Insert...' | Before   | years            |

- Set the **Table** name making sure it corresponds to the correct table, in this example either *f1090\_mum* or *f1090\_baby*.
- There is no action on the table as they are already created.
- Select **Insert** as **Action on data** for both output components.
- Click on Sync columns to retrieve the schema set in the **tMap**.
- In the **Additional columns** area of the DB output component corresponding to the child table (*f1090\_baby*), set the *id\_baby* column so that it reuses the *id* from the parent table.
- In the **SQL expression** field type in: '(Select Last\_Insert\_id()'
- The position is *Before* and the **Reference column** is *years*.
- Add the **tMySQLCommit** component to the design workspace and connect it from the **tFileList** component using a **OnComponentOk** connection in order for the Job to terminate with the transaction commit.
- On the **tMySQLCommit Component** view, select in the list the connection to be used.
- Save your Job and press **F6** to execute it.

```
mysql> select * from f1090_mum
-> ;
+----+-----+
| id | names |
+----+-----+
6	john
7	bruce
8	beth
9	andrew
10	donald
11	betty
12	john
13	bruce
14	beth
15	andrew
16	donald
17	betty
+----+-----+
12 rows in set (0.00 sec)
```

```
mysql> select * from f1090_baby
-> ;
+-----+-----+
| id_baby | years |
+-----+-----+
6	10
7	23
8	34
9	10
10	23
11	34
12	10
13	23
14	34
15	10
16	23
17	34
+-----+-----+
12 rows in set (0.00 sec)
```

The parent table *id* has been reused to feed the *id\_baby* column.

# tMysqlInput

## tMysqlInput properties

|                         |                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Function</b>         | <b>tMysqlInput</b> reads a database and extracts fields based on a query.                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Purpose</b>          | <b>tMysqlInput</b> executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a <b>Main</b> row link. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Usage</b>             | This component covers all possible SQL queries for Mysql databases. |                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Scenario 1: Writing columns from a MySQL database to an output file

In this scenario we will read certain columns from a MySQL database, and then write them to a table in a local output file.

### Dragging and dropping components and linking them together

1. Drop **tMySQLInput** and **tFileOutputDelimited** from the **Palette** onto the workspace.
2. Link **tMySQLInput** to **tFileOutputDelimited** using a **Row > Main** connection.

### Configuring the components

1. Double-click **tMySQLInput** to open its **Basic Settings** view in the **Component** tab.

**mysql(tMySQLInput\_3)**

**Basic settings**

Property Type: Repository | DB (MYSQL):mysql

Advanced settings

DB Version: Mysql 5

Use an existing connection

Host: "localhost" | Port: "3306"

Database: "test"

Username: "root" | Password: \*\*\*\*\*

Schema: Built-In | Edit schema

Table Name: "employees"

Query Type: Built-In | Guess Query | Guess schema

Query: "select id, first\_name, city, salary from employees"

 For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query type** of components are always **Built-in**. You have to complete the relevant settings manually in the specific Job.

2. Define the DB connection details in the corresponding fields.
3. Click **Edit schema** to define the desired schema.

The schema editor opens:

**Schema of mysql**

mysql

| Column     | Db Column  | Key                                 | T...  | DB Type | ✓                                   | N.. | Date ... | L... | P... | D.. |
|------------|------------|-------------------------------------|-------|---------|-------------------------------------|-----|----------|------|------|-----|
| id         | id         | <input checked="" type="checkbox"/> | int   | INT     | <input type="checkbox"/>            |     |          | 10   | 0    | "0" |
| first_name | first_name | <input type="checkbox"/>            | St... | VARCHAR | <input checked="" type="checkbox"/> |     |          | 30   | 0    |     |
| city       | city       | <input type="checkbox"/>            | St... | VARCHAR | <input checked="" type="checkbox"/> |     |          | 30   | 0    |     |
| salary     | salary     | <input type="checkbox"/>            | In... | INT     | <input checked="" type="checkbox"/> |     |          | 10   | 0    |     |

OK Cancel

4. Click the [+] button to add the rows that you will use to define the schema, four columns in this example *id*, *first\_name*, *city* and *salary*.

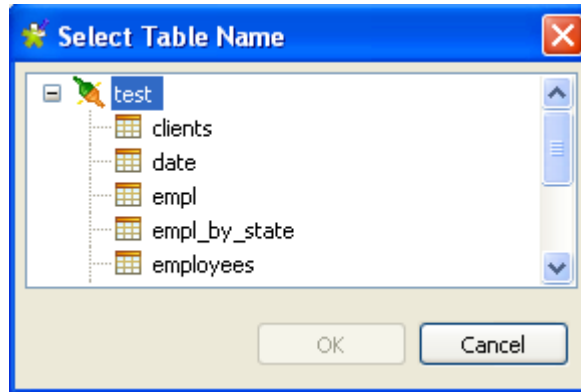

Under **Column**, click in the fields to enter the corresponding column names.

Click the field under **Type** to define the type of data.

Click **OK** to close the schema editor.

5. Next to the **Table Name** field, click the [...] button to select the database table of interest.

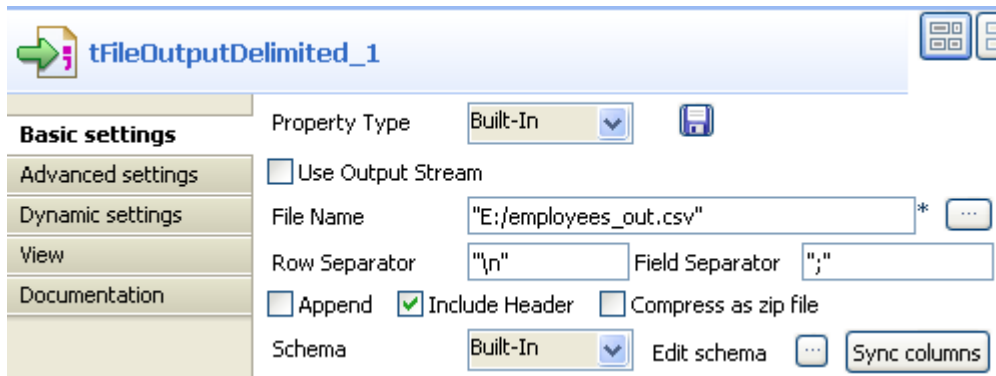

A dialog box displays a tree diagram of all the tables in the selected database:

6. Click the table of interest and then click **OK** to close the dialog box.
7. In the **Query** box, enter the query required to retrieve the desired columns from the table.

8. Double-click **tFileOutputDelimited** to set its **Basic settings** in the **Component** tab.

9. Next to the **File Name** field, click the [...] button to browse your directory to where you want to save the output file, then enter a name for the file.

Select the **Include Header** check box to retrieve the column names as well as the data.

10. Save the Job.

## Executing the Job

The results below can be found after **F6** is pressed to run the Job.

```

1 id;first_name;city;salary
2 1;Martin;Sacramento;9011
3 2;Zachary;Atlanta;8118
4 3;James;Hartford;5087
5 4;Herbert;Charleston;9233
6 5;Herbert;Hartford;6289
7 6;Ulysses;Nashville;6269

```

As shown above, the output file is written with the desired column names and corresponding data, retrieved from the database:

-  The Job can also be run in the **Traces Debug** mode, which allows you to view the rows as they are being written to the output file, in the workspace.

## Scenario 2: Using context parameters when reading a table from a MySQL database

In this scenario, we will read a table from a MySQL database, using a context parameter to refer to the table name.

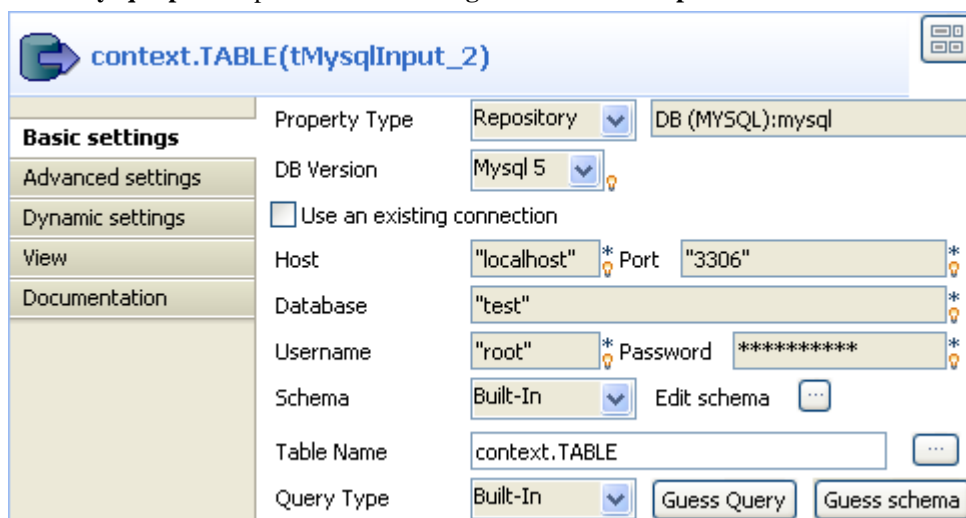

### Dragging and dropping components and linking them together

1. Drop **tMySQLInput** and **tLogRow** from the **Palette** onto the workspace.
2. Link **tMySQLInput** to **tLogRow** using a **Row > Main** connection.

### Configuring the components

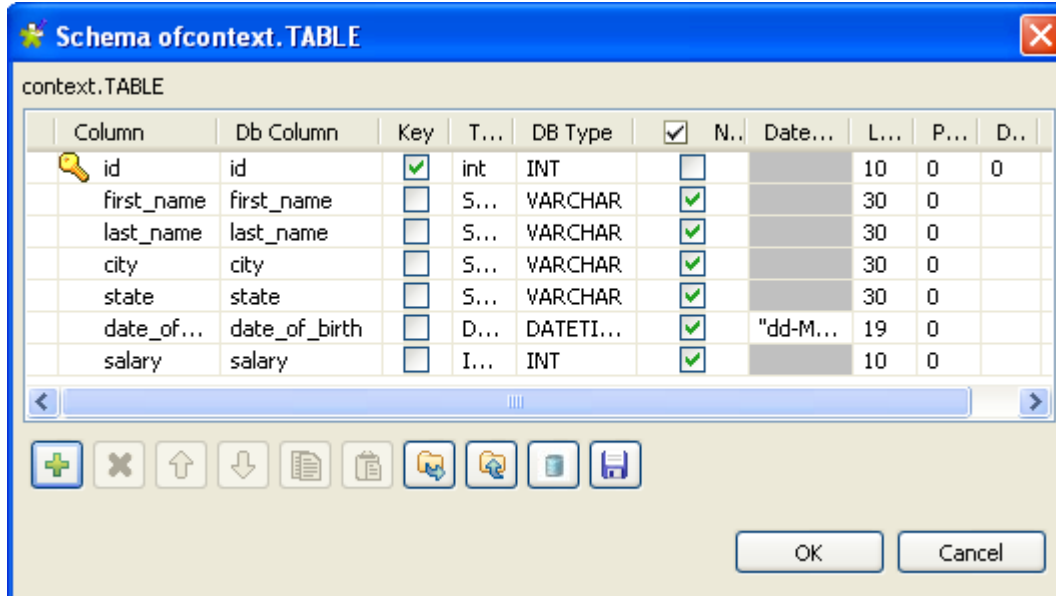

1. Double-click **tMySQLInput** to open its **Basic Settings** view in the **Component** tab.

-  For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query type** of components are always **Built-in**. You have to complete the relevant settings manually in the specific Job.

2. Define the DB connection details in the corresponding fields.
3. Click **Edit schema** to define the desired schema.

The schema editor opens:

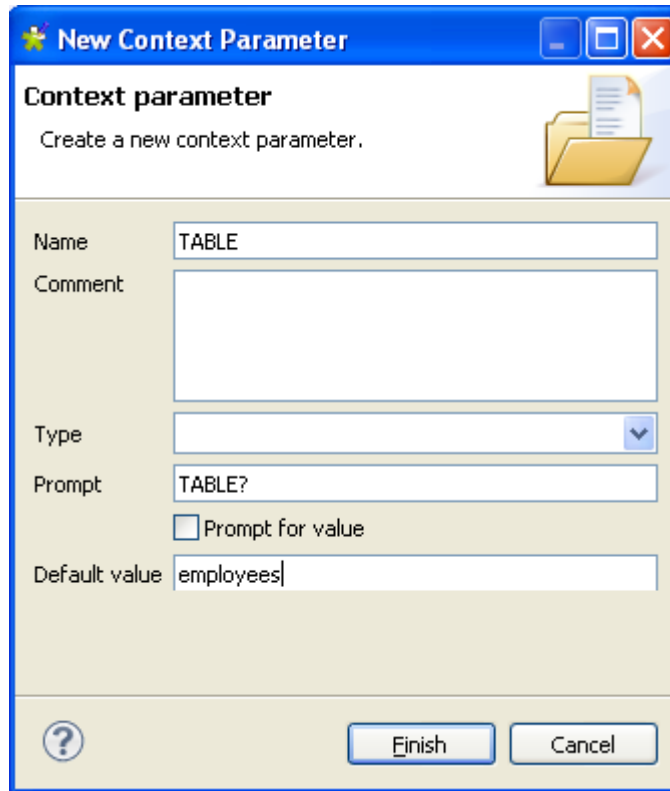

- Click the [+] button to add the rows that you will use to define the schema, seven columns in this example: *id, first\_name, last\_name, city, state, date\_of\_birth* and *salary*.

Under **Column**, click the fields to enter the corresponding column names.

Click the fields under **Type** to define the type of data.

Click **OK** to close the schema editor.

- Put the cursor in the **Table Name** field and press **F5** for context parameter setting.

For more information about context settings, see *Talend Open Studio for Big Data User Guide*.

- Keep the default setting in the **Name** field and type in the name of the database table in the **Default value** field, *employees* in this case.
- Click **Finish** to validate the setting.

The context parameter `context.TABLE` automatically appears in the **Table Name** field.

- Click **Guess Query** to get the query statement.

In this use case, we want to read the records with the salary above 8000. Therefore, we add a *Where* clause and the final query statement is as follows:

```
"SELECT
 "+context.TABLE+".`id`,
 "+context.TABLE+".`first_name`,
 "+context.TABLE+".`last_name`,
 "+context.TABLE+".`city`,
 "+context.TABLE+".`state`,
 "+context.TABLE+".`date_of_birth`,
 "+context.TABLE+".`salary`
FROM "+context.TABLE+"
WHERE
 "+context.TABLE+".`salary` > 8000"
```

- Double-click **tLogRow** to set its **Basic Settings** in the **Component** tab.

- In the **Mode** area, select **Table (print values in cells of a table)** for a better display of the results.
- Save the Job.

## Executing the Job

The results below can be found after **F6** is pressed to run the Job.

| tLogRow_2 |            |           |            |       |               |        |
|-----------|------------|-----------|------------|-------|---------------|--------|
| id        | first_name | last_name | city       | state | date_of_birth | salary |
| 1         | Martin     | Roosevelt | Sacramento | ND    | 19-10-1950    | 9011   |
| 2         | Zachary    | Johnson   | Atlanta    | ND    | 14-11-1978    | 8118   |
| 4         | Herbert    | Harrison  | Charleston | AB    | 15-08-1963    | 9233   |

As shown above, the records with the salary greater than 8000 are retrieved.

# tMysqlLastInsertId

## tMysqlLastInsertId properties

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                              |

| <b>Component family</b> | Databases                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                              |
| <b>Function</b>         | tMysqlLastInsertId fetches the last inserted ID from a selected MySQL Connection.                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                              |
| <b>Purpose</b>          | tMysqlLastInsertId obtains the primary key value of the record that was last inserted in a Mysql table by a user.                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                              |
| <b>Basic settings</b>   | <i>Schema and Edit Schema</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                           | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> . |
|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>Built-in:</b> You create and store the schema locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                     |
|                         | <i>Component list</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Select the relevant tMysqlConnection component in the list if more than one connection is planned for the current job.                                                                                       |
| <b>Usage</b>            | <p>This component is to be used as an intermediary component.</p> <p> <i>If you use this component with tMySqlOutput, verify that the <b>Extend Insert</b> check box in the <b>Advanced Settings</b> tab is not selected. <b>Extend Insert</b> allows you to make a batch insertion, however, if the check box is selected, only the ID of the last line in the last batch will be returned.</i></p> |                                                                                                                                                                                                              |
| <b>Limitation</b>       | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                              |

## Scenario: Get the ID for the last inserted record

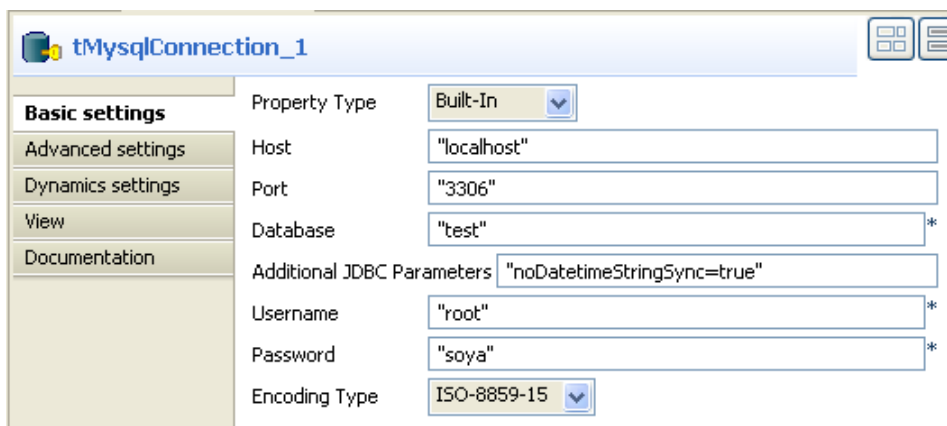

The following Java scenario creates a job that opens a connection to Mysql database, writes the defined data into the database, and finally fetches the last inserted ID on the existing connection.

- Drop the following components from the **Palette** onto the design workspace: **tMySqlConnection**, **tMySqlCommit**, **tFileInputDelimited**, **tMySqlOutput**, **tMysqlLastInsertId**, and **tLogRow**.
- Connect **tMySqlConnection** to **tFileInputDelimited** using an **OnSubjobOk** link.
- Connect **tFileInputDelimited** to **tMySqlCommit** using an **OnSubjobOk** link.
- Connect **tFileInputdelimited** to the three other components using **Row Main** links.

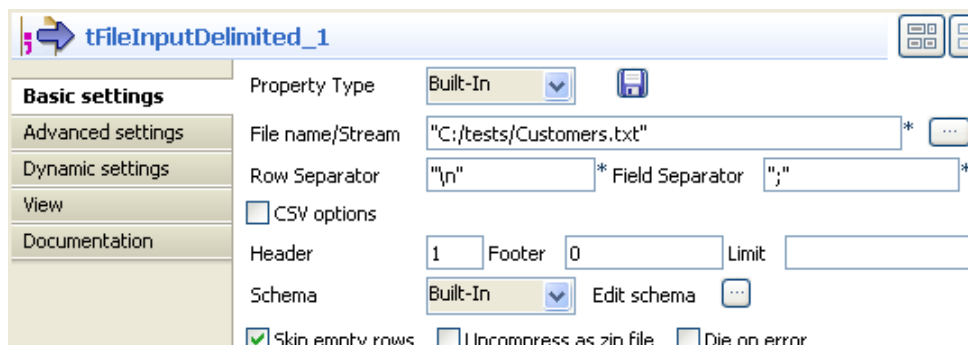

- In the design workspace, select **tMysqlConnection**.
- Click the **Component** tab to define the basic settings for **tMysqlConnection**.
- In the **Basic settings** view, set the connection details.

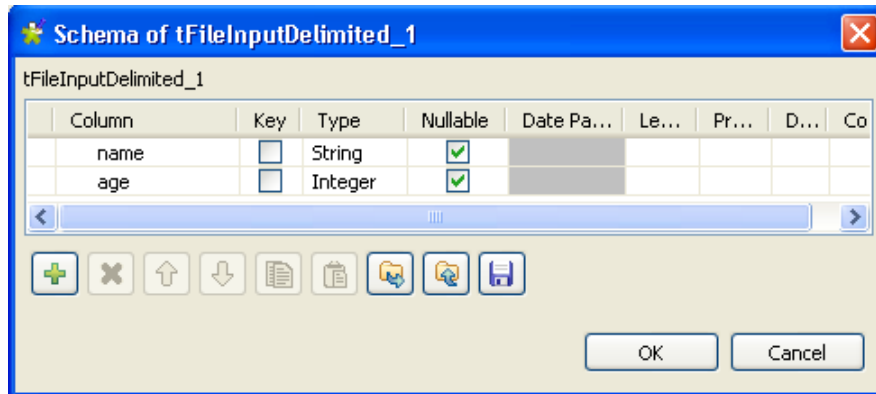

- In the design workspace, select **tMysqlCommit** and click the **Component** tab to define its basic settings.
- On the **Component List**, select the relevant **tMysqlConnection** if more than one connection is used.
- In the design workspace, select **tFileInputDelimited**.
- Click the **Component** tab to define the basic settings of **tFileInputDelimited**.

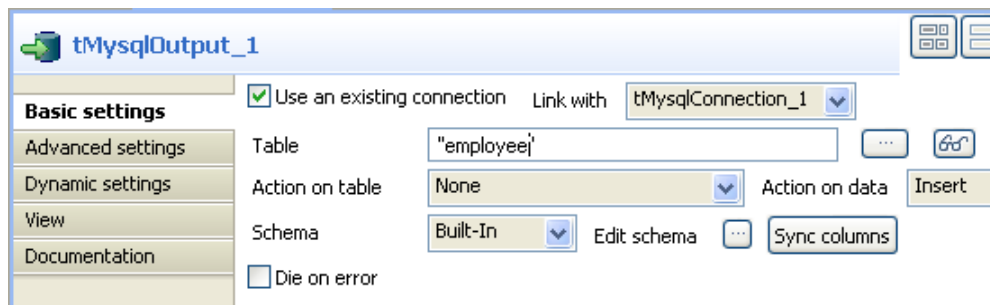

- Fill in a path to the processed file in the **File Name** field. The file used in this example is *Customers*.
- Define the **Row separator** that allow to identify the end of a row. Then define the **Field separator** used to delimit fields in a row.
- Set the header, the footer and the number of processed rows as necessary. In this scenario, we have one header.
- Click the three-dot button next to **Edit Schema** to define the data to pass on to the next component.

Related topics: see *Talend Open Studio for Big Data User Guide*.

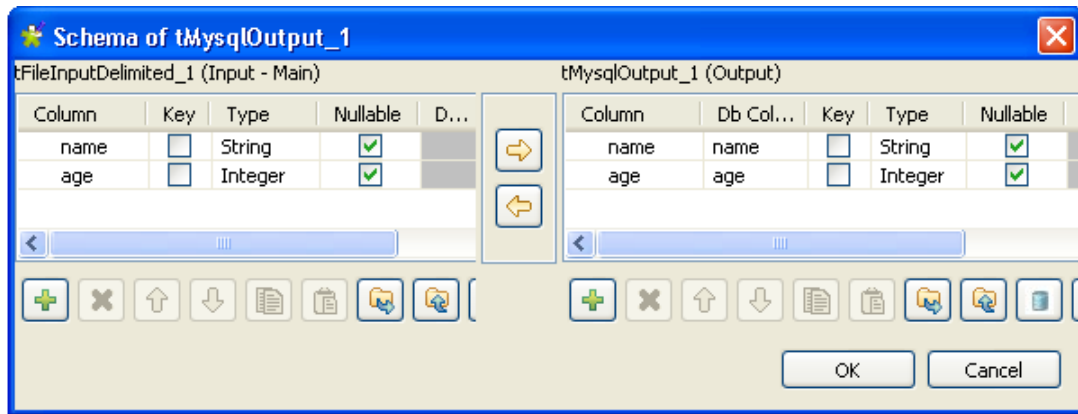

In this scenario, the schema consists of two columns, *name* and *age*. The first holds three employees' names and the second holds the corresponding age for each.

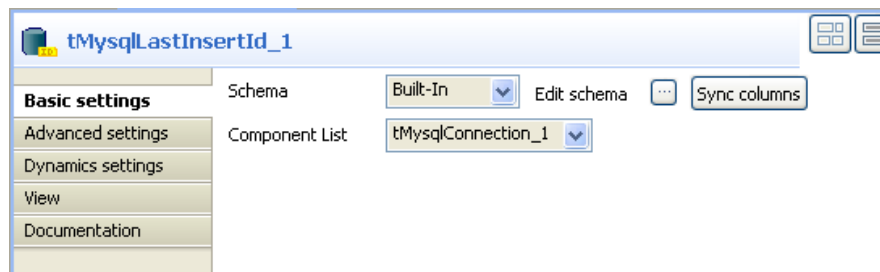

- In the design workspace, select **tMySQLOutput**.
- Click the **Component** tab to define the basic settings of **tMySQLOutput**.

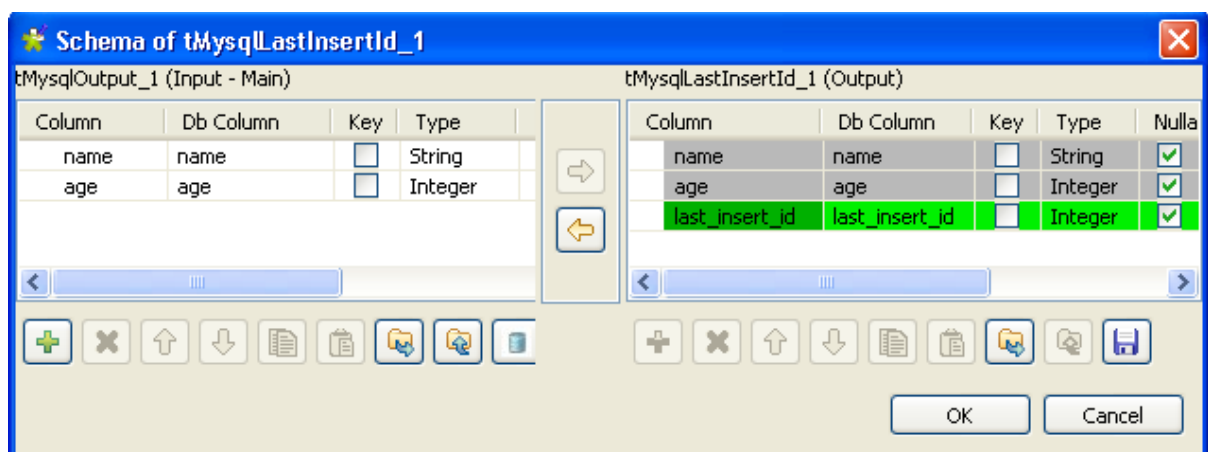

- Select the **Use an existing connection** check box.
- In the **Table** field, enter the name of the table where to write the employees' list, in this example: *employee*.
- Select relevant actions on the **Action on table** and **Action on data** lists. In this example, no action is carried out on table, and the action carried out on data is *Insert*.
- Click **Sync columns** to synchronize columns with the previous component. In this example, the schema to be inserted into the MySQL database table consists of the two columns *name* and *age*.

- In the design workspace, select **tMySQLLastInsertId**.
- Click the **Component** tab to define the basic settings of **tMySQLLastInsertId**.

- On the **Component List**, select the relevant **tMySQLConnection**, if more than one connection is used.
- Click **Sync columns** to synchronize columns with the previous component. In the output schema of **tMySQLLastInsertId**, you can see the read-only column *last\_insert\_id* that will fetch the last inserted ID on the existing connection.

You can select the data type *Long* from the **Type** drop-down list in case of a huge number of entries.

- In the design workspace, select **tLogRow** and click the **Component** tab to define its basic settings. For more information, see [the section called “tLogRow”](#).
- Save your job and press **F6** to execute it.

# tMysqlOutput

## tMysqlOutput properties

However, you will not be able to rollback the operation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|  | <p><i>Action on data</i></p>         | <p>On the data of the table defined, you can perform:</p> <p><b>Insert:</b> Add new entries to the table. If duplicates are found, the job stops.</p> <p><b>Update:</b> Make changes to existing entries.</p> <p><b>Insert or update:</b> Add entries or update existing ones.</p> <p><b>Update or insert:</b> Update existing entries or creates them if they do not exist.</p> <p><b>Delete:</b> Remove entries corresponding to the input flow.</p> <p><b>Replace:</b> Add new entries to the table. If an old row in the table has the same value as a new row for a PRIMARY KEY or a UNIQUE index, the old row is deleted before the new row is inserted.</p> <p><b>Insert or update on duplicate key or unique index:</b> Add entries if the inserted value does not exist or update entries if the inserted value already exists and there is a risk of violating a unique index or primary key.</p> <p><b>Insert Ignore:</b> Add only new rows to prevent duplicate key errors.</p> <p> <i>You must specify at least one column as a primary key on which the <b>Update</b> and <b>Delete</b> operations are based. You can do that by clicking <b>Edit Schema</b> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <b>Advanced settings</b> view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the <b>Use field options</b> check box and then in the <b>Key in update</b> column, select the check boxes next to the column name on which you want to base the update operation. Do the same in the <b>Key in delete</b> column for the deletion operation.</i></p> |
|  | <p><i>Schema and Edit schema</i></p> | <p>A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                          |                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                          |                                          | component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                          |                                          | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                          | <i>Die on error</i>                      | This check box is selected by default. Clear the check box to skip the row in error and complete the process for error-free rows. If needed, you can retrieve the rows in error via a <b>Row &gt; Rejects</b> link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Advanced settings</b> | <i>Additional parameters</i> <i>JDBC</i> | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <b>Use an existing connection</b> check box in the <b>Basic settings</b> .<br><br> You can press <b>Ctrl+Space</b> to access a list of predefined global variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                          | <i>Extend Insert</i>                     | Select this check box to carry out a bulk insert of a defined set of lines instead of inserting lines one by one. The gain in system performance is considerable.<br><br><b>Number of rows per insert:</b> enter the number of rows to be inserted per operation. Note that the higher the value specified, the lower performance levels shall be due to the increase in memory demands.<br><br> This option is not compatible with the <b>Reject</b> link. You should therefore clear the check box if you are using a <b>Row &gt; Rejects</b> link with this component.<br><br> <i>If you are using this component with <b>tMySQLLastInsertID</b>, ensure that the <b>Extend Insert</b> check box in <b>Advanced Settings</b> is not selected. <b>Extend Insert</b> allows for batch loading, however, if the check box is selected, only the ID of the last line of the last batch will be returned.</i> |
|                          | <i>Use batch size</i>                    | Select this check box to activate the batch mode for data processing. In the <b>Batch Size</b> field that appears when this check box is selected, you can type in the number you need to define the batch size to be processed.<br><br> This check box is available only when you have selected, the <b>Update</b> or the <b>Delete</b> option in the <b>Action on data</b> field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                          | <i>Commit every</i>                      | Number of rows to be included in the batch before it is committed to the DB. This option ensures transaction quality (but not rollback) and, above all, a higher performance level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                          | <i>Additional Columns</i>                | This option is not available if you have just created the DB table (even if you delete it beforehand). This option allows you to call SQL functions to perform actions on columns, provided that these are not insert, update or delete actions, or actions that require pre-processing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Usage</b> | <p>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.</p> <p>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a MySQL database. It also allows you to create a reject flow using a <b>Row &gt; Rejects</b> link to filter data in error. For an example of <b>tMySQLOutput</b> in use, see <a href="#">the section called "Scenario 3: Retrieve data in error with a Reject link"</a>.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

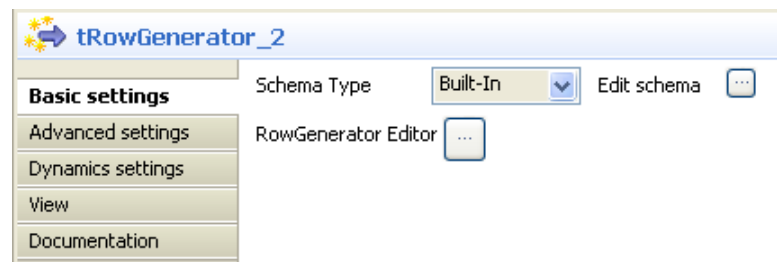

## Scenario 1: Adding a new column and altering data in a DB table

This Java scenario is a three-component job that aims at creating random data using a **tRowGenerator**, duplicating a column to be altered using the **tMap** component, and eventually altering the data to be inserted based on an SQL expression using the **tMySQLOutput** component.

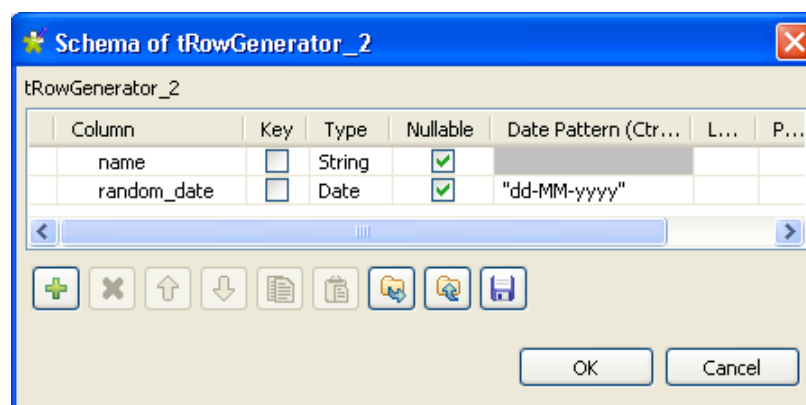

- Drop the following components from the **Palette** onto the design workspace: **tRowGenerator**, **tMap** and **tMySQLOutput**.
- Connect **tRowGenerator**, **tMap**, and **tMySQLOutput** using the **Row Main** link.

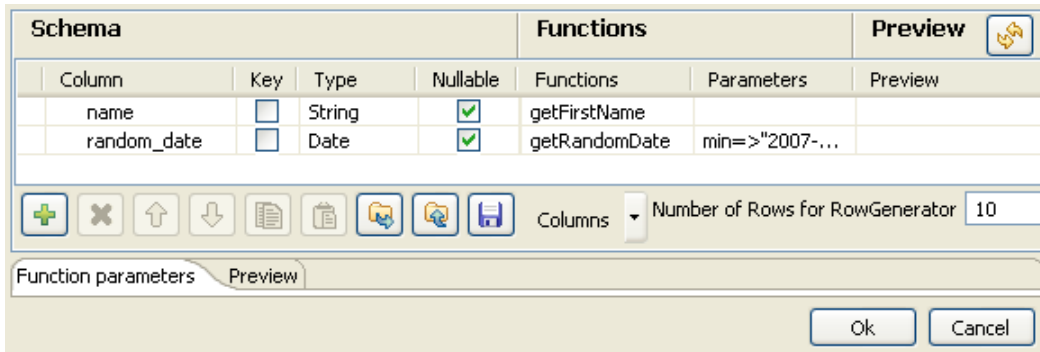

- In the design workspace, select **tRowGenerator** to display its **Basic settings** view.

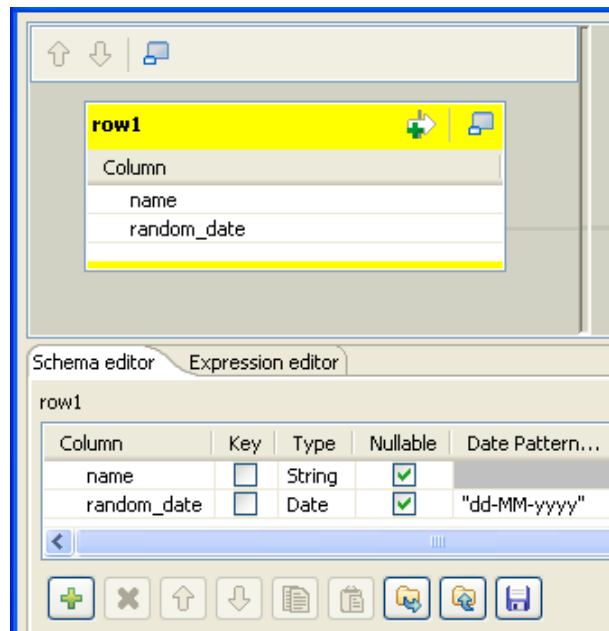

- Click the **Edit schema** three-dot button to define the data to pass on to the **tMap** component, two columns in this scenario, *name* and *random\_date*.

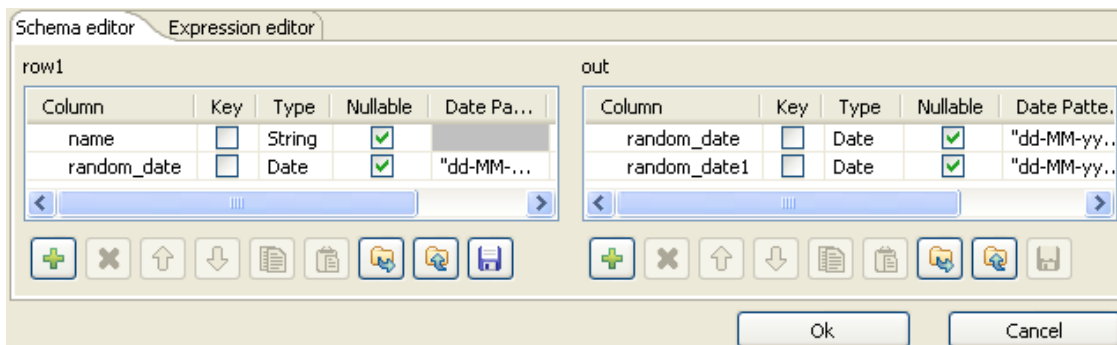

- Click **OK** to close the dialog box.
- Click the **RowGenerator Editor** three-dot button to open the editor and define the data to be generated.

- Click in the corresponding **Functions** fields and select a function for each of the two columns, `getFirstName` for the first column and `getrandomDate` for the second column.
- In the **Number of Rows for Rowgenerator** field, enter 10 to generate ten first name rows and click **Ok** to close the editor.
- Double-click the **tMap** component to open the Map editor. The Map editor opens displaying the input metadata of the **tRowGenerator** component.

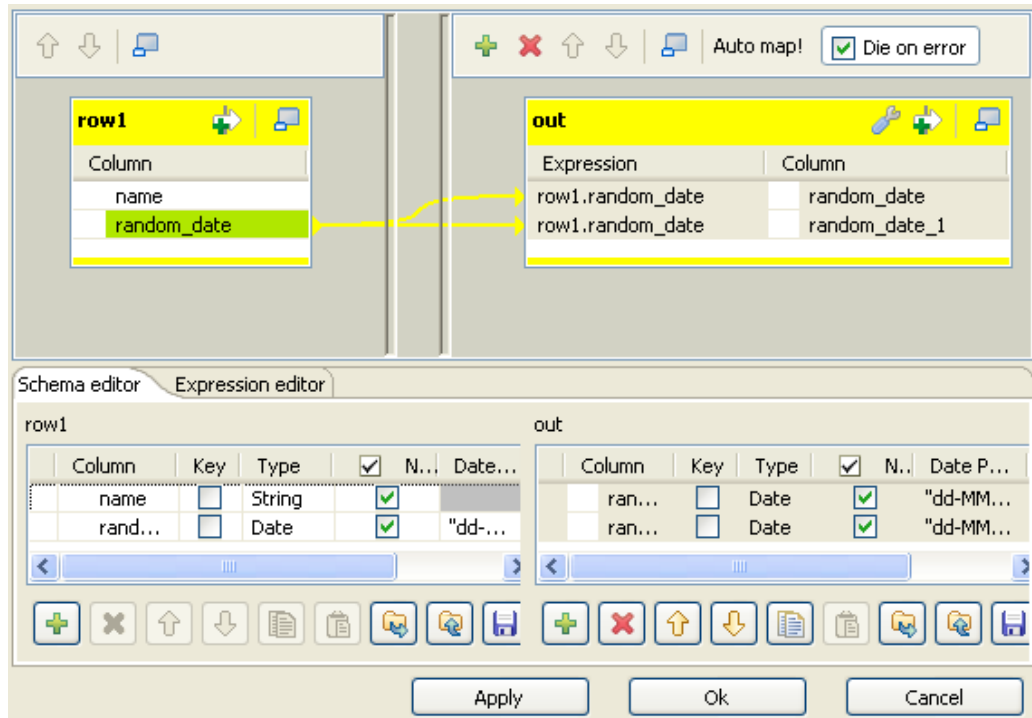

- In the **Schema editor** panel of the Map editor, click the plus button of the output table to add two rows and define the first as `random_date` and the second as `random_date1`.

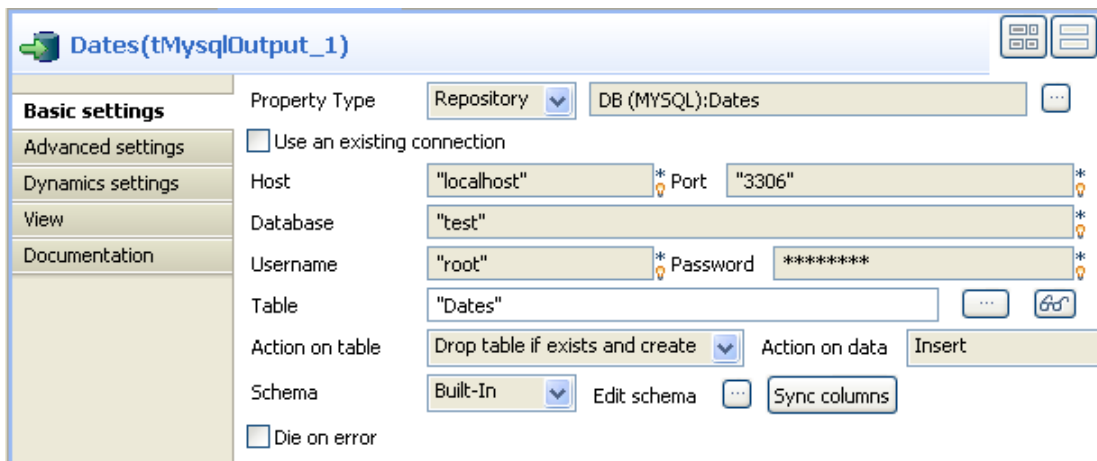

In this scenario, we want to duplicate the `random_date` column and adapt the schema in order to alter the data in the output component.

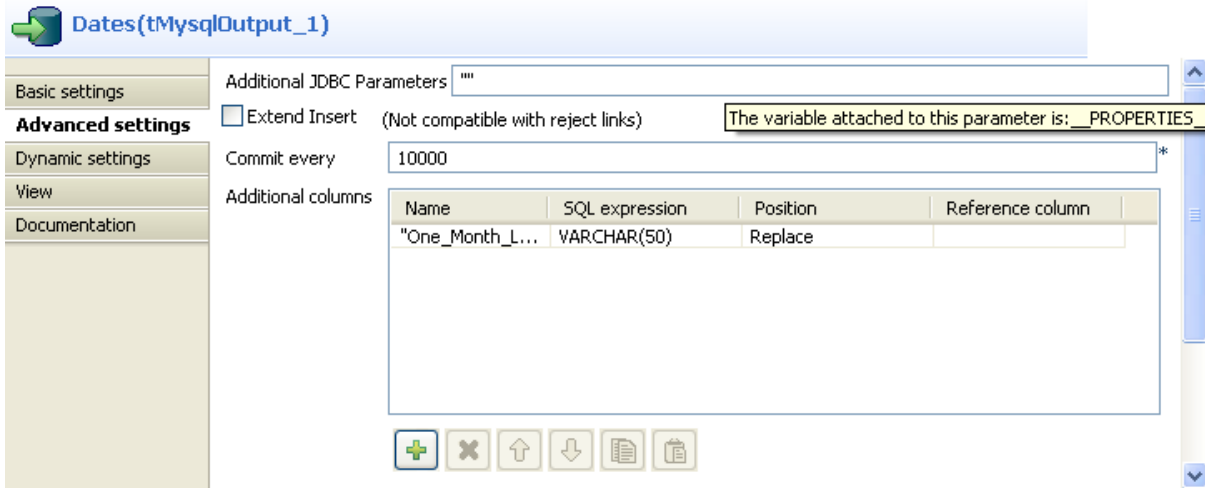

- In the Map editor, drag the *random\_date* row from the input table to the *random\_date* and *random\_date1* rows in the output table.

- Click **OK** to close the editor.
- In the design workspace, double-click the **tMySQLOutput** component to display its **Basic settings** view and set its parameters.

- Define the DB connection details in the corresponding fields.
- Click the three-dot button next to the **Table** field and select the table to be altered, *Dates* in this scenario.
- On the **Action on table** list, select **Drop table if exists and create**, select *Insert* on the **Action on data** list.
- If needed, click **Sync columns** to synchronize with the columns coming from the **tMap** component.
- Click the **Advanced settings** tab to display the corresponding view and set the advanced parameters.

- In the **Additional Columns** area, set the alteration to be performed on columns.

In this scenario, the *One\_month\_later* column replaces *random\_date\_1*. Also, the data itself gets altered using an SQL expression that adds one month to the randomly picked-up date of the *random\_date\_1* column. ex: 2007-08-12 becomes 2007-09-12.

-Enter *One\_Month\_Later* in the **Name** cell.

-In the **SQL expression** cell, enter the relevant addition script to be performed, "adddate(Random\_date, interval 1 month)" in this scenario.

-Select **Replace** on the **Position** list.

-Enter *Random\_date1* on the **Reference column** list.

For this job we duplicated the *random\_date\_1* column in the DB table before replacing one instance of it with the *One\_Month\_Later* column. The aim of this workaround was to be able to view upfront the modification performed.

- Save your job and press **F6** to execute it.

The new *One\_month\_later* column replaces the *random\_date1* column in the DB table and adds one month to each of the randomly generated dates.

| Random_date         | One_Month_Later     |

## Scenario 2: Updating data in a database table

This Java scenario describes a two-component Job that updates data in a MySQL table according to that in a delimited file.

- Drop **tFileInputDelimited** and **tMySQLOutput** from the **Palette** onto the design workspace.
- Connect the two components together using a **Row Main** link.

- Double-click **tFileInputDelimited** to display its **Basic settings** view and define the component properties.

- In the **File Name** field, click the three-dot button and browse to the source delimited file that contains the modifications to propagate in the MySQL table.

In this example, we use the *customer\_update* file that holds four columns: *id*, *CustomerName*, *CustomerAddress* and *idState*. Some of the data in these four columns is different from that in the MySQL table.

| id  | CustomerName                   | CustomerAddress        | idState |
|-----|--------------------------------|------------------------|---------|
| 858 | Froggy's Gourmet Catering      | 1831 Beverly Place #9D | 4       |
| 859 | Dependable Plumbing and Sewer  | 1550 Ridge Rd.         | 25      |
| 860 | Lickmen Restoration            | 1235 Easton Rd.        | 40      |
| 861 | Acturial Enterprises Ltd.      | 3148 cottonwood Ct.    | 18      |
| 862 | Rythmics Ltd.                  | 857 Woodbine Rd        | 30      |
| 863 | Acturial Enterprises Ltd.      | 1482 Concorde Circle   | 48      |
| 864 | Crosstracks Car Wash           | 218 Oakridge Ave.      | 39      |
| 865 | Meonits & Mogogni Inc.         | 616 Cobblestone Cir.   | 17      |
| 866 | Foy Aviation                   | 2220 Grant Blvd.       | 50      |
| 867 | Ebert Music Center             | 12 Broadview Lane      | 29      |
| 868 | janice Mann Accounting Service | 1660 Park Ave.         | 9       |
| 869 | Johnson, Erico & Co CPA's      | 2922 Twin Oaks Drive   | 40      |
| 870 | Corbins, Rodriguez, & Savocchi | 115 Pleasent Ave.      | 18      |
| 871 | Nina's Snow Plowing            | 3385 University Ave.   | 20      |
| 872 | Darcy Frame and Matting Servic | 1101 Deerfield Place   | 47      |
| 873 | Marks, Marks, and Kaplan Ltd.  | 1949 Cloverdale Rd.    | 9       |

- Define the row and field separators used in the source file in the corresponding fields.
- If needed, set **Header**, **Footer** and **Limit**.

In this example, **Header** is set to 1 since the first row holds the names of columns, therefore it should be ignored. Also, the number of processed lines is limited to 2000.

- Click the three-dot button next to **Edit Schema** to open a dialog box where you can describe the data structure of the source delimited file that you want to pass to the component that follows.

| Column                                                                               | Key                                 | Type    | <input checked="" type="checkbox"/> | Nullable                            |
|--------------------------------------------------------------------------------------|-------------------------------------|---------|-------------------------------------|-------------------------------------|
|  id | <input checked="" type="checkbox"/> | Integer | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CustomerName                                                                         | <input type="checkbox"/>            | String  | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CustomerAddress                                                                      | <input type="checkbox"/>            | String  | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| idState                                                                              | <input type="checkbox"/>            | Integer | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |

- Select the **Key** check box(es) next to the column name(s) you want to define as key column(s).

It is necessary to define at least one column as a key column for the Job to be executed correctly. Otherwise, the Job is automatically interrupted and an error message displays on the console.

- In the design workspace, double-click **tMySQLOutput** to open its **Basic settings** view where you can define its properties.

Property Type: Built-In 

Use an existing connection

Host: \* Port: \*

Database: \*

Username: \* Password: \*

Table:   

Action on table: None Action on data: Update

Schema: Built-In  Edit schema  Sync columns

Die on error

- Click **Sync columns** to retrieve the schema of the preceding component. If needed, click the three-dot button next to **Edit schema** to open a dialog box where you can check the retrieved schema.
- Fill in the database connection information in the corresponding fields.
- In the **Table** field, enter the name of the table to update.
- From the **Action on table** list, select the operation you want to perform, **None** in this example since the table already exists.
- From the **Action on data** list, select the operation you want to perform on the data, **Update** in this example.
- Save your Job and press **F6** to execute it.

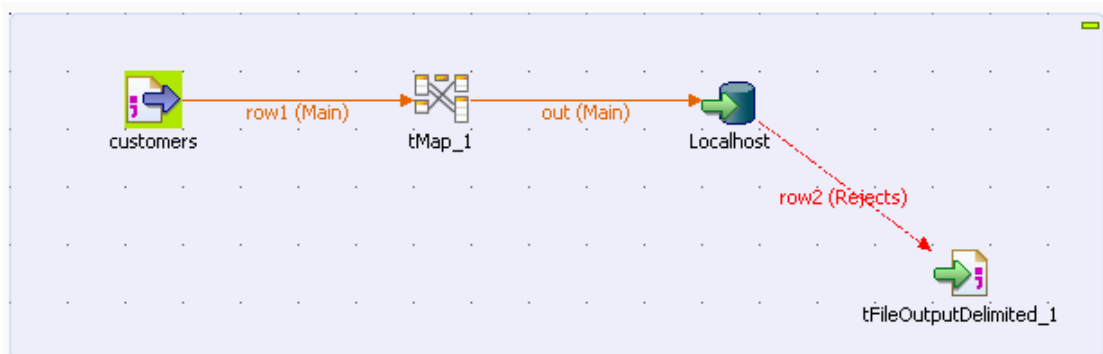

| id  | CustomerName                  | CustomerAddress        | idState |
|-----|-------------------------------|------------------------|---------|
| 858 | Froggy's Gourmet Catering     | 1831 Beverly Place #9D | 4       |

Using your DB browser, you can verify if the MySQL table, *customers*, has been modified according to the delimited file.

In the above example, the database table has always the four columns *id*, *CustomerName*, *CustomerAddress* and *idState*, but certain fields have been modified according to the data in the delimited file used.

## Scenario 3: Retrieve data in error with a Reject link

This scenario describes a four-component Job that carries out migration from a customer file to a MySQL database table and redirects data in error towards a CSV file using a **Reject** link.

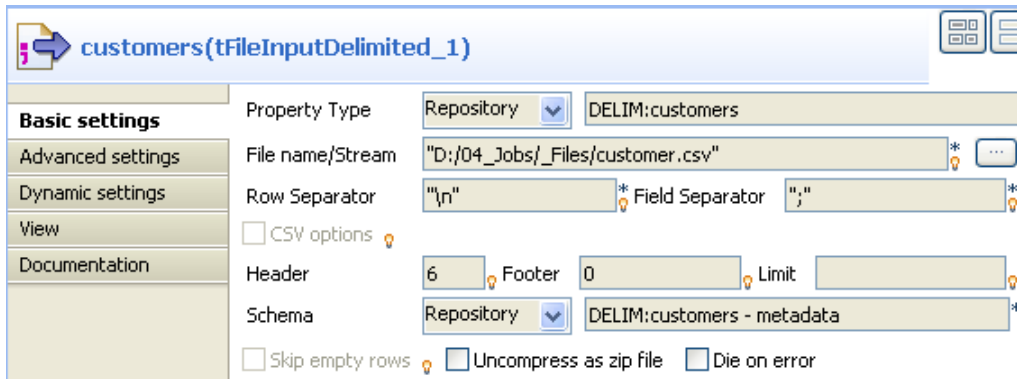

- Drop a **tFileInputDelimited** component from the family **File > Input**, in the **Palette**, and fill in its properties manually in the **Component** tab.
- From the **Palette**, drop a **tMap** from the **Processing** family onto the workspace.
- Drop a **tMysqlOutput** from the **Databases** family in the **Palette** and fill in its properties manually in the **Component** tab.

For more information, see *Talend Open Studio for Big Data User Guide*.

- From the **Palette**, select a **tFileOutputDelimited** from the **File > Output** family, and drop it onto the workspace.

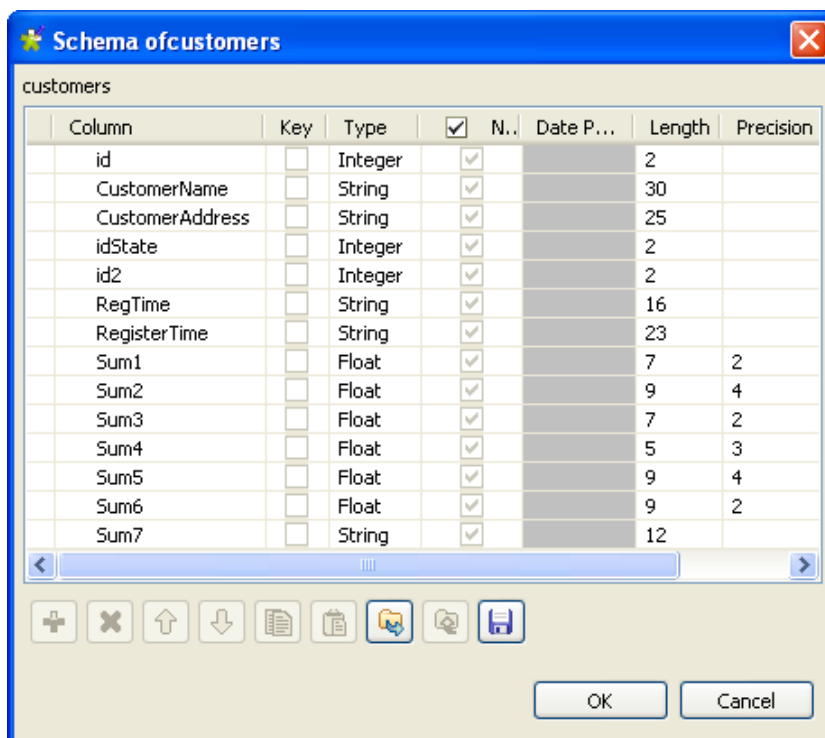

- Link the **customers** component to the **tMap** component, and the **tMap** and **Localhost** with a **Row Main** link. Name this second link *out*.
- Link the **Localhost** to the **tFileOutputDelimited** using a **Row > Reject** link.
- Double-click the **customers** component to display the **Component** view.

 For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query type** of components are always **Built-in**. You have to complete the relevant settings manually in the specific Job.

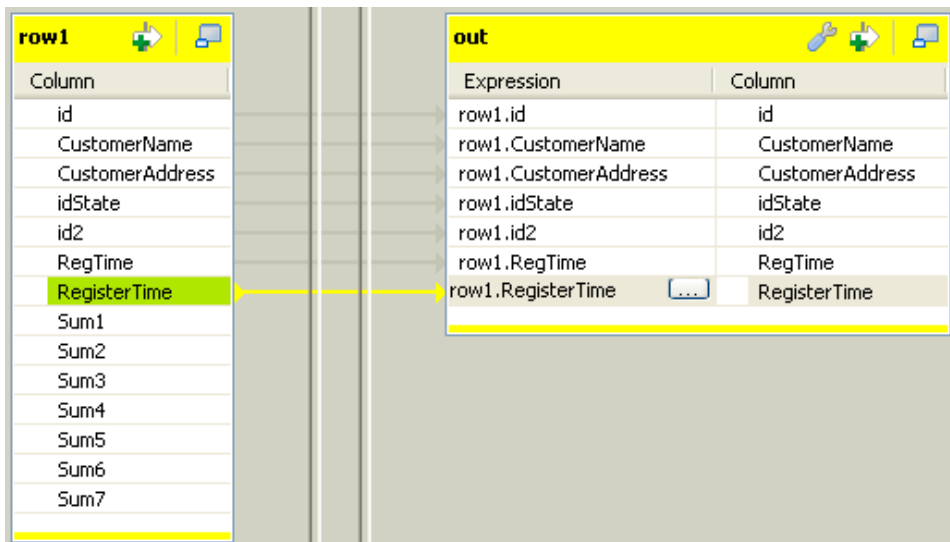

- Define the DB connection details in the corresponding fields.
- Click the [...] button next to the **File Name** field, and fill in the path and the name of the file you want to use.
- In the **Row** and **Field Separator** fields, type in between inverted commas the row and field separator used in the file.
- In the **Header**, **Footer** and **Limit** fields, type in the number of headers and footers to ignore, and the number of rows to which processing should be limited.
- Click the [...] button next to the **Edit schema** field, and set the schema manually.

The schema is as follows:

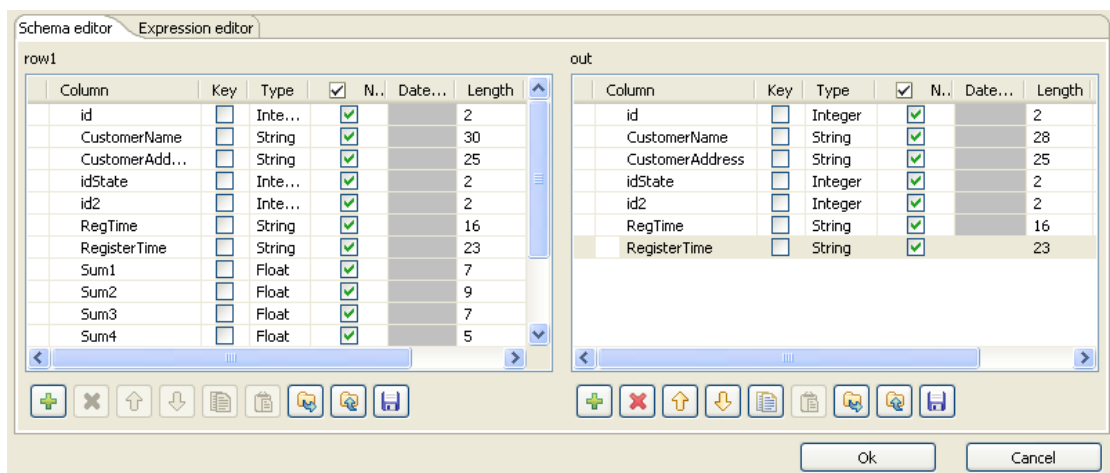

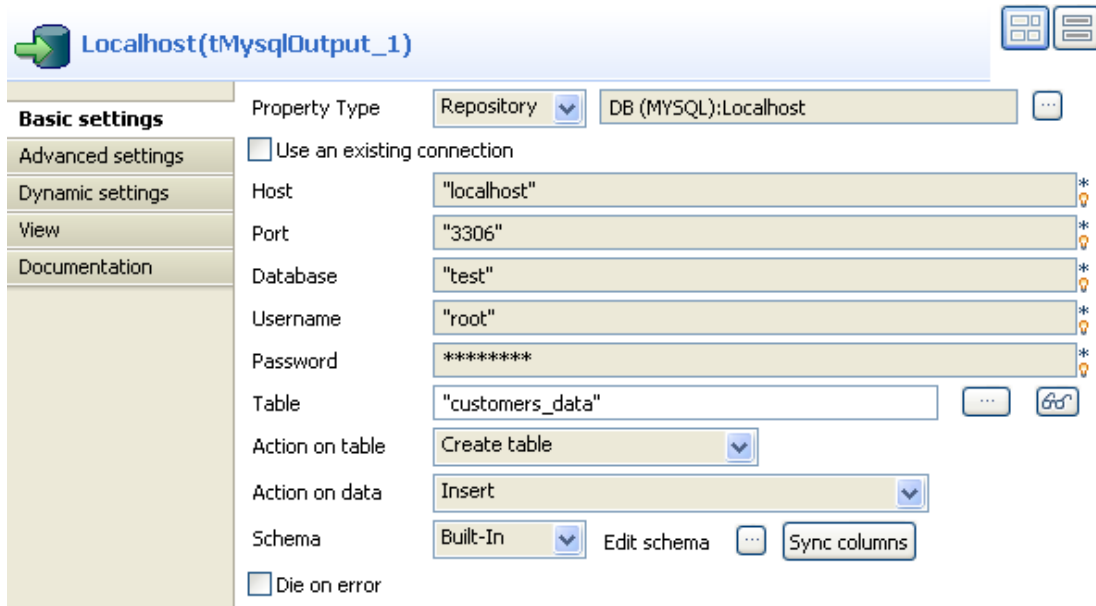

- Double-click the **tMap** component to open its editor.

- Select the *id*, *CustomerName*, *CustomerAddress*, *idState*, *id2*, *RegTime* and *RegisterTime* columns on the table on the left and drop them on the **out** table, on the right.

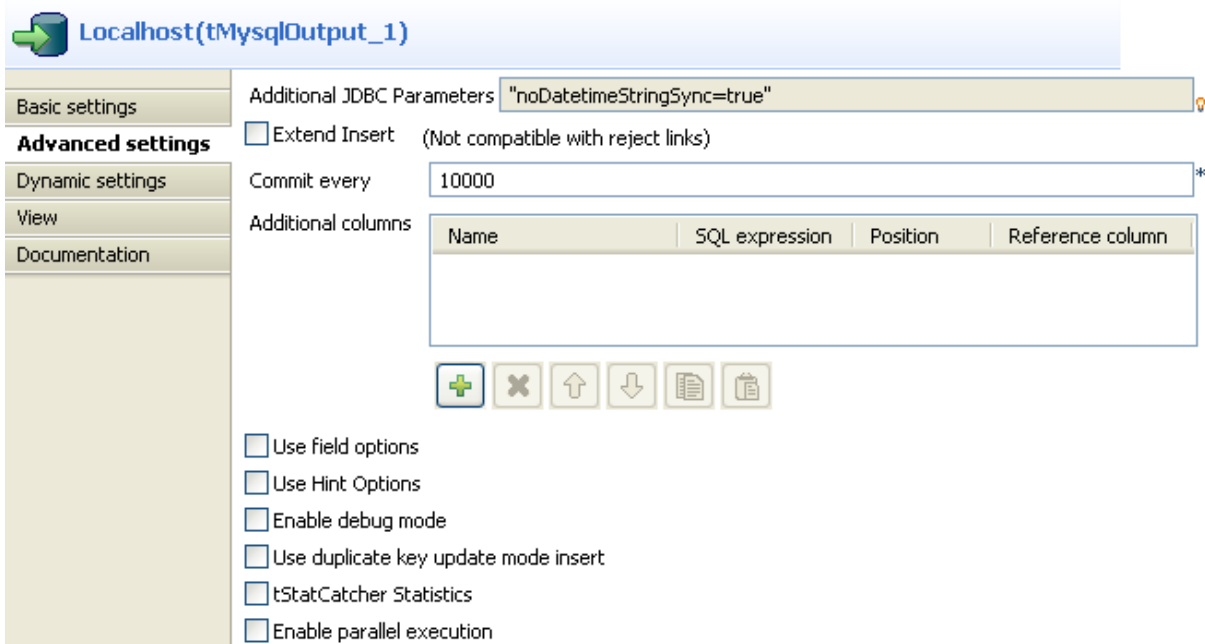

- In the **Schema editor** area, at the bottom of the **tMap** editor, in the right table, change the length of the **CustomerName** column to 28 to create an error. Thus, any data for which the length is greater than 28 will create errors, retrieved with the **Reject** link.
- Click **OK**.
- In the workspace, double-click the output **Localhost** component to display its **Component** view.

 For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query type** of components are always **Built-in**. You have to complete the relevant settings manually in the specific Job.

- Define the DB connection details in the corresponding fields.
- In the **Table** field, type in the name of the table to be created. In this scenario, we call it *customers\_data*.
- In the **Action on data** list, select the **Create table** option.
- Click the **Sync columns** button to retrieve the schema from the previous component.
- Make sure the **Die on error** check box isn't selected, so that the Job can be executed despite the error you just created.
- Click the **Advanced settings** tab of the **Component** view to set the advanced parameters of the component.

- Deselect the **Extend Insert** check box which enables you to insert rows in batch, because this option is not compatible with the **Reject** link.

- Double-click the **tFileOutputDelimited** component to set its properties in the **Component** view.

- Click the [...] button next to the **File Name** field to fill in the path and name of the output file.
- Click the **Sync columns** button to retrieve the schema of the previous component.
- Save your Job and press **F6** to execute it.

The data in error are sent to the delimited file, as well as the error type met. Here, we have: **Data truncation**.

# tMysqlOutputBulk

## tMysqlOutputBulk properties

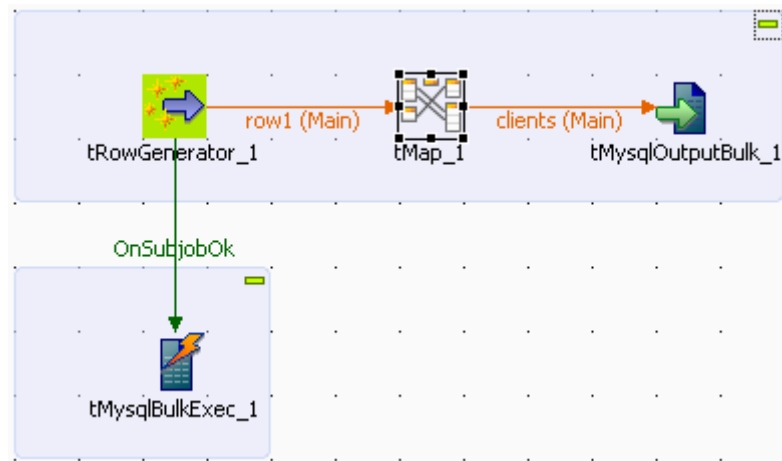

The **tMysqlOutputBulk** and **tMysqlBulkExec** components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the **tMysqlOutputBulkExec** component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

|                          |                                                                                           |                                                                                                                                                                                                              |

| <b>Component family</b>  | Databases/MySQL                                                                           |                                                                                                                                                                                                              |
| <b>Function</b>          | Writes a file with columns based on the defined delimiter and the MySQL standards         |                                                                                                                                                                                                              |
| <b>Purpose</b>           | Prepares the file to be used as parameter in the INSERT query to feed the MySQL database. |                                                                                                                                                                                                              |
| <b>Basic settings</b>    | <i>Property type</i>                                                                      | In <i>Talend Open Studio for Big Data</i> , the Property type is always <b>Built-in</b> .                                                                                                                    |
|                          |                                                                                           | <b>Built-in:</b> No property data stored centrally.                                                                                                                                                          |
|                          | <i>File Name</i>                                                                          | Name of the file to be processed.<br><br>Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                                                              |
|                          | <i>Append</i>                                                                             | Select this check box to add the new rows at the end of the file                                                                                                                                             |
|                          | <i>Schema and Edit Schema</i>                                                             | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> . |
|                          |                                                                                           | <b>Built-in:</b> The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                               |
| <b>Advanced settings</b> | <i>Row separator</i>                                                                      | String (ex: "\n" on Unix) to distinguish rows.                                                                                                                                                               |
|                          | <i>Field separator</i>                                                                    | Character, string or regular expression to separate fields.                                                                                                                                                  |
|                          | <i>Text enclosure</i>                                                                     | Character used to enclose the text.                                                                                                                                                                          |
|                          | <i>Create directory if does not exist</i>                                                 | This check box is selected by default. It creates a directory to hold the output table if required.                                                                                                          |
|                          | <i>Custom the flush buffer size</i>                                                       | Customize the amount of memory used to temporarily store output data. In the <b>Row number field</b> , enter the number of rows after which the memory is to be freed again.                                 |
|                          | <i>Records contain NULL value</i>                                                         | This check box is selected by default. It allows you to take account of NULL value fields. If you clear the check box, the NULL values will automatically be replaced with empty values.                     |
|                          | <i>Check disk space</i>                                                                   | Select the this check box to throw an exception during execution if the disk is full.                                                                                                                        |

|                   |                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                  |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
|                   | <i>Encoding</i>                                                                                                                                                                                                                                                                                                                                                       | Select the encoding from the list or select <b>Custom</b> and define it manually. This field is compulsory for DB data handling. |
|                   | <i>tStatCatcher Statistics</i>                                                                                                                                                                                                                                                                                                                                        | Select this check box to collect the log data at the component level.                                                            |
| <b>Usage</b>      | This component is to be used along with <b>tMySQLBulkExec</b> component. Used together they offer gains in performance while feeding a MySQL database.                                                                                                                                                                                                                |                                                                                                                                  |
| <b>Limitation</b> | Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> . |                                                                                                                                  |

## Scenario: Inserting transformed data in MySQL database

This scenario describes a four-component job which aims at fueling a database with data contained in a file, including transformed data. Two steps are required in this job, first step is to create the file, that will then be used in the second step. The first step includes a transformation phase of the data included in the file.

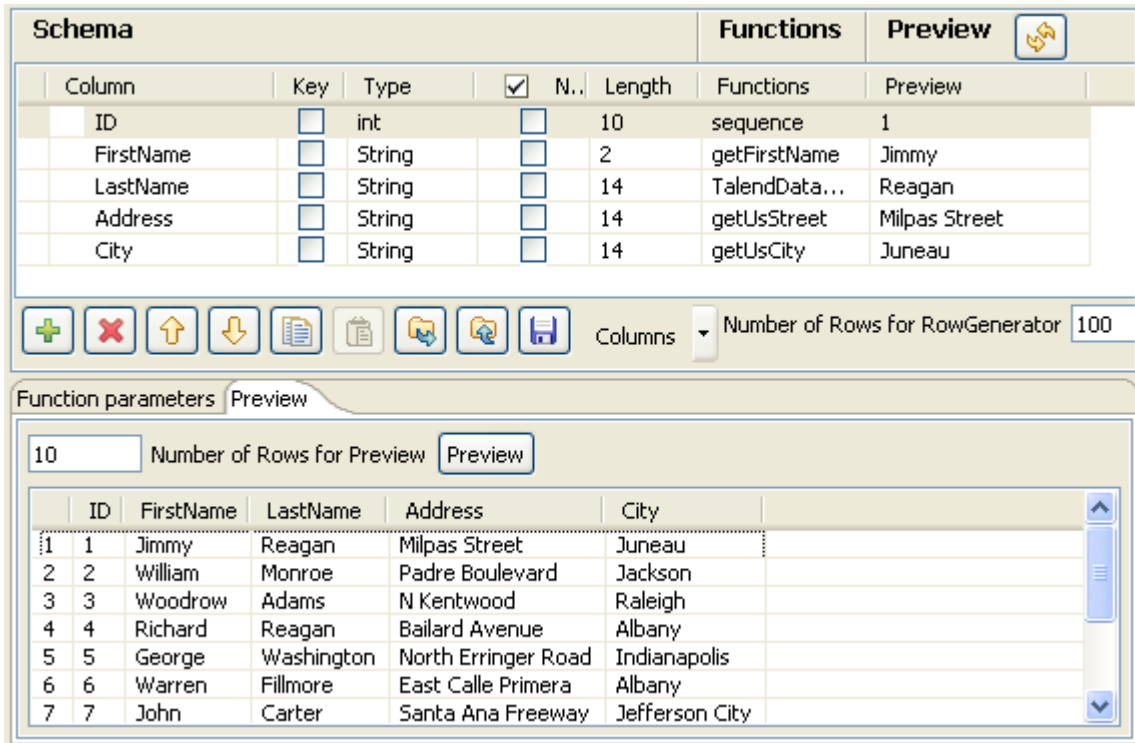

### Dropping and linking components

1. Drag and drop a **tRowGenerator**, a **tMap**, a **tMysqlOutputBulk** as well as a **tMysqlBulkExec** component.
2. Connect the main flow using **row Main** links.
3. And connect the start component (**tRowgenerator** in this example) to the **tMysqlBulkExec** using a **trigger** connection, of type **OnComponentOk**.

### Configuring the components

1. A **tRowGenerator** is used to generate random data. Double-click on the **tRowGenerator** component to launch the editor.

- Define the schema of the rows to be generated and the nature of data to generate. In this example, the *clients* file to be produced will contain the following columns: *ID*, *First Name*, *Last Name*, *Address*, *City* which all are defined as string data but the ID that is of integer type.

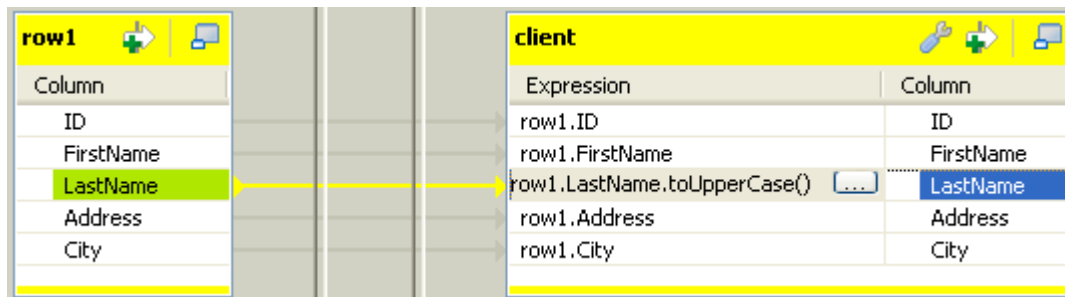

Some schema information don't necessarily need to be displayed. To hide them away, click on **Columns** list button next to the toolbar, and uncheck the relevant entries, such as **Precision** or **Parameters**.

Use the plus button to add as many columns to your schema definition.

Click the Refresh button to preview the first generated row of your output.

- Then select the **tMap** component to set the transformation.
- Drag and drop all columns from the input table to the output table.

- Apply the transformation on the *LastName* column by adding `.toUpperCase()` in its expression field. Then, click **OK** to validate the transformation.
- Double-click on the **tMysqlOutputBulk** component.
- Define the name of the file to be produced in **File Name** field. If the delimited file information is stored in the **Repository**, select it in **Property Type** field, to retrieve relevant data. In this use case the file name is *clients.txt*.

The schema is propagated from the **tMap** component, if you accepted it when prompted.

8. In this example, don't include the header information as the table should already contain it.
9. Click OK to validate the output.
10. Then double-click on the **tMySQLBulkExec** component to set the INSERT query to be executed.
11. Define the database connection details.

For Talend Open Studio for Big Data, the **Property type** and **Schema** of components are always **Built-in**. For how to edit a built-in schema, see *Talend Open Studio for Big Data User Guide*.

12. Set the table to be filled in with the collected data, in the **Table** field.
13. Fill in the column delimiters in the **Field terminated by** area.
14. Make sure the encoding corresponds to the data encoding.

## Saving and executing the Job

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the **Run** tab to execute the Job.

| ID | First Name | Last Name  | Address           | City           |
|----|------------|------------|-------------------|----------------|
| 1  | Martin     | REAGAN     | Hutchinson Rd     | Dover          |
| 2  | Herbert    | REAGAN     | Bailard Avenue    | Frankfort      |
| 3  | Franklin   | WASHINGTON | Bayshore Freeway  | Denver         |
| 4  | Franklin   | CARTER     | Burnett Road      | Frankfort      |
| 5  | Woodrow    | MCKINLEY   | San Ysidro Blvd   | Des Moines     |
| 6  | Bill       | QUINCY     | Fairview Avenue   | Topeka         |
| 7  | Bill       | BUREN      | Calle Real        | Jefferson City |
| 8  | Andrew     | ARTHUR     | Santa Ana Freeway | Indianapolis   |
| 9  | Woodrow    | FORD       | N Harrison St     | Augusta        |
| 10 | Calvin     | COOLIDGE   | Harbor Dr         | Frankfort      |

The *clients* database table is filled with data from the file including upper-case *last name* as transformed in the job.

For simple Insert operations that don't include any transformations, the use of **tMySQLOutputBulkExec** allows you to skip a step in the process and thus improves performance.

# tMysqlOutputBulkExec

## tMysqlOutputBulkExec properties

The **tMysqlOutputBulk** and **tMysqlBulkExec** components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the **tMysqlOutputBulkExec** component.

|                          | <i>Create directory if does not exist</i>                                                                               |             | This check box is selected by default. It creates a directory to hold the output table if required.                                                                                                                                                                                                                                                                                        |
|                          | <i>Custom the flush buffer size</i>                                                                                     |             | Customize the amount of memory used to temporarily store output data. In the <b>Row number field</b> , enter the number of rows after which the memory is to be freed again.                                                                                                                                                                                                               |
|                          | <i>Action on data</i>                                                                                                   |             | On the data of the table defined, you can carry out the following operations:<br><br><b>Insert records in table:</b> Add new records to the table.<br><br><b>Update records in table:</b> Make changes to existing records.<br><br><b>Replace records in table:</b> Replace existing records with new one. <b>Ignore records in table:</b> Ignore existing records or insert the new ones. |
|                          | <i>Records contain NULL value</i>                                                                                       |             | This check box is selected by default. It allows you to take account of NULL value fields. If you clear the check box, the NULL values will automatically be replaced with empty values.                                                                                                                                                                                                   |
|                          | <i>Encoding</i>                                                                                                         |             | Select the encoding from the list or select <b>Custom</b> and define it manually. This field is compulsory for DB data handling.                                                                                                                                                                                                                                                           |
|                          | <i>tStatCatcher Statistics</i>                                                                                          |             | Select this check box to collect the log data at the component level.                                                                                                                                                                                                                                                                                                                      |
| <b>Usage</b>             | This component is mainly used when no particular transformation is required on the data to be loaded onto the database. |             |                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Limitation</b>        | n/a                                                                                                                     |             |                                                                                                                                                                                                                                                                                                                                                                                            |

## Scenario: Inserting data in MySQL database

This scenario describes a two-component Job which carries out the same operation as the one described for [the section called “tMysqlOutputBulk properties”](#) and [the section called “tMysqlBulkExec properties”](#), although no data is transformed.

- Drop a **tRowGenerator** and a **tMysqlOutputBulkExec** component from the **Palette** to the design workspace.
- Connect the components using a link such as **Row > Main**.
- Set the **tRowGenerator** parameters the same way as in the section called “Scenario: Inserting transformed data in MySQL database”. The schema is made of four columns including: *ID*, *First Name*, *Last Name*, *Address* and *City*.
- In the workspace, double-click the **tMysqlOutputBulkExec** to display the **Component** view and set the properties.

For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query type** of components are always **Built-in**. You have to complete the relevant settings manually in the specific Job.

- Define the database connection details in the corresponding fields.
- In the **Action on table** field, select the **None** option as you want to insert the data into a table which already exists.
- In the **Table** field, enter the name of the table you want to populate, the name being *clients* in this example.
- In the **Local filename** field, indicate the access path and the name of the file which contains the data to be added to the table. In this example, the file is *clients.txt*.
- Click on the **Advanced settings** tab to define the component’s advanced parameters.

- In the **Action on data** list, select the **Insert records in table** to insert the new data in the table.

- Press **F6** to run the Job.

The result should be pretty much the same as in [the section called “Scenario: Inserting transformed data in MySQL database”](#), but the data might differ as these are regenerated randomly everytime the Job is run.

# tMysqlRollback

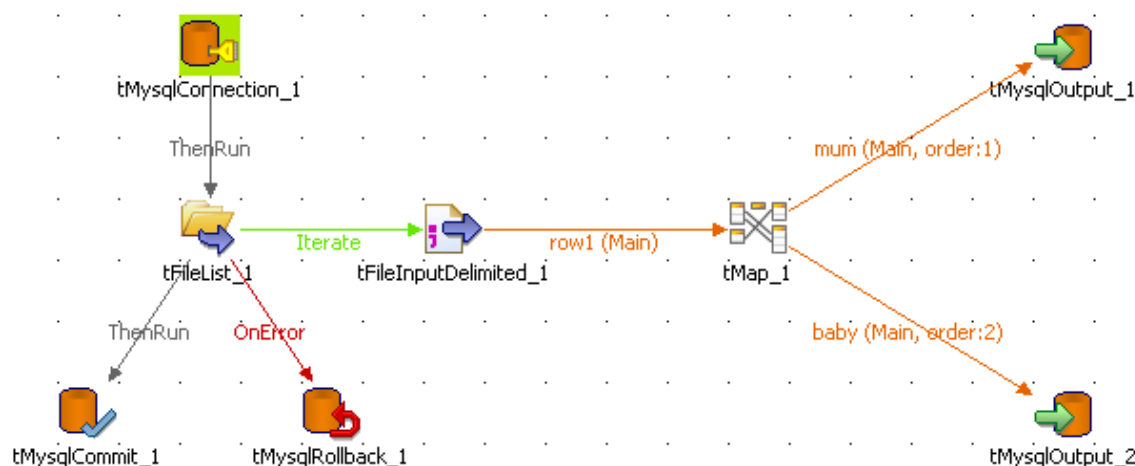

## tMysqlRollback properties

This component is closely related to **tMysqlCommit** and **tMysqlConnection**. It usually does not make much sense to use these components independently in a transaction.

|                          |                                                                                                                                       |                                                                                                                       |

| <b>Component family</b>  | Databases                                                                                                                             |                                                                                                                       |
| <b>Function</b>          | Cancel the transaction commit in the connected DB.                                                                                    |                                                                                                                       |
| <b>Purpose</b>           | Avoids to commit part of a transaction involuntarily.                                                                                 |                                                                                                                       |
| <b>Basic settings</b>    | <i>Component list</i>                                                                                                                 | Select the <b>tMysqlConnection</b> component in the list if more than one connection are planned for the current job. |
|                          | <i>Close Connection</i>                                                                                                               | Clear this check box to continue to use the selected connection once the component has performed its task.            |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                                                                                        | Select this check box to collect log data at the component level.                                                     |
| <b>Usage</b>             | This component is to be used along with Mysql components, especially with <b>tMysqlConnection</b> and <b>tMysqlCommit</b> components. |                                                                                                                       |
| <b>Limitation</b>        | n/a                                                                                                                                   |                                                                                                                       |

## Scenario: Rollback from inserting data in mother/daughter tables

Based on [the section called “Scenario: Inserting data in mother/daughter tables”](#), insert a rollback function in order to prevent unwanted commit.

- Drag and drop a **tMysqlRollback** to the design workspace and connect it to the Start component.
- Set the Rollback unique field on the relevant DB connection.

This complementary element to the job ensures that the transaction will not be partly committed.

# tMysqlRow

## tMysqlRow properties

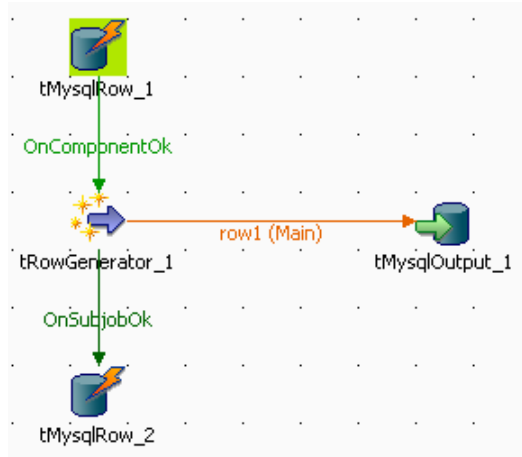

|                         |                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Function</b>         | <b>tMysqlRow</b> is the specific component for this database query. It executes the SQL query stated in the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Purpose</b>          | Depending on the nature of the query and the database, <b>tMysqlRow</b> acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                          | <i>Query</i>                             | Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                          | <i>Die on error</i>                      | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <b>Row &gt; Rejects</b> link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Advanced settings</b> | <i>Additional parameters</i> <i>JDBC</i> | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <b>Use an existing connection</b> check box in the <b>Basic settings</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                          | <i>Propagate QUERY's recordset</i>       | Select this check box to insert the result of the query in a COLUMN of the current flow. Select this column from the <b>use column</b> list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                          | <i>Use PreparedStatement</i>             | Select this checkbox if you want to query the database using a PreparedStatement. In the <b>Set PreparedStatement Parameter</b> table, define the parameters represented by “?” in the SQL instruction of the <b>Query</b> field in the <b>Basic Settings</b> tab.<br><br><b>Parameter Index:</b> Enter the parameter position in the SQL instruction.<br><br><b>Parameter Type:</b> Enter the parameter type.<br><br><b>Parameter Value:</b> Enter the parameter value.<br><br> This option is very useful if you need to execute the same query several times. Performance levels are increased |
|                          | <i>Commit every</i>                      | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                          | <i>tStatCatcher Statistics</i>           | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Usage</b>             |                                          | This component offers the flexibility of the DB query and covers all possible SQL queries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Scenario 1: Removing and regenerating a MySQL table index

This scenario describes a four-component job that removes a table index, applies a select insert action onto a table then regenerates the index.

- Select and drop the following components onto the design workspace: **tMysqlRow** (x2), **tRowGenerator**, and **tMysqlOutput**.
- Connect **tRowGenerator** to **tMysqlInput**.
- Using a **OnComponentOk** connections, link the first **tMysqlRow** to **tRowGenerator** and **tRowGenerator** to the second **tMysqlRow**.
- Select the **tMysqlRow** to fill in the DB **Basic settings**.
- Define the DB connection details in the corresponding fields.
- Click the [...] button next to **Edit schema** and define the schema columns.
- Propagate the properties and schema details onto the other components of the Job.
- Type in the following SQL statement to alter the database entries: drop index <index\_name> on <table\_name>
- Select the second **tMysqlRow** component, check the DB properties and schema.
- Type in the SQL statement to recreate an index on the table using the following statement: create index <index\_name> on <table\_name> (<column\_name>)

The **tRowGenerator** component is used to generate automatically the columns to be added to the DB output table defined.

- Select the **tMysqlOutput** component and fill in the DB connection properties. The table to be fed is named: *comprehensive*.
- The schema should be automatically inherited from the data flow coming from the **tLogRow**. Edit the schema to check its structure and check that it corresponds to the schema expected on the DB table specified.
- The **Action on table** is *None* and the **Action on data** is *Insert*.
- No additional Columns is required for this job.
- Press **F6** to run the job.

If you manage to watch the action on DB data, you can notice that the index is dropped at the start of the job and recreated at the end of the insert action.

## Scenario 2: Using PreparedStatement objects to query data

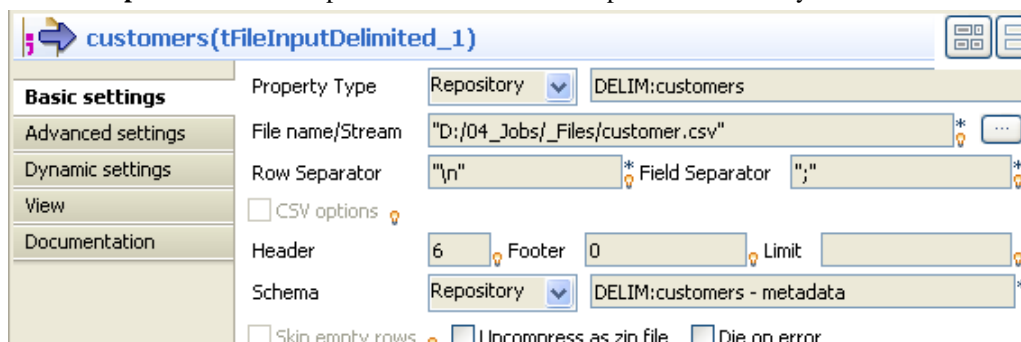

This scenario describes a four component job which allows you to link a table column with a client file. The MySQL table contains a list of all the American States along with the State ID, while the file contains the customer information including the ID of the State in which they live. We want to retrieve the name of the State for each client, using an SQL query. In order to process a large volume of data quickly, we use a PreparedStatement object which means that the query is executed only once rather than against each row in turn. Then each row is sent as a parameter. Note that PreparedStatement object can also be used in avoiding SQL injection.

For this scenario, we use a file and a database for which we have already stored the connection and properties in the Repository metadata.

 *This scenario is for reference only. For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query type** of components are always **Built-in**. You have to drop all the required components from the **Palette** and complete the relevant settings manually in the specific Job.*

- In the **Repository**, expand the **Metadata** and **File delimited** nodes.
- Select the metadata which corresponds to the client file you want to use in the Job. Here, we are using the *customers* metadata.
- Slide the metadata onto the workspace and double-click **tFileInputDelimited** in the **Components** dialog box so that the **tFileInputDelimited** component is created with the parameters already set.

- In the **Schema** list, select **Built-in** so that you can modify the component’s schema. Then click on [...] next to the **Edit schema** field to add a column into which the name of the State will be inserted.

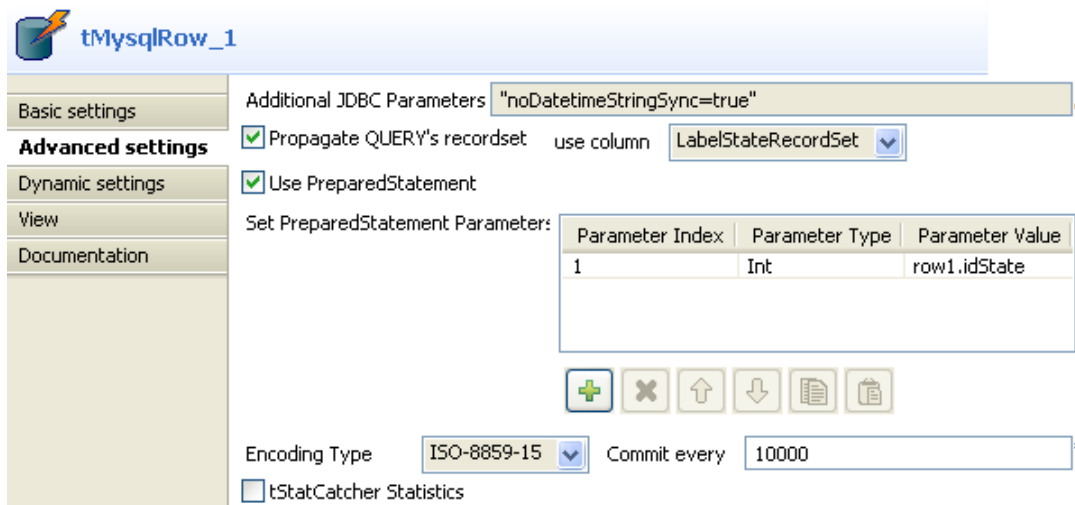

- Click on the [+] button to add a column to the schema. Rename this column *LabelStateRecordSet* and select **Object** from the **Type** list. Click **OK** to save your modifications.
- From the **Palette**, select the **tMySQLRow**, **tParseRecordSet** and **tFileOutputDelimited** components and drop them onto the workspace.
- Connect the four components using **Row > Main** type links.
- Double click **tMySQLRow** to set its properties in the **Basic settings** tab of the **Component view**.

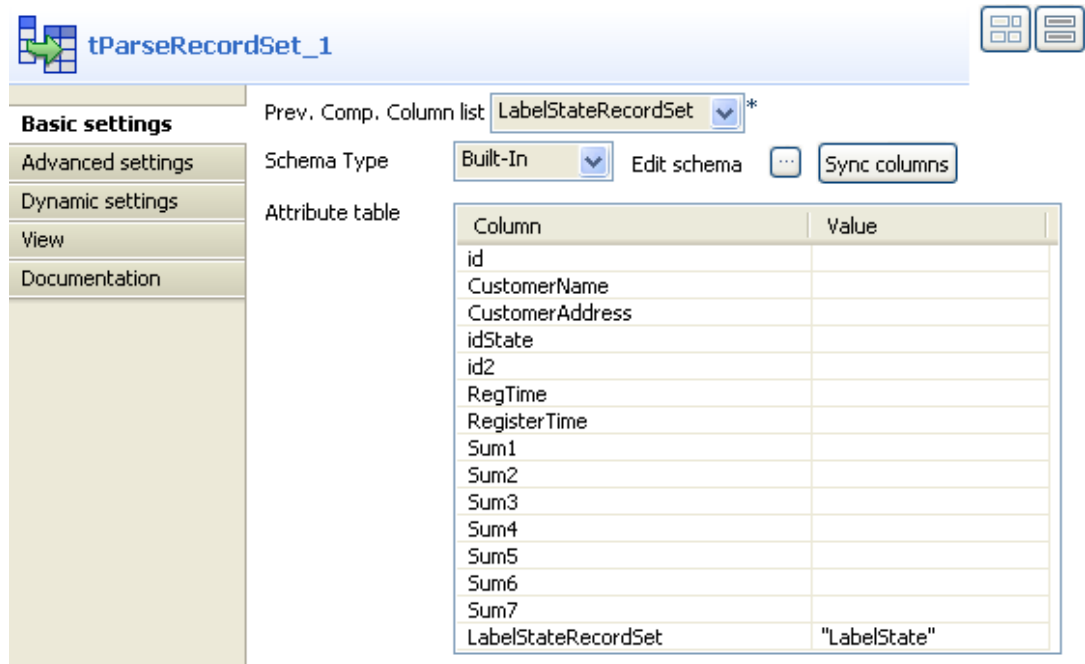

- In the **Property Type** list, select **Repository** and click on the [...] button to select a database connection from the metadata in the Repository. The **DB Version, Host, Port, Database, Username** and **Password** fields are completed automatically. If you are using the **Built-in** mode, complete these fields manually.
- From the **Schema** list, select **Built-in** to set the schema properties manually and add the *LabelStateRecordSet* column, or click directly on the **Sync columns** button to retrieve the schema from the preceding component.
- In the **Query** field, enter the SQL query you want to use. Here, we want to retrieve the names of the American States from the *LabelState* column of the MySQL table, *us\_state*: "SELECT LabelState FROM us\_state WHERE idState=?".

The question mark, "?", represents the parameter to be set in the **Advanced settings** tab.

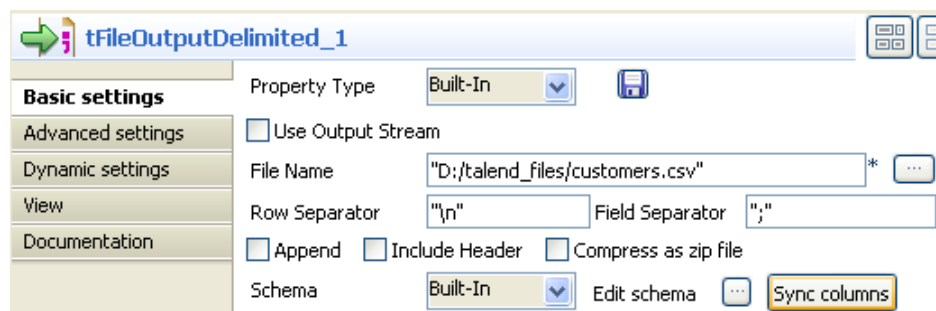

- Click **Advanced settings** to set the components advanced properties.

- Select the **Propagate QUERY's recordset** check box and select the *LabelStateRecordSet* column from the **use column** list to insert the query results in that column.
- Select the **Use PreparedStatement** check box and define the parameter used in the query in the **Set PreparedStatement Parameters** table.
- Click on the [+] button to add a parameter.
- In the **Parameter Index** cell, enter the parameter position in the SQL instruction. Enter "1" as we are only using one parameter in this example.
- In the **Parameter Type** cell, enter the type of parameter. Here, the parameter is a whole number, hence, select **Int** from the list.
- In the **Parameter Value** cell, enter the parameter value. Here, we want to retrieve the name of the State based on the State ID for every client in the input file. Hence, enter "row1.idState".
- Double click **tParseRecordSet** to set its properties in the **Basic settings** tab of the **Component** view.

- From the **Prev. Comp. Column list**, select the preceding components column for analysis. In this example, select *LabelStateRecordSet*.
- Click on the **Sync columns** button to retrieve the schema from the preceding component. The **Attribute table** is automatically completed with the schema columns.
- In the **Attribute table**, in the **Value** field which corresponds to the *LabelStateRecordSet*, enter the name of the column containing the State names to be retrieved and matched with each client, within double quotation marks. In this example, enter "*LabelState*".
- Double click **tFileOutputDelimited** to set its properties in the **Basic settings** tab of the **Component** view.

- In the **File Name field**, enter the access path and name of the output file.
- Click **Sync columns** to retrieve the schema from the preceding component.
- Save your Job and press **F6** to run it.

Note that the SP schema can hold more columns than there are paramaters used in the procedure.<br><br>Select the <b>Type</b> of parameter:<br><br><b>IN:</b> Input parameter<br><br><b>OUT:</b> Output parameter/return value<br><br><b>IN OUT:</b> Input parameters is to be returned as value, likely after modification through the procedure (function).<br><br><b>RECORDSET:</b> Input parameters is to be returned as a set of values, rather than single value. |

|                   |                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   |  Check the <b>tPostgresqlCommit</b> component if you want to analyze a set of records from a database table or DB query and return single records. |
| <b>Usage</b>      | This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.                                                                                                     |
| <b>Limitation</b> | The Stored Procedures syntax should match the Database syntax.                                                                                                                                                                      |

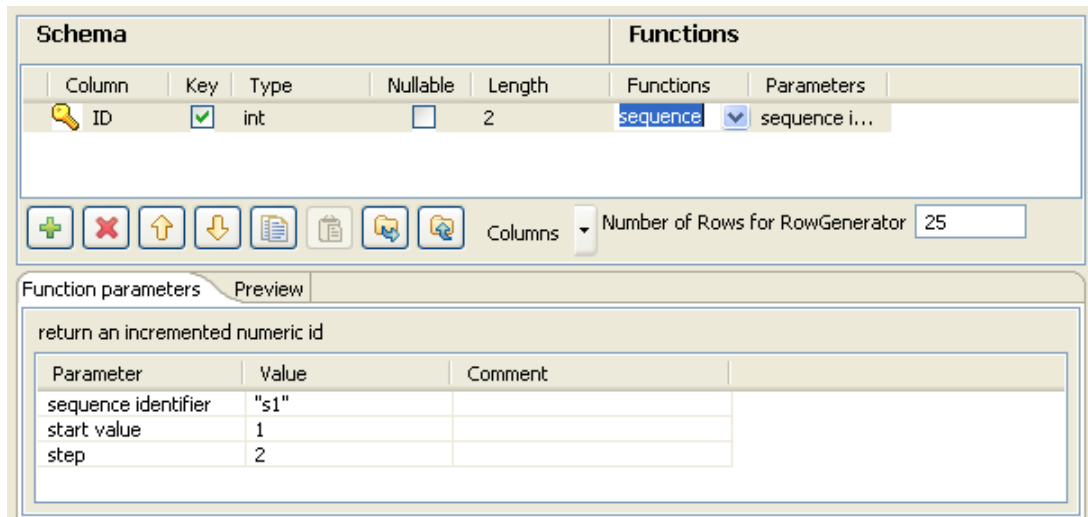

## Scenario: Finding a State Label using a stored procedure

The following job aims at finding the State labels matching the odd State IDs in a Mysql two-column table. A stored procedure is used to carry out this operation.

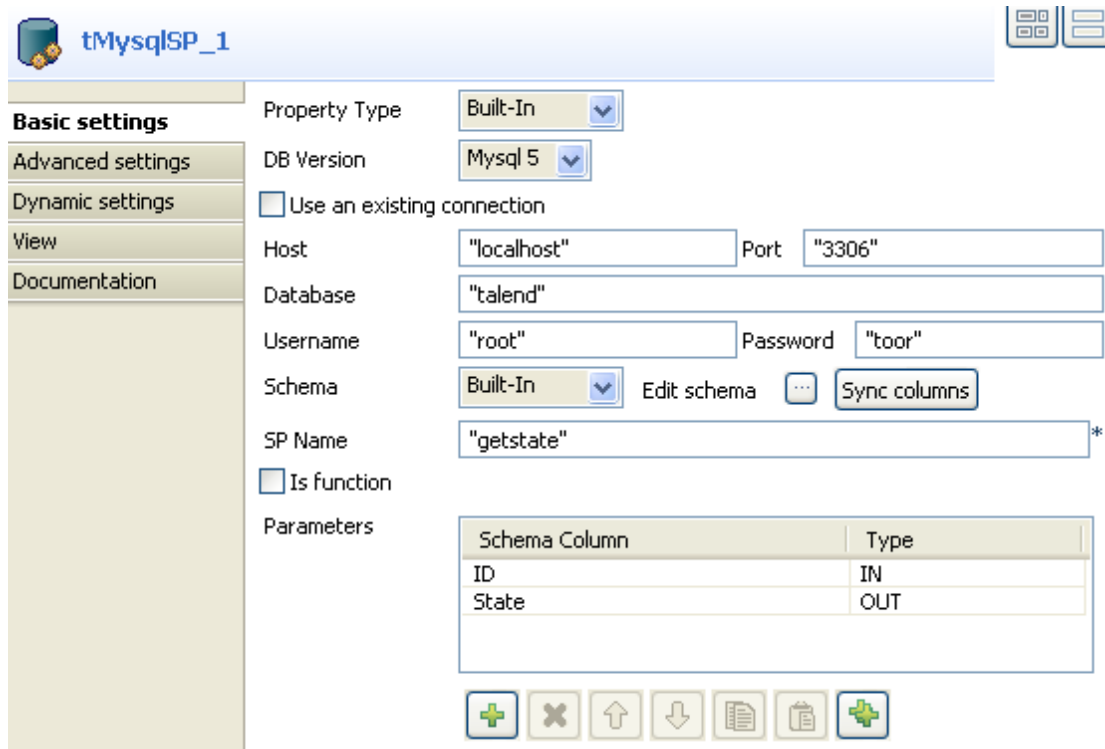

- Drag and drop the following components used in this example: **tRowGenerator**, **tMysqlSP**, **tLogRow**.
- Connect the components using the **Row Main** link.
- The **tRowGenerator** is used to generate the odd id number. Double-click on the component to launch the editor.

- Click on the **Plus** button to add a column to the schema to generate.
- Select the **Key** check box and define the **Type** to **Int**.
- The **Length** equals to 2 digits max.
- Use the preset function called **sequence** but customize the Parameters in the lower part of the window.

- Change the **Value** of **step** from 1 to 2 for this example, still starting from 1.
- Set the **Number of generated rows** to 25 in order for all the odd State id (of 50 states) to be generated.
- Click **OK** to validate the configuration.
- Then select the **tMySQLSP** component and define its properties.

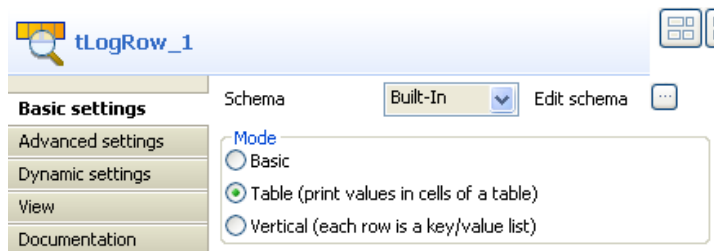

- Define the DB connection details in the corresponding fields.
- Click **Sync Column** to retrieve the generated schema from the preceding component.
- Then click **Edit Schema** and add an extra column to hold the State Label to be output, in addition to the ID.
- Type in the name of the procedure in the **SP Name** field as it is called in the Database. In this example, *getstate*. The procedure to be executed states as follows:

```
DROP PROCEDURE
```

```
IF EXISTS `talend`.`getstate` $$
CREATE DEFINER=`root`@`localhost` PROCEDURE `getstate`(IN pid INT, OUT
pstate VARCHAR(50))
BEGIN
SELECT LabelState INTO pstate FROM us_states WHERE idState = pid;
END $$
```

- In the **Parameters** area, click the plus button to add a line to the table.
- Set the **Column** field to *ID*, and the **Type** field to *IN* as it will be given as input parameter to the procedure.
- Add a second line and set the **Column** field to *State* and the **Type** to *Out* as this is the output parameter to be returned.
- Eventually, set the **tLogRow** component properties.

- Synchronize the schema with the preceding component.
- And select the **Print values in cells of a table** check box for reading convenience.
- Then save your Job and execute it.

```
Starting job MySQLSP at 17:24 23/08/2007.
+-----+
| tLogRow_1 |
+-----+
| ID | State |
+-----+
1	Alabama
3	Arizona
5	California
7	Connecticut
9	Florida
11	Hawaii
13	Illinois
15	Iowa
17	Kentucky
19	Maine
21	Massachusetts
23	Minnesota
25	Missouri
27	Nebraska
29	New Hampshire
31	New Mexico
33	North Carolina
+-----+
```

The output shows the state labels corresponding to the odd state ids as defined in the procedure.

Check the **tPostgresqlCommit** component if you want to analyze a set of records from a database table or DB query and return single records.

## Related scenario

For **tMysqlTableList** related scenario, see [the section called “Scenario: Iterating on a DB table and listing its column names”](#).

# tOracleBulkExec

## tOracleBulkExec properties

The **tOracleOutputBulk** and **tOracleBulkExec** components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the **tOracleOutputBulkExec** component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

|              | <i>Convert columns and table names to uppercase</i>                                      | Select this check box to uppercase the names of the columns and the name of the table.                                                                                                                                                                                                                                                                                    |
|              | <i>tStatCatcher Statistics</i>                                                           | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                                                         |
| <b>Usage</b> | This dedicated component offers performance and flexibility of Oracle DB query handling. |                                                                                                                                                                                                                                                                                                                                                                           |

## Scenario: Truncating and inserting file data into Oracle DB

This scenario describes how to truncate the content of an Oracle DB and load an input file content. The related job is composed of three components that respectively creates the content, output this content into a file to be loaded onto the Oracle database after the DB table has been truncated.

- Drop the following components: **tOracleInput**, **tFileOutputDelimited**, **tOracleBulkExec** from the **Palette** to the design workspace
- Connect the **tOracleInput** with the **tFileOutputDelimited** using a **row main** link.
- And connect the **tOracleInput** to the **tOracleBulkExec** using a **OnSubjobOk** trigger link.
- Define the Oracle connection details. We recommend you to store the DB connection details in the Metadata repository in order to retrieve them easily at any time in any job.

**tOracleInput\_1**

For Talend Open Studio for Big Data, the **Property type** and **Schema** of components are always **Built-in**. For how to edit a built-in schema, see *Talend Open Studio for Big Data User Guide*.

- Define the schema, if it isn't stored either in the **Repository**. In this example, the schema is as follows: *ID\_Contract, ID\_Client, Contract\_type, Contract\_Value*.
- Define the **tFileOutputDelimited** component parameters, including output **File Name**, **Row separator** and **Fields delimiter**.
- Then double-click on the **tOracleBulkExec** to define the DB feeding properties.

Property Type Built-In

Use an existing connection

Connection Type Oracle SID

DB Version Oracle 11

Host

Port

Database

Schema

Username \*

Password \*

Table \*

Action on table None

Data file name \*

Action on data Insert \*

Schema Type Built-In Edit schema

- In the **Property Type**, select **Repository** mode if you stored the database connection details under the **Metadata** node of the **Repository** or select **Built-in** mode to define them manually. In this scenario, we use the **Built-in** mode.
- Thus, set the connection parameters in the following fields: **Host**, **Port**, **Database**, **Schema**, **Username**, and **Password**.
- Fill in the name of the **Table** to be fed and the **Action on data** to be carried out, in this use case: **insert**.
- In the **Schema** field, select **Built-in** mode, and click [...] button next to the **Edit schema** field to describe the structure of the data to be passed on to the next component.
- Click the **Advanced settings** view to configure the advanced settings of the component.

Advanced separator(for number)    Thousands separator \*    Decimal separator \*

Use existing control file

Record format \*    Record terminator

Specify .ctl file's INTO TABLE clause manually

Field terminated by     Field terminator \*

Use fields enclosure

Use schema's Date Pattern to load Date field

Specify field condition

Preserve blanks     Trailing null columns

Load options

| Parameter                           | Value |
|-------------------------------------|-------|
| DIRECT(Direct path load):TRUE FALSE | TRUE  |

NLS Language

Set Parameter NLS\_TERRITORY    NLS Territory

Encoding Type

Output

Convert columns and table to uppercase

tStatCatcher Statistics

- Select the **Use an existing control file** check box if you want to use a control file (.ctl) storing the status of the physical structure of the database. Or, fill in the following fields manually: **Record format**, **Specify .ctl file's INTO TABLE clause manually**, **Field terminated by**, **Use field enclosure**, **Use schema's Date Pattern to load Date field**, **Specify field condition**, **Preserve blanks**, **Trailing null columns**, **Load options**, **NLS Language** et **Set Parameter NLS\_TERRITORY** according to your database.
- Define the **Encoding** as in preceding steps.
- For this scenario, in the **Output** field, select **to console** to output the standard output of the database to the console.

Press **F6** to run the job. The log output displays in the **Run** tab and the table is fed with the parameter file data.

## Related scenario

This component is closely related to **tOracleConnection** and **tOracleRollback**. It usually doesn't make much sense to use one of these without using a **tOracleConnection** component to open a connection for the current transaction.

For **tOracleCommit** related scenario, see [the section called "tMysqlConnection"](#)

# tOracleConnection

## tOracleConnection Properties

This component is closely related to **tOracleCommit** and **tOracleRollback**. It usually doesn't make much sense to use one of these without using a **tOracleConnection** component to open a connection for the current transaction.

| <b>Usage</b>      | This component is to be used along with Oracle components, especially with <b>tOracleCommit</b> and <b>tOracleRollback</b> components. |                                                                                                                                                                                                                                                                                                                                                  |
| <b>Limitation</b> | n/a                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                  |

## Related scenario

This component is closely related to **tOracleCommit** and **tOracleRollback**. It usually doesn't make much sense to use one of these without using a **tOracleConnection** component to open a connection for the current transaction.

For **tOracleConnection** related scenario, see [the section called "tMysqlConnection"](#)

# tOracleInput

| <b>Function</b>         | <b>tOracleInput</b> reads a database and extracts fields based on a query.                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Purpose</b>          | <b>tOracleInput</b> executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Usage</b>             | This component covers all possible SQL queries for Oracle databases.                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                              |
| <b>Limitation</b>        | Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> . |                                                                                                                                                                                                              |

## Scenario 1: Using context parameters when reading a table from an Oracle database

In this scenario, we will read a table from an Oracle database, using a context parameter to refer to the table name.

## Dragging and dropping components and linking them together

1. Drop **tOracleInput** and **tLogRow** from the **Palette** onto the workspace.
2. Link **tOracleInput** to **tLogRow** using a **Row > Main** connection.

## Configuring the components

1. Double-click **tOracleInput** to open its **Basic Settings** view in the **Component** tab.

| tOracleInput_2                                      |                                   |
|-----------------------------------------------------|-----------------------------------|
| Property Type                                       | Built-In                          |
| <input type="checkbox"/> Use an existing connection |                                   |
| Connection Type                                     | Oracle SID                        |
| DB Version                                          | Oracle 11                         |
| Host                                                | "192.168.0.19"                    |
| Port                                                | "1521"                            |
| Database                                            | "talend" * Oracle schema "TALEND" |
| Username                                            | "talend" * Password "oracle"      |
| Schema                                              | Built-In Edit schema              |
| Table Name                                          | context.TABLE                     |
| Query Type                                          | Built-In                          |

2. In the **Host** field, enter the Oracle database server's IP address, *"192.168.0.19"* in this example.

In the **Port** field, enter the port number, *"1521"* in this example.

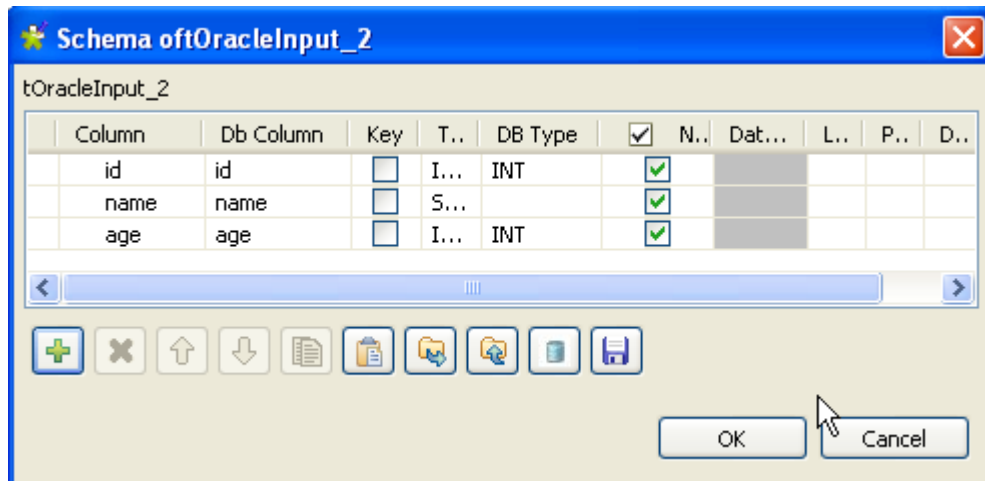

In the **Database** field, enter the database name, *"talend"* in this example.

In the **Oracle schema** field, enter the Oracle schema name, *"TALEND"* in this example.

In the **Username** and **Password** fields, enter the authentication details, respectively *"talend"* and *"oracle"* in this example.

3. Set the **Schema** as **Built-In** and click **Edit schema** to define the desired schema.

The schema editor opens:

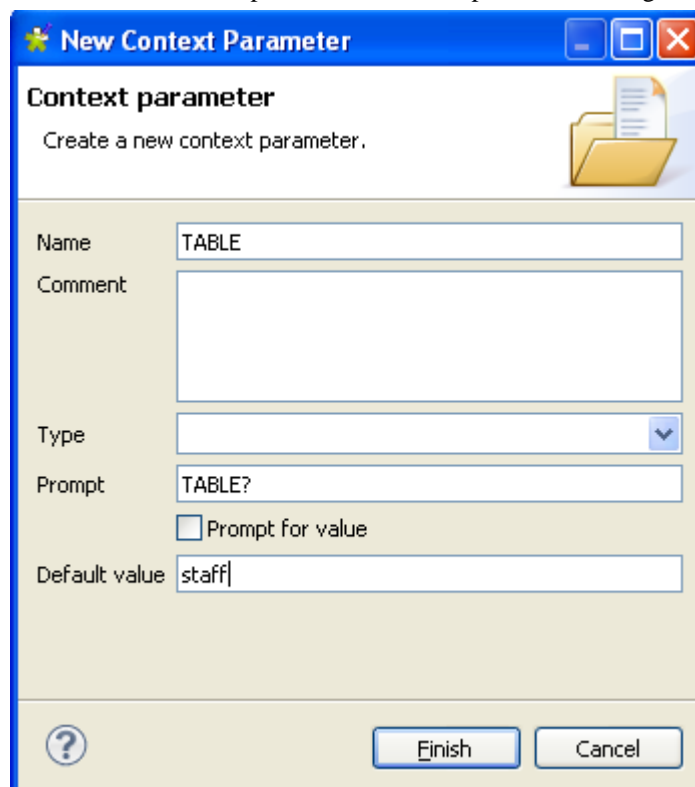

- Click the [+] button to add the rows that you will use to define the schema, three columns in this example: *id*, *name* and *age*.

Under **Column**, click the fields to enter the corresponding column names.

Click the fields under **Type** to define the type of data.

Click **OK** to close the schema editor.

- Put the cursor in the **Table Name** field and press **F5** for context parameter setting.

For more information about context settings, see *Talend Open Studio for Big Data User Guide*.

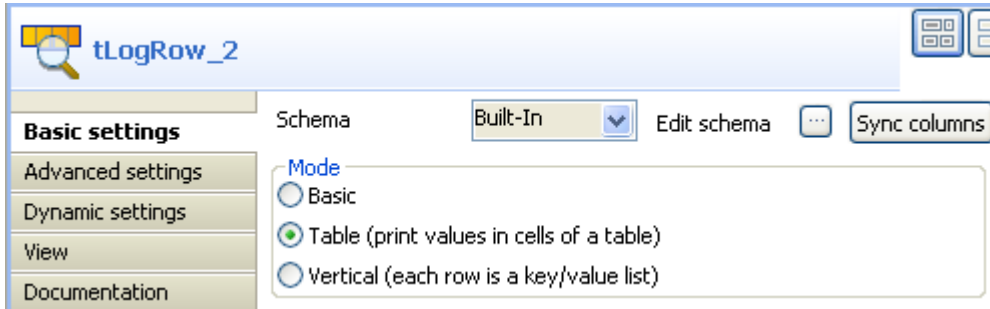

- Keep the default setting in the **Name** field and type in the name of the database table in the **Default value** field, *staff* in this use case.
- Click **Finish** to validate the setting.

The context parameter `context.TABLE` automatically appears in the **Table Name** field.

- In the **Query type** list, select **Built-In**. Then, click **Guess Query** to get the query statement.

```
"SELECT
 TALEND." + context.TABLE + ".id,
 TALEND." + context.TABLE + ".name,
 TALEND." + context.TABLE + ".age
FROM TALEND." + context.TABLE
```

- Double-click **tLogRow** to set its **Basic Settings** in the **Component** tab.

- In the **Mode** area, select **Table (print values in cells of a table)** for a better display of the results.

- Save the Job.

## Executing the Job

The results below can be found after **F6** is pressed to run the Job.

| tLogRow_2 |         |     |
|-----------|---------|-----|
| id        | name    | age |
| 1         | Bill    | 92  |
| 2         | Woodrow | 75  |
| 3         | Chester | 42  |
| 4         | Millard | 32  |
| 5         | Herbert | 70  |
| 6         | Lyndon  | 27  |

|  | <i>Username</i> and <i>Password</i> | DB user authentication data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|  | <i>Table</i>                        | Name of the table to be written. Note that only one table can be written at a time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|  | <i>Action on table</i>              | <p>On the table defined, you can perform one of the following operations:</p> <p><b>None:</b> No operation is carried out.</p> <p><b>Drop and create a table:</b> The table is removed and created again.</p> <p><b>Create a table:</b> The table does not exist and gets created.</p> <p><b>Create a table if not exists:</b> The table is created if it does not exist.</p> <p><b>Drop a table if exists and create:</b> The table is removed if it already exists and created again.</p> <p><b>Clear a table:</b> The table content is deleted.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|  | <i>Action on data</i>               | <p>On the data of the table defined, you can perform:</p> <p><b>Insert:</b> Add new entries to the table. If duplicates are found, job stops.</p> <p><b>Update:</b> Make changes to existing entries</p> <p><b>Insert or update:</b> Add entries or update existing ones.</p> <p><b>Update or insert:</b> Update existing entries or create it if non existing</p> <p><b>Delete:</b> Remove entries corresponding to the input flow.</p> <p> <i>It is necessary to specify at least one column as a primary key on which the <b>Update</b> and <b>Delete</b> operations are based. You can do that by clicking <b>Edit Schema</b> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <b>Advanced settings</b> view where you can simultaneously define primary keys for the <b>Update</b> and <b>Delete</b> operations. To do that: Select the <b>Use field</b></i></p> |

|                          |                                 |             |                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|---------------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                 |             | <i>options</i> check box and then in the <b>Key in update column</b> , select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the <b>Key in delete column</b> for the Delete operation.                                                                                                                                         |
|                          | <i>Schema and schema</i>        | <i>Edit</i> | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> .                                                                                                                                                                                |
|                          |                                 |             | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                                                                                                                   |
|                          | <i>Die on error</i>             |             | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <b>Row &gt; Rejects</b> link.                                                                                                                                                                         |
| <b>Advanced settings</b> | <i>Additional parameters</i>    | <i>JDBC</i> | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <b>Use an existing connection</b> check box in the <b>Basic settings</b> .<br><br> You can press <b>Ctrl+Space</b> to access a list of predefined global variables. |
|                          | <i>Commit every</i>             |             | Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.                                                                                                                                                                                |
|                          | <i>tStat Catcher Statistics</i> |             | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                                                                           |
|                          | <i>Additional Columns</i>       |             | This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.                                                                                                                              |
|                          |                                 |             | <b>Name:</b> Type in the name of the schema column to be altered or inserted as new column.                                                                                                                                                                                                                                                                                                 |
|                          |                                 |             | <b>SQL expression:</b> Type in the SQL statement to be executed in order to alter or insert the relevant column data.                                                                                                                                                                                                                                                                       |
|                          |                                 |             | <b>Position:</b> Select <b>Before</b> , <b>Replace</b> or <b>After</b> following the action to be performed on the reference column.                                                                                                                                                                                                                                                        |
|                          |                                 |             | <b>Reference column:</b> Type in a column of reference that the <b>tDBOutput</b> can use to place or replace the new or altered column.                                                                                                                                                                                                                                                     |
|                          | <i>Use field options</i>        |             | Select this check box to customize a request, especially when there is double action on data.                                                                                                                                                                                                                                                                                               |
|                          | <i>Use Hint Options</i>         |             | Select this check box to activate the hint configuration area which helps you optimize a query's execution. In this area, parameters are:                                                                                                                                                                                                                                                   |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                             |

|                   | <i>Convert columns and table to uppercase</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Select this check box to set the names of columns and table in upper case.                                                                                                                                                                                                                  |
|                   | <i>Enable debug mode</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Select this check box to display each step during processing entries in a database.                                                                                                                                                                                                         |
|                   | <i>Use Batch Size</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | <p>When selected, enables you to define the number of lines in each processed batch.</p> <p> <i>This option is available only when you do not Use an existing connection in <b>Basic settings</b>.</i></p> |
|                   | <i>Support null in “SQL WHERE” statement</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Select this check box to validate null in “SQL WHERE” statement.                                                                                                                                                                                                                            |
| <b>Usage</b>      | <p>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.</p> <p>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Oracle database. It also allows you to create a reject flow using a <b>Row &gt; Rejects</b> link to filter data in error. For an example of <b>tMysqlOutput</b> in use, see <a href="#">the section called “Scenario 3: Retrieve data in error with a Reject link”</a>.</p> |                                                                                                                                                                                                                                                                                             |
| <b>Limitation</b> | <p>Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i>. For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i>.</p>                                                                                                                                                       |                                                                                                                                                                                                                                                                                             |

## Related scenarios

For **tOracleOutput** related topics, see:

- [the section called “Scenario: Writing a row to a table in the MySql database via an ODBC connection”](#).
- [the section called “Scenario 1: Adding a new column and altering data in a DB table”](#).

# tOracleOutputBulk

## tOracleOutputBulk properties

The **tOracleOutputBulk** and **tOracleBulkExec** components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the **tOracleOutputBulkExec** component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

- [the section called “Scenario: Inserting data in MySQL database”](#).
- [the section called “Scenario: Truncating and inserting file data into Oracle DB”](#).

# tOracleOutputBulkExec

## tOracleOutputBulkExec properties

The **tOracleOutputBulk** and **tOracleBulkExec** components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the **tOracleOutputBulkExec** component.

|                          | <i>Create directory if not exists</i>  |     | This check box is selected by default. It creates a directory to hold the output table if required.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                          | <i>Append</i>                          |     | Select this check box to add the new rows at the end of the file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                          | <i>Action on data</i>                  |     | On the data of the table defined, you can perform:<br><br><b>Insert:</b> Add new entries to the table. If duplicates are found, job stops.<br><br><b>Update:</b> Make changes to existing entries<br><br><b>Insert or update:</b> Add entries or update existing ones.<br><br><b>Update or insert:</b> Update existing entries or create it if non existing<br><br><b>Truncate:</b> Remove all entries from table.                                                                                                                                        |
|                          | <i>Schema</i> and <i>Edit Schema</i>   |     | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> .                                                                                                                                                                                                                                                                                                                                              |
|                          | <i>Field separator</i>                 |     | Character, string or regular expression to separate fields.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                          | <i>Encoding</i>                        |     | Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Advanced settings</b> | <i>Advanced separator (for number)</i> |     | Select this check box to change data separators for numbers:<br><br><b>Thousands separator:</b> define separators you want to use for thousands.                                                                                                                                                                                                                                                                                                                                                                                                          |

|                   |                                                                                                                         |                                                                                                                                                                        |
|-------------------|-------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   |                                                                                                                         | <b>Decimal separator:</b> define separators you want to use for decimals.                                                                                              |
|                   | <i>Use existing control file</i>                                                                                        | Select this check box and browse to the .ctl control file you want to use.                                                                                             |
|                   | <i>Field separator</i>                                                                                                  | Character, string or regular expression to separate fields.                                                                                                            |
|                   | <i>Row separator</i>                                                                                                    | String (ex: “\n” on Unix) to separate rows.                                                                                                                            |
|                   | <i>Specify .ctl file’s INTO TABLE clause manually</i>                                                                   | Select this check box to enter manually the INTO TABLE clause of the control file directly into the code.                                                              |
|                   | <i>Use schema’s Date Pattern to load Date field</i>                                                                     | Select this check box to use the date model indicated in the schema for dates.                                                                                         |
|                   | <i>Specify field condition</i>                                                                                          | Select this check box to define a condition for loading data.                                                                                                          |
|                   | <i>Preserve blanks</i>                                                                                                  | Select this check box to preserve blank spaces.                                                                                                                        |
|                   | <i>Trailing null columns</i>                                                                                            | Select this check box to load data with all empty columns.                                                                                                             |
|                   | <i>Load options</i>                                                                                                     | Click + to add data loading options:<br><br><b>Parameter:</b> select a loading parameter from the list.<br><br><b>Value:</b> enter a value for the parameter selected. |
|                   | <i>NLS Language</i>                                                                                                     | From the drop-down list, select the language for your data if the data is not in Unicode.                                                                              |
|                   | <i>Set Parameter NLS_TERRITORY</i>                                                                                      | Select this check box to modify the conventions used for date and time formats. The default value is that of the operating system.                                     |
|                   | <i>Encoding</i>                                                                                                         | Select the encoding from the list or select <b>Custom</b> and define it manually. This field is compulsory for DB data handling.                                       |
|                   | <i>Set Oracle Encoding Type</i>                                                                                         | Select this check box to type in the character set next to the <b>Oracle Encoding Type</b> field.                                                                      |
|                   | <i>Output</i>                                                                                                           | Select the type of output for the standard output of the Oracle database:<br><br><b>to console,</b><br><br><b>to global variable.</b>                                  |
|                   | <i>Convert columns and table names to uppercase</i>                                                                     | Select this check box to put columns and table names in upper case.                                                                                                    |
|                   | <i>Bulk file parameters</i>                                                                                             | Set the parameters <b>Buffer Size</b> and <b>StringBuilder Size</b> for a performance gain according to the memory size.                                               |
|                   | <i>tStatCatcher Statistics</i>                                                                                          | Select this check box to gather the job processing metadata at a job level as well as at each component level.                                                         |
| <b>Usage</b>      | This component is mainly used when no particular transformation is required on the data to be loaded onto the database. |                                                                                                                                                                        |
| <b>Limitation</b> | n/a                                                                                                                     |                                                                                                                                                                        |

## Related scenarios

# tOracleRollback

## tOracleRollback properties

This component is closely related to **tOracleCommit** and **tOracleConnection**. It usually doesn't make much sense to use these components independently in a transaction.

|                          |                                                                                                                                          |                                                                                                                        |

| <b>Usage</b>             | This component is to be used along with Oracle components, especially with <b>tOracleConnection</b> and <b>tOracleCommit</b> components. |                                                                                                                        |
| <b>Limitation</b>        | n/a                                                                                                                                      |                                                                                                                        |

## Related scenario

This component is closely related to **tOracleConnection** and **tOracleCommit**. It usually doesn't make much sense to use one of these without using a **tOracleConnection** component to open a connection for the current transaction.

For **tOracleRollback** related scenario, see [the section called "tMySQLRollback"](#)

# tOracleRow

| <b>Function</b>         | <b>tOracleRow</b> is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Purpose</b>          | Depending on the nature of the query and the database, <b>tOracleRow</b> acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                          |                                    | <b>Repository:</b> Select the relevant query stored in the Repository. The Query field gets accordingly filled in.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                          | <i>Query</i>                       | Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                          | <i>Die on error</i>                | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <b>Row &gt; Rejects</b> link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Advanced settings</b> | <i>Propagate QUERY's recordset</i> | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the <b>use column</b> list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                          | <i>Use PreparedStatement</i>       | <p>Select this checkbox if you want to query the database using a PreparedStatement. In the <b>Set PreparedStatement Parameter</b> table, define the parameters represented by “?” in the SQL instruction of the <b>Query</b> field in the <b>Basic Settings</b> tab.</p> <p><b>Parameter Index:</b> Enter the parameter position in the SQL instruction.</p> <p><b>Parameter Type:</b> Enter the parameter type.</p> <p><b>Parameter Value:</b> Enter the parameter value.</p> <p> This option is very useful if you need to execute the same query several times. Performance levels are increased. You can also use PreparedStatement to avoid SQL injection. For a detailed scenario of utilizing this feature, see <a href="#">the section called “Scenario 2: Using PreparedStatement objects to query data”</a>.</p> |
|                          | <i>Commit every</i>                | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                          | <i>tStatCatcher Statistics</i>     | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Usage</b>             |                                    | This component offers the flexibility of the DB query and covers all possible SQL queries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|  | <i>Username</i> and <i>Password</i>   | DB user authentication data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|  | <i>Schema</i> and <i>Edit Schema</i>  | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> .                                                                                                                                                                                                                                                                                                                                                                                                 |
|  |                                       | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|  | <i>SP Name</i>                        | Type in the exact name of the Stored Procedure (or Function)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|  | <i>Is Function / Return result in</i> | Select this check box, if the stored procedure is a function and one value only is to be returned.<br><br>Select on the list the schema column, the value to be returned is based on.                                                                                                                                                                                                                                                                                                                                                                                                                        |
|  | <i>Parameters</i>                     | Click the Plus button and select the various <b>Schema Columns</b> that will be required by the procedures. Note that the SP schema can hold more columns than there are parameters used in the procedure.                                                                                                                                                                                                                                                                                                                                                                                                   |
|  |                                       | Select the <b>Type</b> of parameter:<br><br><b>IN:</b> Input parameter<br><br><b>OUT:</b> Output parameter/return value<br><br><b>IN OUT:</b> Input parameter is to be returned as value, likely after modification through the procedure (function).<br><br><b>RECORDSET:</b> Input parameters is to be returned as a set of values, rather than single value.<br><br> Check the <b>tPostgresqlCommit</b> component if you want to analyze a set of records from a database table or DB query and return single records. |
|  |                                       | The <b>Custom Type</b> is used when a <b>Schema Column</b> you want to use is user-defined. Two <b>Custom Type</b> columns are available in the <b>Parameters</b> table. In the first <b>Custom Type</b> column:<br><br>- Select the check box in the <b>Custom Type</b> column when the corresponding <b>Schema Column</b> you want to use is of user-defined type.<br><br>- If all listed <b>Schema Columns</b> in the <b>Parameters</b> table are of custom type, you can select the check box before <b>Custom Type</b> once for them all.                                                               |
|  |                                       | Select a database type from the <b>DB Type</b> list to map the source database type to the target database type:<br><br>- <b>Auto-Mapping:</b> Map the source database type to the target database type automatically.(default)<br><br>- <b>CLOB:</b> Character large object<br><br>- <b>BLOB:</b> Binary large object                                                                                                                                                                                                                                                                                       |

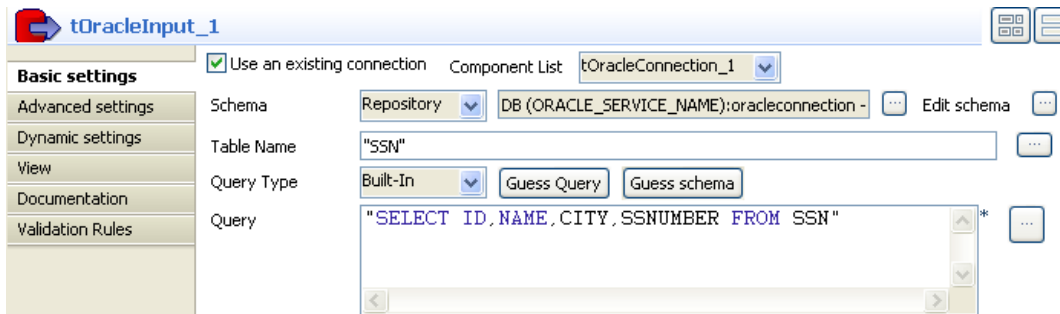

|                          |                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                   |

## Scenario: Checking number format using a stored procedure

The following job aims at connecting to an Oracle Database containing Social Security Numbers and their holders' name, calling a stored procedure that checks the SSN format of against a standard ###-##-#### format. Then the verification output results, 1 for valid format and 0 for wrong format get displayed onto the execution console.

- Drag and drop the following components from the **Palette**: **tOracleConnection**, **tOracleInput**, **tOracleSP** and **tLogRow**.
- Link the **tOracleConnection** to the **tOracleInput** using a **Then Run** connection as no data is handled here.
- And connect the other components using a **Row Main** link as rows are to be passed on as parameter to the SP component and to the console.
- In the **tOracleConnection**, define the details of connection to the relevant Database. You will then be able to reuse this information in all other DB-related components.
- Then select the **tOracleInput** and define its properties.

 *For Talend Open Studio for Big Data, the **Property type** and **Schema** of components are always **Built-in**. For how to edit a built-in schema, see Talend Open Studio for Big Data User Guide.*

- Select the **Use an existing connection** check box and select the **tOracleConnection** component in the list in order to reuse the connection details that you already set.
- Select **Repository** as **Property type** as the Oracle schema is defined in the DB Oracle connection entry of the Repository. If you haven't recorded the Oracle DB details in the **Repository**, then fill in the Schema name manually.
- Then select **Repository** as **Schema**, and retrieve the relevant schema corresponding to your Oracle DB table.

|   | ID  | NAME    | CITY | SSNUMBER    |
|---|----------------------------------------------------------------------------------------|---------|------|-------------|
| 1 | 1                                                                                      | Jack    | LA   | 123-45-6789 |
| 2 | 2                                                                                      | Tom     | NYC  | 123-A5-6789 |
| 3 | 3                                                                                      | Bill    | SF   | 123=45-6789 |
| 4 | 4                                                                                      | Jana    | NYC  | 236-52-2956 |
| 5 | 5                                                                                      | Brandon | SLC  | 561-52-B267 |

- In this example, the SSN table has a four-column schema that includes *ID*, *NAME*, *CITY* and *SSNUMBER*.
- In the **Query** field, type in the following Select query or select it in the list, if you stored it in the Repository.

```
select ID, NAME, CITY, SSNUMBER from SSN
```

- Then select the **tOracleSP** and define its **Basic settings**.

Use an existing connection    Component List: tOracleConnection\_1

Schema: Repository    DB (ORACLE\_SERVICE\_NAME):oracleconnection -    Edit schema    Sync columns

SP Name: "is\_ssn"

Is function    Return result in: SSN\_Valid    DBType: AUTO-MAPPING

| Schema | Column   | Type | DBType       | Custom T...              | Custom Type | Custom Name |
|--------|----------|------|--------------|--------------------------|-------------|-------------|
|        | SSNUMBER | IN   | AUTO-MAPPING | <input type="checkbox"/> | STRUCT      |             |

- Like for the **tOracleInput** component, select **Repository** in the **Property type** field and select the **Use an existing connection** check box, then select the relevant entries in the respective list.
- The schema used for the **tOracleSP** slightly differs from the input schema. Indeed, an extra column (*SSN\_Valid*) is added to the Input schema. This column will hold the format validity status (*1* or *0*) produced by the procedure.

tOracleSP\_1 (Output)

| Column    | D... | Key                                 | Type   | Nullable                 | Dat... | L... | P.. | D.. |
|-----------|------|-------------------------------------|--------|--------------------------|--------|------|-----|-----|
| ID        |      | <input checked="" type="checkbox"/> | float  | <input type="checkbox"/> |        | 22   | 10  |     |
| NAME      |      | <input type="checkbox"/>            | String | <input type="checkbox"/> |        | 50   |     |     |
| CITY      |      | <input type="checkbox"/>            | String | <input type="checkbox"/> |        | 50   |     |     |
| SSNUMBER  |      | <input type="checkbox"/>            | String | <input type="checkbox"/> |        | 12   |     |     |
| SSN_valid |      | <input type="checkbox"/>            | int    | <input type="checkbox"/> |        | 2    |     |     |

- In the **SP Name** field, type in the exact name of the stored procedure (or function) as called in the Database. In this use case, the stored procedure name is *is\_ssn*.
- The basic function used in this particular example is as follows:

```

CREATE OR REPLACE FUNCTION is_ssn(string_in VARCHAR2)
RETURN PLS_INTEGER
IS
-- validating ###-##-#### format
BEGIN
 IF TRANSLATE(string_in, '0123456789A', 'AAAAAAAAAAB') =
 'AAA-AA-AAAA' THEN
 RETURN 1;
 END IF;
 RETURN 0;
END is_ssn;
/

```

- As a return value is expected in this use case, the procedure acts as a function, so select the **Is function** check box.
- The only return value expected is based on the *ssn\_valid* column, hence select the relevant list entry.
- In the **Parameters** area, define the input and output parameters used in the procedure. In this use case, only the *SSNumber* column from the schema is used in the procedure.
- Click the plus sign to add a line to the table and select the relevant column (*SSNumber*) and type (*IN*).
- Then select the **tLogRow** component and click Sync Column to make sure the schema is passed on from the preceding **tOracleSP** component.

- Select the **Print values in cells of a table** check box to facilitate the output reading.
- Then save your job and press **F6** to run it.

```
Starting job OracleSP at 15:14 23/08/2007.

 tLogRow_1

ID |NAME |CITY|SSNUMBER |SSN_Valid

Job OracleSP ended at 15:14 23/08/2007. [exit code=6]
```

On the console, you can read the output results. All input schema columns are displayed eventhough they are not used as parameters in the stored procedure.

The final column shows the expected return value, i.e. whether the SS Number checked is valid or not.

Check the **tPostgresqlCommit** component if you want to analyze a set of records from a database table or DB query and return single records.

# tPostgresqlBulkExec

## tPostgresqlBulkExec properties

**tPostgresqlOutputBulk** and **tPostgresqlBulkExec** components are used together to first output the file that will be then used as parameter to execute the SQL query stated. These two steps compose the **tPostgresqlOutputBulkExec** component, detailed in a separate section. The interest in having two separate elements lies in the fact that it allows transformations to be carried out before the data loading in the database.

|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage</b>      | This component is to be used along with <b>tPostgresqlOutputBulk</b> component. Used together, they can offer gains in performance while feeding a Postgresql database. |
| <b>Limitation</b> | n/a                                                                                                                                                                     |

## Related scenarios

For use cases in relation with **tPostgresqlBulkExec**, see the following scenarios:

- [the section called “Scenario: Inserting transformed data in MySQL database”](#).
- [the section called “Scenario: Inserting data in MySQL database”](#).
- [the section called “Scenario: Truncating and inserting file data into Oracle DB”](#).

# tPostgresqlCommit

## tPostgresqlCommit Properties

This component is closely related to **tPostgresqlCommit** and **tPostgresqlRollback**. It usually does not make much sense to use these components independently in a transaction.

|                          |                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Related scenario

This component is closely related to **tPostgresqlConnection** and **tPostgresqlRollback**. It usually does not make much sense to use one of these without using a **tPostgresqlConnection** component to open a connection for the current transaction.

For **tPostgresqlCommit** related scenario, see [the section called “Scenario: Inserting data in mother/daughter tables”](#).

## Related scenario

This component is closely related to **tPostgresqlCommit** and **tPostgresqlRollback**. It usually doesn't make much sense to use one of these without using a **tPostgresqlConnection** component to open a connection for the current transaction.

For **tPostgresqlConnection** related scenario, see [the section called "tMysqlConnection"](#)

| <b>Function</b>         | <b>tPostgresqlInput</b> reads a database and extracts fields based on a query.                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Purpose</b>          | <b>tPostgresqlInput</b> executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|  | <i>Action on table</i>        | <p>On the table defined, you can perform one of the following operations:</p> <p><b>None:</b> No operation is carried out.</p> <p><b>Drop and create a table:</b> The table is removed and created again.</p> <p><b>Create a table:</b> The table does not exist and gets created.</p> <p><b>Create a table if not exists:</b> The table is created if it does not exist.</p> <p><b>Drop a table if exists and create:</b> The table is removed if already exists and created again.</p> <p><b>Clear a table:</b> The table content is deleted.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|  | <i>Action on data</i>         | <p>On the data of the table defined, you can perform:</p> <p><b>Insert:</b> Add new entries to the table. If duplicates are found, job stops.</p> <p><b>Update:</b> Make changes to existing entries</p> <p><b>Insert or update:</b> Add entries or update existing ones.</p> <p><b>Update or insert:</b> Update existing entries or create it if non existing</p> <p><b>Delete:</b> Remove entries corresponding to the input flow.</p> <p> <i>It is necessary to specify at least one column as a primary key on which the <b>Update</b> and <b>Delete</b> operations are based. You can do that by clicking <b>Edit Schema</b> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <b>Advanced settings</b> view where you can simultaneously define primary keys for the <b>Update</b> and <b>Delete</b> operations. To do that: Select the <b>Use field options</b> check box and then in the <b>Key in update column</b>, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the <b>Key in delete column</b> for the Delete operation.</i></p> |
|  | <i>Schema and Edit Schema</i> | <p>A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i>, the schema is always <b>Built-in</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Usage</b>             | <p>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.</p> <p>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Postgresql database. It also allows you to create a reject flow using a <b>Row &gt; Rejects</b> link to filter data in error. For an example of <b>tMySQLOutput</b> in use, see <a href="#">the section called “Scenario 3: Retrieve data in error with a Reject link”</a>.</p> |                                                                                                                                                                                                                                                                                |
| <b>Limitation</b>        | <p>Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i>. For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i>.</p>                                                                                                                                                           |                                                                                                                                                                                                                                                                                |

## Related scenarios

For **tPostgresqlOutput** related topics, see:

- [the section called “Scenario: Writing a row to a table in the MySQL database via an ODBC connection”](#).
- [the section called “Scenario 1: Adding a new column and altering data in a DB table”](#).

# tPostgresqlOutputBulk

## tPostgresqlOutputBulk properties

The **tPostgresqlOutputBulk** and **tPostgresqlBulkExec** components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the **tPostgresqlOutputBulkExec** component, detailed in a separate section. The advantage of having two separate steps is that it makes it possible to transform data before it is loaded in the database.

- [the section called “Scenario: Inserting data in MySQL database”](#).
- [the section called “Scenario: Truncating and inserting file data into Oracle DB”](#).

# tPostgresqlRollback

## tPostgresqlRollback properties

This component is closely related to **tPostgresqlCommit** and **tPostgresqlConnection**. It usually does not make much sense to use these components independently in a transaction.

| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                                                                                                       | Select this check box to collect log data at the component level.                                                          |
| <b>Usage</b>             | This component is to be used along with Postgresql components, especially with <b>tPostgresqlConnection</b> and <b>tPostgresqlCommit</b> components. |                                                                                                                            |
| <b>Limitation</b>        | n/a                                                                                                                                                  |                                                                                                                            |

## Related scenario

This component is closely related to **tPostgresqlConnection** and **tPostgresqlCommit**. It usually does not make much sense to use one of them without using a **tPostgresqlConnection** component to open a connection for the current transaction.

For **tPostgresqlRollback** related scenario, see [the section called “tMysqlRollback”](#)

# tPostgresqlRow

## tPostgresqlRow properties

|                         |                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Function</b>         | <b>tPostgresqlRow</b> is the specific component for the database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Purpose</b>          | Depending on the nature of the query and the database, <b>tPostgresqlRow</b> acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

# tSybaseBulkExec

## tSybaseBulkExec Properties

The **tSybaseOutputBulk** and **tSybaseBulkExec** components are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the **tSybaseOutputBulkExec** component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the database.

|                         |                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Related scenario

This component is closely related to **tSybaseConnection** and **tSybaseRollback**. It usually does not make much sense to use one of these without using a **tSybaseConnection** component to open a connection for the current transaction.

For **tSybaseCommit** related scenario, see [the section called “Scenario: Inserting data in mother/daughter tables”](#).

# tSybaseConnection

## tSybaseConnection Properties

This component is closely related to **tSybaseCommit** and **tSybaseRollback**. It usually does not make much sense to use one of these without using a **tSybaseConnection** component to open a connection for the current transaction.

|                         |                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                  |

| <b>Function</b>         | <b>tSybaseInput</b> reads a database and extracts fields based on a query.                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Purpose</b>          | <b>tSybaseInput</b> executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|  | <i>Turn on identity insert</i> | Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|  | <i>Action on data</i>          | <p>On the data of the table defined, you can perform:</p> <p><b>Insert:</b> Add new entries to the table. If duplicates are found, job stops.</p> <p><b>Update:</b> Make changes to existing entries</p> <p><b>Insert or update:</b> Add entries or update existing ones.</p> <p><b>Update or insert:</b> Update existing entries or create it if non existing</p> <p><b>Delete:</b> Remove entries corresponding to the input flow.</p> <p> <i>It is necessary to specify at least one column as a primary key on which the <b>Update</b> and <b>Delete</b> operations are based. You can do that by clicking <b>Edit Schema</b> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <b>Advanced settings</b> view where you can simultaneously define primary keys for the <b>Update</b> and <b>Delete</b> operations. To do that: Select the <b>Use field options</b> check box and then in the <b>Key in update column</b>, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the <b>Key in delete column</b> for the Delete operation.</i></p> |
|  | <i>Schema and Edit schema</i>  | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

This option ensures transaction quality (but not rollback) and, above all, better performance at execution.                                                                                                                                                                                                                                                                              |
|                          | <i>Additional Columns</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.                                                                                                                                                                                                                            |
|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | <b>Name:</b> Type in the name of the schema column to be altered or inserted as new column                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Usage</b>             | <p>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.</p> <p>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Sybase database. It also allows you to create a reject flow using a <b>Row &gt; Rejects</b> link to filter data in error. For an example of <b>tMySQLOutput</b> in use, see <a href="#">the section called “Scenario 3: Retrieve data in error with a Reject link”</a>.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Limitation</b>        | Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Related scenarios

For use cases in relation with **tSybaseOutput**, see:

- the section called “Scenario: Writing a row to a table in the MySQL database via an ODBC connection”.
- the section called “Scenario 1: Adding a new column and altering data in a DB table”.

# tSybaseOutputBulk

## tSybaseOutputBulk properties

The **tSybaseOutputBulk** and **tSybaseBulkExec** components are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the **tSybaseOutputBulkExec** component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the database.

|                          | <i>Bcp utility</i>                | Name of the utility to be used to copy data over to the Sybase server.                                                                                                                                                                                                                                                                                                                                                                   |
|                          | <i>Batch row number</i>           | Number of lines in each processed batch.                                                                                                                                                                                                                                                                                                                                                                                                 |
|                          | <i>Table</i>                      | Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.                                                                                                                                                                                                                                                                                    |
|                          | <i>Action on table</i>            | <p>On the table defined, you can perform one of the following operations:</p> <p><b>None:</b> No operation is carried out.</p> <p><b>Drop and create a table:</b> The table is removed and created again.</p> <p><b>Create a table:</b> The table does not exist and gets created.</p> <p><b>Create a table if not exists:</b> The table is created if it does not exist.</p> <p><b>Clear a table:</b> The table content is deleted.</p> |
|                          | <i>File Name</i>                  | <p>Name of the file to be processed.</p> <p>Related topic: see <i>Talend Open Studio for Big Data User Guide</i>.</p>                                                                                                                                                                                                                                                                                                                    |
|                          | <i>Append</i>                     | Select this check box to add the new rows at the end of the records.                                                                                                                                                                                                                                                                                                                                                                     |
|                          | <i>Schema and Edit Schema</i>     | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. The schema is either <b>Built-in</b> or stored remotely in the <b>Repository</b> .                                                                                                                                                                                                                             |
|                          |                                   | <b>Built-in:</b> You create and store the schema locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                                                                                                                                                                 |
|                          |                                   | <b>Repository:</b> You have already created and stored the schema in the Repository, hence can be reused. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                                                                                                                                         |
| <b>Advanced settings</b> | <i>Use an interface file</i>      | Select this check box to specify an interface file in the field <b>Interface file</b> .                                                                                                                                                                                                                                                                                                                                                  |
|                          | <i>Additional JDBC parameters</i> | Specify additional connection properties in the existing DB connection, to allow specific character set support. E.G.: CHARSET=KANJISJIS_OS to get support of Japanese characters.                                                                                                                                                                                                                                                       |
|                          | <i>Action on data</i>             | <p>On the data of the table defined, you can perform:</p> <p><b>Bulk Insert:</b> Add multiple entries to the table. If duplicates are found, job stops.</p> <p><b>Bulk Update:</b> Make simultaneous changes to multiple entries.</p>                                                                                                                                                                                                    |
|                          | <i>Field terminator</i>           | <p>Character, string or regular expression to separate fields.</p> <p> <i>As a combination of tSybaseOutputBulk and tSybaseBulkExec, this component does not allow the use of Sybase-oriented row/field separators,</i></p>                                                                                                                           |

|                   |                                                                                                                         |                                                                                                                                                                                                                                                                                            |
|-------------------|-------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   |                                                                                                                         | such as \x09. To achieve the desired effect (for example, displaying fields in the tabular form), you need to use <b>tSybaseOutputBulk</b> and <b>tSybaseBulkExec</b> together to replace <b>tSybaseOutputBulkExec</b> , with \t used in the former component and \x09 used in the latter. |
|                   | <i>DB Row terminator</i>                                                                                                | String (ex: “\n” on Unix) to distinguish rows in the DB.                                                                                                                                                                                                                                   |
|                   | <i>First row NO. of file</i>                                                                                            | Type in the number of the file row where the action should start at.                                                                                                                                                                                                                       |
|                   | <i>FILE Row terminator</i>                                                                                              | Character, string or regular expression to separate fields in a file.                                                                                                                                                                                                                      |
|                   | <i>Include Head</i>                                                                                                     | Select this check box to include the column header.                                                                                                                                                                                                                                        |
|                   | <i>Encoding</i>                                                                                                         | Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.                                                                                                                                                                  |
|                   | <i>Output</i>                                                                                                           | Select the type of output for the standard output of the Sybase database:<br><br><b>to console,</b><br><br><b>to global variable.</b>                                                                                                                                                      |
|                   | <i>tStatCatcher Statistics</i>                                                                                          | Select this check box to collect log data at the component level.                                                                                                                                                                                                                          |
| <b>Usage</b>      | This component is mainly used when no particular transformation is required on the data to be loaded onto the database. |                                                                                                                                                                                                                                                                                            |
| <b>Limitation</b> | n/a                                                                                                                     |                                                                                                                                                                                                                                                                                            |

## Related scenarios

# tSybaseRollback

## tSybaseRollback properties

This component is closely related to **tSybaseCommit** and **tSybaseConnection**. It usually does not make much sense to use these components independently in a transaction.

| <b>Function</b>         | <b>tSybaseRow</b> is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Purpose</b>          | Depending on the nature of the query and the database, <b>tSybaseRow</b> acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
