Table of Contents

Preface	xix		
General information	xix		
Purpose	xix		
Audience	xix		
Typographical conventions	xix		
History of changes	xix		
Feedback and Support	xxi		
Big Data components	1		
tHBaseClose	2		
tHBaseClose properties	2		
Related scenario	2		
tHBaseConnection	3		
tHBaseConnection properties	3		
Related scenario	4		
tHBaseInput	5		
tHBaseInput properties	5		
Scenario: Exchanging customer data with HBase	6		
tHBaseOutput	13		
tHBaseOutput properties	13		
Related scenario	14		
tHCatalogInput	15		
tHCatalogInput Properties	15		
Related scenario	16		
tHCatalogLoad	17		
tHCatalogLoad Properties	17		
Related scenario	18		
tHCatalogOperation	19		
tHCatalogOperation Properties	19		
Scenario: HCatalog table management on Hortonworks Data Platform	24		
tHCatalogOutput	33		
tHCatalogOutput Properties	33		
Related scenario	35		
tHDFSConnection	36		
tHDFSConnection properties	36		
Related scenario	37		
tHDFSDelete	38		
tHDFSDelete properties	38		
Related scenario	39		
tHDFSGet	40		
tHDFSGet properties	40		
Scenario: Computing data with Hadoop distributed file system	41		
tHDFSInput	48		
tHDFSInput properties	48		
Related scenario	49		
tHDFSOutput	50		
tHDFSOutput properties	50		
Related scenario	51		
tHDFSPut	52		
tHDFSPut properties	52		
Related scenario	53		
tHiveClose	54		
tHiveClose properties	54		
Related scenario	54		
tHiveConnection	55		
tHiveConnection properties	55		
Related scenario	56		
tHiveInput	57		
tHiveInput properties	57		
Related scenarios	59		
tHiveRow	60		
tHiveRow properties	60		
Related scenarios	61		
tPigAggregate	63		
tPigAggregate Properties	63		
Related scenario	63		
tPigCode	64		
tPigCode Properties	64		
Scenario: Selecting a column of data from an input file and store it into a local file	64		
tPigCross	68		
tPigCross Properties	68		
Related scenario	68		
tPigDistinct	69		
tPigDistinct Properties	69		
Related scenario	69		
tPigFilterColumns	70		
tPigFilterColumns Properties	70		
Related Scenario	70		
tPigFilterRow	71		
tPigFilterRow Properties	71		
Scenario: Filtering rows of data based on a condition and saving the result to a local file	71		
tPigJoin	75		
tPigJoin Properties	75		
Scenario: Joining two files based on an exact match and saving the result to a local file	76		
tPigLoad	82		
tPigLoad Properties	82		
Related Scenario	84		
tPigSort	85		
tPigSort Properties	85		
Scenario: Sorting data in ascending order	85		
tPigStoreResult	89		
tPigStoreResult Properties	89		
Related Scenario	90		
tSqoopExport	91		
tSqoopExport Properties	91		
Related scenario	92		
tSqoopImport	93		
tSqoopImport Properties	93		
Related scenario	94		
tSqoopImportAllTables	95		
tSqoopImportAllTables Properties	95		
Related scenario	96		
Business components	97		
tAlfrescoOutput	98		
tAlfrescoOutput Properties	98		
Scenario: Creating documents on an Alfresco server	103		
tMarketoInput	108		
tMarketoInput Properties	108		
Related Scenario	110		
tMarketoListOperation	111		
tMarketoListOperation Properties	111		
Scenario: Adding a lead record to a list in the Marketo DB	112		
tMarketoOutput	116		
tMarketoOutput Properties	116		
Scenario: Data transmission between Marketo DB and an external system... ..	117		
tMicrosoftCrmInput	123		
tMicrosoftCrmInput Properties	123		
Scenario: Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows	124		
tMicrosoftCrmOutput	130		
tMicrosoftCrmOutput Properties	130		
Related Scenario	131		
tOpenbravoERPInput	132		
tOpenbravoERPInput properties	132		
Related Scenario	133		
tOpenbravoERPOutput	134		

tOpenbravoERPOutput properties	134	tSugarCRMInput Properties	204
Related scenario	134	Scenario: Extracting account data from SugarCRM	204
tSageX3Input	135	tSugarCRMOutput	207
tSageX3Input Properties	135	tSugarCRMOutput Properties	207
Scenario: Using query key to extract data from a given Sage X3 system.....	136	Related Scenario	207
tSageX3Output	140	tVtigerCRMInput	208
tSageX3Output Properties	140	tVtigerCRMInput Properties	208
Scenario: Using a Sage X3 Web service to insert data into a given Sage X3 system	141	Related Scenario	209
tSalesforceBulkExec	145	tVtigerCRMOutput	210
tSalesforceBulkExec Properties	145	tVtigerCRMOutput Properties	210
Related Scenario:	146	Related Scenario	211
tSalesforceConnection	147	Business Intelligence components	213
tSalesforceConnection properties	147	tDB2SCD	214
Related scenario	148	tDB2SCD properties	214
tSalesforceGetDeleted	149	Related scenarios	215
tSalesforceGetDeleted properties	149	tDB2SCELT	216
Scenario: Recovering deleted data from the Salesforce server	150	tDB2SCELT Properties	216
tSalesforceGetServerTimestamp	153	Related Scenario	218
tSalesforceGetServerTimestamp properties	153	tGreenplumSCD	219
Related scenarios	154	tGreenplumSCD Properties	219
tSalesforceGetUpdated	155	Related scenario	220
tSalesforceGetUpdated properties	155	tInformixSCD	221
Related scenarios	156	tInformixSCD properties	221
tSalesforceInput	157	Related scenario	222
tSalesforceInput Properties	157	tIngresSCD	223
Scenario: Using queries to extract data from a Salesforce database	159	tIngresSCD Properties	223
tSalesforceOutput	163	Related scenario	224
tSalesforceOutput Properties	163	tMSSqlSCD	225
Scenario 1: Deleting data from the Account object	165	tMSSqlSCD Properties	225
Scenario 2: Gathering erroneous data while inserting data to a module at Salesforce.com	166	Related scenario	226
tSalesforceOutputBulk	170	tMysqlSCD	227
tSalesforceOutputBulk Properties	170	tMysqlSCD Properties	227
Scenario: Inserting transformed bulk data into your Salesforce.com	170	Scenario: Tracking changes using Slowly Changing Dimensions (type 0 through type 3)	230
tSalesforceOutputBulkExec	175	tMysqlSCELT	238
tSalesforceOutputBulkExec Properties	175	tMysqlSCELT Properties	238
Scenario: Inserting bulk data into your Salesforce.com	176	Related Scenario	240
tSAPBWInput	180	tOracleSCD	241
tSAPBWInput Properties	180	tOracleSCD Properties	241
Scenario: Reading data from SAP BW database	181	Related scenario	242
tSAPCommit	185	tOracleSCELT	243
tSAPCommit Properties	185	tOracleSCELT Properties	243
Related scenario	185	Related Scenario	245
tSAPConnection	186	tPaloCheckElements	246
tSAPConnection properties	186	tPaloCheckElements Properties	246
Related scenarios	186	Related scenario	248
tSAPIInput	187	tPaloConnection	249
tSAPIInput Properties	187	tPaloConnection Properties	249
Scenario 1: Retrieving metadata from the SAP system	189	Related scenario	249
Scenario 2: Reading data in the different schemas of the RFC_READ_TABLE function	195	tPaloCube	250
tSAPOutput	201	tPaloCube Properties	250
tSAPOutput Properties	201	Scenario: Creating a cube in an existing database	252
Related scenario	202	tPaloCubeList	254
tSAPRollback	203	tPaloCubeList Properties	254
tSAPRollback properties	203	Discovering the read-only output schema of tPaloCubeList	255
Related scenarios	203	Scenario: Retrieving detailed cube information from a given database.....	256
tSugarCRMInput	204	tPaloDatabase	258
		tPaloDatabase Properties	258
		Scenario: Creating a database	259
		tPaloDatabaseList	261
		tPaloDatabaseList Properties	261
		Discovering the read-only output schema of tPaloDatabaseList	262
		Scenario: Retrieving detailed database information from a given Palo server	263
		tPaloDimension	265

tPaloDimension Properties	265	tAmazonMysqlCommit	331
Scenario: Creating a dimension with elements	269	tAmazonMysqlCommit Properties	331
tPaloDimensionList	274	Related scenario	331
tPaloDimensionList Properties	274	tAmazonMysqlConnection	332
Discovering the read-only output schema of tPaloDimensionList	276	tAmazonMysqlConnection Properties	332
Scenario: Retrieving detailed dimension information from a given database	276	Scenario: Inserting data in mother/ daughter tables	333
tPaloInputMulti	278	tAmazonMysqlInput	337
tPaloInputMulti Properties	278	tAmazonMysqlInput properties	337
Scenario: Retrieving dimension elements from a given cube	280	Scenario1: Writing columns from a MySQL database to an output file	338
tPaloOutput	284	tAmazonMysqlOutput	342
tPaloOutput Properties	284	tAmazonMysqlOutput properties	342
Related scenario	285	Scenario 1: Adding a new column and altering data in a DB table	346
tPaloOutputMulti	286	Scenario 2: Updating data in a database table	350
tPaloOutputMulti Properties	286	Scenario 3: Retrieve data in error with a Reject link	352
Scenario 1: Writing data into a given cube	288	tAmazonMysqlRollback	358
Scenario 2: Rejecting inflow data when the elements to be written do not exist in a given cube	291	tAmazonMysqlRollback properties	358
tPaloRule	295	Scenario: Rollback from inserting data in mother/daughter tables	358
tPaloRule Properties	295	tAmazonMysqlRow	360
Scenario: Creating a rule in a given cube	296	tAmazonMysqlRow properties	360
tPaloRuleList	299	Scenario 1: Removing and regenerating a MySQL table index	362
tPaloRuleList Properties	299	Scenario 2: Using PreparedStatement objects to query data	363
Discovering the read-only output schema of tPaloRuleList	300	tAmazonOracleClose	368
Scenario: Retrieving detailed rule information from a given cube	301	tAmazonOracleClose properties	368
tParAccelSCD	303	Related scenario	368
tParAccelSCD Properties	303	tAmazonOracleCommit	369
Related scenario	304	tAmazonOracleCommit Properties	369
tPostgresPlusSCD	305	Related scenario	369
tPostgresPlusSCD Properties	305	tAmazonOracleConnection	370
Related scenario	306	tAmazonOracleConnection Properties	370
tPostgresPlusSCDELT	307	Related scenario	371
tPostgresPlusSCDELT Properties	307	tAmazonOracleInput	372
Related Scenario	309	tAmazonOracleInput properties	372
tPostgresqlSCD	310	Related scenarios	373
tPostgresqlSCD Properties	310	tAmazonOracleOutput	374
Related scenario	311	tAmazonOracleOutput properties	374
tPostgresqlSCDELT	312	Related scenarios	377
tPostgresqlSCDELT Properties	312	tAmazonOracleRollback	378
Related Scenario	314	tAmazonOracleRollback properties	378
tSPSSInput	315	Related scenario	378
tSPSSInput properties	315	tAmazonOracleRow	379
Scenario: Displaying the content of an SPSS .sav file	315	tAmazonOracleRow properties	379
tSPSSOutput	318	Related scenarios	380
tSPSSOutput properties	318	tMarketoInput	382
Scenario: Writing data in an .sav file ..	318	tMarketoListOperation	383
tSPSSProperties	321	tMarketoOutput	384
tSPSSProperties properties	321	tSalesforceBulkExec	385
Related scenarios	321	tSalesforceConnection	386
tSPSSStructure	322	tSalesforceGetDeleted	387
tSPSSStructure properties	322	tSalesforceGetServerTimestamp	388
Related scenarios	322	tSalesforceGetUpdated	389
tSybaseSCD	323	tSalesforceInput	390
tSybaseSCD properties	323	tSalesforceOutput	391
Related scenarios	324	tSalesforceOutputBulk	392
tSybaseSCDELT	325	tSalesforceOutputBulkExec	393
tSybaseSCDELT Properties	325	tSugarCRMInput	394
Related Scenario	327	tSugarCRMOutput	395
Cloud components	329	Custom Code components	397
tAmazonMysqlClose	330	tGroovy	398
tAmazonMysqlClose properties	330	tGroovy properties	398
Related scenario	330	Related Scenarios	398
		tGroovyFile	399
		tGroovyFile properties	399

Scenario: Calling a file which contains Groovy code	399	Scenario 1: Checking and correcting the postal code, city and street	471
tJava	401	Scenario 2: Checking and correcting the postal code, city and street, as well as rejecting the unfeasible	475
tJava properties	401	Databases - traditional components	477
Scenario: Printing out a variable content	401	tAccessBulkExec	478
tJavaFlex	405	tAccessBulkExec properties	478
tJavaFlex properties	405	Related scenarios	479
Scenario 1: Generating data flow	405	tAccessCommit	480
Scenario 2: Processing rows of data with tJavaFlex	408	tAccessCommit Properties	480
tJavaRow	412	Related scenario	480
tJavaRow properties	412	tAccessConnection	481
Scenario: Transforming data line by line using tJavaRow	412	tAccessConnection Properties	481
tLibraryLoad	416	Scenario: Inserting data in parent/child tables	481
tLibraryLoad properties	416	tAccessInput	485
Scenario: Checking the format of an e-mail addressl	416	tAccessInput properties	485
tSetGlobalVar	419	Related scenarios	486
tSetGlobalVar properties	419	tAccessOutput	487
Scenario: Printing out the content of a global variable	419	tAccessOutput properties	487
Data Quality components	421	Related scenarios	489
tAddCRCRow	422	tAccessOutputBulk	490
tAddCRCRow properties	422	tAccessOutputBulk properties	490
Scenario: Adding a surrogate key to a file	422	Related scenarios	490
tChangeFileEncoding	425	tAccessOutputBulkExec	492
tExtractRegexFields	426	tAccessOutputBulkExec properties	492
tFuzzyMatch	427	Related scenarios	494
tFuzzyMatch properties	427	tAccessRollback	495
Scenario 1: Levenshtein distance of 0 in first names	428	tAccessRollback properties	495
Scenario 2: Levenshtein distance of 1 or 2 in first names	430	Related scenarios	495
Scenario 3: Metaphonic distance in first name	431	tAccessRow	496
tIntervalMatch	432	tAccessRow properties	496
tIntervalMatch properties	432	Related scenarios	497
Scenario: Identifying Ip country	432	tAS400Close	499
tReplaceList	435	tAS400Close properties	499
tReplaceList Properties	435	Related scenario	499
Scenario: Replacement from a reference file	436	tAS400Commit	500
tSchemaComplianceCheck	439	tAS400Commit Properties	500
tSchemaComplianceCheck Properties	439	Related scenario	500
Scenario: Validating data against schema	440	tAS400Connection	501
tUniqRow	444	tAS400Connection Properties	501
tUniqRow Properties	444	Related scenario	501
Scenario 1: Deduplicating entries	445	tAS400Input	503
tUniservBTGeneric	448	tAS400Input properties	503
tUniservBTGeneric properties	448	Related scenarios	504
Scenario: Execution of a Job in the	450	tAS400LastInsertId	505
tUniservRTConvertName	454	tAS400LastInsertId properties	505
tUniservRTConvertName properties	454	Related scenario	505
Scenario: Analysis of a name line and assignment of the salutation	455	tAS400Output	506
tUniservRTMailBulk	459	tAS400Output properties	506
tUniservRTMailBulk properties	459	Related scenarios	508
Scenario: Creating an index pool	459	tAS400Rollback	509
tUniservRTMailOutput	463	tAS400Rollback properties	509
tUniservRTMailOutput properties	463	Related scenarios	509
Related scenarios	464	tAS400Row	510
tUniservRTMailSearch	465	tAS400Row properties	510
tUniservRTMailSearch properties	465	Related scenarios	511
Scenario: Adding contacts to the mailRetrieval index pool	466	tDB2BulkExec	513
tUniservRTPost	470	tDB2BulkExec properties	513
tUniservRTPost properties	470	Related scenarios	515
		tDB2Close	516
		tDB2Close properties	516
		Related scenario	516
		tDB2Commit	517
		tDB2Commit Properties	517
		Related scenario	517
		tDB2Connection	518
		tDB2Connection properties	518
		Related scenarios	519
		tDB2Input	520
		tDB2Input properties	520

Related scenarios	521	Related scenarios	572
tDB2Output	522	tMSSqlOutputBulk	573
tDB2Output properties	522	tMSSqlOutputBulk properties	573
Related scenarios	525	Related scenarios	573
tDB2Rollback	526	tMSSqlOutputBulkExec	575
tDB2Rollback properties	526	tMSSqlOutputBulkExec properties	575
Related scenarios	526	Related scenarios	577
tDB2Row	527	tMSSqlRollback	578
tDB2Row properties	527	tMSSqlRollback properties	578
Related scenarios	528	Related scenario	578
tDB2SCD	530	tMSSqlRow	579
tDB2SCDELT	531	tMSSqlRow properties	579
tDB2SP	532	Related scenarios	581
tDB2SP properties	532	tMSSqlSCD	582
Related scenarios	533	tMSSqlSP	583
tInformixBulkExec	534	tMSSqlSP Properties	583
tInformixBulkExec Properties	534	Related scenario	584
Related scenario	536	tMSSqlTableList	586
tInformixClose	537	tMSSqlTableList Properties	586
tInformixClose properties	537	Related scenario	586
Related scenario	537	tMysqlBulkExec	587
tInformixCommit	538	tMysqlBulkExec properties	587
tInformixCommit properties	538	Related scenarios	589
Related Scenario	538	tMysqlClose	590
tInformixConnection	539	tMysqlClose properties	590
tInformixConnection properties	539	Related scenario	590
Related scenario	540	tMysqlColumnList	591
tInformixInput	541	tMysqlColumnList Properties	591
tInformixInput properties	541	Scenario: Iterating on a DB table and	
Related scenarios	541	listing its column names	591
tInformixOutput	542	tMysqlCommit	594
tInformixOutput properties	542	tMysqlCommit Properties	594
Related scenarios	544	Related scenario	594
tInformixOutputBulk	545	tMysqlConnection	595
tInformixOutputBulk properties	545	tMysqlConnection Properties	595
Related scenario	546	Scenario: Inserting data in mother/	
tInformixOutputBulkExec	547	daughter tables	595
tInformixOutputBulkExec properties	547	tMysqlInput	599
Related scenario	549	tMysqlInput properties	599
tInformixRollback	550	Scenario 1: Writing columns from a	
tInformixRollback properties	550	MySQL database to an output file	600
Related Scenario	550	Scenario 2: Using context parameters	
tInformixRow	551	when reading a table from a MySQL	
tInformixRow properties	551	database	603
Related scenarios	553	tMysqlLastInsertId	606
tInformixSCD	554	tMysqlLastInsertId properties	606
tInformixSP	555	Scenario: Get the ID for the last	
tInformixSP properties	555	inserted record	606
Related scenario	556	tMysqlOutput	611
tMSSqlBulkExec	558	tMysqlOutput properties	611
tMSSqlBulkExec properties	558	Scenario 1: Adding a new column	
Related scenarios	560	and altering data in a DB table	615
tMSSqlColumnList	561	Scenario 2: Updating data in a	
tMSSqlColumnList Properties	561	database table	619
Related scenario	561	Scenario 3: Retrieve data in error	
tMSSqlClose	562	with a Reject link	621
tMSSqlClose properties	562	tMysqlOutputBulk	626
Related scenario	562	tMysqlOutputBulk properties	626
tMSSqlCommit	563	Scenario: Inserting transformed data	
tMSSqlCommit properties	563	in MySQL database	627
Related scenarios	563	tMysqlOutputBulkExec	631
tMSSqlConnection	564	tMysqlOutputBulkExec properties	631
tMSSqlConnection properties	564	Scenario: Inserting data in MySQL	
Related scenarios	565	database	632
tMSSqlInput	566	tMysqlRollback	635
tMSSqlInput properties	566	tMysqlRollback properties	635
Related scenarios	567	Scenario: Rollback from inserting	
tMSSqlLastInsertId	568	data in mother/daughter tables	635
tMSSqlLastInsertId properties	568	tMysqlRow	637
Related scenario	568	tMysqlRow properties	637
tMSSqlOutput	569	Scenario 1: Removing and	
tMSSqlOutput properties	569	regenerating a MySQL table index	639

Scenario 2: Using PreparedStatement objects to query data	640	tPostgresqlOutputBulk	701
tMysqlSCD	645	tPostgresqlOutputBulk properties	701
tMysqlCDELT	646	Related scenarios	702
tMysqlSP	647	tPostgresqlOutputBulkExec	703
tMysqlSP Properties	647	tPostgresqlOutputBulkExec properties	703
Scenario: Finding a State Label using a stored procedure	648	Related scenarios	704
tMysqlTableList	651	tPostgresqlRollback	705
tMysqlTableList Properties	651	tPostgresqlRollback properties	705
Related scenario	651	Related scenario	705
tOracleBulkExec	652	tPostgresqlRow	706
tOracleBulkExec properties	652	tPostgresqlRow properties	706
Scenario: Truncating and inserting file data into Oracle DB	655	Related scenarios	707
tOracleClose	658	tPostgresqlSCD	708
tOracleClose properties	658	tPostgresqlSCDELT	709
Related scenario	658	tSybaseBulkExec	710
tOracleCommit	659	tSybaseBulkExec Properties	710
tOracleCommit Properties	659	Related scenarios	712
Related scenario	659	tSybaseClose	713
tOracleConnection	660	tSybaseClose properties	713
tOracleConnection Properties	660	Related scenario	713
Related scenario	661	tSybaseCommit	714
tOracleInput	662	tSybaseCommit Properties	714
tOracleInput properties	662	Related scenario	714
Scenario 1: Using context parameters when reading a table from an Oracle database	663	tSybaseConnection	715
Related scenarios	666	tSybaseConnection Properties	715
tOracleOutput	667	Related scenarios	715
tOracleOutput properties	667	tSybaseInput	716
Related scenarios	670	tSybaseInput Properties	716
tOracleOutputBulk	671	Related scenarios	717
tOracleOutputBulk properties	671	tSybaseIQBulkExec	718
Related scenarios	672	tSybaseIQBulkExec Properties	718
tOracleOutputBulkExec	673	Related scenarios	720
tOracleOutputBulkExec properties	673	tSybaseIQOutputBulkExec	721
Related scenarios	675	tSybaseIQOutputBulkExec properties	721
tOracleRollback	677	Related scenarios	723
tOracleRollback properties	677	tSybaseOutput	724
Related scenario	677	tSybaseOutput Properties	724
tOracleRow	678	Related scenarios	726
tOracleRow properties	678	tSybaseOutputBulk	728
Related scenarios	680	tSybaseOutputBulk properties	728
tOracleSCD	681	Related scenarios	729
tOracleSCDELT	682	tSybaseOutputBulkExec	730
tOracleSP	683	tSybaseOutputBulkExec properties	730
tOracleSP Properties	683	Related scenarios	732
Scenario: Checking number format using a stored procedure	685	tSybaseRollback	733
tOracleTableList	689	tSybaseRollback properties	733
tOracleTableList properties	689	Related scenarios	733
Related scenarios	689	tSybaseRow	734
tPostgresqlBulkExec	690	tSybaseRow Properties	734
tPostgresqlBulkExec properties	690	Related scenarios	736
Related scenarios	692	tSybaseSCD	737
tPostgresqlCommit	693	tSybaseSCDELT	738
tPostgresqlCommit Properties	693	tSybaseSP	739
Related scenario	693	tSybaseSP properties	739
tPostgresqlClose	694	Related scenarios	740
tPostgresqlClose properties	694	Databases - appliance/datawarehouse components	741
Related scenario	694	tGreenplumBulkExec	742
tPostgresqlConnection	695	tGreenplumBulkExec Properties	742
tPostgresqlConnection Properties	695	Related scenarios	744
Related scenario	695	tGreenplumClose	745
tPostgresqlInput	696	tGreenplumClose properties	745
tPostgresqlInput properties	696	Related scenario	745
Related scenarios	697	tGreenplumCommit	746
tPostgresqlOutput	698	tGreenplumCommit Properties	746
tPostgresqlOutput properties	698	Related scenario	746
Related scenarios	700	tGreenplumConnection	747
		tGreenplumConnection properties	747
		Related scenarios	747
		tGreenplumGPLoad	749

Preface

General information

Purpose

This Reference Guide provides use cases and details about how to set parameters for the major components found in the **Palette** of *Talend Open Studio for Big Data*.

Information presented in this document applies to *Talend Open Studio for Big Data* releases version 5.1.x.

Audience

This guide is for users and administrators of *Talend Open Studio for Big Data*.

The layout of GUI screens provided in this document may vary slightly from your actual GUI.

Typographical conventions

This guide uses the following typographical conventions:

- text in **bold**: window and dialog box buttons and fields, keyboard keys, menus, and menu options,
- text in [**bold**]: window, wizard, and dialog box titles,
- text in `courier`: system parameters typed in by the user,
- text in *italics*: file, schema, column, row, and variable names referred to in all use cases, and also names of the fields in the Basic and Advanced setting views referred to in the property table for each component,
- The  icon indicates an item that provides additional information about an important point. It is also used to add comments related to a table or a figure,
- The  icon indicates a message that gives information about the execution requirements or recommendation type. It is also used to refer to situations or information the end-user need to be aware of or pay special attention to.

History of changes

The following table lists changes made in the *Talend Open Studio for Big Data Reference Guide*.

Version	Date	History of Change
v5.0_a	12/12/2011	Updates in <i>Talend Open Studio for Big Data Reference Guide</i> include:

Version	Date	History of Change
		<ul style="list-style-type: none"> • Post-migration restructuring. • Updated documentation to reflect new product names. For further information , see the Talend website. • Added Cloud, Technical and DotNET chapters. • New components in the Business Intelligence, Data Quality, ESB, Technical, Processing, Cloud, DotNET chapters include: tHashInput, tHashOutput, tJasperOutput, tSplitRow, tRESTRrequest components... • Modifications in the settings and scenarios of many components to match the modifications in the GUI.
v5.0_b	13/02/2012	<p>Updates in <i>Talend Open Studio for Big Data Reference Guide</i> include:</p> <ul style="list-style-type: none"> • Updated the formatting of parts of the Components Reference Guide. • Added a legal notice to the Components Reference Guide. • Added a new component in the Business chapter: tSAPBWInput. • Updated the properties tables and scenarios of certain components to match the modifications in the GUI.
v5.1_a	28/05/2012	<p>Updates in <i>Talend Open Studio for Big Data Reference Guide</i> include:</p> <ul style="list-style-type: none"> • Created <i>Talend Open Studio for Big Data Reference Guide</i>. • Added Big Data family components. • New components in the Big Data chapter include: tHCatalogInput, tHCatalogLoad, tHCatalogOperation and tHCatalogOutput. • Updated the Properties tables and scenarios of certain components to match the modifications in the GUI. • New components in the Internet family: tSetKerberosConfiguration. • New components in the Data Quality family: tUniservBTGeneric, tUniservRTConvertName, tUniservRTMailBulk, tUniservRTMailOutput, tUniservRTMailSearch and tUniservRTPost.
v5.1_b	05/07/2012	<p>Updates in <i>Talend Open Studio for Big Data Reference Guide</i> include:</p> <ul style="list-style-type: none"> • Split the Databases chapter into three chapters: <i>Databases - traditional compoments</i>, <i>Databases - appliance components</i>, and <i>Databases - other components</i>. • Added a scenario for tFileInputMSPositional.

Version	Date	History of Change
		<ul style="list-style-type: none">• Added information regarding missing JARs for certain components.• Adapted the documentation of a number of components to <i>Talend Open Studio for Big Data</i>.

Feedback and Support

Your feedback is valuable. Do not hesitate to give your input, make suggestions or requests regarding this documentation or product and find support from the **Talend** team, on **Talend**'s Forum website at:

<http://talendforge.org/forum>

Big Data components

This chapter details the main components that you can find in **Big Data** family of the **Palette**.

This document will provide you with an overview of our big data components for Hadoop Distributed File System (HDFS), HBase, Hive, Pig and Sqoop. To reference the remainder of the studio, please refer to *Talend Open Studio for Big Data User Guide*.

*For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query Type** of components are always **Built-in**. For how to edit a Built-in schema, see *Talend Open Studio for Big Data User Guide*.*

Also, if you have any questions, concerns or general comments please take part in our product forums which can be found at: <http://www.talendforge.org/forum/index.php>

Thank you for using Talend Open Studio for Big Data.

tHBaseClose

tHBaseClose properties

Component family	Big Data / HBase	
Function	tHBaseClose closes the transaction committed in the connected DB.	
Purpose	This component closes a transaction.	
Basic settings	<i>Component list</i>	Select the tHBaseConnection component in the list if more than one connection are planned for the current Job.
Advanced settings	<i>tStat Catcher Statistics</i>	Select this check box to collect log data at the component level.
Usage	This component is to be used along with HBase components, especially with tHBaseConnection .	
Limitation	n/a	

Related scenario

For a scenario in which **tHBaseClose** is used, see [the section called “ Scenario: Exchanging customer data with HBase ”](#).

tHBaseConnection

tHBaseConnection properties

Component Family	Big Data / HBase	
Function	tHBaseConnection opens a connection to a database in order to make a transaction.	
Purpose	This component allows you to commit all of the Job data to an output database in just a single transaction, once the data has been validated.	
Basic settings	<i>Property type</i>	In <i>Talend Open Studio for Big Data</i> , the Property type is always Built-in . - Built-in : no property data stored centrally.
	<i>HBase version</i>	Select a HBase version from the list: Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper. Apache 0.20.203: You need to precise the access to the Apache 0.20.203 to be used. Apache 1.0.0: You need to precise the access to the Apache Hadoop 1.0.0 to be used.
	<i>Zookeeper quorum</i>	Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between Talend and HBase.
	<i>Zookeeper client port</i>	Type in the number of the client listening port of the Zookeeper service you are using.
Advanced settings	<i>Properties</i>	If you need to use custom configuration for your HBase, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those corresponding ones defined earlier for your HBase. For example, you need to define the value of the <i>dfs.replication</i> property as <i>1</i> for the HBase configuration. Then you need to add one row to this table using the plus button and type in the name and the value of this property in this row.
	<i>tStatCatcher Statistics</i>	Select this check box to collect the log data at a component level.
Usage	This component is generally used with other HBase components, particularly tHBaseClose .	
Limitation	n/a	

Related scenario

For a scenario in which **tHBaseConnection** is used, see [the section called “ Scenario: Exchanging customer data with HBase ”](#).

tHBaseInput

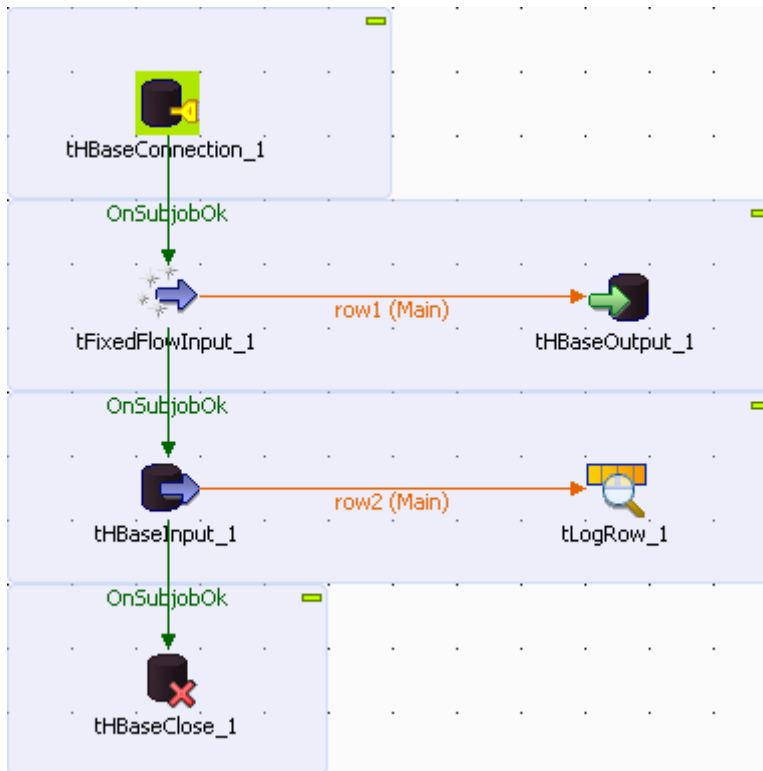

tHBaseInput properties

Component family	Big Data / HBase	
Function	tHBaseInput reads the corresponding database and extracts fields of selection.	
Purpose	tHBaseInput extracts columns corresponding to schema definition. Then it passes these columns to the next component via a Main row link.	
Basic settings	<i>Property type</i>	In <i>Talend Open Studio for Big Data</i> , the Property type is always Built-in . - Built-in : No property data stored centrally.
	<i>Use an existing connection</i>	Select this check box and select the appropriate tHBaseConnection component from the Component list if you want to re-use the connection parameters that you have already defined.
	<i>HBase version</i>	Select a HBase version from the list: Hortonworks Data Platform 1.0 : You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper. Apache 0.20.203 : You need to precise the access to the Apache 0.20.203 to be used. Apache 1.0.0 : You need to precise the access to the Apache Hadoop 1.0.0 to be used.
	<i>Zookeeper quorum</i>	Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between Talend and HBase.
	<i>Zookeeper client port</i>	Type in the number of the client listening port of the Zookeeper service you are using.
	<i>Schema and Edit schema</i>	A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in : The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Table name</i>	Type in the name of the HBase table from which you need to extract columns.
	<i>Mapping</i>	Complete this table to specify the column or columns to be extracted and the corresponding column family or families. The Column column of this table is automatically filled once you have defined the schema.

Advanced settings	<i>tStat Catcher Statistics</i>	Select this check box to collect log data at the component level.
	<i>Properties</i>	<p>If you need to use custom configuration for your HBase, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those corresponding ones defined earlier for your HBase.</p> <p>For example, you need to define the value of the <i>dfs.replication</i> property as <i>1</i> for the HBase configuration. Then you need to add one row to this table using the plus button and type in the name and the value of this property in this row.</p> <p> This table is not available when you are using an existing connection by selecting the Using an existing connection check box in the Basic settings view.</p>
Usage	This component is a start component of a Job and always needs an output link.	

Scenario: Exchanging customer data with HBase

In this scenario, a six-component Job is used to exchange customer data with a given HBase.

The six components are:

- **tHBaseConnection**: creates a connection to your HBase database.
- **tFixedFlowInput**: creates the data to be written into your HBase. In the real use case, this component could be replaced by the other input components like **tFileInputDelimited**.

- **tHBaseOutput**: writes the data it receives from the preceding component into your HBase.
- **tHBaseInput**: extracts the columns of interest from your HBase.
- **tLogRow**: presents the execution result.
- **tHBaseClose**: closes the transaction.

To replicate this scenario, proceed as the following sections illustrate.

Before starting the replication, your Hbase and Zookeeper service should have been correctly installed and well configured. This scenario explains only how to use Talend solution to make data transaction with a given HBase.

Dropping and linking the components

To do this, proceed as follows:

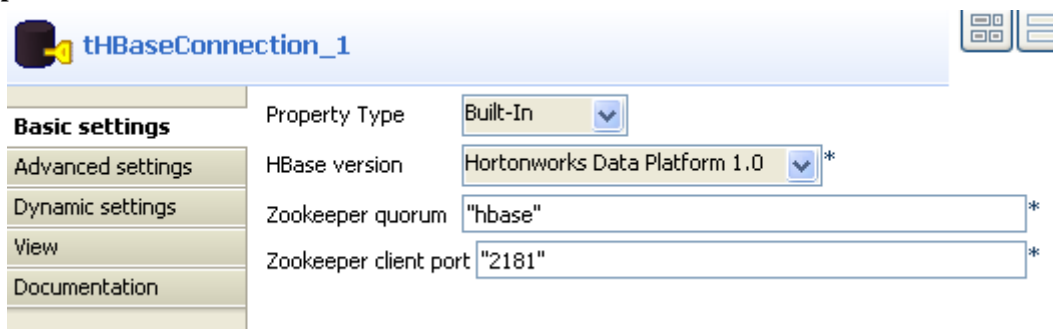

1. Drop **tHBaseConnection**, **tFixedFlowInput**, **tHBaseOutput**, **tHBaseInput**, **tLogRow** and **tHBaseClose** from Palette onto the Design workspace.
2. Right-click **tHBaseConnection** to open its contextual menu and select the **Trigger > On Subjob Ok** link from this menu to connect this component to **tFixedFlowInput**.
3. Do the same to create the **OnSubjobOk** link from **tFixedFlowInput** to **tHBaseInput** and then to **tHBaseClose**.
4. Right-click **tFixedFlowInput** and select the **Row > Main** link to connect this component to **tHBaseOutput**.
5. Do the same to create the **Main** link from **tHBaseInput** to **tLogrow**.

The components to be used in this scenario are all placed and linked. Then you need continue to configure them successively.

Configuring the connection

To configure the connection to your Zookeeper service and thus to the HBase of interest, proceed as follows:

1. On the Design workspace of your Studio, double-click the **tHBaseConnection** component to open its **Component** view.

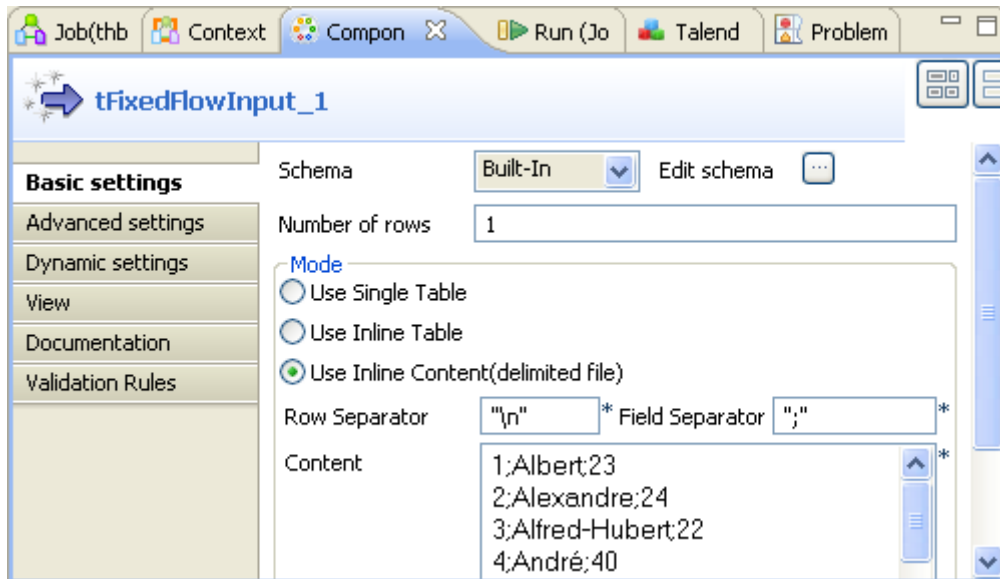

2. Select **Hortonworks Data Platform 1.0** from the **HBase version** list.
3. In the **Zookeeper quorum** field, type in the name or the URL of the Zookeeper service you are using. In this example, the name of the service in use is *hbase*.

- In the **Zookeeper client port** field, type in the number of client listening port. In this example, it is *2181*.

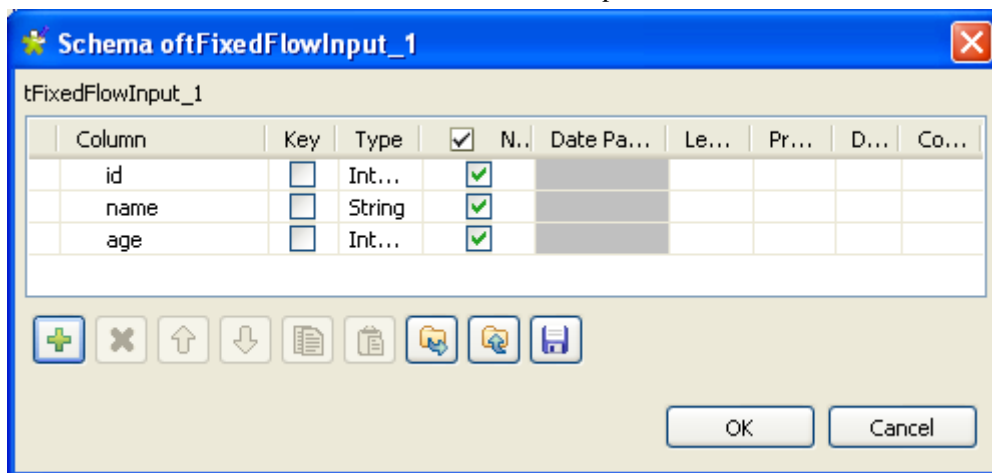

Configuring the process of writing data into the HBase

To do this, proceed as follows:

- On the Design workspace, double-click the **tFixedFlowInput** component to open its **Component** view.

- In this view, click the three-dot button next to **Edit schema** to open the schema editor.

- Click the plus button three times to add three rows and in the **Column** column, rename the three rows respectively as: *id*, *name* and *age*.
- In the **Type** column, click each of these rows and from the drop-down list, select the data type of every row. In this scenario, they are **Integer** for *id* and *age*, **String** for *name*.
- Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.
- In the **Mode** area, select the **Use Inline Content (delimited file)** to display the fields for editing.
- In the **Content** field, type in the delimited data to be written into the HBase, separated with the semicolon ";". In this example, they are:

```

1;Albert;23
2;Alexandre;24
3;Alfred-Hubert;22
4;André;40
5;Didier;28
6;Anthony;35
7;Artus;32
8;Benoît;56
9;Catherine;34
10;Charles;21
11;Christophe;36
12;Christian;67
13;Clément ;64
14;Danniel;54
15;Elisabeth;58
16;Emile;32
17;Gregory;30

```

8. Double-click **tHBaseOutput** to open its **Component** view.

If this component does not have the same schema of the preceding component, a warning icon appears. In this case, click the **Sync columns** button to retrieve the schema from the preceding one and once done, the warning icon disappears.

tHBaseOutput_1

Use an existing connection tHBaseConnection_1

Schema: Built-In Edit schema

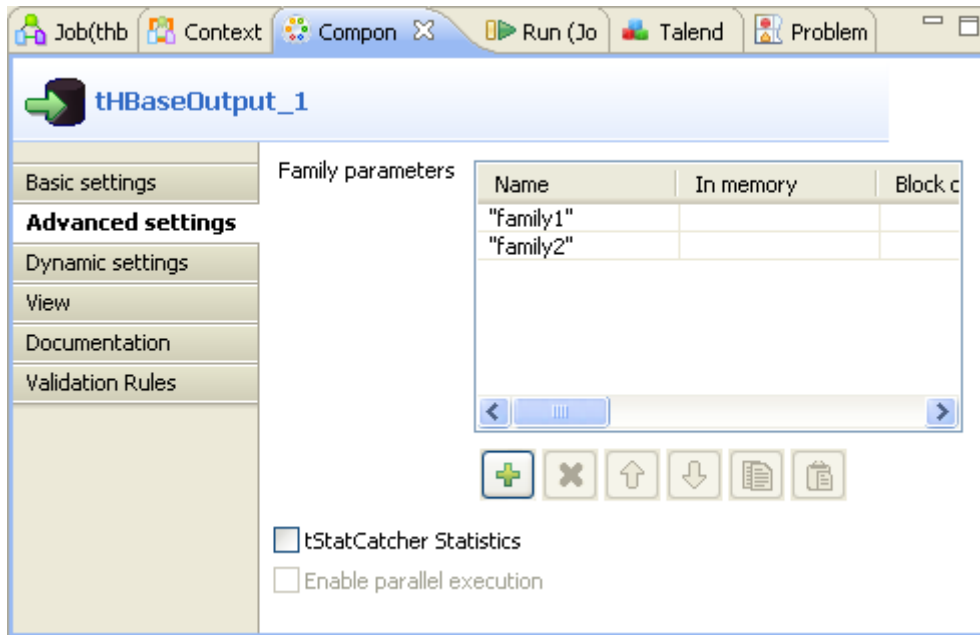

Table name: "customer"

Action on table: Drop table if exists and create Custom Row Key

Column	Family name
id	"family1"
name	"family2"
age	"family1"

Die on error

9. Select the **Use an existing connection** check box and then select the connection you have configured earlier. In this example, it is *tHBaseConnection_1*.
10. In the **Table name** field, type in the name of the table to be created in the HBase. In this example, it is *customer*.
11. In the **Action on table** field, select the action of interest from the drop-down list. In this scenario, select **Drop table if exists and create**. This way, if a table named *customer* exists already in the HBase, it will be disabled and deleted before creating this current table.
12. Click the **Advanced settings** tab to open the corresponding view.

13. In the **Family parameters** table, add two rows by clicking the plus button, rename them as *family1* and *family2* respectively and then leave the other columns empty. These two column families will be created in the HBase using the default family performance options.

 The **Family parameters** table is available only when the action you have selected in the **Action on table** field is to create a table in HBase. For further information about this **Family parameters** table, see [the section called "tHBaseOutput"](#).

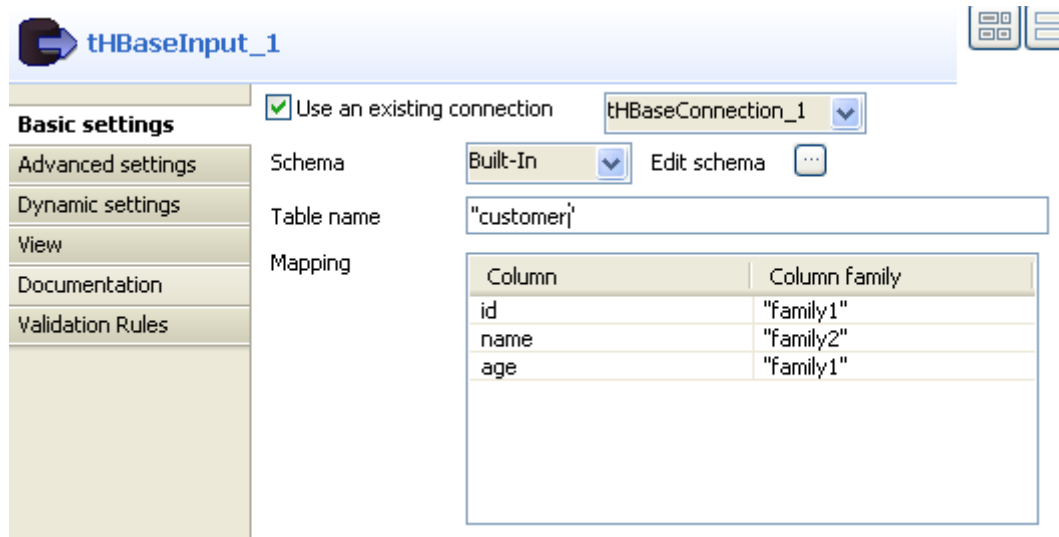

14. In the **Families** table of the **Basic settings** view, enter the family names in the **Family name** column, each corresponding to the column this family contains. In this example, the *id* and the *age* columns belong to *family1* and the *name* column to *family2*.

 These column families should already exist in the HBase to be connected to; if not, you need to define them in the **Family parameters** table of the **Advanced settings** view for creating them at runtime.

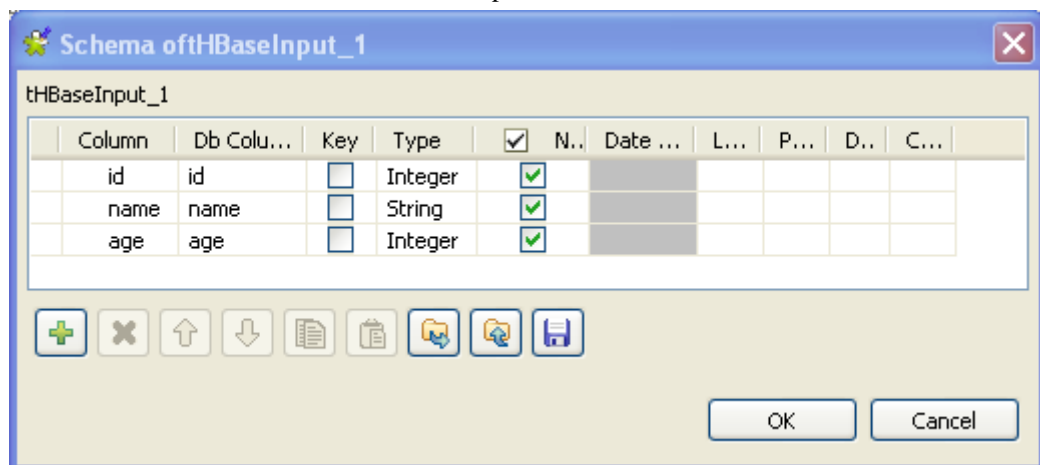

Configuring the process of extracting data from the HBase

To do this, perform the following operations:

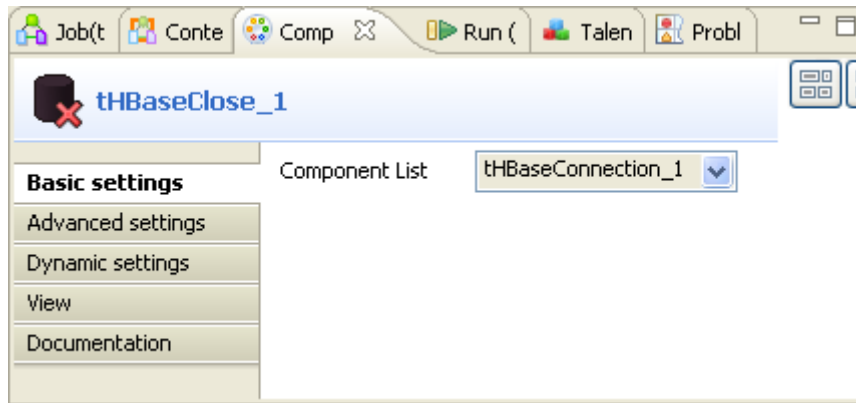

1. Double-click **tHBaseInput** to open its **Component** view.

2. Select the **Use an existing connection** check box and then select the connection you have configured earlier. In this example, it is *tHBaseConnection_1*.
3. Click the three-dot button next to **Edit schema** to open the schema editor.

4. Click the plus button three times to add three rows and rename them as *id*, *name* and *age* respectively in the **Column** column. This means that you extract these three columns from the HBase.
5. Select the types for each of the three columns. In this example, **Integer** for *id* and *age*, **String** for *name*.
6. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.
7. In the **Table name** field, type in the table from which you extract the columns of interest. In this scenario, the table is *customer*.
8. In the **Mapping** table, the **Column** column has been already filled automatically since the schema was defined, so simply enter the name of every family in the **Column family** column, each corresponding to the column it contains.
9. Double-click **tHBaseClose** to open its **Component** view.

10. In the **Component List** field, select the connection you need to close. In this example, this connection is *tHBaseConnection_1*.

Executing the Job

To execute this Job, press **F6**.

Once done, the **Run** view is opened automatically, where you can check the execution result.

These columns of interest are extracted and you can process them according to your needs.

Login to your HBase database, you can check the *customer* table this Job has created.

tHBaseOutput

tHBaseOutput properties

Component family	Big Data / HBase	
Function	tHBaseOutput receives data from its preceding component, creates a table in a given HBase database and writes the received data into this HBase table.	
Purpose	tHBaseOutput writes columns of data into a given tHBase database.	
Basic settings	<i>Property type</i>	In <i>Talend Open Studio for Big Data</i> , the Property type is always Built-in . - Built-in : No property data stored centrally.
	<i>Use an existing connection</i>	Select this check box and select the appropriate tHBaseConnection component from the Component list if you want to re-use the connection parameters that you have already defined.
	<i>HBase version</i>	Select a HBase version from the list: Hortonworks Data Platform 1.0 : You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper. Apache 0.20.203 : You need to precise the access to the Apache 0.20.203 to be used. Apache 1.0.0 : You need to precise the access to the Apache Hadoop 1.0.0 to be used in this mode.
	<i>Zookeeper quorum</i>	Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between Talend and HBase.
	<i>Zookeeper client port</i>	Type in the number of the client listening port of the Zookeeper service you are using.
	<i>Schema and Edit schema</i>	A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in . Built-in : The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Table name</i>	Type in the name of the HBase table you need create.
	<i>Action on table</i>	Select the action you need to take for creating an HBase table.
	<i>Custom Row Key</i>	Select this check box to use the customized row keys. Once selected, the corresponding field appears. Then type in the user-defined row key to index the rows of the HBase table being created.

		For example, you can type in "France"+Numeric.sequence("s1",1,1) to produce the row key series: <i>France1</i> , <i>France2</i> , <i>France3</i> and so on.
	<i>Families</i>	Complete this table to specify the column or columns to be created and the corresponding column family or families they belong to respectively. The Column column of this table is automatically filled once you have defined the schema.
Advanced settings	<i>Properties</i>	<p>If you need to use custom configuration for your HBase, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those corresponding ones defined earlier for your HBase.</p> <p>For example, you need to define the value of the <i>dfs.replication</i> property as <i>1</i> for the HBase configuration. Then you need to add one row to this table using the plus button and type in the name and the value of this property in this row.</p> <p> This table is not available when you are using an existing connection by selecting the Using an existing connection check box in the Basic settings view.</p>
	<i>tStat Catcher Statistics</i>	Select this check box to collect log data at the component level.
 Only available for creating a HBase table	<i>Family parameters</i>	Type in the names and, when needs be, the custom performance options of the column families to be created. These options are all attributes defined by the HBase data model, so for further explanation about these options, see your HBase manual.
Usage	This component is normally an end component of a Job and always needs an input link.	

Related scenario

For related scenario to **tHBaseOutput**, see [the section called “ Scenario: Exchanging customer data with HBase ”](#).

tHCatalogInput

tHCatalogInput Properties

Component family	Big Data / HCatalog	
Function	This component allows you to read data from HCatalog managed database and send data in the talend flow.	
Purpose	The tHCatalogInput component reads data from the specified HCatalog managed database and sends data in the talend flow to the console or to a specified local file by connecting this component to a proper component.	
Basic settings	<i>Schema and Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>HCatalog version</i>	Select a Hadoop version from the list: Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper.
	<i>Templeton hostname</i>	Fill this field with the URL of Templeton Webservice.  Templeton is a webservice API for Hadoop. It allows you to move data directly into/out-of HDFS through WebHDFS. For further information about Templeton, see http://people.apache.org/~thejas/templeton_doc_latest .
	<i>Templeton port</i>	Fill this field with the port of URL of Templeton Webservice. By default, this value is <i>50111</i> .  Templeton is a webservice API for Hadoop. It allows you to move data directly into/out-of HDFS through WebHDFS. For further information about Templeton, see http://people.apache.org/~thejas/templeton_doc_latest .
	<i>Database</i>	The database in which the HCatalog managed tables are placed.
	<i>Table</i>	Fill this field to operate on one or multiple tables in the specified database.
	<i>Partition</i>	Fill this field to specify one or more partitions for the partition operation on a specified table. When you specify multiple partitions, use commas to separate

		<p>every two partitions and use double quotation marks to quote the partition string.</p> <p> For further information about Partition, see https://cwiki.apache.org/Hive/languagemanual-ddl.html#LanguageManualDDL-AddPartitions.</p>
	<i>Username</i>	Fill this field with the username for the DB authentication.
	<i>Die on error</i>	This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.
Advanced settings	<i>Retrieve the HCatalog logs</i>	Select this check box to retrieve log files generated during HCatalog operations.
	<i>Standard Output Folder</i>	<p>Fill this field with the path to which log files are stored.</p> <p> This field is enabled only when you selected Retrieve the HCatalog logs check box.</p>
	<i>Error Output Folder</i>	<p>Fill this field with the path to which error log files are stored.</p> <p> This field is enabled only when you selected Retrieve the HCatalog logs check box.</p>
	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Usage	This component is commonly used as the starting component in a Job.	
Limitation	<p>Knowledge of Hive Data Definition Language and HCatalog Data Definition Language is required. For further information about Hive Data Definition Language, see https://cwiki.apache.org/confluence/display/Hive/LanguageManual+DDL. For further information about HCatalog Data Definition Language, see https://cwiki.apache.org/confluence/display/HCATALOG/Design+Document+-+Java+APIs+for+HCatalog+DDL+Commands.</p>	

Related scenario

For a related scenario, see [the section called “Scenario: HCatalog table management on Hortonworks Data Platform”](#).

tHCatalogLoad

tHCatalogLoad Properties

Component family	Big Data / HCatalog	
Function	This component allows you to write data into an established HCatalog managed table from an existing file in HDFS.	
Purpose	The tHCatalogLoad component writes data into an established HCatalog managed table from an existing file in HDFS.	
Basic settings	<i>HCatalog version</i>	Select a Hadoop version from the list: Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper.
	<i>Templeton hostname</i>	Fill this field with the URL of Templeton Webservice.  Templeton is a webservice API for Hadoop. It allows you to move data directly into/out-of HDFS through WebHDFS. For further information about Templeton, see Templeton 0.1.0 .
	<i>Templeton port</i>	Fill this field with the port of URL of Templeton Webservice. By default, this value is <i>50111</i> .  Templeton is a webservice API for Hadoop. It allows you to move data directly into/out-of HDFS through WebHDFS. For further information about Templeton, see Templeton 0.1.0 .
	<i>Database</i>	Fill this field to specify an existing database in HDFS.
	<i>Table</i>	Fill this field to specify an existing table in HDFS.
	<i>Partition</i>	Fill this field to specify one or more partitions for the partition operation on the specified table. When you specify multiple partitions, use commas to separate every two partitions and use double quotation marks to quote the partition string.  For further information about Partition , see Operation on Partitions in Hive .
	<i>Username</i>	Fill this field with the username for the DB authentication.
	<i>File location</i>	Fill this field with the HDFS location to which loaded data is stored.
Advanced settings	<i>Retrieve the HCatalog logs</i>	Select this check box to retrieve log files generated during HCatalog operations.
	<i>Standard Output Folder</i>	Fill this field with the path to which log files are stored.

		 This field is enabled only when you selected Retrieve the HCatalog logs check box.
	<i>Error Output Folder</i>	Fill this field with the path to which error log files are stored.  This field is enabled only when you selected Retrieve the HCatalog logs check box.
	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Usage	This component can be used in a single-component Job or used together with a subjob.	
Limitation	Knowledge of Hive Data Definition Language and HCatalog Data Definition Language is required. For further information about Hive Data Definition Language, see Hive Data Definition Language . For further information about HCatalog Data Definition Language, see HCatalog Data Definition Language .	

Related scenario

For a related scenario, see [the section called “Scenario: HCatalog table management on Hortonworks Data Platform”](#).

tHCatalogOperation

tHCatalogOperation Properties

Component family	Big Data / HCatalog	
Function	This component allows you to manage the data stored in HCatalog managed database/table/partition in HDFS.	
Purpose	The tHCatalogOperation component offers a platform on which you can operate in HCatalog managed database/table/partition in HDFS.	
Basic settings	<i>Schema and Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>HCatalog version</i>	Select a Hadoop version from the list: Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper.
	<i>Templeton hostname</i>	Fill this field with the URL of Templeton Webservice.  Templeton is a webservice API for Hadoop. It allows you to move data directly into/out-of HDFS through WebHDFS. For further information about Templeton, see http://people.apache.org/~thejas/templeton_doc_latest .
	<i>Templeton port</i>	Fill this field with the port of URL of Templeton Webservice. By default, the value for this field is <i>50111</i> .  Templeton is a webservice API for Hadoop. It allows you to move data directly into/out-of HDFS through WebHDFS. For further information about Templeton, see http://people.apache.org/~thejas/templeton_doc_latest .
	<i>Operation on</i>	Select an object from the list for the DB operation as follows: Database: The HCatalog managed database in HDFS. Table: The HCatalog managed table in HDFS. Partition: The partition specified by the user.
	<i>Operation</i>	Select an action from the list for the DB operation as follows: Create/Drop/Drop if exist/Drop and

		create/Drop if exist and create. For further information about the DB operation in HDFS, see https://cwiki.apache.org/Hive/languagemanual-ddl.html .
	<i>Create the table only if it doesn't exist already</i>	Select this check box to avoid creating duplicate table when you create a table.  This check box is enabled only when you select Table from the Operation on list.
	<i>Database</i>	Fill this field with the name of the database in which the HCatalog managed tables are placed.
	<i>Table</i>	Fill this field to operate on one or multiple tables in a database or on a specified HDFS location.  This field is enabled only when you select Table from the Operation on list. For further information about the operation on Table , see https://cwiki.apache.org/Hive/languagemanual-ddl.html#LanguageManualDDL-Create%252FDropTable .
	<i>Partition</i>	Fill this field to specify one or more partitions for the partition operation on a specified table. When you specify multiple partitions, use comma to separate every two partitions and use double quotation marks to quote the partition string.  This field is enabled only when you select Partition from the Operation on list. For further information about the operation on Partition , see https://cwiki.apache.org/Hive/languagemanual-ddl.html#LanguageManualDDL-AddPartitions .
	<i>Username</i>	Fill this field with the username for the DB authentication.
	<i>Database location</i>	Fill this field with the location of the database file in HDFS.  This field is enabled only when you select Database from the Operation on list.
	<i>Database description</i>	The description for the database to be created.  This field is enabled only when you select Database from the Operation on list.
	<i>Create an external table</i>	Select this field to create an external table in an alternative path defined in the Set HDFS location field in the Advanced settings view. For further information about creating external table, see https://cwiki.apache.org/Hive/languagemanual-ddl.html#LanguageManualDDL-CreateTable .  This check box is enabled only when you select Table from the Operation on list and Create/Drop and create/Drop if exist and create from the Operation list.

	<i>Format</i>	<p>Select a file format from the list to specify the format of the external table you want to create:</p> <p>TEXTFILE: Plain text files.</p> <p>RCFILE: Record Columnar files. For further information about RCFILE, see http://hive.apache.org/docs/r0.4.0/api/org/apache/hadoop/hive/ql/io/RCFile.html.</p> <p> RCFILE is only available starting with Hive 0.6.0. This list is enabled only when you select Table from the Operation on list and Create/Drop and create/Drop if exist and create from the Operation list.</p>
	<i>Set partitions</i>	<p>Select this check box to set the partition schema by clicking the Edit schema to the right of Set partitions check box. The partition schema is either built-in or remote in the Repository.</p> <p> This check box is enabled only when you select Table from the Operation on list and Create/Drop and create/Drop if exist and create from the Operation list. You must follow the rules of using partition schema in HCatalog managed tables. For more information about the rules in using partition schema, see http://incubator.apache.org/hcatalog/docs/r0.2.0/inputoutput.html#Partition+Schema+Semantics.</p>
		<p>Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i>.</p>
		<p>Repository: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see <i>Talend Open Studio for Big Data User Guide</i>.</p>
	<i>Set the user group to use</i>	<p>Select this check box to specify the user group.</p> <p> This check box is enabled only when you select Drop/Drop if exist/Drop and create/Drop if exist and create from the Operation list. By default, the value for this field is <i>root</i>. For more information about the user group in the server, contact your system administrator.</p>
	<i>Option</i>	<p>Select a clause when you drop a database.</p> <p> This list is enabled only when you select Database from the Operation on list and Drop/Drop if exist/Drop and create/Drop if exist and create from the Operation list. For more information about Drop operation on database, see https://cwiki.apache.org/Hive/languagemanual-</p>

		ddl.html#LanguageManualDDL-DropDatabase .
	<i>Set the permissions to use</i>	<p>Select this check box to specify the permissions needed by the operation you select from the Operation list.</p> <p> This check box is enabled only when you select Drop/Drop if exist/Drop and create/Drop if exist and create from the Operation list. By default, the value for this field is <i>rwxrwx-r-x</i>. For more information on user permissions, contact your system administrator.</p>
	<i>Set File location</i>	<p>Fill this field to specify a path to which partitioned data is stored.</p> <p> This check box is enabled only when you select Partition from the Operation on list and Create/Drop and create/Drop if exist and create from the Operation list. For further information about storing partitioned data in HDFS, see https://cwiki.apache.org/Hive/languagemanual-ddl.html#LanguageManualDDL-AddPartitions.</p>
	<i>Die on error</i>	This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.
Advanced settings	<i>Comment</i>	<p>Fill this field with the comment for the table you want to create.</p> <p> This field is enabled only when you select Table from the Operation on list and Create/Drop and create/Drop if exist and create from the Operation list in the Basic settings view.</p>
	<i>Set HDFS location</i>	<p>Select this check box to specify an HDFS location to which the table you want to create is saved. Deselect it to save the table you want to create in the warehouse directory defined in the key <i>hive.metastore.warehouse.dir</i> in Hive configuration file <i>hive-site.xml</i>.</p> <p> This check box is enabled only when you select Table from the Operation on list and Create/Drop and create/Drop if exist and create from the Operation list in the Basic settings view. For further information about saving data in HDFS, see https://cwiki.apache.org/Hive/languagemanual-ddl.html#LanguageManualDDL-CreateTable.</p>
	<i>Set row format(terminated by)</i>	<p>Select this check box to use and define the row formats when you want to create a table:</p> <p>Field: Select this check box to use Field as the row format. The default value for this field is <code>"\u0001"</code>. You can also specify a customized char in this field.</p>

		<p>Collection Item: Select this check box to use Collection Item as the row format. The default value for this field is "\u0002". You can also specify a customized char in this field.</p> <p>Map Key: Select this check box to use Map Key as the row format. The default value for this field is "\u0003". You can also specify a customized char in this field.</p> <p>Line: Select this check box to use Line as the row format. The default value for this field is "\n". You can also specify a customized char in this field.</p> <p> This check box is enabled only when you select Table from the Operation on list and Create/Drop and create/Drop if exist and create from the Operation list in the Basic settings view. For further information about row formats in the HCatalog managed table, see https://cwiki.apache.org/Hive/languagemanual-ddl.html#LanguageManualDDL-CreateTable.</p>
	<i>Properties</i>	<p>Click [+] to add one or more lines to define table properties. The table properties allow you to tag the table definition with your own metadata key/value pairs. Make sure that values in both Key row and Value row must be quoted in double quotation marks.</p> <p> This table is enabled only when you select Database/Table from the Operation on list and Create/Drop and create/Drop if exist and create from the Operation list in the Basic settings view. For further information about table properties, see https://cwiki.apache.org/Hive/languagemanual-ddl.html#LanguageManualDDL-CreateTable.</p>
	<i>Retrieve the HCatalog logs</i>	Select this check box to retrieve log files generated during HCatalog operations.
	<i>Standard Output Folder</i>	<p>Fill this field with the path to which log files are stored.</p> <p> This field is enabled only when you selected Retrieve the HCatalog logs check box.</p>
	<i>Error Output Folder</i>	<p>Fill this field with the path to which error log files are stored.</p> <p> This field is enabled only when you selected Retrieve the HCatalog logs check box.</p>
	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Usage	This component is commonly used in a single-component Job or used together with a subjob.	
Limitation	Knowledge of Hive Data Definition Language and HCatalog Data Definition Language is required. For further information about Hive Data Definition Language, see https://cwiki.apache.org/confluence/display/Hive/	

[LanguageManual+DDL](#). For further information about HCatalog Data Definition Language, see <https://cwiki.apache.org/confluence/display/HCATALOG/Design+Document++Java+APIs+for+HCatalog+DDL+Commands>.

Scenario: HCatalog table management on Hortonworks Data Platform

This scenario describes a six-component Job that includes the common operations for the HCatalog table management on Hortonworks Data Platform. Sub-sections in this scenario covers DB operations including:

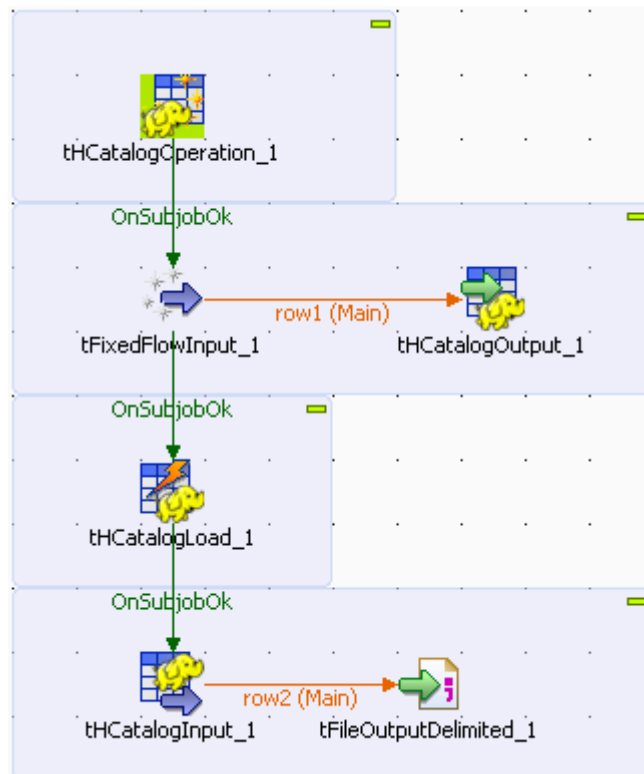

- Creating a table to the database in HDFS;
- Writing data to the HCatalog managed table;
- Writing data to the partitioned table using **tHCatalogLoad**;
- Reading data from the HCatalog managed table;
- Outputting the data read from the table in HDFS.

Knowledge of Hive Data Definition Language and HCatalog Data Definition Language is required. For further information about Hive Data Definition Language, see <https://cwiki.apache.org/confluence/display/Hive/LanguageManual+DDL>. For further information about HCatalog Data Definition Language, see <https://cwiki.apache.org/confluence/display/HCATALOG/Design+Document++Java+APIs+for+HCatalog+DDL+Commands>.

Setting up the Job

1. Drop the following components from the **Palette** to the design workspace: **tHCatalogOperation**, **tHCatalogLoad**, **tHCatalogInput**, **tHCatalogOutput**, **tFixedFlowInput**, and **tFileOutputDelimited**.

- Right-click **tHCatalogOperation** to connect it to **tFixedFlowInput** component using a **Trigger>OnSubjobOk** connection.
- Right-click **tFixedFlowInput** to connect it to **tHCatalogOutput** using a **Row > Main** connection.
- Right-click **tFixedFlowInput** to connect it to **tHCatalogLoad** using a **Trigger > OnSubjobOk** connection.
- Right-click **tHCatalogLoad** to connect it to the **tHCatalogInput** component using a **Trigger > OnSubjobOk** connection.
- Right-click **tHCatalogInput** to connect it to **tFileOutputDelimited** using a **Row > Main** connection.

Creating a table in HDFS

- Double-click **tHCatalogOperation** to open its **Basic settings** view.

The screenshot shows the 'Basic settings' view for the 'tHCatalogOperation_1' component. The left sidebar contains tabs for 'Basic settings', 'Advanced settings', 'Dynamic settings', 'View', and 'Documentation'. The main area is divided into several sections:

- Schema:** Set to 'Built-In' with an 'Edit schema' button.
- HCatalog version:** Set to 'Hortonworks Data Platform 1.0'.
- Templeton Configuration:** Includes 'Templeton hostname' ('192.168.0.131') and 'Templeton port' ('50111').
- Operation on:** Set to 'Table' and 'Operation' set to 'Drop if exist and create'.
- Create the table only it doesn't exist already
- HCatalog Configuration:** Includes 'Database' ('talend'), 'Table' ('Customer'), and 'Username' ('hdp').
- Drop Configuration:** Includes checked options for 'Set the user group to use' ('root') and 'Set the permissions to use' ('rwxrwxr-x').
- Create Table Configuration:** Includes an unchecked option for 'Create an external table', 'Format' set to 'TEXTFILE', and checked options for 'Set partitions' ('Built-In') and 'Die on error'.

- Click **Edit schema** to define the schema for the table to be created.

The screenshot shows the 'Edit schema' view for 'tHCatalogOperation_1'. It displays a table with the following columns and data:

Column	Key	Type	✓	N..	Date ...	L...	P...	D..
age	<input type="checkbox"/>	Integer	<input checked="" type="checkbox"/>					
country	<input type="checkbox"/>	String	<input checked="" type="checkbox"/>					
name	<input type="checkbox"/>	String	<input checked="" type="checkbox"/>					

Below the table is a toolbar with icons for adding, deleting, moving, and saving the schema.

3. Click [+] to add at least one column to the schema and click **OK** when you finish setting the schema. In this scenario, the columns added to the schema are: *name*, *country* and *age*.
4. Fill the **Templeton hostname** field with URL of the Templeton webservice you are using. In this scenario, fill this field with "192.168.0.131".
5. Fill the **Templeton port** field with the port for **Templeton hostname**. By default, the value for this field is "50111".
6. Select **Table** from the **Operation on** list and **Drop if exist and create** from the **Operation** list to create a table in HDFS.
7. Fill the **Database** field with an existing database name in HDFS. In this scenario, the database name is "talend".
8. Fill the **Table** field with the name of the table to be created. In this scenario, the table name is "Customer".
9. Fill the **Username** field with the username for the DB authentication.
10. Select the **Set the user group to use** check box to specify the user group. The default user group is "root", you need to specify the value for this field according to real practice.
11. Select the **Set the permissions to use** check box to specify the user permission. The default value for this field is "rwxrwxr-x".
12. Select the **Set partitions** check box to enable the partition schema.
13. Click the **Edit schema** button next to the **Set partitions** check box to define the partition schema.
14. Click [+] to add one column to the schema and click **OK** when you finish setting the schema. In this scenario, the column added to the partition schema is: *match_age*.

Writing data to the existing table

1. Double-click **tFixedFlowInput** to open its **Basic settings** view.

The screenshot shows the configuration for a tFixedFlowInput component. The 'Basic settings' tab is active. The 'Schema' is set to 'Built-In'. The 'Number of rows' is set to 8. Under 'Mode', 'Use Inline Table' is selected. The 'Inline Table' contains the following data:

age	country	name
"27"	"Tunisia"	"Abu"
"31"	"Senegal"	"Anelka"
"26"	"Morocco"	"Karim"
"33"	"Senegal"	"Drogba"
"27"	"Japan"	"Ito"
"26"	"Algeria"	"Zeid"
"33"	"Japan"	"Hidetoshi"
"28"	"Lebanon"	"Nasri"

At the bottom of the table, there are icons for adding (+), deleting (x), moving up (↑), moving down (↓), and a clipboard icon. Below the table, there is a radio button for 'Use Inline Content(delimited file)'.

2. Click **Edit schema** to define a same schema as the one you defined in **tHCatalogOperation**.

- Fill the **Number of rows** field with integer 8.
- Select **Use Inline Table** in the **Mode** area.
- Click [+] to add new lines in the inline table.
- Double-click **tHCatalogOutput** to open its **Basic settings** view.

The screenshot shows the 'Basic settings' view for a component named 'tHCatalogOutput_1'. The interface includes a sidebar on the left with options like 'Basic settings', 'Advanced settings', 'Dynamic settings', 'View', 'Documentation', and 'Validation Rules'. The main configuration area is divided into several sections:

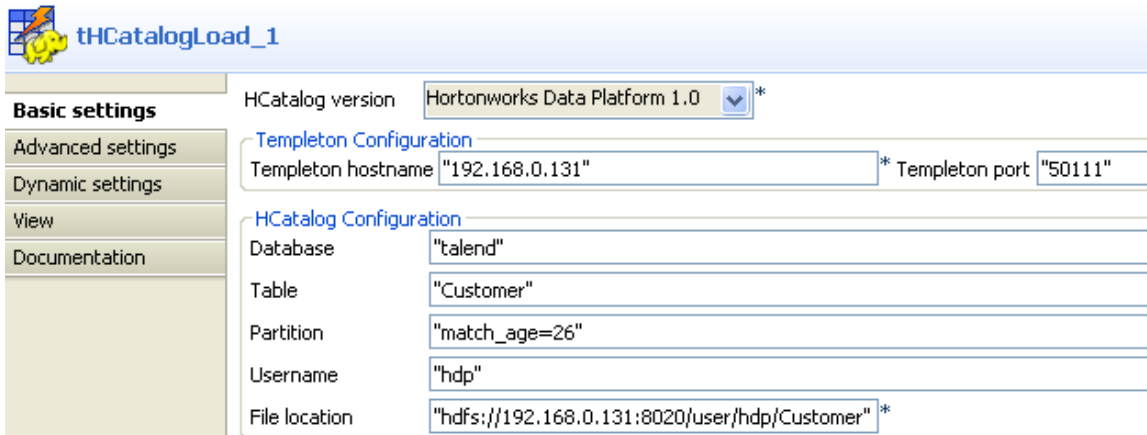

- Schema:** Set to 'Built-In' with an 'Edit schema' button and a 'Sync columns' button.
- HCatalog version:** Set to 'Hortonworks Data Platform 1.0'.
- HDFS Configuration:**
 - NameNode URI: "/192.168.0.131"
 - File name: "/user/hdp/Customer/Customer.csv"
 - Action: 'Overwrite'
- Templetion Configuration:**
 - Templetion hostname: "192.168.0.131"
 - Templetion port: "50111"
- HCatalog Configuration:**
 - Database: "talend"
 - Table: "Customer"
 - Partition: "match_age=27"
 - Username: "hdp"
 - File location: "hdfs://192.168.0.131:8020/user/hdp/Customer"

At the bottom, there is a checkbox labeled 'Die on error' which is currently unchecked.

- Click **Sync columns** to retrieve the schema defined in the preceding component.
- Fill the **NameNode URI** field with the URI to the NameNode. In this scenario, this URL is "192.168.0.131".
- Fill the **File name** field with the HDFS location of the file you write data to. In this scenario, the file location is "/user/hdp/Customer/Customer.csv".
- Select **Overwrite** from the **Action** list.
- Fill the **Templetion hostname** field with URL of the Templetion webservice you are using. In this scenario, fill this field with "192.168.0.131".
- Fill the **Templetion port** field with the port for **Templetion hostname**. By default, the value for this field is "50111".
- Fill the **Database** field, the **Table** field, the **Username** field with the same value you specified in **tHCatalogOperation**.
- Fill the **Partition** field with "match_age=27".
- Fill the **File location** field with the HDFS location to which the table will be saved. In this example, use "hdfs://192.168.0.131:8020/user/hdp/Customer".

Writing data to the partitioned table using tHCatalogLoad

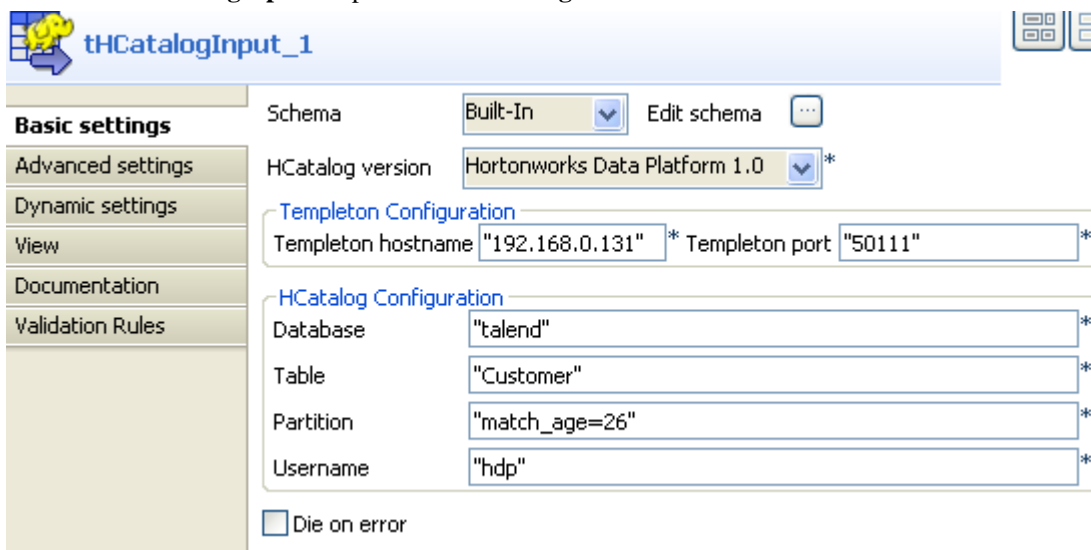

- Double-click **tHCatalogLoad** to open its **Basic settings** view.

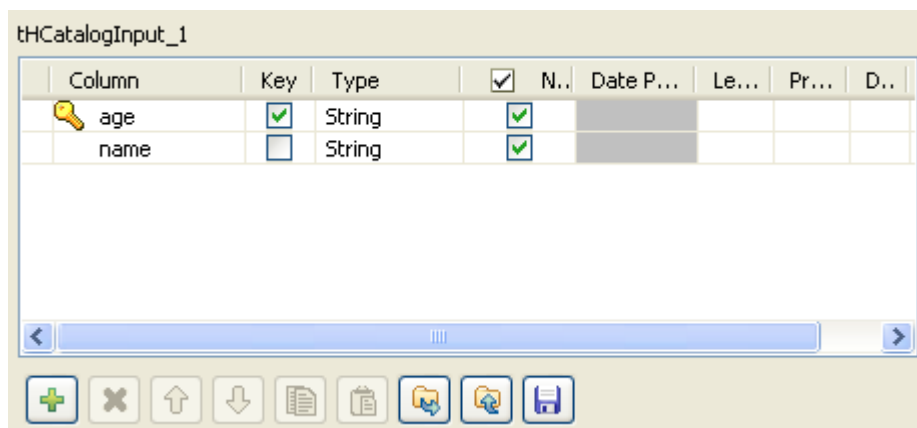

2. Fill the **Partition** field with "match_age=26".
3. Do the rest of the settings in the same way as configuring **tHCatalogOperation**.

Reading data from the table in HDFS

1. Double-click **tHCatalogInput** to open its **Basic settings** view.

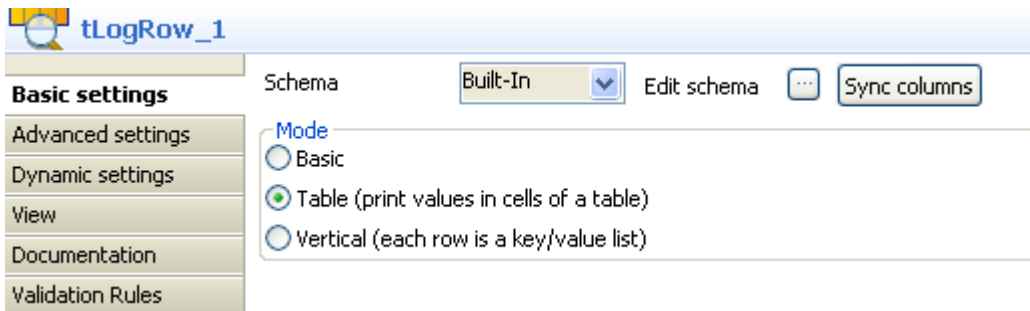

2. Click **Edit schema** to define the schema of the table to be read from the database.

- Click **[+]** to add at least one column to the schema. In this scenario, the columns added to the schema are *age* and *name*.
- Fill the **Partition** field with "*match_age=26*".
- Do the rest of the settings in the same way as configuring **tHCatalogOperation**.

Outputting the data read from the table in HDFS to the console

- Double-click **tLogRow** to open its **Basic settings** view.

- Click **Sync columns** to retrieve the schema defined in the preceding component.
- Select **Table** from the **Mode** area.

Job execution

Press **CTRL+S** to save your Job and **F6** to execute it.

```

+-----+
| tLogRow_1 |
+-----+
| age | name |
+-----+
| 27 | Tunisia |
| 31 | Senegal |
| 26 | Morocco |
| 33 | Senegal |
| 27 | Japan |

tHCatalogOutput

tHCatalogOutput Properties

Component family	Big Data / HCatalog	
Function	This component allows you to write data into an HCatalog managed table using Talend data flow.	
Purpose	The tHCatalogOutput component writes data into a HCatalog managed table using Talend data flow.	
Basic settings	<i>Schema</i> and <i>Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>HCatalog version</i>	Select a Hadoop version from the list: Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper.
	<i>NameNode URI</i>	Type in the URI of the NameNode in HDFS.
	<i>File name</i>	Browse to, or enter the location of the file which you write data to. This file is created automatically if it does not exist.
	<i>Action</i>	Select a DB operation in HDFS: Create: Creates a file with data using the file name defined in the File Name field. Overwrite: Overwrites the data in the file specified in the File Name field. Append: Inserts the data into the file specified in the File Name field. The specified file is created automatically if it does not exist.
	<i>Templeton hostname</i>	Fill this field with the URL of Templeton Webservice.  Templeton is a webservice API for Hadoop. It allows you to move data directly into/out-of HDFS through WebHDFS. For further information about Templeton, see http://people.apache.org/~thejas/templeton_doc_latest .
	<i>Templeton port</i>	Fill this field with the port of URL of Templeton Webservice. By default, this value is <i>50111</i> .

		 Templeton is a webservice API for Hadoop. It allows you to move data directly into/out-of HDFS through WebHDFS. For further information about Templeton, see http://people.apache.org/~thejas/templeton_doc_latest .
	<i>Database</i>	Fill this field to specify an existing database in HDFS.
	<i>Table</i>	Fill this field to specify an existing table in HDFS.
	<i>Partition</i>	<p>Fill this field to specify one or more partitions for the partition operation on the specified table. When you specify multiple partitions, use commas to separate every two partitions and use double quotation marks to quote the partition string.</p> <p> For further information about Partition, see https://cwiki.apache.org/Hive/languagemanual-ddl.html#LanguageManualDDL-AddPartitions.</p>
	<i>Username</i>	Fill this field with the username for the DB authentication.
	<i>File location</i>	Fill this field with the path to which source data file is stored.
	<i>Die on error</i>	This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.
Advanced settings	<i>Retrieve the HCatalog logs</i>	Select this check box to retrieve log files generated during HCatalog operations.
	<i>Standard Output Folder</i>	<p>Fill this field with the path to which log files are stored.</p> <p> This field is enabled only when you selected Retrieve the HCatalog logs check box.</p>
	<i>Error Output Folder</i>	<p>Fill this field with the path to which error log files are stored.</p> <p> This field is enabled only when you selected Retrieve the HCatalog logs check box.</p>
	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Usage	This component is commonly used together with an input component.	
Limitation	<p>Knowledge of Hive Data Definition Language and HCatalog Data Definition Language is required. For further information about Hive Data Definition Language, see https://cwiki.apache.org/confluence/display/Hive/LanguageManual+DDL. For further information about HCatalog Data Definition Language, see https://cwiki.apache.org/confluence/display/HCATALOG/Design+Document+-+Java+APIs+for+HCatalog+DDL+Commands.</p>	

Related scenario

For a related scenario, see [the section called “Scenario: HCatalog table management on Hortonworks Data Platform”](#).

tHDFSConnection

tHDFSConnection properties

Component family	Big Data / Hadoop	
Function	tHDFSConnection provides connection to the Hadoop distributed file system (HDFS) of interest at runtime.	
Purpose	tHDFSConnection connects to a given HDFS so that the other Hadoop components can reuse the connection it creates to communicate with this HDFS.	
Basic settings	<i>Hadoop version</i>	<p>Select a Hadoop version from the list:</p> <p>Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper.</p> <p>Apache 1.0.0: You need to precise the access to the Apache Hadoop 1.0.0 to be used in this mode.</p> <p>Apache 0.20.204: You need to precise the access to the Apache 0.20.204 to be used.</p> <p>Cloudera 0.20 CDH3U1: You need to precise the access to the Cloudera 0.20 Hadoop (CDH3 Update1) to be used.</p> <p>Apache 0.20.2: You need to precise the access to the Apache 0.20.2 to be used.</p> <p>MapR: You need to precise the access to the MapR distribution for Apache Hadoop to be used.</p>
	<i>NameNode URI</i>	Type in the URI of the NameNode corresponding to the Apache or the Cloudera Hadoop to be used.
	<i>User name</i>	User authentication name of HDFS.
	<i>Group</i>	Enter the membership including the authentication user under which the HDFS instances were started. This field is available only when you select Apache 0.20.2 or MapR from the Hadoop version list.
	<i>Hadoop properties</i>	<p>If you need to use custom configuration for the Hadoop of interest, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those corresponding ones defined earlier for the same Hadoop.</p> <p>For further information about the properties required by Hadoop, see the Hadoop documentation.</p>
Advanced settings	<i>tStatCatcher Statistics</i>	Select this check box to collect log data at the component level.
Usage	This component is generally used with other Hadoop components.	

Limitations

To run **tHDFSConnection**, version 1.6+ of JRE is required.

Related scenario

No scenario is available for this component yet.

tHDFSDelete

tHDFSDelete properties

Component family	Big Data / Hadoop	
Function	tHDFSDelete deletes a file located on a given Hadoop distributed file system (HDFS).	
Purpose	tHDFSDelete deletes a file on a given HDFS.	
Basic settings	<i>Schema and Edit Schema</i>	<p>A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i>, the schema is always Built-in.</p> <p>Click Edit Schema to make changes to the schema.</p>
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Use an existing connection</i>	<p>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</p> <p> When a Job contains the parent Job and the child Job, Component list presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, you can use Dynamic settings to share the intended connection. In this case, make sure that the connection name is unique and distinctive all over through the two Job levels. For more information about Dynamic settings, see <i>Talend Open Studio for Big Data User Guide</i>.</p>
	<i>Hadoop version</i>	<p>Select a Hadoop version from the list:</p> <p>Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper.</p> <p>Apache 1.0.0: You need to precise the access to the Apache Hadoop 1.0.0 to be used in this mode.</p> <p>Apache 0.20.204: You need to precise the access to the Apache 0.20.204 to be used.</p> <p>Cloudera 0.20 CDH3U1: You need to precise the access to the Cloudera 0.20 Hadoop (CDH3 Update1) to be used.</p>

		<p>Apache 0.20.2: You need to precise the access to the Apache 0.20.2 to be used.</p> <p>MapR: You need to precise the access to the MapR distribution for Apache Hadoop to be used.</p>
	<i>NameNode URI</i>	Type in the URI of the NameNode corresponding to the Apache or the Cloudera Hadoop to be used.
	<i>User name</i>	User authentication name of HDFS.
	<i>Group</i>	Enter the membership including the authentication user under which the HDFS instances were started. This field is available only when you select Apache 0.20.2 or MapR from the Hadoop version list.
	<i>File or Directory Path</i>	Fill this field with the path to the file or folder to be deleted on HDFS.
Advanced settings	<i>Hadoop properties</i>	<p>If you need to use custom configuration for the Hadoop of interest, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those corresponding ones defined earlier for the same Hadoop.</p> <p>For further information about the properties required by Hadoop, see the Hadoop documentation.</p>
	<i>tStatCatcher Statistics</i>	Select this check box to collect log data at the component level.
Usage		
Limitations	To run tHDFSDelete , version 1.6+ of JRE is required.	

Related scenario

No scenario is available for this component yet.

tHDFSGet

tHDFSGet properties

Component family	Big Data / Hadoop	
Function	tHDFSGet gets data from Hadoop distributed file system(HDFS).	
Purpose	tHDFSGet connects to Hadoop distributed file system, helping to obtain large-scale files with optimized performance.	
Basic settings	<i>Use an existing connection</i>	<p>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</p> <p> When a Job contains the parent Job and the child Job, Component list presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, you can use Dynamic settings to share the intended connection. In this case, make sure that the connection name is unique and distinctive all over through the two Job levels. For more information about Dynamic settings, see <i>Talend Open Studio for Big Data User Guide</i>.</p>
	<i>Hadoop version</i>	<p>Select a Hadoop version from the list:</p> <p>Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper.</p> <p>Apache 1.0.0: You need to precise the access to the Apache Hadoop 1.0.0 to be used in this mode.</p> <p>Apache 0.20.204: You need to precise the access to the Apache 0.20.204 to be used.</p> <p>Cloudera 0.20 CDH3U1: You need to precise the access to the Cloudera 0.20 Hadoop (CDH3 Update1) to be used.</p> <p>Apache 0.20.2: You need to precise the access to the Apache 0.20.2 to be used.</p> <p>MapR: You need to precise the access to the MapR distribution for Apache Hadoop to be used.</p>
	<i>Host</i>	IP address of the Hadoop distributed file system server.
	<i>Port</i>	Listening port number of HDFS server.
	<i>User name</i>	User authentication name of HDFS

	<i>Group</i>	Enter the membership including the authentication user under which the HDFS instances were started. This field is available only when you select Apache 0.20.2 or MapR from the Hadoop version list.
	<i>HDFS directory</i>	Location of the source files in HDFS.
	<i>Local directory</i>	Local directory to store the files obtained from HDFS.
	<i>Overwrite file</i>	Options to overwrite or not the existing file with the new one.
	<i>Append</i>	Select this check box to add the new rows at the end of the records
	<i>Files</i>	In the Files area, the fields to be completed are: - File mask : type in the file name to be selected from HDFS. Regular expression is available. - New name : give a new name to the obtained file.
	<i>Die on error</i>	This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows.
	<i>tStatCatcher Statistics</i>	Select this check box to collect log data at the component level.
Usage	This component combines HDFS connection and data extraction, thus used as a single-component subjob or to prepare data to feed the input flow of a Job. It is often connected to the Job using OnSubJobOk or OnComponentOk link, depending on the context.	
Limitations	To run tHDFSGet and tHDFSput , version 1.6+ of JRE is required.	

Scenario: Computing data with Hadoop distributed file system

The following scenario describes a simple Job that creates a file in a defined directory, get it into and out of HDFS, subsequently store it to another local directory, and read it at the end of the Job.

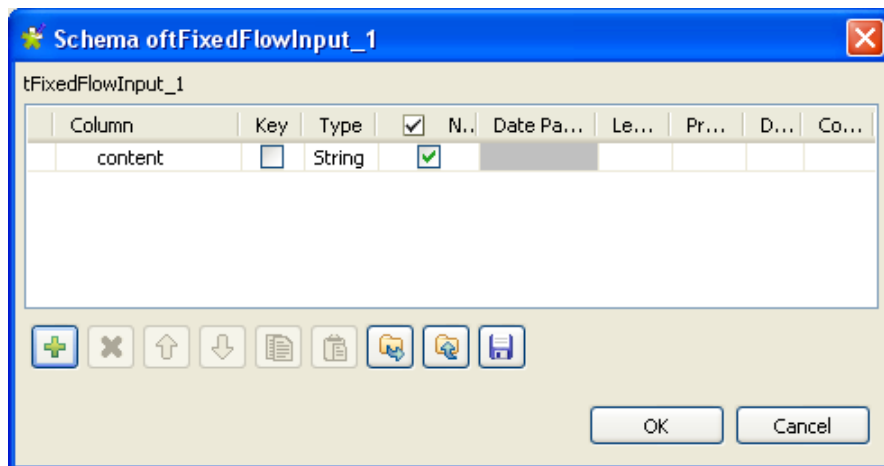

Setting up the Job

1. Drop the following components from the **Palette** onto the design workspace: **tFixedFlowInput**, **tFileOutputDelimited**, **tHDFSput**, **tHDFSGet**, **tFileInputDelimited** and **tLogRow**.
2. Connect **tFixedFlowInput** to **tFileOutputDelimited** using a **Row > Main** connection.
3. Connect **tFileInputDelimited** to **tLogRow** using a **Row > Main** connection.
4. Connect **tFixedFlowInput** to **tHDFSput** using an **OnSubjobOk** connection.
5. Connect **tHDFSput** to **tHDFSGet** using an **OnSubjobOk** connection.
6. Connect **tHDFSGet** to **tFileInputDelimited** using an **OnSubjobOk** connection.

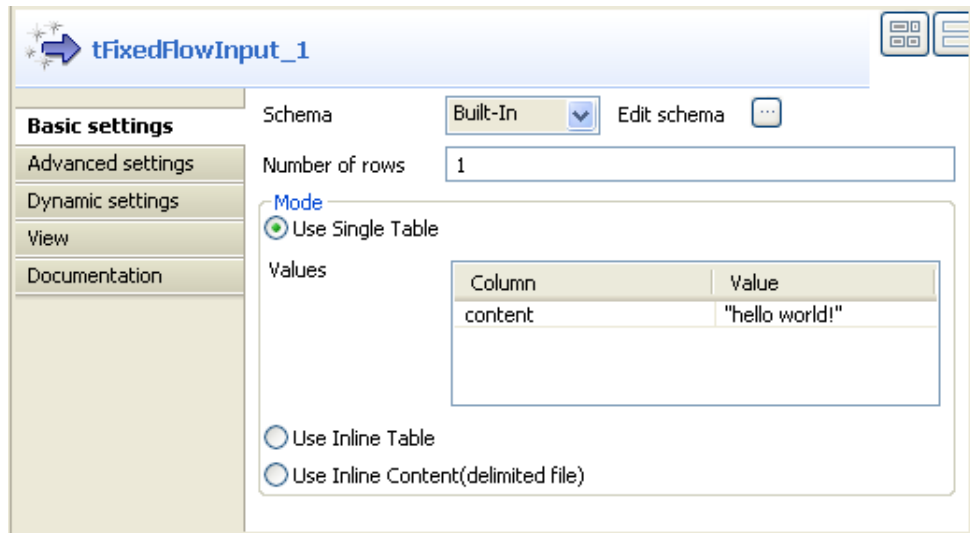

Configuring the input component

1. Double-click **tFixedFlowInput** to define the component in its **Basic settings** view.
2. Set the **Schema** to **Built-In** and click the three-dot [...] button next to **Edit Schema** to describe the data structure you want to create from internal variables. In this scenario, the schema contains one column: *content*.

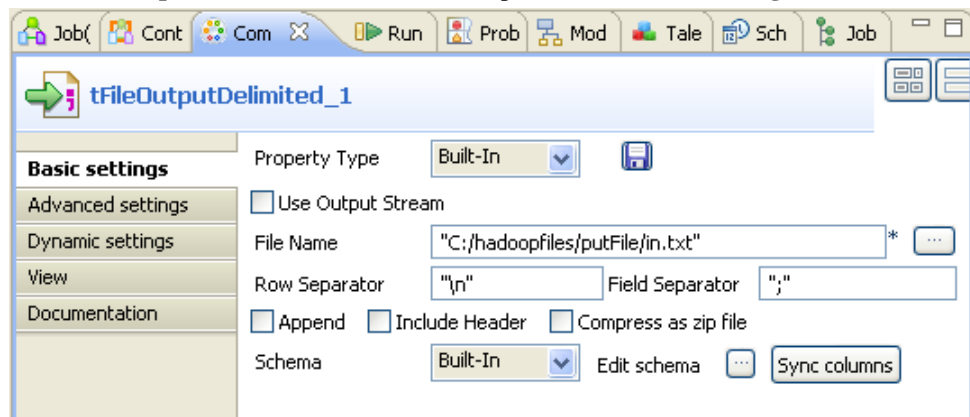

3. Click the plus button to add the parameter line.
4. Click **OK** to close the dialog box and accept to propagate the changes when prompted by the studio.
5. In **Basic settings**, define the corresponding value in the **Mode** area using the **Use Single Table** option. In this scenario, the value is *"Hello world!"*.

Configuring the tFileOutputDelimited component

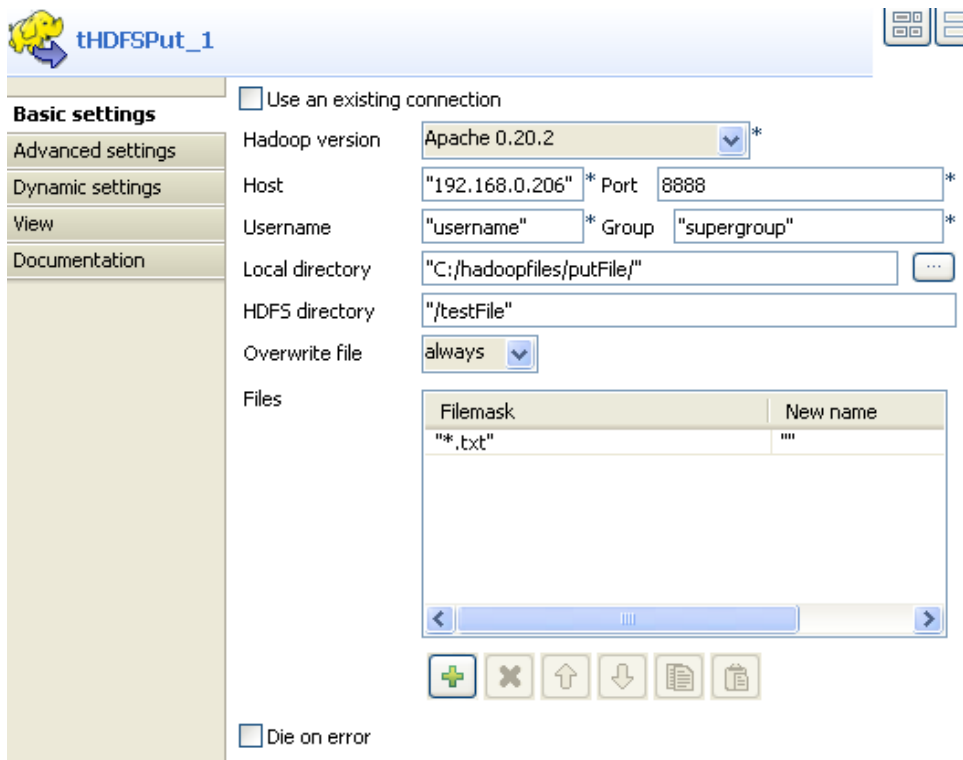

1. Double-click **tFileOutputDelimited** to define the component in its **Basic settings** view.

2. Click the [...] button next to the **File Name** field and browse to the output file you want to write data in, *in.txt* in this example.

Loading the data from the local file

1. Double-click **tHDFSPut** to define the component in its **Basic settings** view.

2. Select Apache 0.20.2 from the **Hadoop version** list.
3. In the **Host**, the **Port**, the **Username**, the **Group** fields, enter the connection parameters to the HDFS.
4. Next to the **Local directory** field, click the three-dot [...] button to browse to the folder with the file to be loaded into the HDFS. In this scenario, the directory has been specified while configuring **tFileOutputDelimited**: *C:/hadoopfiles/putFile/*.
5. In the **HDFS directory** field, type in the intended location in HDFS to store the file to be loaded. In this example, it is */testFile*.
6. Click the **Overwrite file** field to stretch the drop-down.
7. From the menu, select **always**.
8. In the **Files** area, click the plus button to add a row in which you define the file to be loaded.
9. In the **File mask** column, enter **.*.txt* to replace *newLine* between quotation marks and leave the **New name** column as it is. This allows you to extract all the *.txt* files in the specified directory without changing their names. In this example, the file is *in.txt*.

Getting the data from the HDFS

1. Double-click **tHDFSGet** to define the component in its **Basic settings** view.

The screenshot shows the configuration window for the **tHDFSGet_1** component. The **Basic settings** tab is selected. The configuration includes:

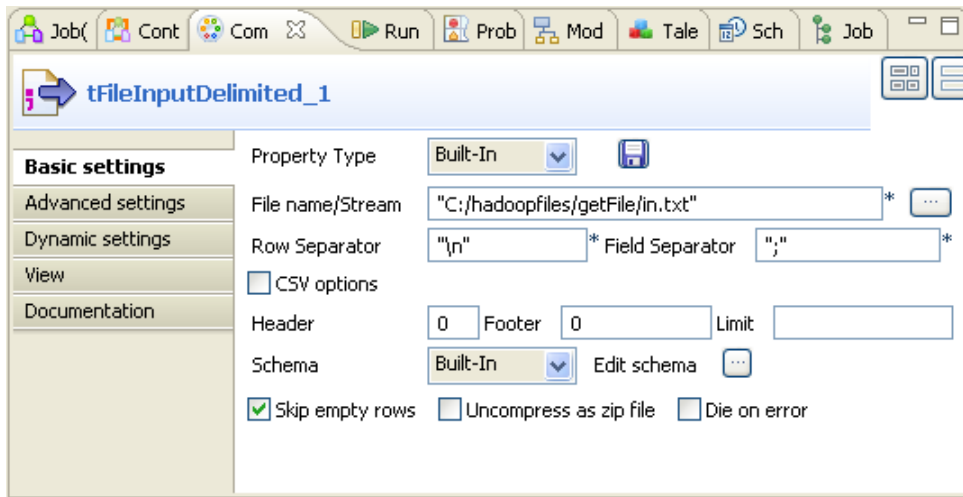

- Use an existing connection:**
- Hadoop version:** Apache 0.20.2
- Host:** "192.168.0.206"
- Port:** 8888
- Username:** "username"
- Group:** "supergroup"
- HDFS directory:** "/testFile"
- Local directory:** "C:/hadoopfiles/putFile/"
- Overwrite file:** always
- Append:**
- Files:**

Filemask	New name
..txt	''
- Die on error:**

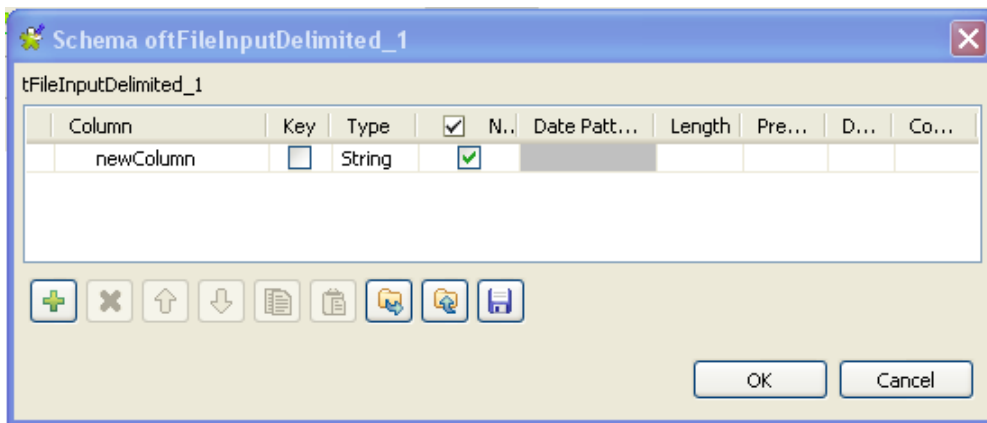

2. Select Apache 0.20.2 from the **Hadoop version** list.
3. In the **Host**, the **Port**, the **Username**, the **Group** fields, enter the connection parameters to the HDFS.
4. In the **HDFS directory** field, type in location storing the loaded file in HDFS. In this example, it is */testFile*.
5. Next to the **Local directory** field, click the three-dot [...] button to browse to the folder intended to store the files that are extracted out of the HDFS. In this scenario, the directory is: *C:/hadoopfiles/getFile/*.
6. Click the **Overwrite file** field to stretch the drop-down.
7. From the menu, select **always**.
8. In the **Files** area, click the plus button to add a row in which you define the file to be extracted.
9. In the **File mask** column, enter **.*.txt* to replace *newLine* between quotation marks and leave the **New name** column as it is. This allows you to extract all the *.txt* files from the specified directory in the HDFS without changing their names. In this example, the file is *in.txt*.

Reading data from the HDFS and saving the data locally

1. Double-click **tFileInputDelimited** to define the component in its **Basic settings** view.

2. Set property type to **Built-In**.
3. Next to the **File Name/Stream** field, click the three-dot button to browse to the file you have obtained from the HDFS. In this scenario, the directory is *C:/hadoopfiles/getFile/in.txt*.
4. Set **Schema** to **Built-In** and click **Edit schema** to define the data to pass on to the **tLogRow** component.

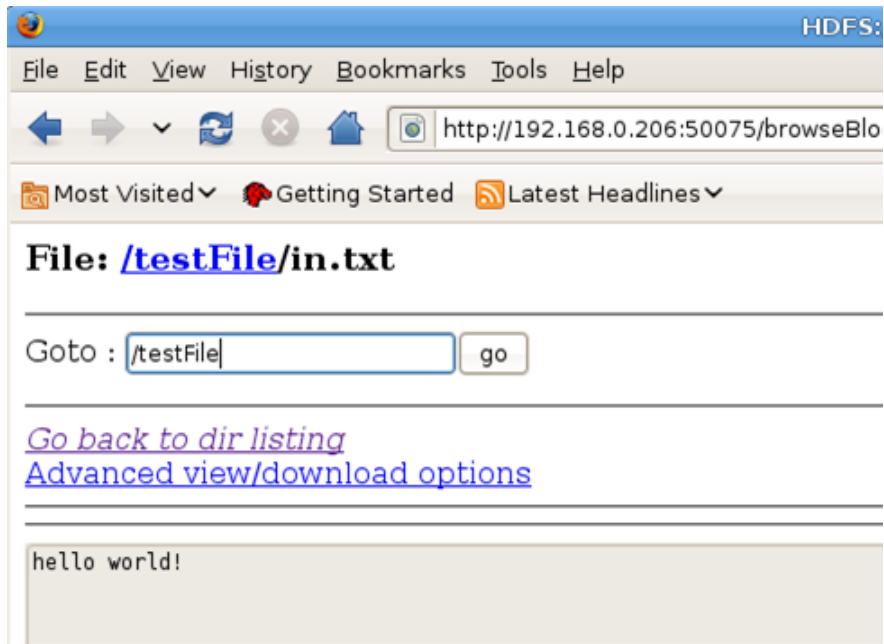

5. Click the plus button to add a new column.
6. Click **OK** to close the dialog box and accept to propagate the changes when prompted by the studio.

Executing the Job

Save the Job and press **F6** to execute it.

The *in.txt* file is created and loaded into the HDFS.

The file is also extracted from the HDFS by **tHDFSGet** and is read by **tFileInputDelimited**.

```
Starting job feature11717_hadoop_get_put at 18:09 04/05/2010.  
[statistics] connecting to socket on port 3637  
[statistics] connected  
hello world!  
[statistics] disconnected  
Job feature11717_hadoop_get_put ended at 18:09 04/05/2010.  
Exit code=0
```

tHDFSInput

tHDFSInput properties

Component family	Big Data / Hadoop	
Function	tHDFSInput reads a file located on a given Hadoop distributed file system (HDFS) and puts the data of interest from this file into a Talend schema. Then it passes the data to the component that follows.	
Purpose	tHDFSInput extracts the data in a HDFS file for other components to process it.	
Basic settings	<i>Schema and Edit Schema</i>	<p>A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i>, the schema is always Built-in.</p> <p>Click Edit Schema to make changes to the schema.</p>
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Use an existing connection</i>	<p>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</p> <p> When a Job contains the parent Job and the child Job, Component list presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, you can use Dynamic settings to share the intended connection. In this case, make sure that the connection name is unique and distinctive all over through the two Job levels. For more information about Dynamic settings, see your studio user guide.</p>
	<i>Hadoop version</i>	<p>Select a Hadoop version from the list:</p> <p>Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper.</p> <p>Apache 1.0.0: You need to precise the access to the Apache Hadoop 1.0.0 to be used in this mode.</p> <p>Apache 0.20.204: You need to precise the access to the Apache 0.20.204 to be used.</p> <p>Cloudera 0.20 CDH3U1: You need to precise the access to the Cloudera 0.20 Hadoop (CDH3 Update1) to be used.</p>

		<p>Apache 0.20.2: You need to precise the access to the Apache 0.20.2 to be used.</p> <p>MapR: You need to precise the access to the MapR distribution for Apache Hadoop to be used.</p>
	<i>NameNode URI</i>	Type in the URI of the NameNode corresponding to the Apache or the Cloudera Hadoop to be used.
	<i>User name</i>	User authentication name of HDFS.
	<i>Group</i>	Enter the membership including the authentication user under which the HDFS instances were started. This field is available only when you select Apache 0.20.2 or MapR from the Hadoop version list.
	<i>File Name</i>	Browse to, or enter the path to the source files in HDFS.
Advanced settings	<i>Hadoop properties</i>	<p>If you need to use custom configuration for the Hadoop of interest, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those corresponding ones defined earlier for the same Hadoop.</p> <p>For further information about the properties required by Hadoop, see the Hadoop documentation.</p>
	<i>tStatCatcher Statistics</i>	Select this check box to collect log data at the component level.
Usage	This component needs an output link.	
Limitations	To run tHDFSInput , version 1.6+ of JRE is required.	

Related scenario

For a related scenario, see [the section called “Scenario 1: Writing data in a delimited file”](#).

tHDFSOutput

tHDFSOutput properties

Component family	Big Data / Hadoop	
Function	tHDFSOutput writes data flows it receives onto a given Hadoop distributed file system (HDFS).	
Purpose	tHDFSOutput writes data of interest into a file and creates this file on a given HDFS.	
Basic settings	<i>Schema and Edit Schema</i>	<p>A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i>, the schema is always Built-in.</p> <p>Click Edit Schema to make changes to the schema.</p>
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Use an existing connection</i>	<p>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</p> <p> When a Job contains the parent Job and the child Job, Component list presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, you can use Dynamic settings to share the intended connection. In this case, make sure that the connection name is unique and distinctive all over through the two Job levels. For more information about Dynamic settings, see your studio user guide.</p>
	<i>Hadoop version</i>	<p>Select a Hadoop version from the list:</p> <p>Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper.</p> <p>Apache 1.0.0: You need to precise the access to the Apache Hadoop 1.0.0 to be used in this mode.</p> <p>Apache 0.20.204: You need to precise the access to the Apache 0.20.204 to be used.</p> <p>Cloudera 0.20 CDH3U1: You need to precise the access to the Cloudera 0.20 Hadoop (CDH3 Update1) to be used.</p>

		<p>Apache 0.20.2: You need to precise the access to the Apache 0.20.2 to be used.</p> <p>MapR: You need to precise the access to the MapR distribution for Apache Hadoop to be used.</p>
	<i>NameNode URI</i>	Type in the URI of the NameNode corresponding to the Apache or the Cloudera Hadoop to be used.
	<i>User name</i>	User authentication name of HDFS.
	<i>Group</i>	Enter the membership including the authentication user under which the HDFS instances were started. This field is available only when you select Apache 0.20.2 or MapR from the Hadoop version list.
	<i>File Name</i>	Browse to, or enter the location of the file which you write data to. This file is created automatically if it does not exist.
	<i>Action</i>	<p>Select an operation in HDFS:</p> <p>Create: Creates a file with data using the file name defined in the File Name field.</p> <p>Overwrite: Overwrites the data in the file specified in the File Name field.</p> <p>Append: Inserts the data into the file specified in the File Name field. The specified file is created automatically if it does not exist.</p>
Advanced settings	<i>Hadoop properties</i>	<p>If you need to use custom configuration for the Hadoop of interest, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those corresponding ones defined earlier for the same Hadoop.</p> <p>For further information about the properties required by Hadoop, see the Hadoop documentation.</p>
	<i>tStatCatcher Statistics</i>	Select this check box to collect log data at the component level.
Usage	This component needs an input component from which the input data can be retrieved.	
Limitations	To run tHDFSOutput , version 1.6+ of JRE is required.	

Related scenario

For a related scenario, see [the section called “Scenario 1: Writing data in a delimited file”](#).

tHDFSPut

tHDFSPut properties

Component family	Big Data / Hadoop	
Function	tHDFSPut loads data into Hadoop distributed file system(HDFS).	
Purpose	tHDFSPut connects to Hadoop distributed file system to load large-scale files into it with optimized performance.	
Basic settings	<i>Hadoop version</i>	<p>Select a Hadoop version from the list:</p> <p>Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper.</p> <p>Apache 1.0.0: You need to precise the access to the Apache Hadoop 1.0.0 to be used in this mode.</p> <p>Apache 0.20.204: You need to precise the access to the Apache 0.20.204 to be used.</p> <p>Cloudera 0.20 CDH3U1: You need to precise the access to the Cloudera 0.20 Hadoop (CDH3 Update1) to be used.</p> <p>Apache 0.20.2: You need to precise the access to the Apache 0.20.2 to be used.</p> <p>MapR: You need to precise the access to the MapR distribution for Apache Hadoop to be used.</p>
	<i>Host</i>	IP address of the Hadoop distributed file system server.
	<i>Port</i>	Listening port number of HDFS server.
	<i>User name</i>	User authentication name of HDFS.
	<i>Group</i>	Enter the membership including the authentication user under which the HDFS instances were started. This field is available only when you select Apache 0.20.2 or MapR from the Hadoop version list.
	<i>HDFS directory</i>	Location to store the files in HDFS.
	<i>Local directory</i>	Local directory where are stored the files to be loaded into HDFS.
	<i>Overwrite file</i>	Options to overwrite or not the existing file with the new one.
	<i>Files</i>	<p>In the Files area, the fields to be completed are:</p> <ul style="list-style-type: none"> - File mask: type in the file name to be selected from the local directory. Regular expression is available. - New name: give a new name to the loaded file.

	<i>Die on error</i>	This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows.
	<i>tStatCatcher Statistics</i>	Select this check box to collect log data at the component level.
Usage	This component combines HDFS connection and data extraction, thus usually used as a single-component subjob but also possible as output or end object.	
Limitations	To run tHDFSGet and tHDFSPut , version 1.6+ of JRE is required.	

Related scenario

For related scenario, see [the section called “Scenario: Computing data with Hadoop distributed file system”](#).

tHiveClose

tHiveClose properties

Component Family	Big Data / Hive	
Function	tHiveClose closes an active connection to a database.	
Purpose	This component closes connection to a Hive databases.	
Basic settings	<i>Component list</i>	If there is more than one connection used in the Job, select tHiveConnection from the list.
Advanced settings	<i>tStatCatcher Statistics</i>	Select this check box to collect the log data at a component level.
Usage	This component is generally used as an input component. It requires an output component.	
Limitation	n/a	

Related scenario

This component is for use with **tHiveConnection**. It is generally used along with **tHiveConnection** as the latter allows you to open a connection for the transaction which is underway.

For a scenario in which **tHiveClose** might be used, see [the section called “tMysqlConnection”](#).

tHiveConnection

tHiveConnection properties

Database Family	Big Data / Hive	
Function	tHiveConnection opens a connection to a database in order that a transaction may be made.	
Purpose	This component allows you to commit all of the Job data to an output database in just a single transaction, once the data has been validated.	
Basic settings	<i>Property type</i>	In <i>Talend Open Studio for Big Data</i> , the Property type is always Built-in .
		Built-in: No property data stored centrally.
	<i>Hive version</i>	Select a Hive version from the list: Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper. Apache 0.20.203: You need to precise the access to the Apache 0.20.203 to be used. Apache 1.0.0: You need to precise the access to the Apache Hadoop 1.0.0 to be used in this mode.
	<i>Connection mode</i>	Select a connection mode from the list: Standalone: This connection mode is available when the Hive version is Apache 0.20.203 or Apache 1.0.0. Embedded: This connection mode is available when the Hive version is Apache 1.0.0 or Hortonworks Data Platform 1.0.
	<i>Host</i>	Database server IP address.
	<i>Port</i>	DB server listening port.
	<i>Database</i>	Fill this field with the name of the database.  This field is not available when you select Embedded from the Connection mode list.
	<i>Username</i> and <i>Password</i>	DB user authentication data.
	<i>Encoding</i>	Select the encoding type from the list or select Custom and define it manually. This field is compulsory for DB data handling.
	<i>Use or register a shared DB Connection</i>	Select this check box to share your connection or fetch a connection shared by a parent or child Job. This allows you to share one single DB connection among several DB connection components from different Job levels that can be either parent or child.

		Shared DB Connection Name: set or type in the shared connection name.
Advanced settings	<i>tStatCatcher Statistics</i>	Select this check box to collect the log data at a component level.
Usage	This component is generally used with other Informix components, particularly tHiveClose .	
Limitation	n/a	

Related scenario

For a scenario in which **tHiveConnection**, might be used, see [the section called “Scenario: Inserting data in mother/daughter tables”](#).

tHiveInput

tHiveInput properties

Component family	Big Data / Hive	
Function	tHiveInput is the dedicated component to the Hive database (the Hive data warehouse system). It executes the given HiveQL query in order to extract the data of interest from Hive. It provides the SQLBuilder tool to help you write your HiveQL statements easily.	
Purpose	tHiveInput executes the select queries to extract the corresponding data and sends the data to the component that follows.	
Basic settings	<i>Property type</i>	In <i>Talend Open Studio for Big Data</i> , the Property type is always Built-in .
		Built-in: No property data stored centrally.
Basic settings	<i>Use an existing connection</i>	<p>Select this check box and click the relevant tHiveConnection component from the Component List to reuse the connection details you already defined.</p> <p> When a Job contains the parent Job and the child Job, Component list presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, make sure that the available connection components are sharing the intended connection.</p> <p>For more information on how to share a DB connection across Job levels, see Use or register a shared DB connection in any database connection component corresponding to the database you are using.</p> <p>Otherwise, you can as well deactivate the connection components and use Dynamic settings of the component to specify the intended connection manually. In this case, make sure the connection name is unique and distinctive all over through the two Job levels. For more information about Dynamic settings, see <i>Talend Open Studio for Big Data User Guide</i>.</p>
	<i>Hive version</i>	<p>Select a Hive version from the list:</p> <p>Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper.</p> <p>Apache 0.20.203: You need to precise the access to the Apache 0.20.203 to be used.</p>

		Apache 1.0.0: You need to precise the access to the Apache Hadoop 1.0.0 to be used in this mode.
	<i>Connection mode</i>	Select a connection mode from the list: Standalone: This connection mode is available when the Hive version is Apache 0.20.203 or Apache 1.0.0. Embedded: This connection mode is available when the Hive version is Apache 1.0.0 or Hortonworks Data Platform 1.0.
	<i>Host</i>	Database server IP address.
	<i>Port</i>	Listening port number of DB server.
	<i>Database</i>	Fill this field with the name of the database.  This field is not available when you select Embedded from the Connection mode list.
	<i>Username</i> and <i>Password</i>	DB user authentication data.
	<i>Schema</i> and <i>Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in: The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Table Name</i>	Name of the table to be processed.
	<i>Query type</i>	In <i>Talend Open Studio for Big Data</i> , the Query type is always Built-in .
		Built-in: Fill in manually the query statement or build it graphically using SQLBuilder
	<i>Guess Query</i>	Click the Guess Query button to generate the query which corresponds to your table schema in the Query field.
	<i>Guess schema</i>	Click this button to retrieve the schema from the table.
	<i>Query</i>	Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.
Advanced settings	<i>Trim all the String/Char columns</i>	Select this check box to remove leading and trailing whitespace from all the String/Char columns.
	<i>Trim column</i>	Remove leading and trailing whitespace from defined columns.  Clear the Trim all the String/Char columns check box to enable Trim column in this field.
	<i>tStat Catcher Statistics</i>	Select this check box to collect log data at the component level.
Usage	This component offers the benefit of flexible DB queries and covers all possible Hive QL queries.	

Related scenarios

For related topic, see [the section called “Scenario 1: Writing columns from a MySQL database to an output file”](#).

tHiveRow

tHiveRow properties

Component family	Big Data / Hive	
Function	tHiveRow is the dedicated component for this database. It executes the HiveQL query stated in the specified database. The row suffix means the component implements a flow in the Job design although it does not provide output.	
Purpose	Depending on the nature of the query and the database, tHiveRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write your HiveQL statements easily.	
Basic settings	<i>Property type</i>	In <i>Talend Open Studio for Big Data</i> , the Property type is always Built-in .
		Built-in: No property data stored centrally.
	<i>Use an existing connection</i>	<p>Select this check box and click the relevant tHiveConnection component from the Component List to reuse the connection details you already defined.</p> <p> When a Job contains the parent Job and the child Job, Component list presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, make sure that the available connection components are sharing the intended connection.</p> <p>For more information on how to share a DB connection across Job levels, see Use or register a shared DB connection in any database connection component corresponding to the database you are using.</p> <p>Otherwise, you can as well deactivate the connection components and use Dynamic settings of the component to specify the intended connection manually. In this case, make sure the connection name is unique and distinctive all over through the two Job levels. For more information about Dynamic settings, see your studio user guide.</p>
	<i>Hive version</i>	<p>Select a Hive version from the list:</p> <p>Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 which supports Apache Hadoop projects including HDFS, MapR, Hive, HBase, Pig and Zookeeper.</p> <p>Apache 0.20.203: You need to precise the access to the Apache 0.20.203 to be used.</p>

		Apache 1.0.0: You need to precise the access to the Apache Hadoop 1.0.0 to be used in this mode.
	<i>Connection mode</i>	Select a connection mode from the list: Standalone: This connection mode is available when the Hive version is Apache 0.20.203 or Apache 1.0.0. Embedded: This connection mode is available when the Hive version is Apache 1.0.0 or Hortonworks Data Platform 1.0.
	<i>Host</i>	Database server IP address.
	<i>Port</i>	Listening port number of DB server.
	<i>Database</i>	Fill this field with the name of the database.  This field is not available when you select Embedded from the Connection mode list.
	<i>Username</i> and <i>Password</i>	DB user authentication data.
	<i>Schema</i> and <i>Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in: The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Table Name</i>	Name of the table to be processed.
		Built-in: Fill in manually the query statement or build it graphically using SQLBuilder
	<i>Guess Query</i>	Click the Guess Query button to generate the query which corresponds to your table schema in the Query field.
	<i>Query</i>	Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.
	<i>Die on error</i>	This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.
Advanced settings	<i>Propagate QUERY's recordset</i>	Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.
	<i>tStat Catcher Statistics</i>	Select this check box to collect log data at the component level.
Usage	This component offers the benefit of flexible DB queries and covers all possible Hive QL queries.	

Related scenarios

For related topics, see:

- [the section called “Scenario: Resetting a DB auto-increment”](#)

- [the section called “Scenario 1: Removing and regenerating a MySQL table index”](#).

tPigAggregate

tPigAggregate Properties

Component family	Big Data / Hadoop	
Function	This component allows you to group the original data by column and add one or more additional columns to the output of preceding grouped data.	
Purpose	The tPigAggregate component adds one or more additional columns to the output of the grouped data to create data to be used by Pig.	
Basic settings	<i>Schema and Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in: The schema will be created and stored locally for this component only. Related topic: <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Group by</i>	Click the plus button to add one or more columns to set tuples in the source data as group condition.
	<i>Operations</i>	Click the plus button to add one or more columns to generate one or more additional output columns based on conditions: Additional Output Column: Select a column in the original data as output column. Function: Functions for operation on input data. Input Column: Select a column in the original data as input column.
Advanced settings	<i>Increase parallelism</i>	Select this check box to set the number of reduce tasks for the MapReduce Jobs.
	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Usage	This component is commonly used as intermediate step together with input component and output component.	
Limitation	Knowledge of Pig scripts is required.	

Related scenario

For a **tPigAggregate** related scenario, [the section called “Scenario 1: Aggregating values and sorting data”](#) of **tAggregateRow**.

tPigCode

tPigCode Properties

Component family	Big Data / Hadoop	
Function	This component allows you to enter personalized Pig code to integrate it in Talend program. You can execute this code only once.	
Purpose	tPigCode extends the functionalities of a Talend Job through using Pig scripts.	
Basic settings	<i>Schema and Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Scripts</i>	Type in Pig scripts you want to execute according to the task you need to perform. For further information about Pig functions syntax specific to Talend , see: http://pig.apache.org/docs/r0.8.0/udf.html
Advanced settings	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Usage	This component is commonly used as intermediate step together with input component and output component.	
Limitation	Knowledge of Pig scripts is required.	

Scenario: Selecting a column of data from an input file and store it into a local file

This scenario describes a three-component Job that selects a column of data that matches filter condition defined in **tPigCode** and stores the result into a local file.

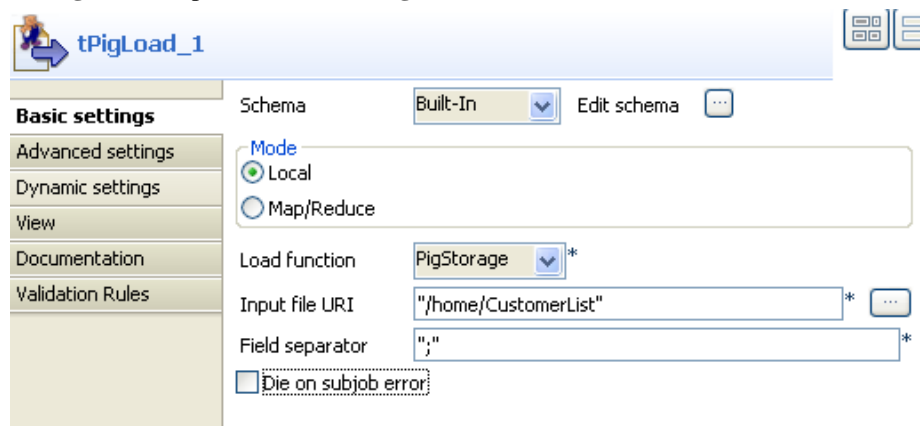

Setting up the Job

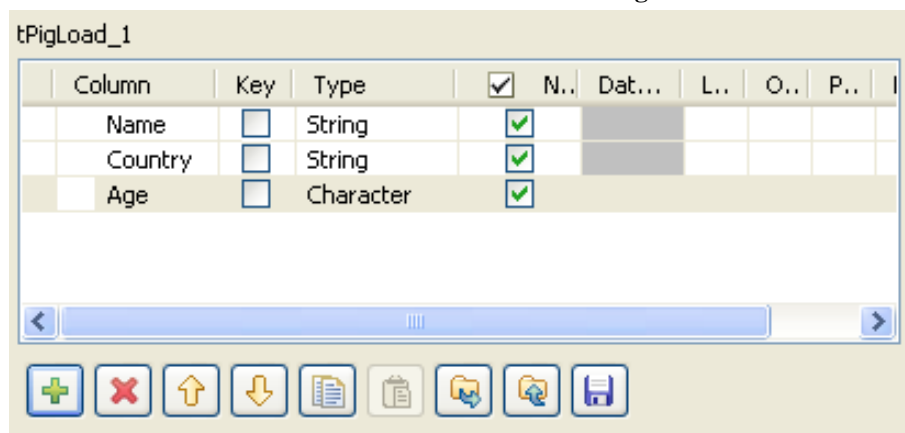

1. Drop the following components from the **Palette** to the design workspace: **tPigCode**, **tPigLoad**, **tPigStoreResult**.
2. Right-click **tPigLoad** to connect it to **tPigCode** using a **Row > Pig Combine** connection.
3. Right-click **tPigCode** to connect it to **tPigStoreResult** using a **Row > Pig Combine** connection.

Loading the data

1. Double-click **tPigLoad** to open its **Basic settings** view.

2. Click the three-dot button next to **Edit schema** to add columns for **tPigLoad**.

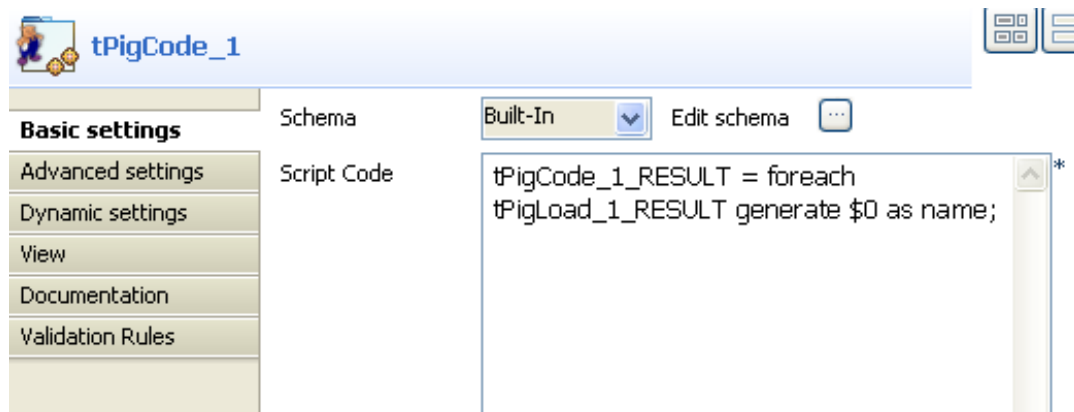

3. Click the plus button to add *Name*, *Country* and *Age* and click **OK** to save the setting.
4. Select **Local** from the **Mode** area.
5. Fill in the **Input filename** field with the full path to the input file.

In this scenario, the input file is *CustomerList* which contains rows of names, country names and age.

6. Select **PigStorage** from the **Load function** list.
7. Leave rest of the settings as they are.

Configuring the tPigCode component

1. Double-click **tPigCode** component to open its **Basic settings** view.

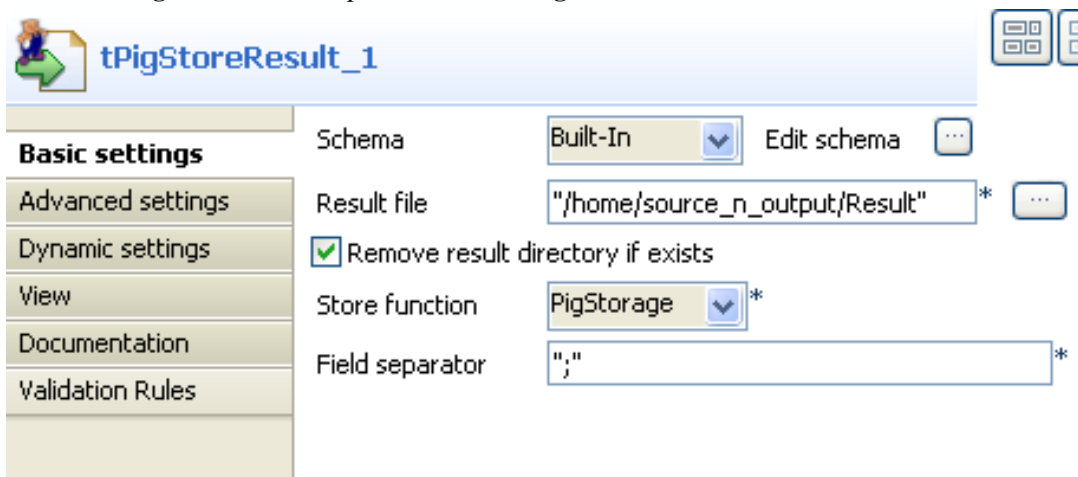

2. Click **Sync columns** to retrieve the schema structure from the preceding component.
3. Fill in the **Script Code** field with following expression:

```
tPigCode_1_RESULT = foreach tPigLoad_1_RESULT generate $0 as name;
```

This filter expression selects column *Name* from *CustomerList*.

Saving the result data to a local file

1. Double-click **tPigStoreResult** to open its **Basic settings** view.

2. Click **Sync columns** to retrieve the schema structure from the preceding component.
3. Fill in the **Result file** field with the full path to the result file.
In this scenario, the result is saved in *Result* file.
4. Select **Remove result directory if exists**.
5. Select **PigStorage** from the **Store function** list.
6. Leave rest of the settings as they are.

Executing the Job

Save your Job and press **F6** to run it.

A screenshot of a software window titled "Result" with a close button (x). The window displays a list of names in a monospaced font, one per line. The names are: Name, Mike, Silvia, Romeo, Ahmad, Toyota, Manik, Natasha, Billy, Eminem, Bill, Fenricka, Huamei, Selena, Julio, Pantalion, Simao, Nancy, Gaddafi, Zidane, Didi, Juan, Bob, Mario, and Ricky.

The *Result* file is generated containing the selected column of data.

tPigCross

tPigCross Properties

Component family	Big Data / Hadoop	
Function	This component allows you to compute the cross data of two or more relations.	
Purpose	The tPigCross component uses CROSS operator to compute the Cartesian product.	
Basic settings	<i>Schema and Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Cross filename</i>	Fill in the path of the file to be computed.
Advanced settings	<i>Use partitioner</i>	Select this check box to specify the Hadoop Partitioner that controls the partitioning of the keys of the intermediate map-outputs. For further information about the usage of Hadoop Partitioner, see: http://hadoop.apache.org/common/docs/r0.20.2/api/org/apache/hadoop/mapred/Partitioner.html
	<i>Increase parallelism</i>	Select this check box to set the number of reduce tasks for the MapReduce Jobs
	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Usage	This component is commonly used as intermediate step together with input component and output component.	
Limitation	Knowledge of Pig scripts is required.	

Related scenario

No scenario is available for this component yet.

tPigDistinct

tPigDistinct Properties

Component family	Big Data / Hadoop	
Function	This component allows you to remove duplicate tuples in a relation.	
Purpose	The tPigDistinct component removes duplicate tuples in a relation.	
Basic settings	<i>Schema and Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
Advanced settings	<i>Increase parallelism</i>	Select this check box to set the number of reduce tasks for the MapReduce Jobs
	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Usage	This component is commonly used as intermediate step together with input component and output component.  <i>This component will not maintain the original order in the input file.</i>	
Limitation	Knowledge of Pig scripts is required.	

Related scenario

For more information regarding the **tPigDistinct** component in use, see [the section called “Scenario: Filtering rows of data based on a condition and saving the result to a local file”](#) of **tPigFilterRow**.

tPigFilterColumns

tPigFilterColumns Properties

Component family	Big Data / Hadoop	
Function	This component allows you to select one or more columns from a relation based on defined condition.	
Purpose	This tPigFilterColumns component selects data or filters out data from a relation based on defined filter conditions.	
Basic settings	<i>Schema and Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
Advanced settings	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Usage	This component is commonly used as intermediate step together with input component and output component.	
Limitation	Knowledge of Pig script is required.	

Related Scenario

For a **tPigFilterColumns** related scenario, see [the section called “Scenario: Joining two files based on an exact match and saving the result to a local file” of tPigJoin](#).

tPigFilterRow

tPigFilterRow Properties

Component family	Big Data / Hadoop	
Function	The tPigFilterRow component filters the input flow in a Pig chain based on conditions set on given column(s).	
Purpose	This component is used to filter the input flow in a Pig chain based on conditions set on one or more columns.	
Basic settings	<i>Schema and Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Filter configuration</i>	Click the Add button beneath the Filter configuration table to set one or more filter conditions.  This table disappears if you select Use advanced filter .
	<i>Use advanced filter</i>	Select this check box to define advanced filter condition by entering customized filter expression in the Filter field.
Advanced settings	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Usage	This component is commonly used as an intermediate step in a Pig chain.	
Limitation	Knowledge of Pig scripts is required.	

Scenario: Filtering rows of data based on a condition and saving the result to a local file

This scenario describes a four-component Job that filters a list of customers to find out customers from a particular country, and saves the result list to a local file. Before the input data is filtered, duplicate entries are first removed from the list.

The input file contains three columns: *Name*, *Country*, and *Age*, and it has some duplicate entries, as shown below:

```
Mario;PuertoRico;49
Mike;USA;22
```

```
Ricky;PuertoRico;37
Silvia;Spain;20
Billy;Canada;21
Ricky;PuertoRico;37
Romeo;UK;19
Natasha;Russia;25
Juan;Cuba;23
Bob;Jamaica;55
Mario;PuertoRico;49
```

Dropping and linking components

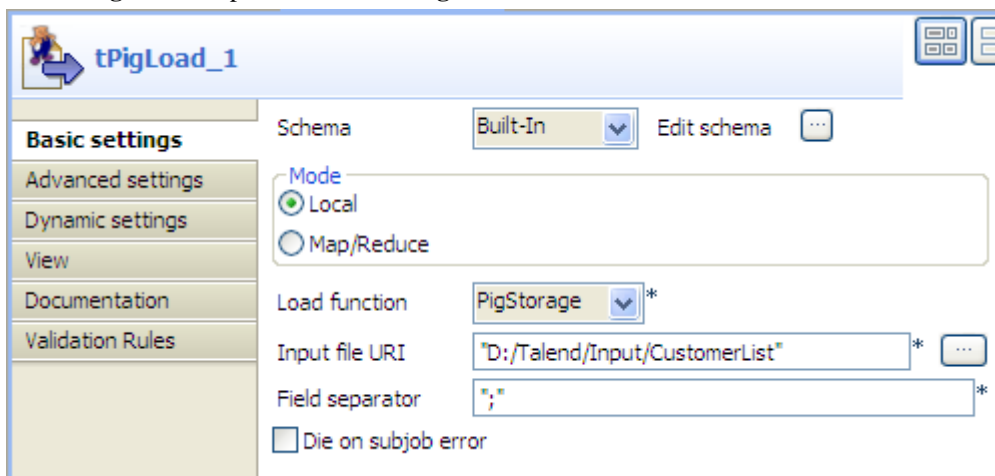

1. Drop the following components from the **Palette** to the design workspace: **tPigLoad**, **tPigDistinct**, **tPigFilterRow**, and **tPigStoreResult**.
2. Right-click **tPigLoad**, select **Row > Pig Combine** from the contextual menu, and click **tPigDistinct** to link these two components.
3. Repeat this operation to link **tPigDistinct** to **tPigFilterRow**, and **tPigFilterRow** to **tPigStoreResult** using **Row > Pig Combine** connections to form a Pig chain.

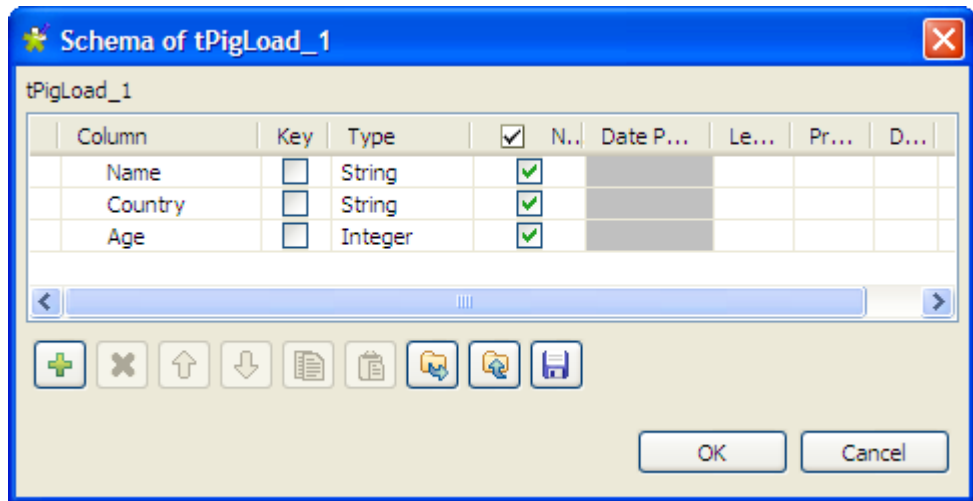

Configuring the components

Loading the input data and removing duplicates

1. Double-click **tPigLoad** to open its **Basic settings** view.

2. Click the [...] button next to **Edit schema** to open the [Schema] dialog box.

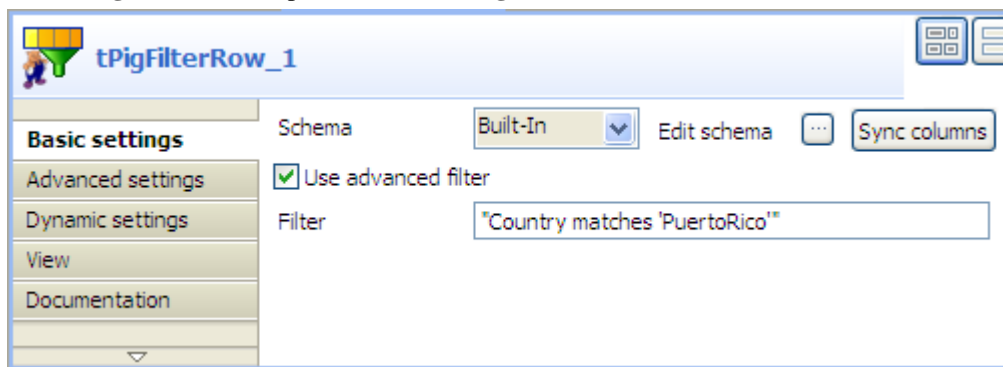

3. Click the [+] button to add three columns according to the data structure of the input file: *Name* (string), *Country* (string) and *Age* (integer), and then click **OK** to save the setting and close the dialog box.
4. Click **Local** in the **Mode** area.
5. Fill in the **Input file URI** field with the full path to the input file.
6. Select **PigStorage** from the **Load function** list, and leave rest of the settings as they are.
7. Double-click **tPigDistinct** to open its **Basic settings** view, and click **Sync columns** to make sure that the input schema structure is correctly propagated from the preceding component.

This component will remove any duplicates from the data flow.

Configuring the filter

1. Double-click **tPigFilterRow** to open its **Basic settings** view.

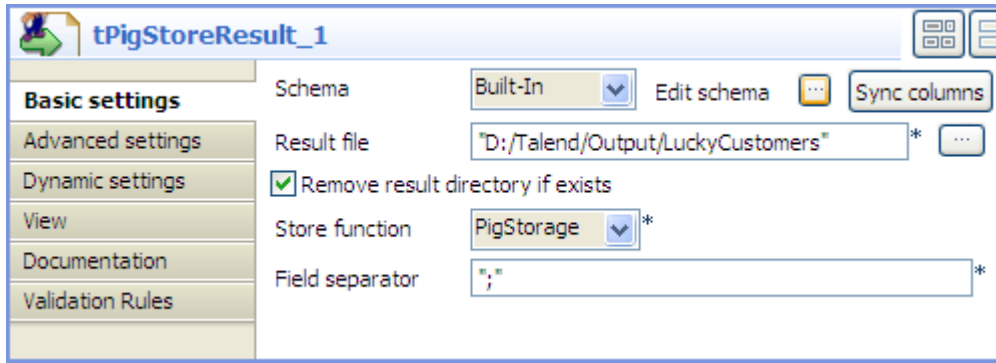

2. Click **Sync columns** to make sure that the input schema structure is correctly propagated from the preceding component.
3. Select **Use advanced filter** and fill in the **Filter** field with filter expression:

```
"Country matches 'PuertoRico'"
```

This filter expression selects rows of data that contains "PuertoRico" in the *Country* column.

Configuring the file output

1. Double-click **tPigStoreResult** to open its **Basic settings** view.

2. Click **Sync columns** to make sure that the input schema structure is correctly propagated from the preceding component.
3. Fill in the **Result file** field with the full path to the result file.
4. If the target file already exists, select the **Remove result directory if exists** check box.
5. Select **PigStorage** from the **Store function** list, and leave rest of the settings as they are.

Saving and executing the Job

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click the **Run** button on the **Run** tab to run the Job.

The result file contains the information of customers from the specified country.

tPigJoin

tPigJoin Properties

Component family	Big Data / Hadoop	
Function	This component allows you to perform join of two files based on join keys.	
Purpose	The tPigJoin component is used to perform inner joins and outer joins of two files based on join keys to create data that will be used by Pig.	
Basic settings	<i>Schema and Edit schema</i>	<p>A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i>, the schema is always Built-in.</p> <p> To make this component work, two schemas must be set: the schema of the main flow and the schema of the lookup flow. In the output part of the main schema, the columns of the main input file must be manually concatenated with those of the lookup file.</p>
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Filename</i>	Fill in the path of the Lookup file .
	<i>Join key</i>	Click the plus button to add lines to set the Join key for Input file and Lookup file .
	<i>Join mode</i>	<p>Select a join mode from the list:</p> <p>inner-join: Select this mode to perform an inner join of two or more relations based on Join keys.</p> <p>left-outer-join: Select this mode to performs a left outer join of two or more relations based on Join keys.</p> <p>right-outer-join: Select this mode to performs a right outer join of two or more relations based on Join keys.</p> <p>full-outer-join: Select this mode to combine the effect of applying both left and right outer joins.</p> <p>For further information about inner join and outer join, see: http://en.wikipedia.org/wiki/Join_%28SQL%29</p>
Advanced settings	<i>Optimize the join</i>	<p>Select this check box to optimize the performance of joins using REPLICATED, SKEWED, or MERGE joins. For further information about optimized joins, see: http://pig.apache.org/docs/r0.8.0/piglatin_ref1.html#Specialized+Joins</p>
	<i>Use partitioner</i>	Select this check box to specify the Hadoop Partitioner that controls the partitioning of the keys of the intermediate map-

		outputs. For further information about the usage of Hadoop Partitioner, see: http://hadoop.apache.org/common/docs/r0.20.2/api/org/apache/hadoop/mapred/Partitioner.html
	<i>Increase parallelism</i>	Select this check box to set the number of reduce tasks for the MapReduce Jobs
	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Usage	This component is commonly used as intermediate step together with input component and output component.	
Limitation	Knowledge of Pig scripts is required.	

Scenario: Joining two files based on an exact match and saving the result to a local file

This scenario describes a four-component Job that combines data of an input file and a reference file that matches a given join key, removes unwanted columns, and then saves the final result to a local file.

The main input file contains the information about people's IDs, first names, last names, group IDs, and salaries, as shown below:

```
1;Woodrow;Johnson;3;1013.39
2;Millard;Monroe;2;8077.59
3;Calvin;Eisenhower;3;6866.88
4;Lyndon;Wilson;3;5726.28
5;Ronald;Garfield;2;4158.58
6;Rutherford;Buchanan;3;2897.00
7;Calvin;Coolidge;1;6650.66
8;Ulysses;Roosevelt;2;7854.78
9;Grover;Tyler;1;5226.88
10;Bill;Tyler;2;8964.66
```

The reference file contains only the information of group IDs and group names:

```
1;group_A
2;group_B
```

Dropping and linking the components

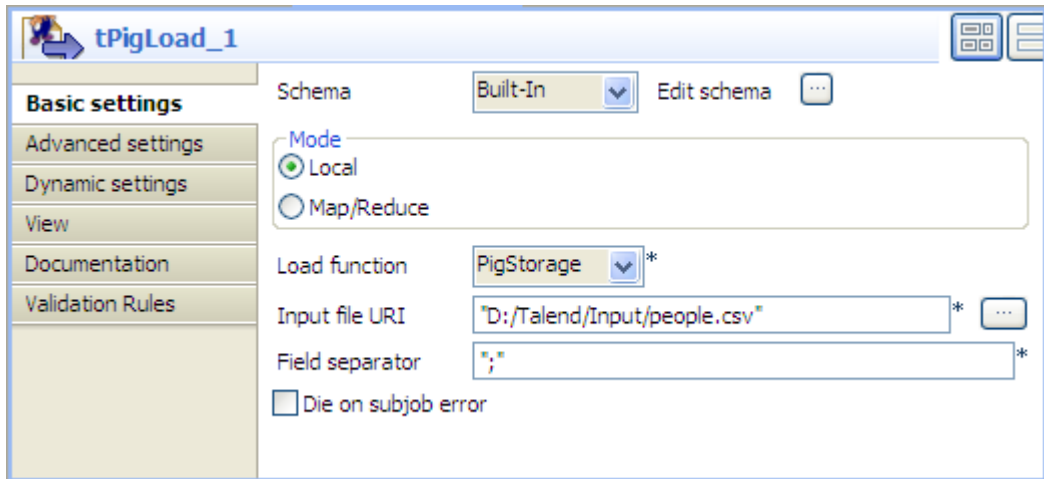

- Drop the following components from the **Palette** to the design workspace: **tPigLoad**, **tPigJoin**, **tPigFilterColumns**, and **tPigStoreResult**.
- Connect these components in a series using **Row > Pig Combine** connections.

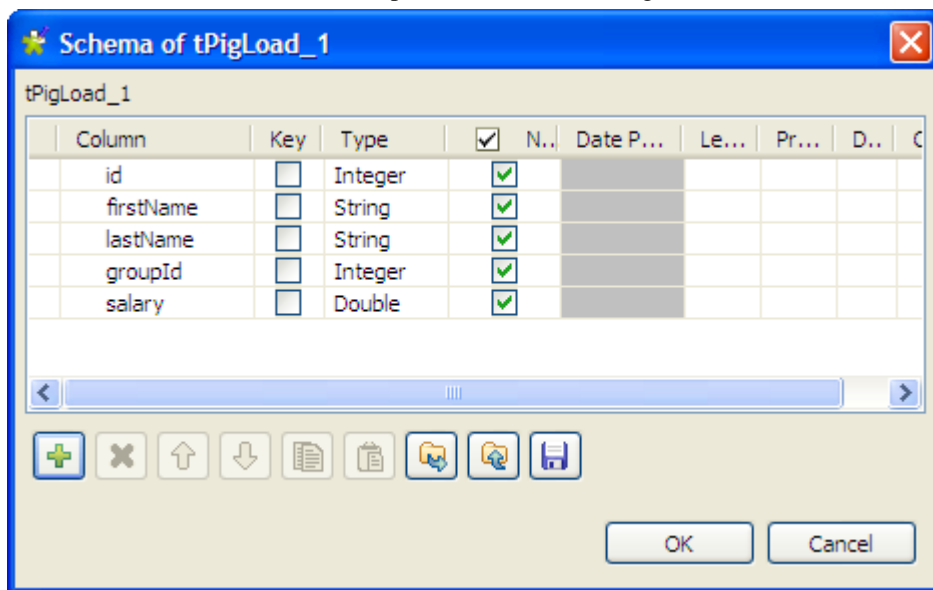

Configuring the components

Loading the main input file

1. Double-click **tPigLoad** to open its **Basic settings** view.

2. Click the [...] button next to **Edit schema** to open the **[Schema]** dialog box.

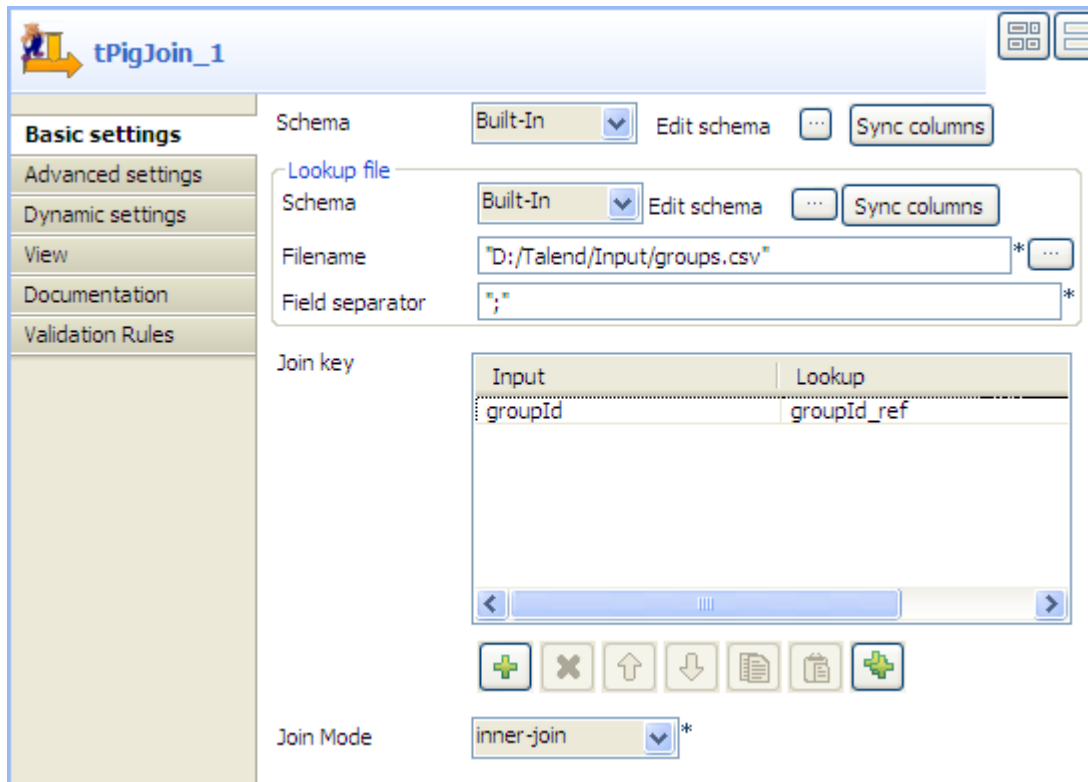

3. Click the [+] button to add columns, name them and define the column types according to the structure of the input file. In this example, the input schema has five columns: *id* (integer), *firstName* (string), *lastName* (string), *groupId* (integer), and *salary* (double).

Then click **OK** to validate the setting and close the dialog box.

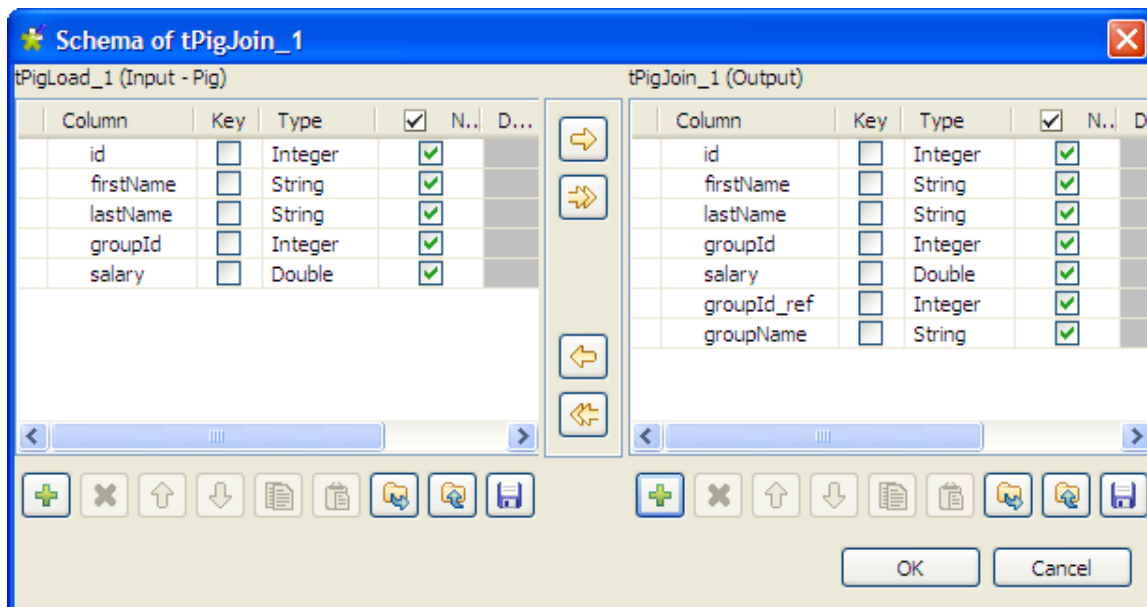

4. Click **Local** in the **Mode** area.
5. Select **PigStorage** from the **Load function** list.
6. Fill in the **Input file URI** field with the full path to the input file, and leave the rest of the setting as they are.

Loading the reference file and setting up an inner join

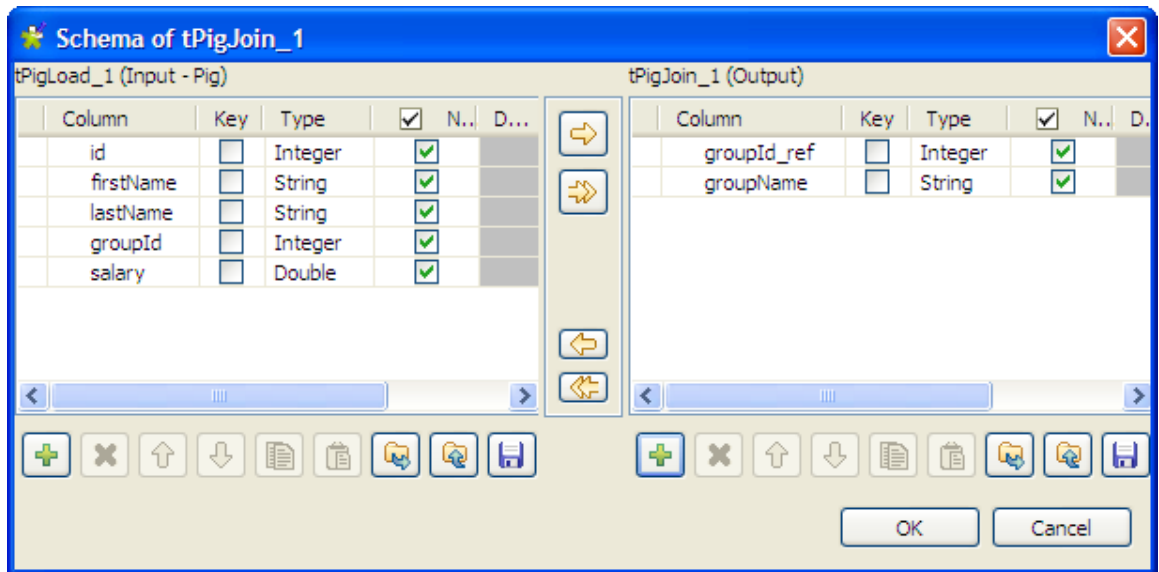

1. Double-click **tPigJoin** to open its **Basic settings** view.

- Click the [...] for the main schema to open the [Schema] dialog box.

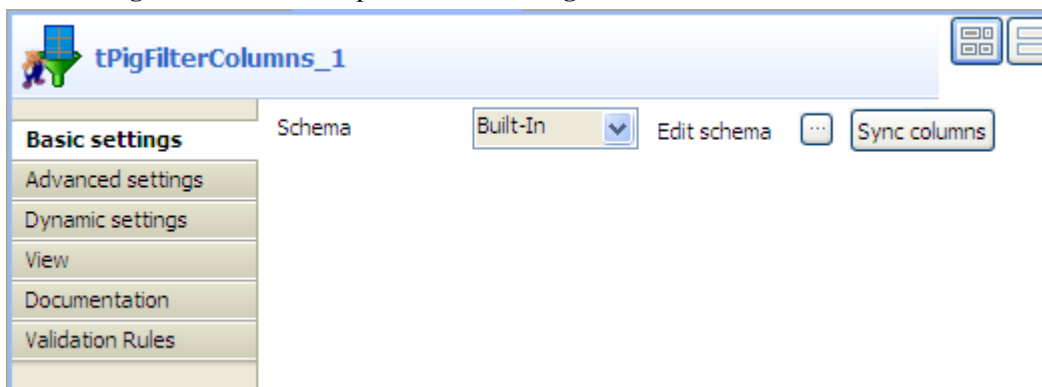

- Check that input schema is correctly retrieved from the preceding component. If needed, click the [->>] button to copy all the columns of the input schema to the output schema.
- Click the [+] button under the output panel to add new columns according to the data structure of the reference file, *groupId_ref* (integer) and *groupName* (string) in this example. Then click **OK** to close the dialog box.
- Click the [...] for the schema lookup flow to open the [Schema] dialog box.

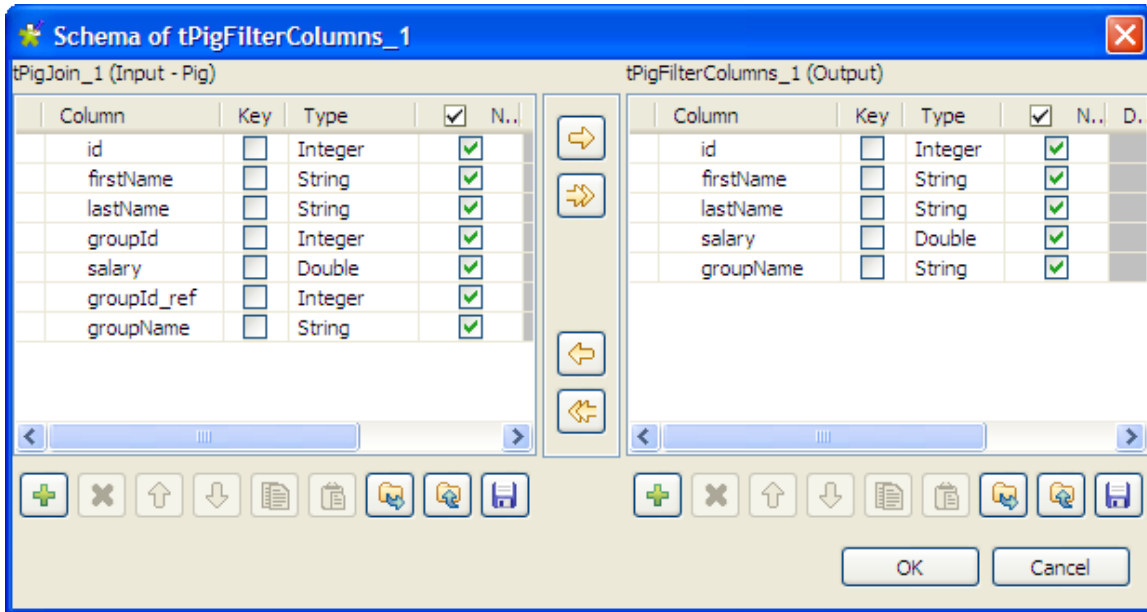

6. Click the [+] button under the output panel to add two columns: *groupId_ref* (integer) and *groupName* (string), and then click **OK** to close the dialog box.
7. In the **Filename** field, specify the full path to the reference file.
8. Click the [+] button under the **Join key** table to add a new line, and select *groupId* and *groupId_ref* respectively from the **Input** and **Lookup** lists to match data from the main input flow with data from the lookup flow based on the group ID.
9. From the **Join Mode** list, select **inner-join**.

Defining the final output schema and the output file

1. Double-click **tPigFilterColumns** to open its **Basic settings** view.

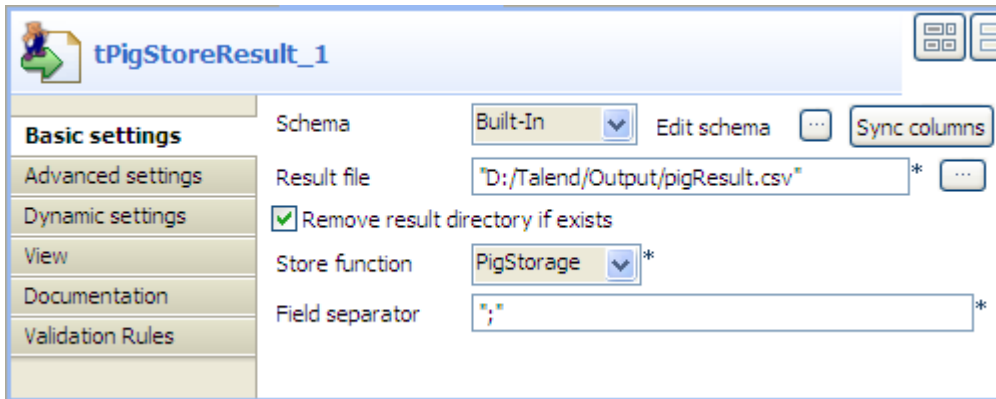

2. Click the [...] button next to **Edit schema** to open the **[Schema]** dialog box.

- From the input schema, select the columns you want to include in your result file by clicking them one after another while pressing the **Shift** key, and click the [->] button to copy them to the output schema. Then, click **OK** to validate the schema setting and close the dialog box.

In this example, we want the result file to include all the information except the group IDs.

- Double-click **tPigStoreResult** to open its **Basic settings** view.

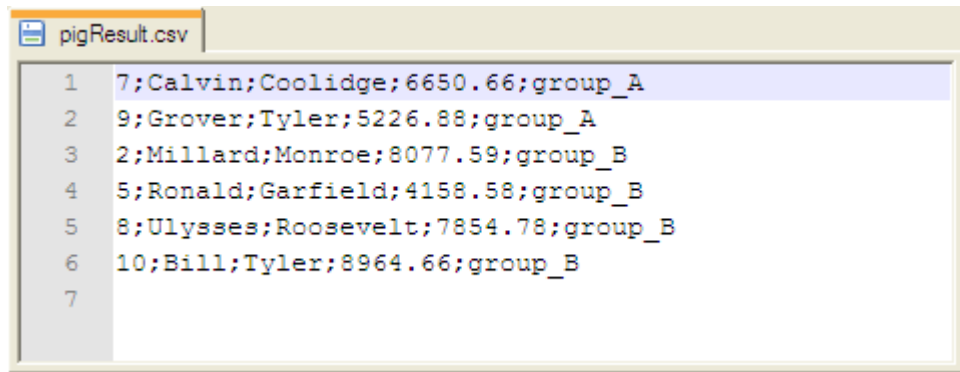

- Click **Sync columns** to retrieve the schema structure from the preceding component.
- Fill in the **Result file** field with the full path to the result file, and select the **Remove result file directory if exists** check box.
- Select **PigStorage** from the **Store function** list, and leave rest of the settings as they are.

Saving and executing the Job

- Press **Ctrl+S** to save your Job.
- Press **F6** or click **Run** on the **Run** tab to run the Job.

The result file includes all the information related to people of group A and group B, except their group IDs.

The image shows a screenshot of a text editor window with a single tab titled 'pigResult.csv'. The window contains a list of seven lines of text, each representing a record in a CSV format. The records are as follows:

Line	Record
1	7;Calvin;Coolidge;6650.66;group_A
2	9;Grover;Tyler;5226.88;group_A
3	2;Millard;Monroe;8077.59;group_B
4	5;Ronald;Garfield;4158.58;group_B
5	8;Ulysses;Roosevelt;7854.78;group_B
6	10;Bill;Tyler;8964.66;group_B
7	

tPigLoad

tPigLoad Properties

Component family	Big Data / Hadoop	
Function	This component allows you to set up a connection to the data source for a current transaction.	
Purpose	The tPigLoad component loads original input data to an output stream in just one single transaction, once the data has been validated.	
Basic settings	<i>Schema</i> and <i>Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Local</i>	Click this radio button to run Pig scripts in Local mode. In this mode, all files are installed and run from your local host and file system.
	<i>Map/Reduce</i>	<p>Click this radio button to run Pig scripts in Map/Reduce mode:</p> <p>Hortonworks Data Platform 1.0: You need to precise the access to the Hortonworks Data Platform 1.0 (based upon Apache Hadoop 0.20.205) to be used.</p> <p>Apache 0.20.2: You need to precise the access to the Apache 0.20.2 to be used.</p> <p>Cloudera 0.20 CDH3U1: You need to precise the access to the Cloudera 0.20 Hadoop (CDH3 Update1) to be used.</p> <p>MapR: You need to precise the access to the MapR distribution for Apache Hadoop to be used.</p> <p>Apache 1.0.0: You need to precise the access to the Apache Hadoop 1.0.0 to be used in this mode.</p> <p>When selecting any one of the options above, you need to complete the following fields:</p> <ul style="list-style-type: none"> • NameNode URI: Type in the URI of the NameNode corresponding to the Map/Reduce version to be used. • JobTracker host: Type in the URI of the JobTracker corresponding to the Map/Reduce version to be used. • HCat Metastore: Type in the URI of the HCat metastore: "<i>thrift://<hcatalog server hostname>:9933</i>".

		 For further information about the usage of HCat Metastore, see http://incubator.apache.org/hcatalog/docs/r0.2.0/loadstore.html .
	<i>Load function</i>	<p>Select a load function for data to be loaded:</p> <p>PigStorage: Loads data in UTF-8 format.</p> <p>BinStorage: Loads data in machine-readable format.</p> <p>TextLoader: Loads unstructured data in UTF-8 format.</p> <p>HCatLoader: Loads data from HCataLog managed tables using Pig scripts.</p> <p> HCatLoader is available only when you select Hortonworks Data Platform 1.0 from the Version list. For further information about the usage of HCatLoader, see http://incubator.apache.org/hcatalog/docs/r0.2.0/loadstore.html#HCatLoader.</p>
	<i>Input file URI</i>	<p>Fill in this field with the full local path to the input file.</p> <p> This field is not available when you select HCatLoader from the Load function list.</p>
	<i>HCataLog Configuration</i>	<p>Fill the following fields to configure HCataLog managed tables on HDFS(Hadoop distributed file system):</p> <p>Database: The database in which tables are placed.</p> <p>Table: The table in which data is stored.</p> <p>Partition filter: Fill this field with the partition keys to list partitions by filter.</p> <p>Register jar: Fill the Jar path field with the path to the jar files listed in the Column field.</p> <p> HCataLog Configuration area is enabled only when you select HCatLoader from the Load function list. For further information about the usage of HCataLog, see http://incubator.apache.org/hcatalog/docs/r0.2.0/. For further information about the usage of Partition filter, see https://cwiki.apache.org/confluence/display/HCATALOG/Design+Document+-+Java+APIs+for+HCatalog+DDL+Commands.</p>
	<i>Field separator</i>	<p>Type in the separator you need to use for the input data.</p> <p> This field is enabled only when you select PigStorage from the Load function list.</p>
	<i>Die on subjob error</i>	<p>This check box is cleared by default, meaning to skip the row on subjob error and to complete the process for error-free rows.</p>

Advanced settings	<i>Hadoop Properties</i>	Complete this table using the customized Hadoop parameters, if any, to override the default ones.
	<i>Properties</i>	Complete this table using the customized Pig set configuration, if any, to override the default one. For example, the <i>default_parallel</i> key used in Pig could be set as 20.
	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Usage	This component is always used to start a Pig chain.	
Limitation	Knowledge of Pig scripts is required. If you select HCatLoader as the load function, knowledge of HCataLog DDL(HCataLog Data Definition Language, a subset of Hive Data Definition Language) is required. For further information about HCataLog DDL, see http://incubator.apache.org/hcatalog/docs/r0.2.0/cli.html .	

Related Scenario

For further information regarding the **tPigLoad** component in use, see [the section called “Scenario: Filtering rows of data based on a condition and saving the result to a local file”](#) of **tPigFilterRow**.

tPigSort

tPigSort Properties

Component family	Big Data / Hadoop	
Function	This component allows you to sort a relation based on one or more defined sort keys.	
Purpose	The tPigSort component is used to sort relation based on one or more defined sort keys.	
Basic settings	<i>Schema</i> and <i>Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Sort key</i>	Click the Add button beneath the Sort key table to add one or more lines to specify column and sorting order for each sort key.
Advanced settings	<i>Increase parallelism</i>	Select this check box to set the number of reduce tasks for the MapReduce Jobs
	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Usage	This component is commonly used as intermediate step together with input component and output component.	
Limitation	Knowledge of Pig scripts is required.	

Scenario: Sorting data in ascending order

This scenario describes a three-component Job that sorts rows of data based on one or more sorting conditions and stores the result into a local file.

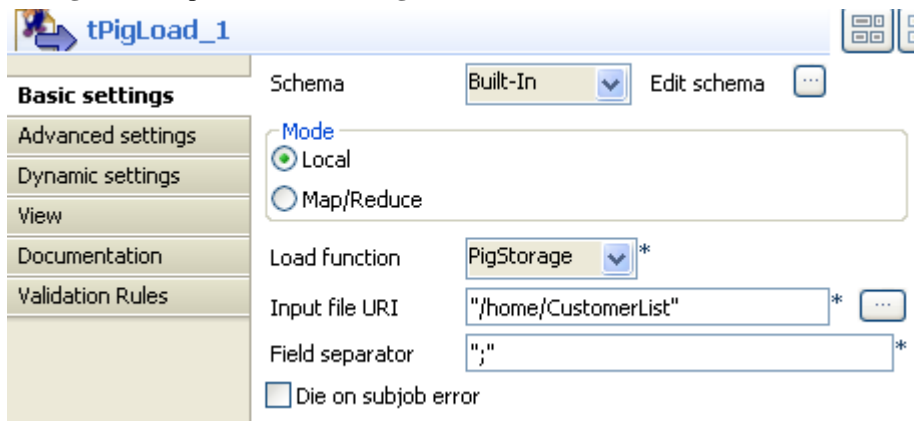

Setting up the Job

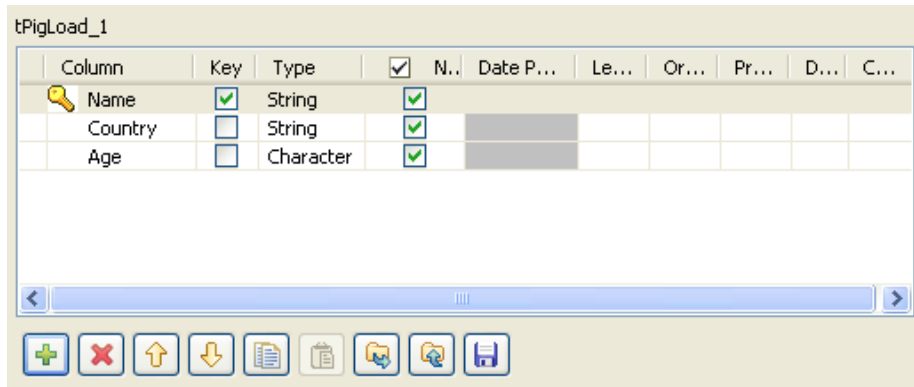

1. Drop the following components from the **Palette** to the design workspace: **tPigSort**, **tPigLoad**, **tPigStoreResult**.
2. Connect **tPigLoad** to **tPigFilterRow** using a **Row > Pig Combine** connection.
3. Connect **tPigFilterRow** to **tPigStoreResult** using a **Row > Pig Combine** connection.

Loading the data

1. Double-click **tPigLoad** to open its **Basic settings** view.

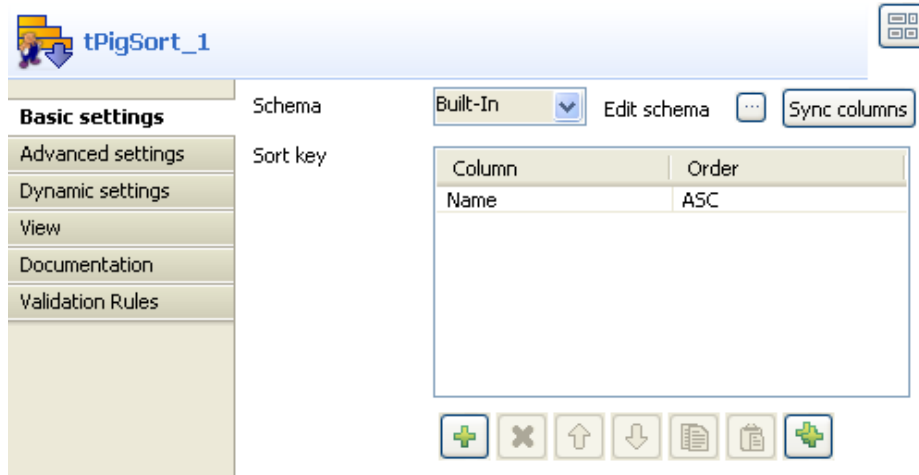

2. Click the [...] button next to **Edit schema** to add columns for **tPigLoad**.

3. Click the [+] button to add *Name*, *Country* and *Age* and click **OK** to save the setting.
4. Select **Local** from the **Mode** area.
5. Fill in the **Input filename** field with the full path to the input file.
In this scenario, the input file is *CustomerList* that contains rows of names, country names and age.
6. Select **PigStorage** from the **Load function** list.
7. Leave rest of the settings as they are.

Setting the sorting condition

1. Double-click **tPigSort** to open its **Basic settings** view.

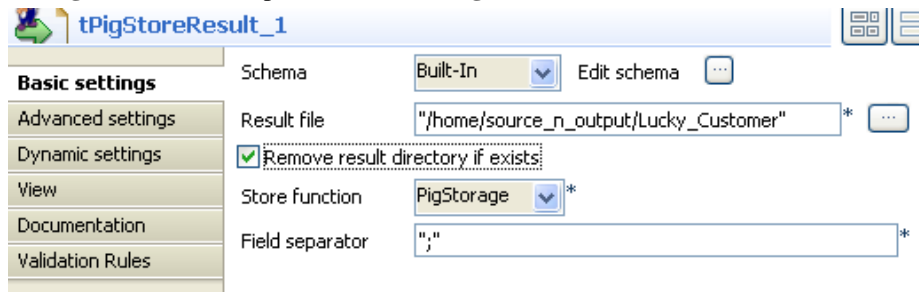

2. Click **Sync columns** to retrieve the schema structure from the preceding component.
3. Click the [+] button beneath the **Sort key** table to add a new sort key. Select *Age* from the **Column** list and select **ASC** from the **Order** list.

This sort key will sort the data in *CustomerList* in ascending order based on *Age*.

Saving the data to a local file

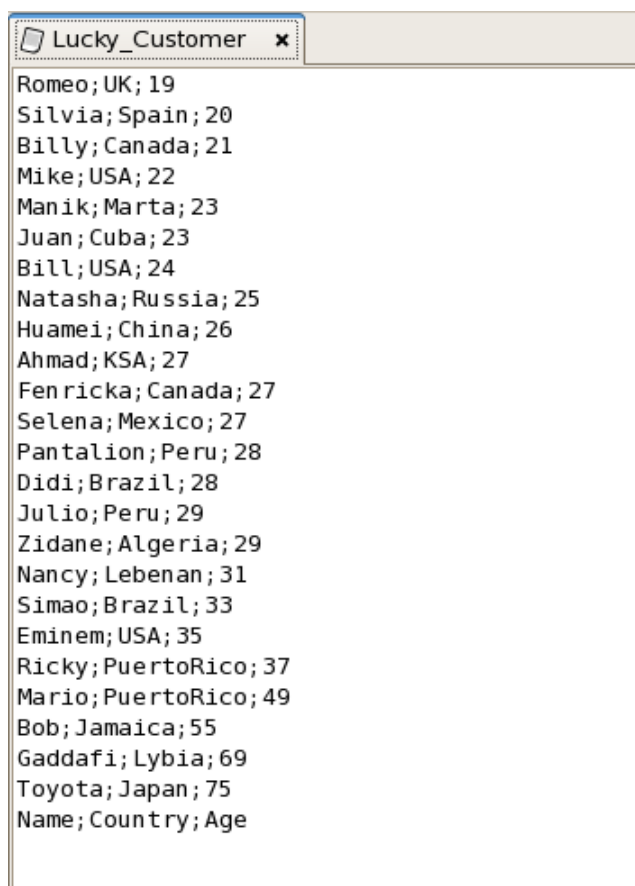

1. Double-click **tPigStoreResult** to open its **Basic settings** view.

2. Click **Sync columns** to retrieve the schema structure from the preceding component.
3. Select **Remove result directory if exists**.
4. Fill in the **Result file** field with the full path to the result file.
In this scenario, the result of filter is saved in *Lucky_Customer* file.
5. Select **PigStorage** from the **Store function** list.
6. Leave rest of the settings as they are.

Executing the Job

Save your Job and press **F6** to run it.

The *Lucky_Customer* file is generated containing the data in ascending order based on *Age*.

tPigStoreResult

tPigStoreResult Properties

Component family	Big Data / Hadoop	
Function	This component allows you to store the result of your Pig Job into a defined data storage space.	
Purpose	The tPigStoreResult component is used to store the result into defined data storage space.	
Basic settings	<i>Schema and Edit Schema</i>	A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in .
		Built-in: The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .
	<i>Result file</i>	Select the path to the result file in which data is stored.
	<i>Remove result directory if exists</i>	Select this check box to remove an existing result directory.  This check box is disabled when you select HCatStorer from the Store function list.
	<i>Store function</i>	Select a store function for data to be stored: PigStorage: Stores data in UTF-8 format. BinStorage: Stores data in machine-readable format. PigDump: Stores data as tuples in human-readable UTF-8 format. HCatStorer: Stores data in HCatalog managed tables using Pig scripts.
	<i>HCatalog Configuration</i>	Fill the following fields to configure HCatalog managed tables on HDFS(Hadoop distributed file system): Database: The database in which tables are placed. Table: The table in which data is stored. Partition filter: Fill this field with the partition keys to list partitions by filter. Register jar: Fill the Jar path field with the path to the jar files listed in the Column field.  HCatalog Configuration area is enabled only when you select HCatStorer from the Store function list. For further information

		<p>about the usage of HCataLog, see http://incubator.apache.org/hcatalog/docs/r0.2.0/. For further information about the usage of Partition filter, see https://cwiki.apache.org/confluence/display/HCATALOG/Design+Document+-+Java+APIs+for+HCatalog+DDL+Commands.</p>
	<i>Field separator</i>	<p>Type in the separator you need to use for the output data.</p> <p> This field is enabled only when you select PigStorage from the Store function list.</p>
Advanced settings	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Usage	This component is always used to end a Pig chain.	
Limitation	<p>Knowledge of Pig scripts is required. If you select HCatStorer as the store function, knowledge of HCataLog DDL(HCataLog Data Definition Language, a subset of Hive Data Definition Language) is required. For further information about HCataLog DDL, see http://incubator.apache.org/hcatalog/docs/r0.2.0/cli.html.</p>	

Related Scenario

For more information regarding the **tPigStoreResult** component in use, see [the section called “Scenario: Sorting data in ascending order” of tPigSort](#).

tSqoopExport

tSqoopExport Properties

Component family	Big Data / Sqoop		
Function	tSqoopExport calls sqoop to transfer data from the Hadoop Distributed File System (HDFS) to a relational database management system (RDBMS).		
Purpose	tSqoopExport is used to define the arguments required by Sqoop for transferring data to a RDBMS.		
Basic settings	<i>Connection</i>	Type in the JDBC URL used to connect to the target database.	
	<i>Table Name</i>	Type in the name of the target table which data is transferred to from HDFS. This table must already exist in the target database. The input files are read and parsed into a set of records according to the user-specified delimiters.	
	<i>Export Dir</i>	Type in the path, or browse to the source data to be transferred in HDFS.	
	<i>User name</i> and <i>Password</i>	Type in the authentication information to the target database.	
	<i>Specify Number of Mappers</i>	Select this check box to precise the number of mappers, which is the degree of parallelism used.	
	<i>Print Log</i>	Select this check box to activate the Verbose check box.	
	<i>Verbose</i>	Select this check box to print more information while working, for example, the debugging information.	
	Advanced settings	<i>Direct</i>	Select this check box to use the export fast path.
		<i>Use MySQL default delimiters</i>	Select this check box to use MySQL's default delimiter set
		<i>Additional arguments</i>	Complete this table to use an additional argument.  <i>At each time, only one additional argument is allowed. Use of multiple additional arguments at the same time may lead to exception error..</i>
<i>tStatCatcher Statistics</i>		Select this check box to collect log data at the component level.	
Usage	<p>This component is used standalone.</p> <p>If your HDFS is hosted on a different server from the one hosting your Studio, install a Jobserver of equal or later version than your Studio's in the server of this HDFS and run the Job of interest remotely on this server. For further information about how to run a Job remotely, see <i>Talend Open Studio for Big Data User Guide</i>.</p>		
Connections		<p>Outgoing links (from one component to another):</p> <p>Trigger: Run if; On Subjob Ok; On Subjob Error.</p>	

Related scenario

		Incoming links (from one component to another): Row: Iterate; Trigger: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error For further information regarding connections, see <i>Talend Open Studio for Big Data User Guide</i> .
Limitation	n/a	

Related scenario

No scenario is available for this component yet.

tSqoopImport

tSqoopImport Properties

Component family	Big Data / Sqoop		
Function	tSqoopImport calls Sqoop to transfer data from a relational database management system (RDBMS) such as MySQL or Oracle into the Hadoop Distributed File System (HDFS).		
Purpose	tSqoopImport is used to define the arguments required by Sqoop for writing the data of your interest into HDFS.		
Basic settings	<i>Connection</i>	Type in the JDBC URL used to connect to the database where the source data is stored.	
	<i>User name</i> and <i>Password</i>	Type in the authentication information used to connect to the source database.	
	<i>Table Name</i>	Type in the name of the table to be transferred into HDFS.	
	<i>Append</i>	Select this check box to append transferred data to an existing dataset in HDFS.	
	<i>File format</i>	Select a file format for the data to be transferred. By default, the file format is textfile , but you can as well choose the sequencefile format instead.	
	<i>Specify Number of Mappers</i>	Select this check box to precise the number of map tasks (parallel processes) used to perform the data transfer.	
	<i>Specify Target Dir</i>	Select this check box to type in the path to, or to browse to the target file which you want transfer the source data to in HDFS.	
	<i>Compress</i>	Select this check box to enable compression.	
	<i>Print Log</i>	Select this check box to activate the Verbose check box.	
	<i>Verbose</i>	Select this check box to print more information while working, for example, the debugging information.	
	Advanced settings	<i>Direct</i>	Select this check box to use the import fast path.
		<i>Specify columns</i>	Select this check box to activate the column table where you can specify the data columns you want to transfer into HDFS.
		<i>Use WHERE clause</i>	Select this check box to use a WHERE clause that controls the rows to be transferred. In the activated field, you can type in the condition used to selected the data rows you want. For example, type in <i>id >400</i> to import only rows where the <i>id</i> column has a value greater than 400.
<i>Use MySQL default delimiters</i>		Select this check box to use MySQL's default delimiter set	
	<i>Additional arguments</i>	Complete this table to use an additional argument if you need one.	

Related scenario

		 <p><i>At each time, only one additional argument is allowed. Use of multiple additional arguments at the same time may lead to exception error.</i></p>
	<i>tStatCatcher Statistics</i>	Select this check box to collect log data at the component level.
Usage	<p>This component is used standalone.</p> <p>If your HDFS is hosted on a different server from the one hosting your Studio, install a Jobserver of equal or later version than your Studio's in the server of this HDFS and run the Job of interest remotely on this server. For further information about how to run a Job remotely, see <i>Talend Open Studio for Big Data User Guide</i>.</p>	
Connections		<p>Outgoing links (from one component to another):</p> <p>Trigger: Run if; On Subjob Ok; On Subjob Error.</p> <p>Incoming links (from one component to another):</p> <p>Row: Iterate;</p> <p>Trigger: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error</p> <p>For further information regarding connections, see <i>Talend Open Studio for Big Data User Guide</i>.</p>

tSqoopImportAllTables

tSqoopImportAllTables Properties

Component family	Big Data / Sqoop	
Function	tSqoopImportAllTables calls Sqoop to transfer all of the tables of a relational database management system (RDBMS) such as MySQL or Oracle into the Hadoop Distributed File System (HDFS).	
Purpose	tSqoopImportAllTables is used to define the arguments required by Sqoop for writing all of the tables of a database into HDFS.	
Basic settings	<i>Connection</i>	Type in the JDBC URL used to connect to the database where the source data is stored.
	<i>User name and Password</i>	Type in the authentication information used to connect to the source database.
	<i>File format</i>	Select a file format for the data to be transferred. By default, the file format is textfile , but you can as well choose the sequencefile format instead.
	<i>Specify Number of Mappers</i>	Select this check box to precise the number of map tasks (parallel processes) used to perform the data transfer.
	<i>Compress</i>	Select this check box to enable compression.
	<i>Print Log</i>	Select this check box to activate the Verbose check box.
	<i>Verbose</i>	Select this check box to print more information while working, for example, the debugging information.
	Advanced settings	<i>Direct</i>
<i>Use MySQL default delimiters</i>		Select this check box to use MySQL's default delimiter set
<i>Additional arguments</i>		Complete this table to use an additional argument if you need one.  <i>At each time, only one additional argument is allowed. Use of multiple additional arguments at the same time may lead to exception error.</i>
<i>tStatCatcher Statistics</i>		Select this check box to collect log data at the component level.
Usage	<p>This component is used standalone.</p> <p>If your HDFS is hosted on a different server from the one hosting your Studio, install a Jobserver of equal or later version than your Studio's in the server of this HDFS and run the Job of interest remotely on this server. For further information about how to run a Job remotely, see <i>Talend Open Studio for Big Data User Guide</i>.</p>	
Connections		<p>Outgoing links (from one component to another):</p> <p>Trigger: Run if; On Subjob Ok; On Subjob Error.</p>

Related scenario

		Incoming links (from one component to another): Row: Iterate; Trigger: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error For further information regarding connections, see <i>Talend Open Studio for Big Data User Guide</i> .

Business components

This chapter details the major components that you can find in **Business** group of the **Palette** of *Talend Open Studio for Big Data*.

The Business component family groups connectors that covers specific Business needs, such as reading and writing CRM, or ERP types of database and reading from or writing to an SAP system.

For *Talend Open Studio for Big Data*, the **Property type**, **Schema** and **Query Type** of components are always **Built-in**. For how to edit a Built-in schema, see *Talend Open Studio for Big Data User Guide*.

tAlfrescoOutput

tAlfrescoOutput Properties

Component family	Business	
Function	Creates dematerialized documents in an Alfresco server where they are indexed under meaningful models.	
Purpose	Allows to create and manage documents in an Alfresco server.	
Basic settings	<i>URL</i>	Type in the URL to connect to the Alfresco Web application.
	<i>Login and Password</i>	Type in the user authentication data to the Alfresco server.
	<i>Base</i>	Type in the base path where to put the document, or Select the Map... check box and then in the Column list, select the target location column. Note: When you type in the base name, make sure to use the double backslash (\\) escape character.
	<i>Document Mode</i>	Select in the list the mode you want to use for the created document. Create only: creates a document if it does not exist. Note that an error message will display if you try to create a document that already exists Create or update: creates a document if it does not exist or updates the document if it exists.
	<i>Container Mode</i>	Select in the list the mode you want to use for the destination folder in Alfresco. Update only: updates a destination folder if the folder exists. Note that an error message will display if you try to update a document that does not exist Create or update: creates a destination folder if it does not exist or updates the destination folder if it exists.
	<i>Define Document Type</i>	Click the three-dot button to display the tAlfrescoOutput editor. This editor enables you to: - select the file where you defined the metadata according to which you want to save the document in Alfresco -define the type of the document

		-select any of the aspects in the available aspects list of the model file and click the plus button to add it in the list to the left.
	<i>Property Mapping</i>	Displays the parameters you set in the tAlfrescoOutput editor and according to which the document will be created in the Alfresco server. Note that in the Property Mapping area, you can modify any of the input schemas.
	<i>Schema and Edit schema</i>	A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always Built-in . Click Edit Schema to make changes to the schema.
	<i>Result Log File Name</i>	Browse to the file where you want to save any logs related to the Job execution.
Advanced settings	<i>Configure Target Location Container</i>	Allows to configure the (by default) type of containers (folders) Select this check box to display new fields where you can modify the container type to use your own created types based on the father/child model.
	<i>Configure Permissions</i>	When selected, allows to manually configure access rights to containers and documents. Select the Inherit Permissions check box to synchronize access rights between containers and documents. Click the Plus button to add new lines to the Permissions list, then you can assign roles to user or group columns.
	<i>Encoding</i>	Select the encoding type from the list or select Custom and define it manually. This field is compulsory.
	<i>Association Target Mapping</i>	Allows to create new documents in Alfresco with associated links towards other documents already existing in Alfresco, to facilitate the navigation process for example. To create associations: 1. Open the tAlfresco editor. 2. Click the Add button and select a model where you have already defined aspects that contain associations. 3. Click the drop-down arrow at the top of the editor and select the corresponding document type. 4. Click OK to close the editor and display the created association in the Association Target Mapping list.

	<i>tStatCatcher Statistics</i>	Select this check box to gather the Job processing metadata at a Job level as well as at each component level.
Usage	Usually used as an output component. An input component is required.	
Limitation/Prerequisites	<p>To be able to use the tAlfrescoOutput component, few relevant resources need to be installed: check the <i>Installation Procedure</i> sub section for more information.</p> <p> Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i>. For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i>.</p>	

Installation procedure

To be able to use **tAlfrescoOutput** in *Talend Open Studio for Big Data*, you need first to install the Alfresco server with few relevant resources.

The below sub sections detail the prerequisite and the installation procedure.

Prerequisites

Start with the following operations:

1. Download the file `alfresco-community-tomcat-2.1.0.zip`
2. Unzip the file in an installation folder, for example:

```
C:\Program Files\Java\jdk1.6.0_27
```

3. Install JDK 1.6.0+
 4. Update the environment variable
- ```
JAVA_HOME (JAVA_HOME= C:\alfresco)
```
5. From the installation folder (`C:\alfresco`), launch the alfresco server using the script `alf_start.bat`

 *Make sure that the Alfresco server is launched correctly before start using the **tAlfrescoOutput** component.*

### Installing the Talend Alfresco module

Note that the `talendalfresco_20081014.zip` is provided with the **tAlfrescoOutput** component in *Talend Open Studio for Big Data*.

To install the `talendalfresco` module:

1. From `talendalfresco_20081014.zip` and in the `talendalfresco_20081014\alfresco` folder, look for the following jars: `stax-api-1.0.1.jar`, `wstx-lgpl-3.2.7.jar`,

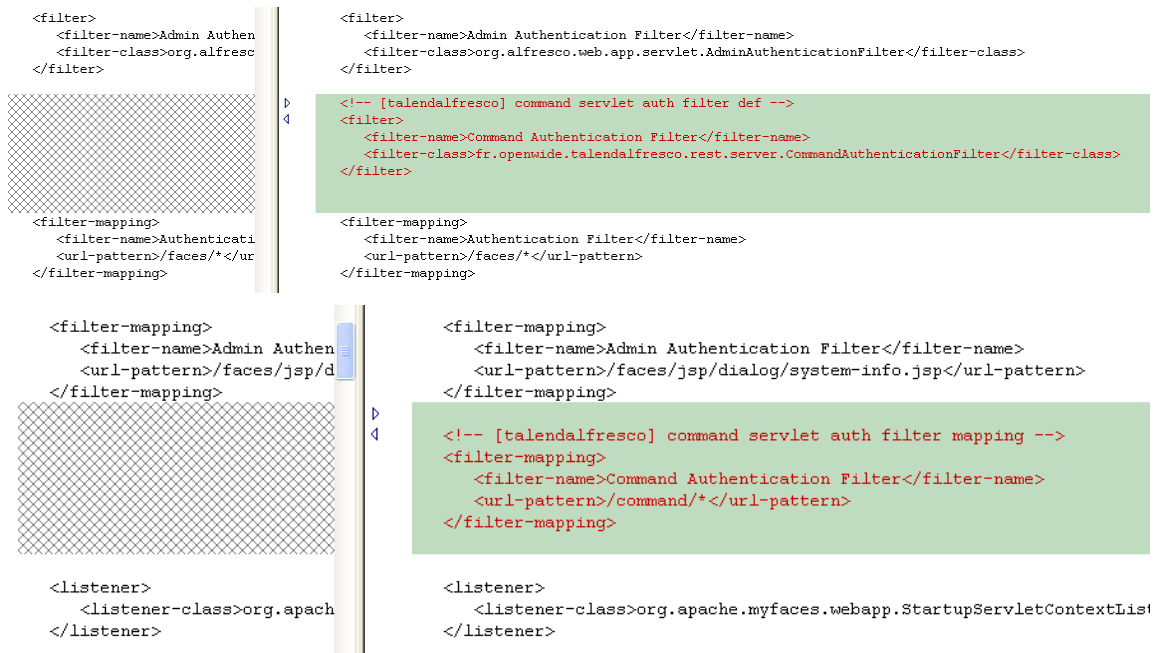

talendalfresco-client\_1.0.jar, and talendalfresco-alfresco\_1.0.jar and move them to C:\alfresco\tomcat\webapps\alfresco\WEB-INF\lib

2. Add the authentication filter of the commands to the web.xml file located in the path

```
C:\alfresco\tomcat\webapps\alfresco\WEB-INF
son WEB-INF/
```

following the model of the example provided in talendalfresco\_20081014/alfresco folder of the zipped file talendalfresco\_20081014.zip

The following figures show the portion of lines (in blue) to add in the file web.xml alfresco.

## Useful information for advanced use

### Installing new types for Alfresco:

From the package\_jeu\_test.zip and in the package\_jeu\_test/fichiers\_conf\_alfresco2.1 folder, look for the following files: xml H76ModelCustom.xml (description of the model), web-client-config-custom.xml (web interface of the model), and custom-model-context.xml (registration of the new model) and paste them in the following folder: C:/alfresco/tomcat/shared/classes/alfresco/extension

### Dates:

- The dates must be of the **Talend** date type java.util.Date.
- Columns without either mapping or default values, for example of the type Date, are written as empty strings.
- Solution: delete all columns without mapping or default values. Note that any modification of the type Alfresco will put them back.

### Content:

- Do not mix up between the file path which content you want to create in Alfresco and its target location in Alfresco.

- Provide a URL! It can target various protocols, among which are file, HTTP and so on.
- For URLs referring to files on the file system, precede them by "file:" for Windows used locally, and by "file:///" for Windows on a network (which accepts as well "file: \\") or for Linux.
- Do not double the backslash in the target base path (automatic escape), unless you type in the path in the basic settings of the **tAlfrescoOutput** component, or doing concatenation in the **tMap** editor for example.

#### Multiple properties or associations:

- It is possible to create only one association by document if it is mapped to a string value, or one or more associations by document if it is mapped to a list value (object).
- You can empty an association by mapping it to an empty list, which you can create, for example, by using `new java.util.ArrayList()` in the **tMap** component.

However, it is impossible to delete an association.

#### Building `List(object)` with **tAggregate**:

- define the table of the relation n-n in a file, containing a name line for example (included in the input rows), and a category line (that can be defined with its mapping in a third file).
- group by: input name, output name.
- operation: output `categoryList`, function `list(object)`, input `category`. ATTENTION `list(object)` and non simple list.

#### - References (documents and folders):

- References are created by mapping one or more existing reference nodes (xpath or namepath) using `String` type or `List(object)`.
- An error in the association or the property of the reference type does not prevent the creation of the node that holds the reference.
- Properties of the reference type are created in the **Basic Settings** view.
- Associations are created in the **Advanced Settings** view.

## Dematerialization, tAlfrescoOutput, and Enterprise Content Management

Dematerialization is the process that convert documents held in physical form into electronic form, and thus helps to move away from the use of physical documentation to the use of electronic Enterprise Content Management (ECM) systems. The range of documents that can be managed with an Enterprise Content Management system include just about everything from basic documents to stock certificates, for example.

Enterprises dematerialize their content via a manual document handling, done by man, or an automatic document handling, machine-based.

Considering the varied nature of the content to be dematerialized, enterprises have to use varied technologies to do it. Scanning paper documents, creating interfaces to capture electronic documents from other applications, converting document images into machine-readable/editable text documents, and so on are examples of the technologies available.

Furthermore, scanned documents and digital faxes are not readable texts. To convert them into machine-readable characters, different character recognition technologies are used. Handwritten Character Recognition (HCR) and Optical Mark Recognition (OMR) are two examples of such technologies.

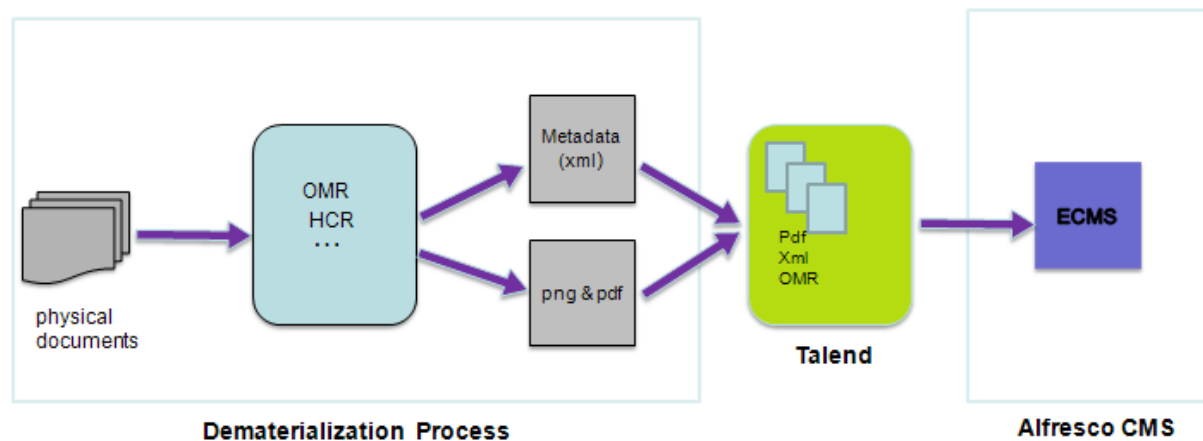

Equally important as the content that is captured in various formats from numerous sources in the dematerialization process is the supporting metadata that allows efficient identification of the content via specific queries.

Now how can this document content along with the related metadata be aggregated and indexed in an Enterprise Content Management system so that it can be retrieved and managed in meaningful ways? **Talend** provides the answer through the **tAlfrescoOutput** component.

The **tAlfrescoOutput** component allows you to stock and manage your electronic documents and the related metadata on the Alfresco server, the leading open source enterprise content management system.

The following figure illustrates **Talend**'s role between the dematerialization process and the Enterprise Content Management system (Alfresco).

ECMS: Enterprise Content Management System  
HCR: Handwritten Character Recognition  
OMR: Optical Mark Recognition

## Scenario: Creating documents on an Alfresco server

This Java scenario describes a two-component Job which aims at creating two document files with the related metadata in an Alfresco server, the java-based Enterprise Control Management system.

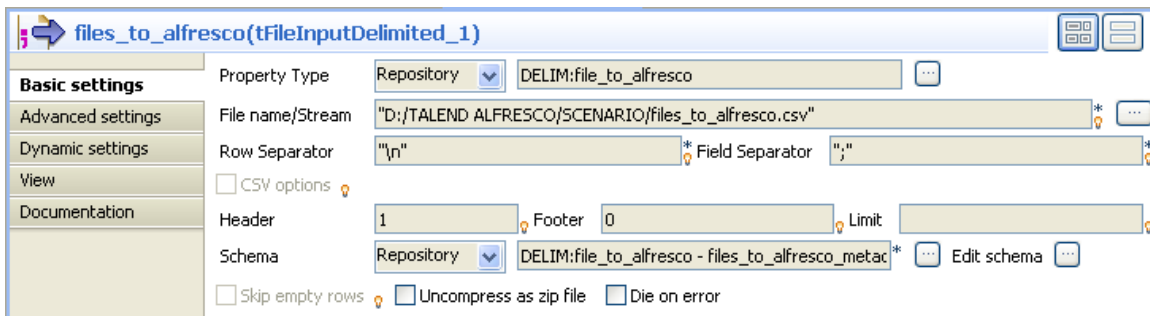

### Setting up your Job

1. Drop the **tFileInputDelimited** and **tAlfrescoOutput** components from the **Palette** onto the design workspace.
2. Connect the two components together using a **Main > Row** connection.

## Setting up the schema

1. In the design workspace, double-click **tFileInputDelimited** to display its basic settings.
2. Set the **File Name** path and all related properties.

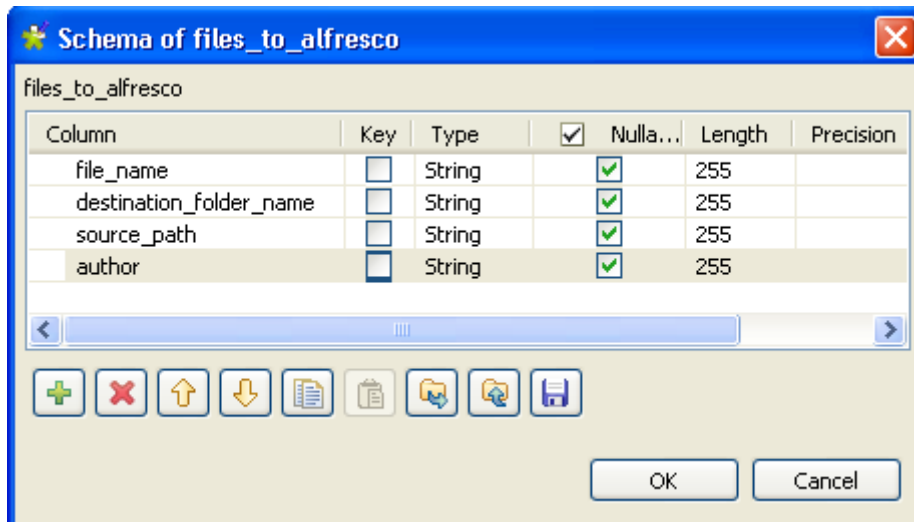

For Talend Open Studio for Big Data, the **Property type** and **Schema** of components are always **Built-in**. For how to edit a built-in schema, see *Talend Open Studio for Big Data User Guide*.

In this scenario, the delimited file provides the metadata and path of two documents we want to create in the Alfresco server. The input schema for the documents consists of four columns: *file\_name*, *destination\_folder\_name*, *source\_path*, and *author*.

|   | A             | B                        | C                                    | D      | E | F |
|---|---------------|--------------------------|--------------------------------------|--------|---|---|
| 1 | file_name;    | destination_folder_name; | source_path;                         | author |   |   |
| 2 | PO_43278.pdf; | FINANCE\PO;              | file:D:/PO/customer1_2009-03-24.pdf; | talend |   |   |
| 3 | PO_43279.pdf; | FINANCE\PO;              | file:D:/PO/customer2_2009-03-24.pdf; | talend |   |   |

And therefore the input schema of the delimited file will be as the following:

## Setting up the connection to the Alfresco server

1. In the design workspace, double-click **tAlfrescoOutput** to display its basic settings.

2. In the **Alfresco Server** area, enter the Alfresco server URL and user authentication information in the corresponding fields.
3. In the **TargetLocation** area, either type in the base name where to put the document in the server, or Select the **Map...** check box and then in the **Column** list, select the target location column, `destination_folder_name` in this scenario.

When you type in the base name, make sure to use the double backslash (\) escape character.

4. In the **Document Mode** list, select the mode you want to use for the created documents.
5. In the **Container Mode** list, select the mode you want to use for the destination folder in Alfresco.

## Defining the document

1. Click the **Define Document Type** three-dot button to open the **tAlfrescoOutput** editor.

2. Click the **Add** button to browse and select the xml file that holds the metadata according to which you want to save the documents in Alfresco.

All available aspects in the selected model file display in the **Available Aspects** list.

You can browse for this model folder locally or on the network. After defining the aspects to use for the document to be created in Alfresco, this model folder is not needed any more.

3. If needed, select in the **Available Aspects** list the aspect(s) to be included in the metadata to write in the Alfresco server. In this scenario we want the author name to be part of the metadata registered in Alfresco.
4. Click the drop-down arrow at the top of the editor to select from the list the type to give to the created document in Alfresco, Content in this scenario.

All the defined aspects used to select the metadata to write in the Alfresco server display in the **Property Mapping** list in the **Basic Settings** view of **tAlfrescoOutput**, three aspects in this scenario, two basic for the Content type (content and name) and an additional one (author).

## Executing your Job

1. Click **Sync columns** to auto propagate all the columns of the delimited file.

If needed, click **Edit schema** to view the output data structure of **tAlfrescoOutput**.

| files_to_alfresco (Input - Main) |                          |        |         |        | tAlfrescoOutput_1 (Output) |                          |        |        |       |
|----------------------------------|--------------------------|--------|---------|--------|----------------------------|--------------------------|--------|--------|-------|
| Column                           | Key                      | Type   | ✓ Nu... | Length | Column                     | Key                      | Type   | ✓ N... | Le... |
| file_name                        | <input type="checkbox"/> | String | ✓       | 255    | file_name                  | <input type="checkbox"/> | String | ✓      | 255   |
| destination_folder_name          | <input type="checkbox"/> | String | ✓       | 255    | destination_folder_name    | <input type="checkbox"/> | String | ✓      | 255   |
| source_path                      | <input type="checkbox"/> | String | ✓       | 255    | source_path                | <input type="checkbox"/> | String | ✓      | 255   |
| author                           | <input type="checkbox"/> | String | ✓       | 6      | author                     | <input type="checkbox"/> | String | ✓      | 6     |

2. Click the three-dot button next to the **Result Log File Name** field and browse to the file where you want to save any logs after Job execution.
3. Save your Job, and press **F6** to execute it.

| row1 (Main)             | Current row : 2                     |
|-------------------------|-------------------------------------|
| file_name               | PO_43279.pdf                        |
| destination_folder_name | FINANCE\PO                          |
| source_path             | file:D:/PO/customer2_2009-03-24.pdf |
| author                  | talend                              |

The two documents are created in Alfresco using the metadata provided in the input schemas.

| <b>Usage</b>             | This component is used as an intermediate component, it requires an input component and an output component. |                                                                                                                                                                                                                          |
| <b>Limitation</b>        | n/a                                                                                                          |                                                                                                                                                                                                                          |

## Scenario: Adding a lead record to a list in the Marketo DB

The following scenario describes a three-component Job that adds a lead record into a list in the Marketo database.

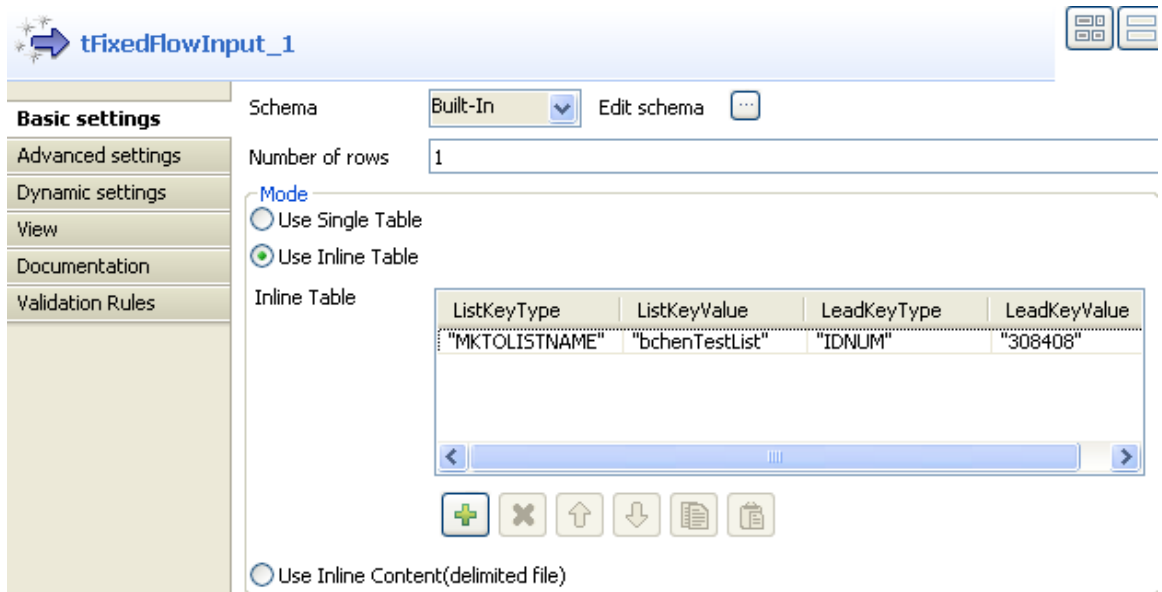

### Setting up the Job

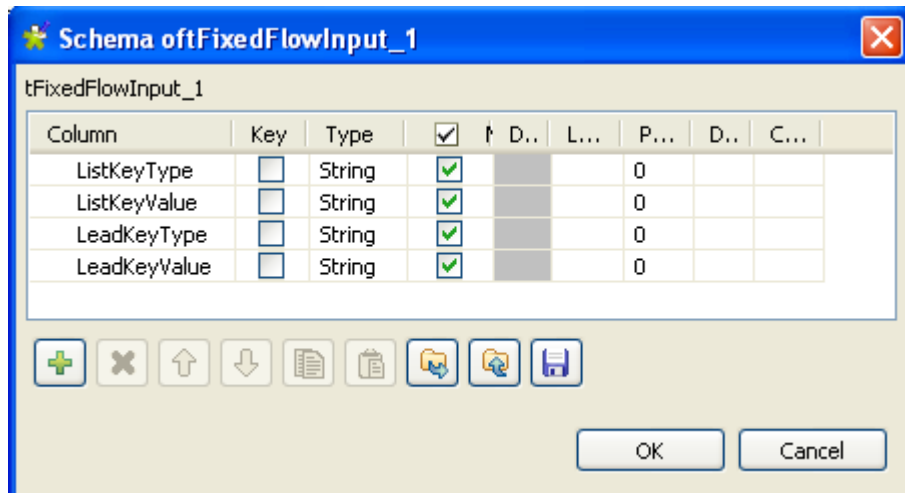

1. Drop **tMarketoListOperation**, **tFixedFlowInput** and **tLogRow** onto the design workspace.
2. Connect **tFixedFlowInput** to **tMarketoListOperation** using a **Row > Main** connection.
3. Connect **tMarketoListOperation** to **tLogRow** using a **Row > Main** connection.

### Configuring the input component

1. Double-click **tFixedFlowInput** to define the component properties in its **Basic settings** view.

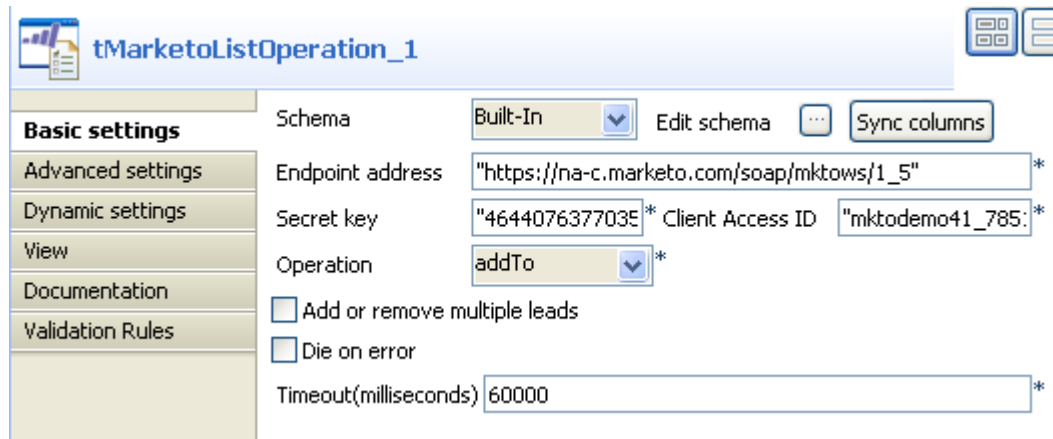

- Click the three-dot button next to **Edit schema** to set the schema manually.

- Click the plus button to add four columns: *ListKeyType*, *ListKeyValue*, *LeadKeyType* and *LeadKeyValue*. Keep the settings as default. Then click **OK** to save the settings.
- In the **Mode** area, select **Use Inline Table**.
- Click the plus button to add a new line and fill the line with respective values. In this example, these values are: *MKTOLISTNAME* for **ListKeyType**, *bchenTestList* for **ListKeyValue**, *IDNUM* for **LeadKeyType** and *308408* for **LeadKeyValue**.

## Configuring tMarketoListOperation

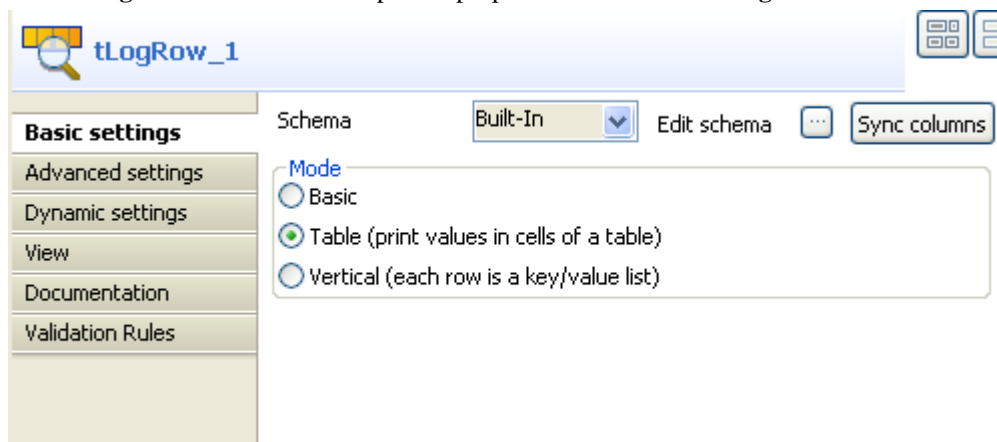

- Double-click **tMarketoListOperation** to define the component properties in its **Basic settings** view.

2. Click the **Sync columns** button to retrieve the schema defined in **tFixedFlowInput**.
3. Type in *1* in the **Number of rows** field.
4. Fill the **Endpoint address** field with the URL of the Marketo Web server. In this example, it is *https://na-c.marketo.com/soap/mktows/1\_5*.  
  
Note that the URL used in this scenario is for demonstration purpose only.
5. Fill the **Secret key** field with encrypted authentication code assigned by Marketo. In this example, it is *464407637703554044DD11AA2211998*.
6. Fill the **Client Access ID** field with the user ID. In this example, it is *mktodemo41\_785133934D1A219*.
7. From the **Operation** list, select **addTo**.
8. Type in the limit of query timeout in the **Timeout** field. In this example, use the default number: *60000*.

## Job Execution

1. Double-click **tLogRow** to define the component properties in its **Basic settings** view.

2. Click the **Sync columns** button to retrieve the schema defined in **tMarketoListOperation**.
3. In the **Mode** area, select **Table**.
4. Save your Job and press **F6** to execute it.

```
Starting job MarketoListOperation at 17:30 12/05/2011.

| <b>Limitation</b>        | n/a                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                |

## Scenario: Data transmission between Marketo DB and an external system

The following scenario describes a five-component Job that inserts Lead records into Marketo database and retrieves these records from Marketo database to a local file. Upon completing the data accessing, the Job displays the number of relevant API calls on the **Run** console.

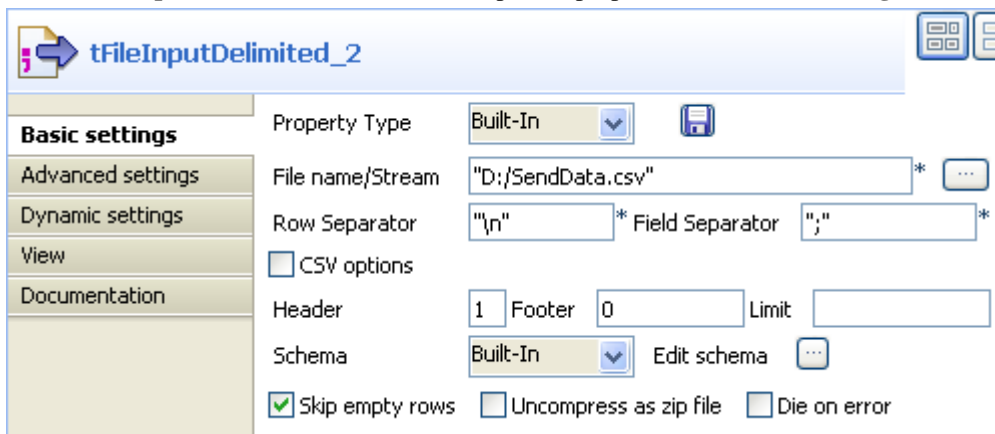

## Setting up the Job

1. Drop **tMarketoOutput**, **tMarketoInput**, **tFileInputDelimited**, **tFileOutputDelimited** and **tJava** from the **Palette** onto the design workspace.
2. Connect **tFileInputDelimited** to **tMarketoOutput** using a **Row > Main** connection.
3. Connect **tMarketoInput** to **tFileOutputDelimited** using a **Row > Main** connection.
4. Connect **tFileInputDelimited** to **tMarketoInput** using a **Trigger > OnSubjectOk** connection.
5. Connect **tMarketoInput** to **tJava** using a **Trigger > OnSubjectOk** connection.

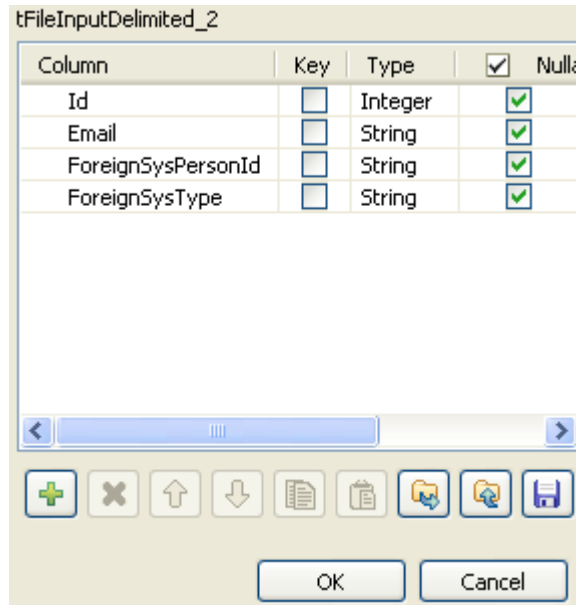

## Configuring tFileInputDelimited

1. Double-click **tFileInputDelimited** to define the component properties in its **Basic settings** view.

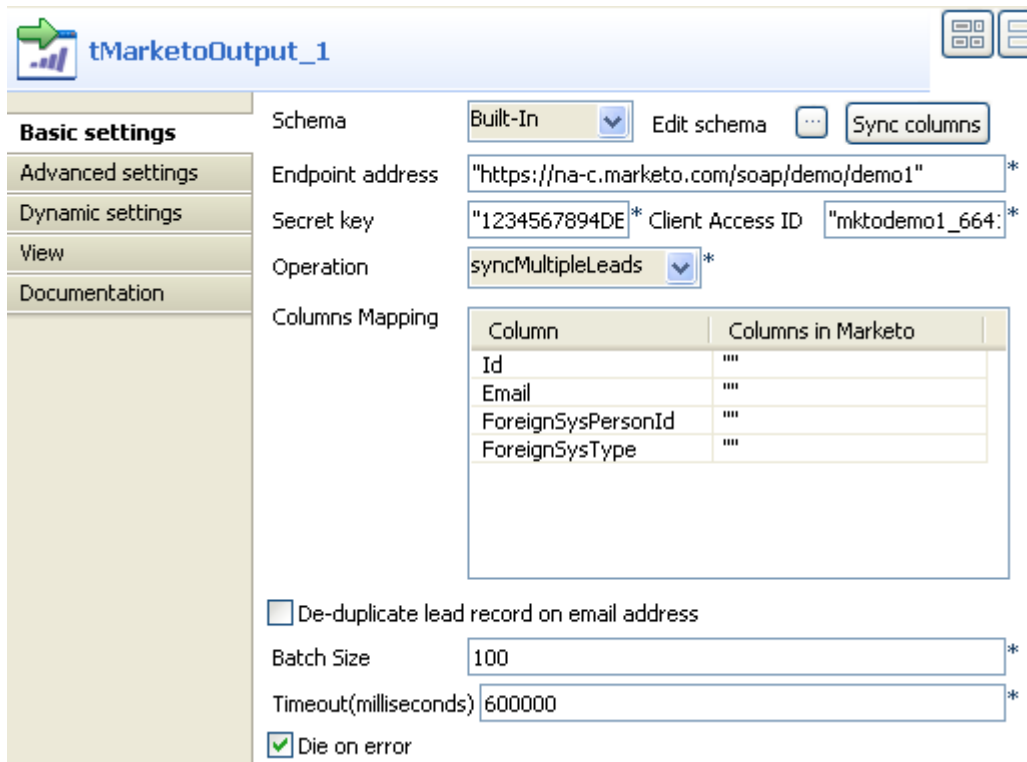

- Click the three-dot button next to the **File name/Stream** field to select the source file for data insertion. In this example, it is *D:/SendData.csv*.
- Click the three-dot button next to **Edit schema** to set the schema manually.

- Click the plus button to add four columns: *Id*, *Email*, *ForeignSysPersonId* and *ForeignSysType*. Set the **Type** of *Id* to Integer and keep the rest as default. Then click **OK** to save the settings.
- Type in *l* in the **Header** field and keep the other settings as default.

## Configuring tMarketoOutput

- Double-click **tMarketoOutput** to define the component properties in its **Basic settings** view.

2. Click the **Sync columns** button to retrieve the schema defined in **tFileInputDelimited** and fill the **Endpoint address** field with the URL of the Marketo Web server. In this example, it is *https://na-c.marketo.com/soap/demo/demo1*.

Note that the URL used in this scenario is for demonstration purpose only.

3. Fill the **Secret key** field with encrypted authentication code assigned by Marketo. In this example, it is *1234567894DEMOONLY987654321*.
4. Fill the **Client Access ID** field with the user ID. In this example, it is *mktodemo1\_1234567894DEMOONLY987654321*.
5. Select **syncMultipleLeads** from the **Operation** list and type in the limit of query timeout in the **Timeout** field. In this example, use the default number: *600000*.

## Configuring tMarketoInput

1. Double-click **tMarketoInput** to define the component properties in its **Basic settings** view.

The screenshot shows the configuration window for the **tMarketoInput\_1** component. The **Basic settings** tab is selected. The configuration includes:

- Endpoint address:** "https://na-c.marketo.com/soap/demo/demo1"
- Secret key:** "1234567894DEMOONLY987654321"
- Client Access ID:** "mktodemo1\_66419D3P"
- Operation:** getLead
- Schema:** Built-In
- Columns Mapping:**

| Column             | Columns in Marketo |
|--------------------|--------------------|
| Id                 | ""                 |
| Email              | "test@talend"      |
| ForeignSysPersonId | ""                 |
| ForeignSysType     | ""                 |
- LeadKey type:** EMAIL
- LeadKey value:** "test@talend.com"
- Timeout(millseconds):** 600000
- Die on error:**

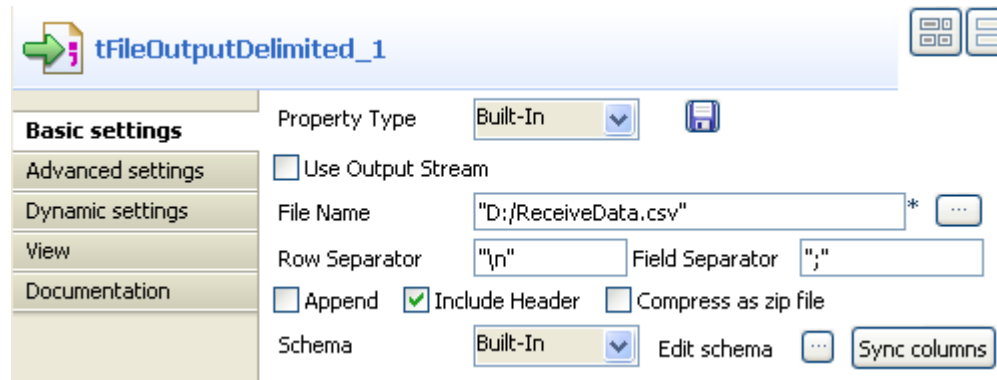

2. From the **Operation** list, select **getLead**.
3. In **Columns Mapping** area, type in *test@talend.com* in **Columns in Marketo** column to set the **Email** column.

Note that all the data used in this scenario is for demonstration purpose only.

4. From the **LeadKey type** list, select **EMAIL** and fill the **LeadKey value** field with *test@talend.com*.
5. Keep the rest of the settings as the corresponding settings in **tMarketoOutput**.

## Configuring tFileOutputDelimited

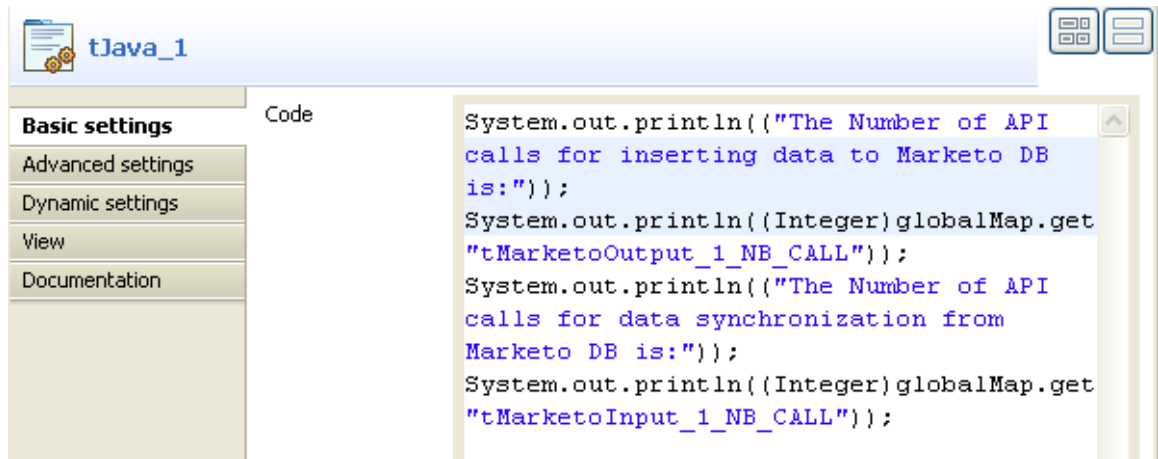

1. Double-click **tFileOutputDelimited** to define the component properties in its **Basic settings** view.

2. Click the three-dot button next to the **File name** field to synchronize data to a local file. In this example, it is *D:/ReceiveData.csv*.
3. Click the **Sync columns** button and keep the rest of the settings as default.

## Using Java scripts to count API calls

1. Double-click **tJava** to add code in its **Basic settings** view.

2. In the **Code** field, type in following code to count the number of API calls throughout the data operations:

```
System.out.println("The Number of API calls for inserting
data to Marketo DB is:");
System.out.println((Integer)globalMap.get("tMarketoOutput_1_NB_CALL"));
System.out.println("The Number of API calls for data synchronization
from Marketo DB is:");
System.out.println((Integer)globalMap.get("tMarketoInput_1_NB_CALL"));
```

## Job execution

1. Save your Job.
2. Press **F6** to execute it.

```
Id;Email;ForeignSysPersonId;ForeignSysType
308434;;;
308436;;;
308435;;;
308431;;;
308432;;;
308433;;;
```

The inserted lead records in the Marketo DB are synchronized to *D:/ReceiveData.csv*.  
*Starting job io at 18:03 25/03/2011.*

```
[statistics] connecting to socket on port 3829
[statistics] connected
The Number of API calls for inserting data to
Marketo DB is:
1
The Number of API calls for data synchronization
from Marketo DB is:
1
[statistics] disconnected
Job io ended at 18:03 25/03/2011. [exit code=0]
```

The number of API calls throughout each data operation is displayed on the **Run** console.

| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                      | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.                                                                       |
| <b>Usage</b>             | Usually used as a Start component. An output component is required. |                                                                                                                                                                                      |
| <b>Limitation</b>        | n/a                                                                 |                                                                                                                                                                                      |

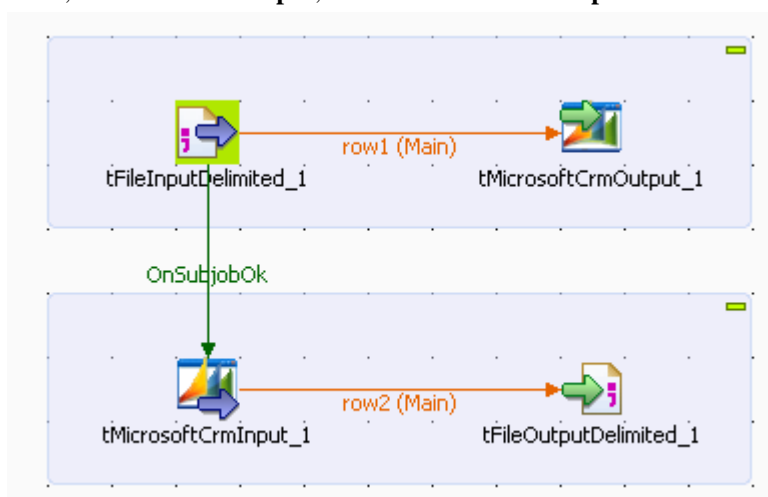

## Scenario: Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows

This scenario describes a four-component Job which aims at writing the data included in a delimited input file in a custom entity in a MicrosoftCRM database. It then extracts specified rows to an output file using the conditions set on certain input columns.

 *If you want to write in a CustomEntity in Microsoft CRM database, make sure to name the columns in accordance with the naming rule set by Microsoft, that is "name\_columname" all in lower case.*

### Setting up the Job

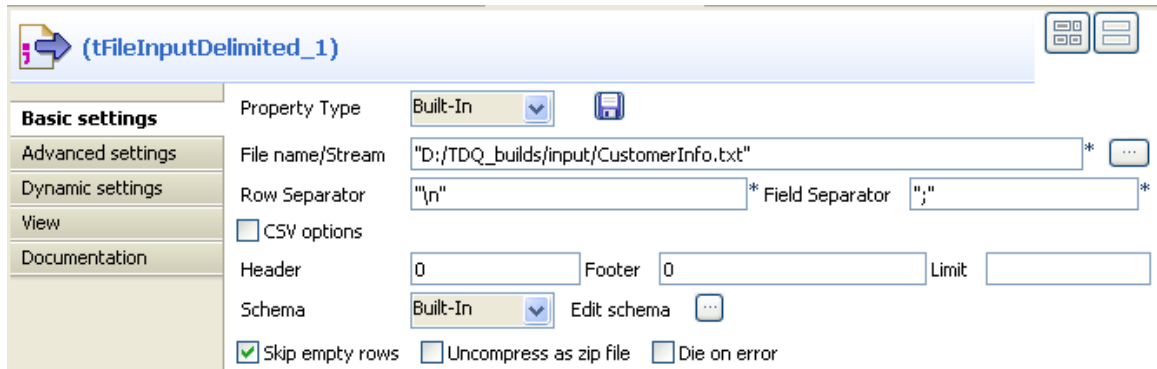

- Drop the following components from the **Palette** to the design workspace: **tFileInputDelimited**, **tFileOutputDelimited**, **tMicrosoftCrmInput**, and **tMicrosoftCrmOutput**.

- Connect **tFileInputDelimited** to **tMicrosoftCrmOutput** using a **Row Main** connection.
- Connect **tMicrosoftCrmInput** to **tFileOutputDelimited** using a **Row Main** connection.
- Connect **tFileInputDelimited** to **tMicrosoftCrmInput** using **OnSubjobOk** connection.

## Configuring tFileInputDelimited

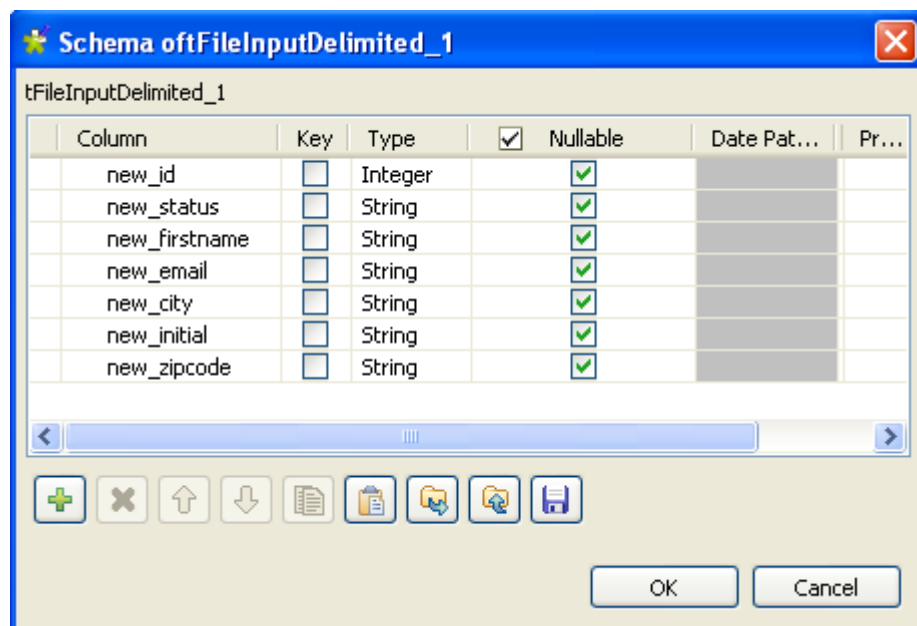

1. Double-click **tFileInputDelimited** to display its **Basic settings** view and define its properties

2. Click the three-dot button next to the **File Name/Input Stream** field and browse to the delimited file that holds the input data. The input file in this example contains the following columns: *new\_id*, *new\_status*, *new\_firstname*, *new\_email*, *new\_city*, *new\_initial* and *new\_zipcode*.

```
new_id;new_status;new_firstname;new_email;new_city;new_initial;new_zipcode
1;married;Paul;pnewman@comp.com;New York;P.M;55677
2;single;Raul;pnewman@comp.com;New York;R.L;55677
3;single;Mary;mnewman@comp.com;Chicago;M.B;66898
4;married;John;jnewman@comp.com;Chicago,J.M;66898
5;single;Martin;mnewman@comp.com;Sunnyvale,M.P;33662
6;married;Janet;jnewman@comp.com;Sunnyvale,J.P;33662
7;married;Harry;hnewman@comp.com;New York;H.M;55677
8;married;Jerry;jnewman@comp.com;New York;J.M;55677
9;married;Alice;anewman@comp.com;New York;A.M;55677
10;single;Jack;jnewman@comp.com;New York;J.M;55677
```

3. In the **Basic settings** view, define the **Row Separator** allowing to identify the end of a row. Then define the **Field Separator** used to delimit fields in a row.
4. If needed, define the header, footer and limit number of processed rows in the corresponding fields. In this example, the header, footer and limits are not set.
5. Click **Edit schema** to open a dialog box where you can define the input schema you want to write in Microsoft CRM database.

6. Click **OK** to close the dialog box.

## Configuring tMicrosoftCrmOutput

1. Double-click **tMicrosoftCrmOutput** to display the component **Basic settings** view and define its properties.

2. Enter the Microsoft Web Service URL as well as the user name and password in the corresponding fields.
3. In the **OrganizeName** field, enter the name that is given the right to access the Microsoft CRM database.
4. In the **Domain field**, enter the domain name of the server on which Microsoft CRM is hosted, and then enter the host IP address and the listening port number in the corresponding fields.
5. In the **Action** list, select the operation you want to carry on. In this example, we want to insert data in a custom entity in Microsoft Crm.
6. In the **Time out** field, set the amount of time (in seconds) after which the Job will time out.
7. In the **Entity** list, select one among those offered. In this example, *CustomEntity* is selected.

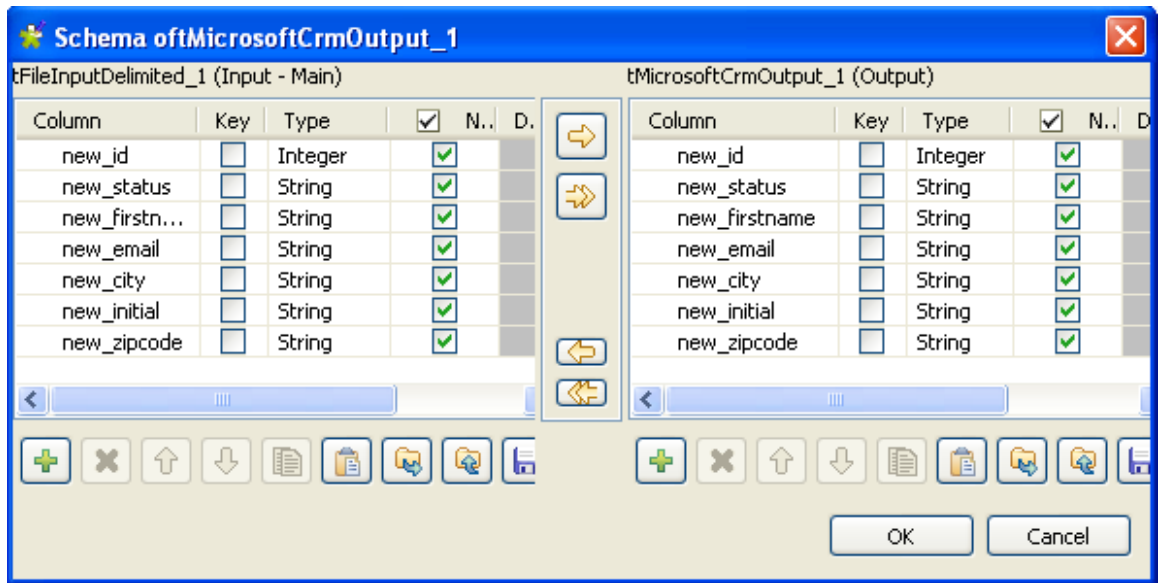

If *CustomEntity* is selected, a **Custom Entity Name** field displays where you need to enter a name for the custom entity.

The **Schema** is then automatically set according to the entity selected. If needed, click **Edit schema** to display a dialog box where you can modify this schema and remove the columns that you do not need in the output.

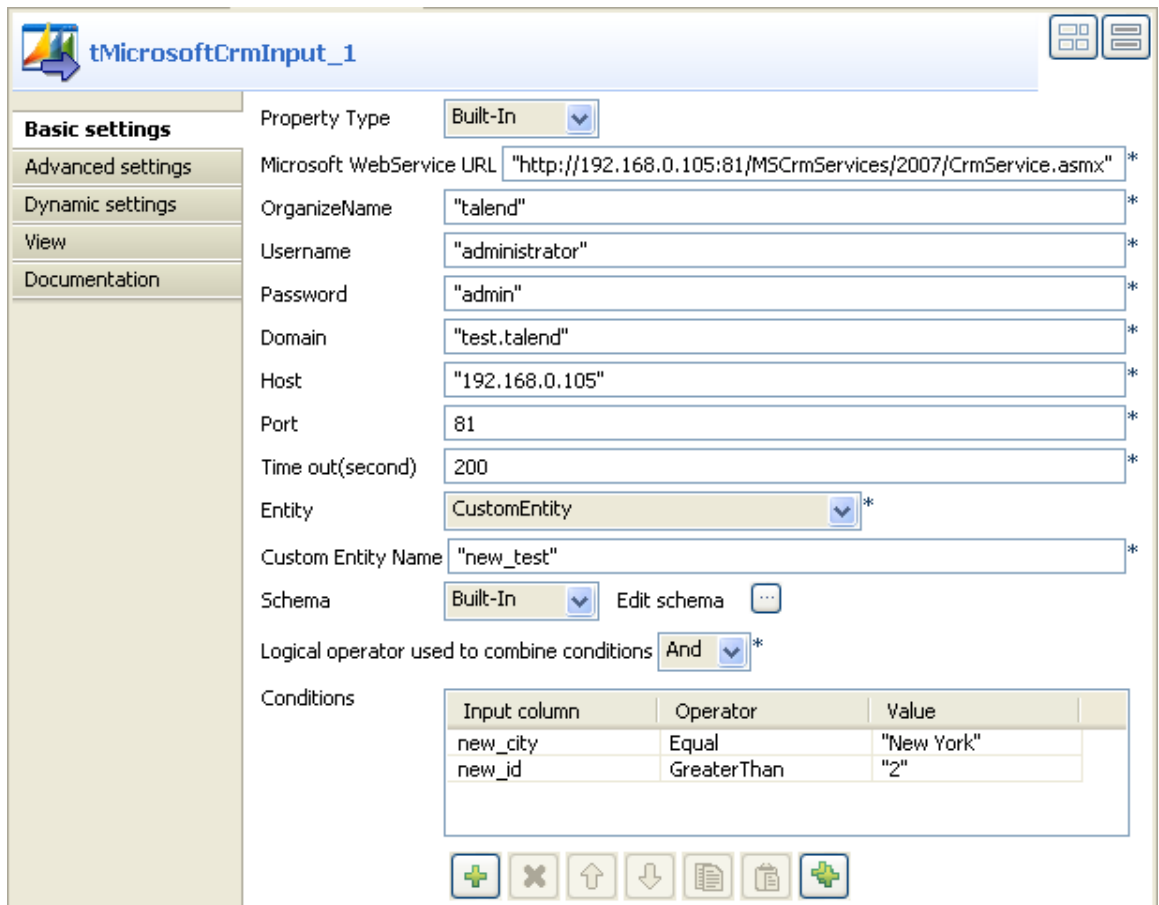

8. Click **Sync columns** to retrieve the schema from the preceding component.

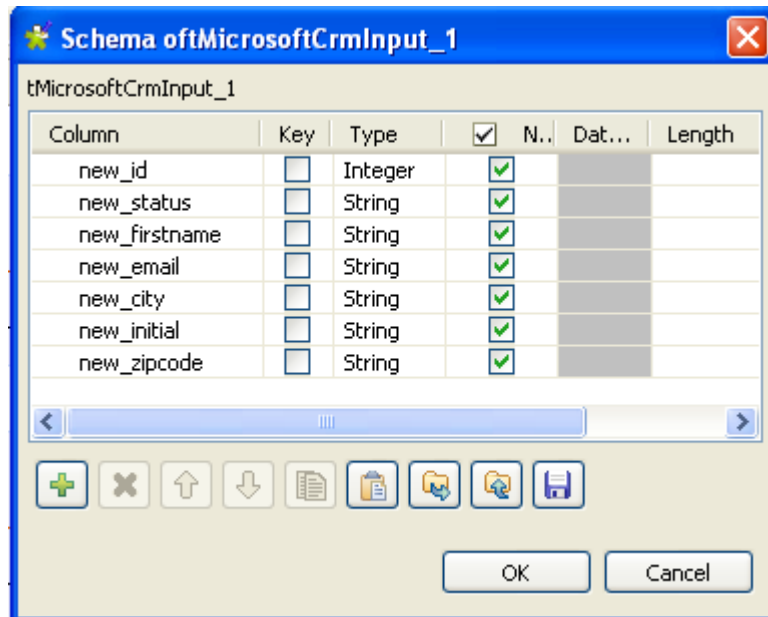

## Configuring tMicrosoftCrmInput

1. Double-click **tMicrosoftCrmInput** to display the component **Basic settings** view and define its properties.

2. Enter the Microsoft Web Service URL as well as the user name and password in the corresponding fields and enter the name that is given the right to access the Microsoft CRM database in the **OrganizeName** field.

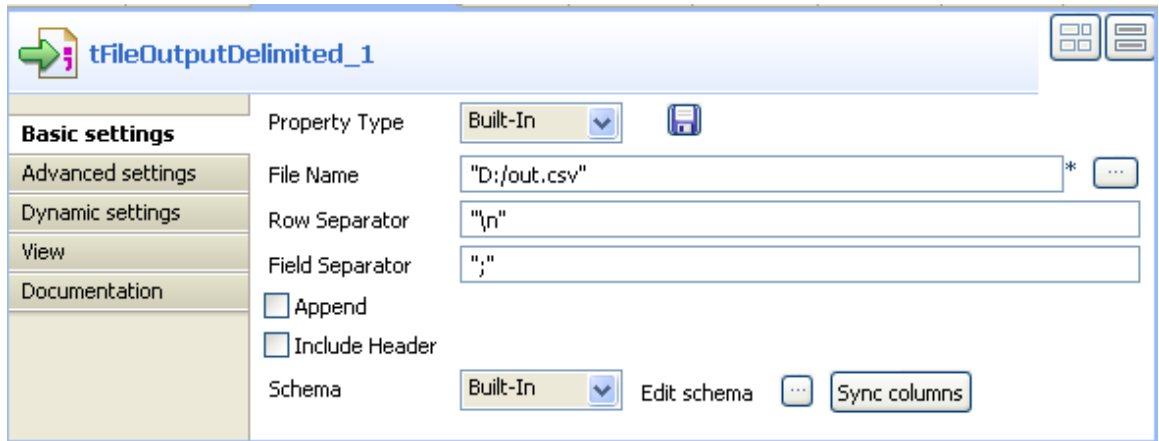

3. In the **Domain field**, enter the domain name of the server on which Microsoft CRM is hosted, and then enter the host IP address and the listening port number in the corresponding fields.
4. In the **Time out** field, set the amount of time (in seconds) after which the Job will time out.
5. In the **Entity** list, select the one among those offered you want to connect to. In this example, *CustomEntity* is selected.
6. The **Schema** is then automatically set according to the entity selected. But you can modify it according to your needs. In this example, you should set the schema manually since you want to access a custom entity. Copy the seven-column schema from **tMicrosoftCrmOutput** and paste it in the schema dialog box in **tMicrosoftCrmInput**.

7. Click **OK** to close the dialog box. You will be prompted to propagate changes. Click **Yes** in the popup message.
8. In the **Basic settings** view, select **And** or **Or** as the logical operator you want to use to combine the conditions you set on the input columns. In this example, we want to set two conditions on two different input columns and we use **And** as the logical operator.
9. In the **Condition** area, click the plus button to add as many lines as needed and then click in each line in the **Input column** list and select the column you want to set condition on. In this example, we want to set conditions on two columns, *new-city* and *new\_id*. We want to extract all customer rows whose city is equal to "New York" and whose id is greater than 2.
10. Click in each line in the **Operator** list and select the operator to bind the input column with its value, in this example **Equal** is selected for *new-city* and **Greater Than** for *new\_id*.
11. Click in each line in the **Value** list and set the column value, New York for *new-city* and 2 for *new\_id* in this example. You can use a fixed or a context value in this field.

## Configuring tFileOutputDelimited

1. Double-click **tFileOutputdelimited** to display the component **Basic settings** view and define its properties.

2. Click the three-dot button next to the **File Name** field and browse to the output file.
3. Set row and field separators in the corresponding fields.
4. Select the **Append** check box if you want to add the new rows at the end of the records.
5. Select the **Include Header** check box if the output file includes a header.
6. Click **Sync columns** to retrieve the schema from the preceding component.

## Job execution

Save the Job and press **F6** to execute it.

|   | A  | B       | C     | D                | E                  |
|---|----|---------|-------|------------------|--------------------|
| 1 | 7  | married | Harry | hnewman@comp.com | New York;H.M;55677 |
| 2 | 8  | married | Jerry | jnewman@comp.com | New York;J.M;55677 |
| 3 | 9  | married | Alice | anewman@comp.com | New York;A.M;55677 |
| 4 | 10 | single  | Jack  | jnewman@comp.com | New York;J.M;55677 |
| 5 |    |         |       |                  |                    |
| 6 |    |         |       |                  |                    |

Only customers who live in New York city and those whose “id” is greater than 2 are listed in the output file you stored locally.

| <b>Limitation</b>        | n/a                                                                 |                                                                                                                                                                                                                                                                                               |

## Scenario: Using query key to extract data from a given Sage X3 system

This scenario describes a two-component Job used to extract one row of data from a given Sage X3 system. The object method is to be called, that means the variable elements of this object thus are attributes. The data used in this scenario can be found in the example provided by Sage X3.

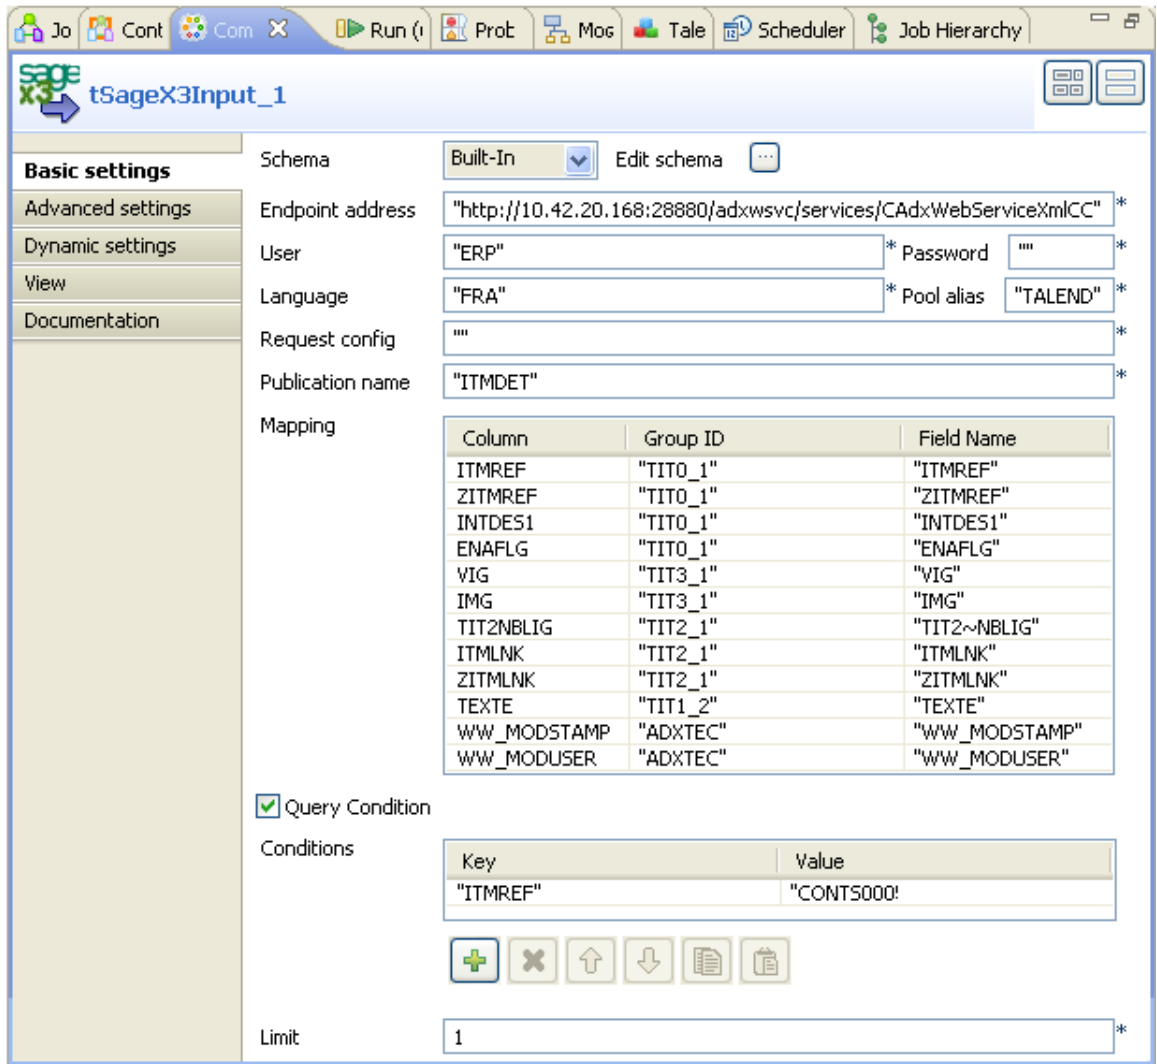

### Setting up the Job

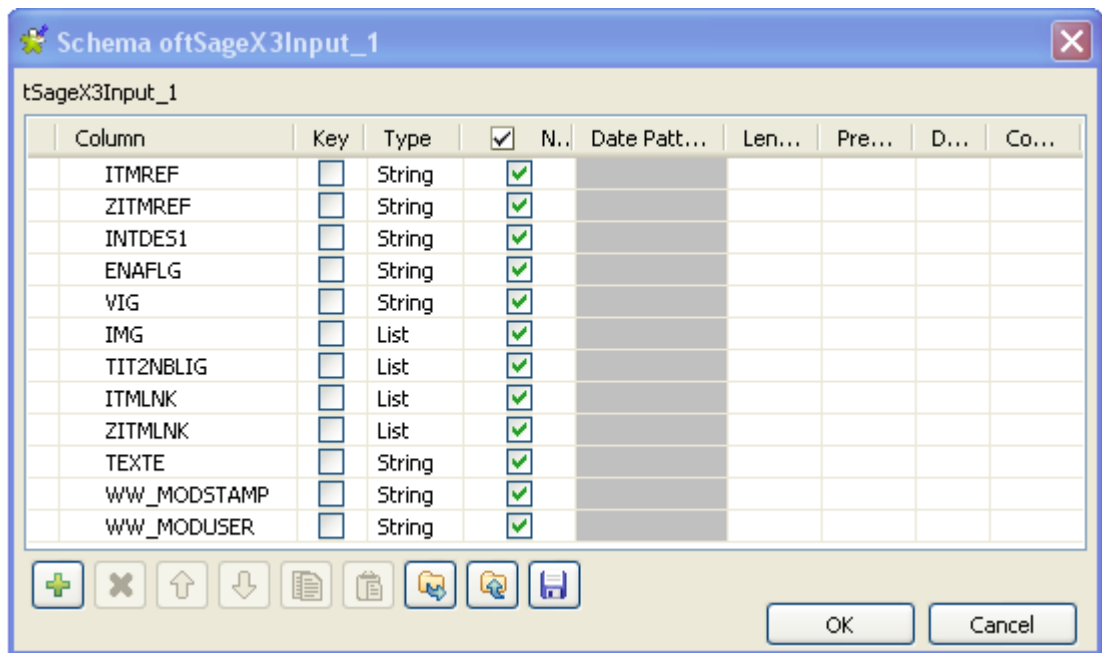

1. Drop the **tSageX3Input** component and the **tLogRow** components onto the workspace from **Palette**.
2. Connect the **tSageX3Input** component to the **tLogRow** component using a **Row > Main** link.

### Configuring the schema of tSageX3Input

1. Double-click **tSageX3Input** to set its properties in the **Basic Settings** view.

- Click the three-dot button next to **Edit schema** to open the schema editor.

- In this editor, click the plus button 12 times beneath the schema table to add 12 rows into this table.

4. Type in the names you want to use for each row. In this example, these rows are named after the publication names of the object attributes set in the Sage X3 Web server. These columns are used to map the corresponding attribute fields in the Sage X3 system.
5. In the **Type** column, click the *IMG* row to display its drop-down list.
6. From the drop-down list, select **List** as this attribute appears twice or even more and do the same to switch the types of the *TIT2NBLIG* row, the *ITMLNK* row and the *ZITMLNK* row to **List** as well for the same reason.
7. Click **OK** to validate this change and accept the propagation prompted by a pop-up dialog box.

## Configuring the connection to the Sage X3 Web server

1. In the **Endpoint address** field, type in the URL address of the Web service provided by the Sage X3 Web server. In this example, it is *http://10.42.20.168:28880/adxwsvc/services/CAdxWebServiceXmlCC*
2. In the **User** field, type in the user name of the given Sage X3. In this example, it is *ERP*.
3. In the **Language** field, type in the name of the X3 language code used to start a connection group. In this example, it is *FRA*.
4. In the **Pool alias** field, type in the name of connection pool to be used. In this example, this connection pool is called *TALEND*.
5. In the **Publication name** field, type in the publication name of the object to be called. In this scenario, the publication name is *ITMDET*.

## Setting up the mapping and configuring the query condition

1. In the **Group ID** column and the **Field name** column of the **Mapping** table, type in values corresponding to the attribute group IDs and the attribute publication names defined in the Sage X3 Web server. In this example, the values are presented in the figure below.

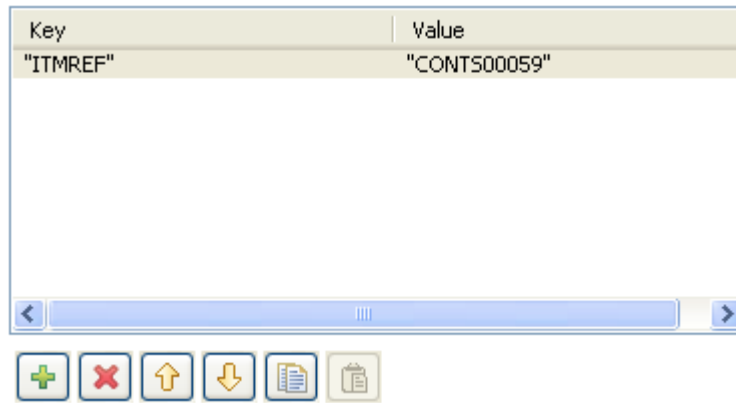

| Column      | Group ID | Field Name     |
|-------------|----------|----------------|
| ITMREF      | "TIT0_1" | "ITMREF"       |
| ZITMREF     | "TIT0_1" | "ZITMREF"      |
| INTDES1     | "TIT0_1" | "INTDES1"      |
| ENAF LG     | "TIT0_1" | "ENAF LG"      |
| VIG         | "TIT3_1" | "VIG"          |
| IMG         | "TIT3_1" | "IMG"          |
| TIT2NBLIG   | "TIT2_1" | "TIT2~NBLIG"   |
| ITMLNK      | "TIT2_1" | "ITMLNK"       |
| ZITMLNK     | "TIT2_1" | "ZITMLNK"      |
| TEXTE       | "TIT1_2" | "TEXTE"        |
| WW_MODSTAMP | "ADXTEC" | "WW_MODSTA..." |
| WW_MODUSER  | "ADXTEC" | "WW_MODUSER"   |

In the **Mapping** table, the **Column** column has been filled automatically with the columns you created in the schema editor.

2. Select the **Query condition** check box to activate the **Conditions** table.
3. Under the **Conditions** table, click the plus button to add one row into the table.
4. In the **Key** column, type in the publication name associated with the object attribute you need to extract data from.

- In the **Value** column, type in the value of the attribute you have selected as the key of the data extraction. In this scenario, it is *CONTS00059*, one of the product references.

## Job execution

- Press **Ctrl+S** to save your Job.
- Press **F6** or click **Run** on the **Run** tab to execute the Job.

The results are displayed on the **Run** console:

|            |                         |                          |             |                    |                       | tLogRow_1           |

## Scenario: Using a Sage X3 Web service to insert data into a given Sage X3 system

This scenario describes a two-component Job used to generate one row of data and insert the data into a given Sage X3 system. You can find the data used in this scenario in the example provided by Sage X3. The Sage X3 Web service is used to access an object.

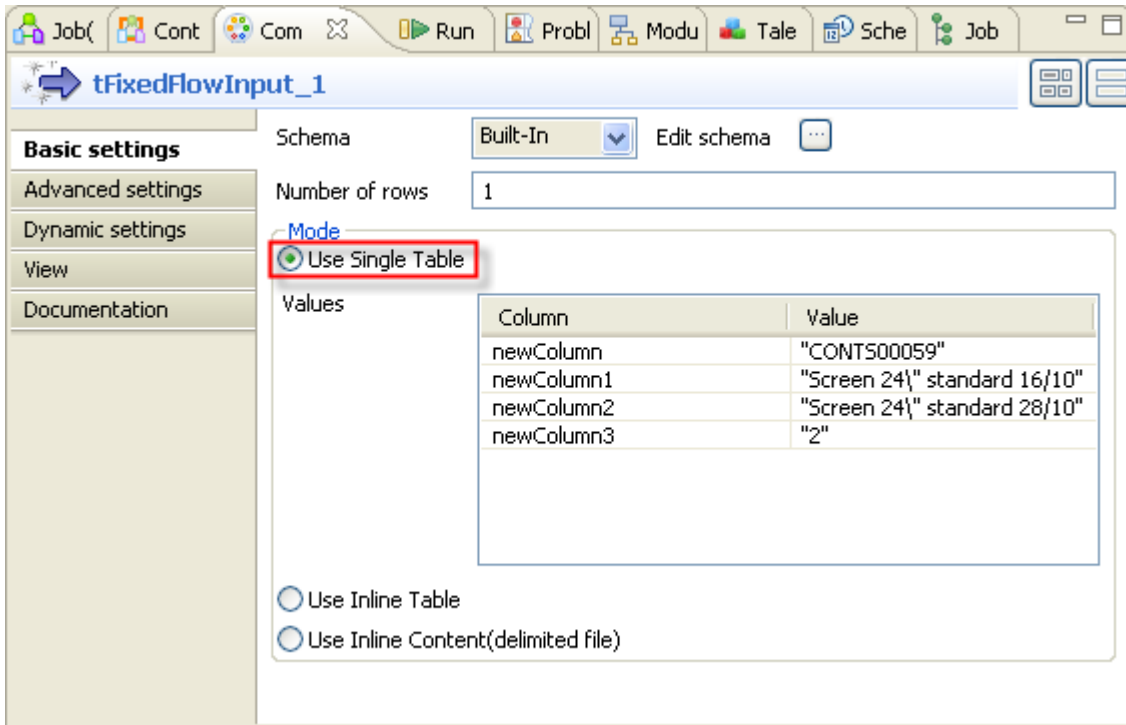

### Setting up the Job

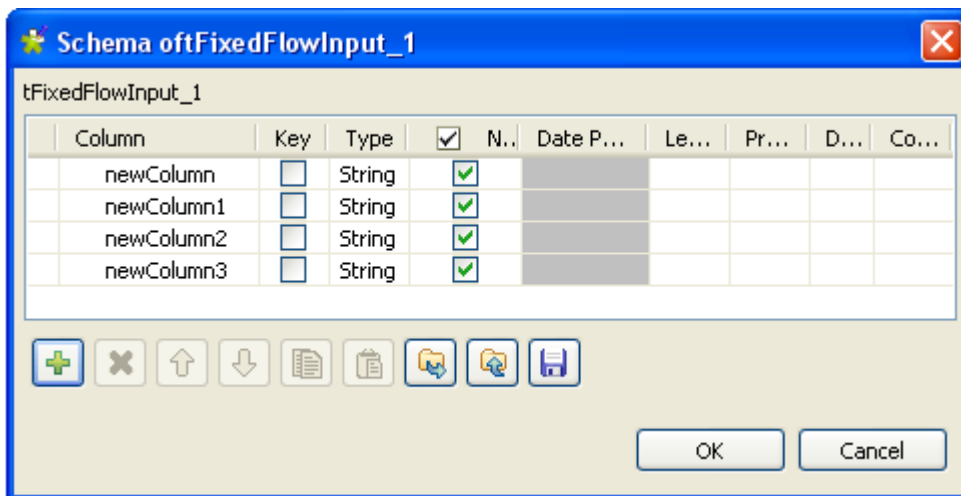

1. Drop the **tFixedFlowInput** and the **tSageX3Output** components onto the workspace from **Palette**.
2. Connect the **tFixedFlowInput** component to the **tSageX3Output** component using a **Row > Main** connection.

## Configuring the schema for the input data

1. Double-click the **tFixedFlowInput** component to set its **Basic Settings** in the **Component** view

2. Click the three-dot button next to **Edit schema** to open the schema editor.

3. In the schema editor and then under the schema table, click the plus button four times to add four rows.
4. Click **OK** to validate this changes and then accept the propagation prompted by the pop-up dialog box. The four rows appear automatically in the **Values** table of the **Component** view.
5. In the **Values** table within the **Mode** area, type in the values for each of the four rows in the **Value** column. In this scenario, the values downward are:

CONTS00059, Screen 24\" standard 16/10, Screen 24\" standard 28/10, 2

*These values in the Value column must be put between quotation marks.*

## Setting up the connection to the Sage X3 Web server

1. Double-click **tSageX3Output** to set its properties from the **Basic Settings** view.

The screenshot shows the configuration window for **tSageX3Output\_1**. The **Basic settings** tab is active, displaying the following fields:

- Schema:** Built-In (dropdown), Edit schema (button), Sync columns (button)
- Endpoint address:** "http://10.42.20.168:28880/adxwsvc/services/CAdxWebService" \*
- User:** "ERP" \*
- Password:** "" \*
- Language:** "FRA" \*
- Pool alias:** "TALEND" \*
- Request config:** "" \*
- Publication name:** "ITMDET" \*
- Action:** insert (dropdown) \*
- Mapping:** A table with columns: Column, Key, Group ID, Field Name.

| Column     | Key                      | Group ID | Field Name |
|------------|--------------------------|----------|------------|
| newColumn  | <input type="checkbox"/> | "TITO_1" | "ITMREF"   |
| newColumn1 | <input type="checkbox"/> | "TITO_1" | "ZITMREF"  |
| newColumn2 | <input type="checkbox"/> | "TITO_1" | "INTDES1"  |
| newColumn3 | <input type="checkbox"/> | "TITO_1" | "ENAF LG"  |

2. In the **Endpoint address** field, type in the URL address of the Web service provided by the Sage X3 Web server. In this example, it is *http://10.42.20.168:28880/adxwsvc/services/CAdxWebServiceXmlCC*
3. In the **User** field, type in the user name of the given Sage X3. In this example, it is *ERP*.
4. In the **Language** field, type in the name of the X3 language code used to start a connection group. In this example, it is *FRA*.
5. In the **Pool alias** field, type in the name of connection pool to be used. In this example, this connection pool is called *TALEND*.
6. In the **Publication name** field, type in the publication name of the object to be called. In this scenario, the publication name is *ITMDET*.
7. In the **Action** field, select **insert** from the drop-down list.

## Setting up the mapping

1. In the **Field name** column of the **Mapping** table, type in the field names of the attributes the selected data action is exercised on.
2. In the **Group ID** column of the **Mapping** table, type in values corresponding to group IDs of the selected attributes. These IDs are defined in the Sage X3 Web server

| Column     | <input type="checkbox"/> Key | Group ID | Field Name |
|------------|------------------------------|----------|------------|
| newColumn  | <input type="checkbox"/>     | "TITO_1" | "ITMREF"   |
| newColumn1 | <input type="checkbox"/>     | "TITO_1" | "ZITMREF"  |
| newColumn2 | <input type="checkbox"/>     | "TITO_1" | "INTDES1"  |
| newColumn3 | <input type="checkbox"/>     | "TITO_1" | "ENAF LG"  |

In the **Mapping** table, the **Column** column has been filled automatically with the columns retrieved from the schema of the preceding component.

## Job execution

Press CTRL+S to save your Job and press **F6** to execute it.

To verify the data that you inserted in this scenario, you can use the **tSageX3Input** component to read the concerned data from the Sage X3 server.

For further information about how to use the **tSageX3Input** component to read data, see [the section called “Scenario: Using query key to extract data from a given Sage X3 system”](#).

# tSalesforceBulkExec

## tSalesforceBulkExec Properties

**tSalesforceOutputBulk** and **tSalesforceBulkExec** components are used together to output the needed file and then execute intended actions on the file for your Salesforce.com. These two steps compose the **tSalesforceOutputBulkExec** component, detailed in a separate section. The interest in having two separate elements lies in the fact that it allows transformations to be carried out before the data loading.

|                         |                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Limitation</b>        | n/a                                                                                                          |                                                                                                                                                                                             |

## Scenario: Recovering deleted data from the Salesforce server

This scenario describes a two-component Job that collects the deleted data over the past 5 days from the Salesforce server.

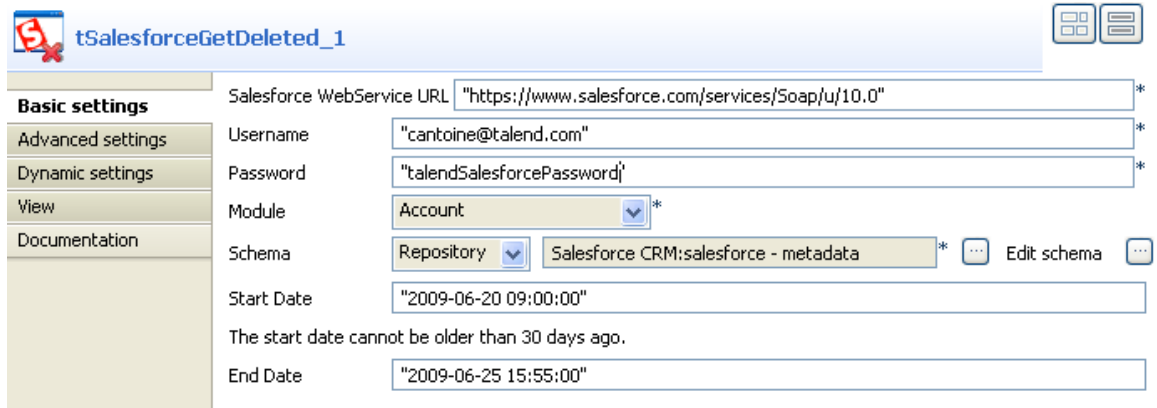

### Setting up the Job

1. Drop **tSalesforceGetDeleted** and **tLogRow** from the **Palette** onto the design workspace.
2. Connect the two components together using a **Row > Main** connection.

### Setting up the connection to the Salesforce server

1. Double-click **tSalesforceGetDeleted** to display its **Basic settings** view and define the component properties.

**tSalesforceGetDeleted\_1**

**Basic settings**

Salesforce Webservice URL: "https://www.salesforce.com/services/Soap/u/10.0" \*

Username: "cantoine@talend.com" \*

Password: "talendSalesforcePassword" \*

Module: Account \*

Schema: Repository | Salesforce CRM:salesforce - metadata \* Edit schema

Start Date: "2009-06-20 09:00:00"

The start date cannot be older than 30 days ago.

End Date: "2009-06-25 15:55:00"

2. In the **Salesforce Webservice URL** field, use the by-default URL of the Salesforce Web service or enter the URL you want to access.
3. In the **Username** and **Password** fields, enter your login and password for the Web service.
4. From the **Module** list, select the object you want to access, **Account** in this example.

## Setting the search condition

1. Click the three-dot button next to the **Edit schema** field to open the dialog box where you can set the schema manually.
2. In the **Start Date** and **End Date** fields, enter respectively the start and end dates for collecting the deleted data using the following date format: "yyyy-MM-dd HH:mm:ss". You can collect deleted data over the past 30 days. In this example, we want to recover deleted data over the past 5 days.

## Job execution

1. Double-click **tLogRow** to display its **Basic settings** view and define the component properties.
2. Click **Sync columns** to retrieve the schema from the preceding component.
3. In the **Mode** area, select **Vertical** to display the results in a tabular form on the console.
4. Press **Ctrl+S** to save your Job and press **F6** to execute it.

*Starting job tSalesforceGetDeleted\_scenario at 17:17 25/06/2009.*

| <b>Limitation</b>        | n/a                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Scenario: Using queries to extract data from a Salesforce database

This scenario describes a four-component Job used to extract specific sets of data from parent and child objects in a Salesforce database.

### Setting up the Job

1. Drop two **tSalesforceInput** components and two **tLogRow** components onto the workspace.
2. Connect each **tSalesforceInput** component to a **tLogRow** component using a **Row > Main** connection for each pair.
3. Connect **tSalesforceInput\_1** to **tSalesforceInput\_2** using an **OnSubjobOk** connection.

### Setting up the connection to the Salesforce server for the parent object

1. Double-click **tSalesforceInput\_1** to set its **Basic Settings** in the **Component** tab.

Property Type

Use an existing connection

Salesforce Webservice URL  \*

Username  \*

Password  \*

Timeout(milliseconds)

Module  \*

Schema

Manual input of SOQL query

Query

Query all records(include deleted records)

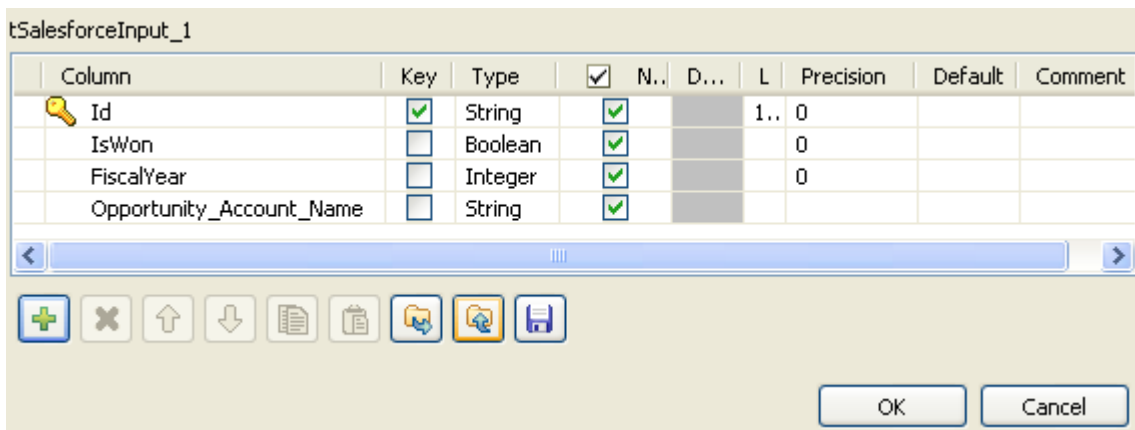

2. Enter the **Salesforce Webservice URL** of the database you want to connect to in the corresponding field.
3. Enter your authentication information in the corresponding **Username** and **Password** fields.
4. Enter the desired query **Timeout (milliseconds)** limit.

## Setting the query and the schema for the parent object

1. Select the **Module** (salesforce object) you want to query.
2. Select the **Manual input of SOQL Query** check box and enter your query scripts in the enabled **Query** field.

The query scripts you enter should follow the SOQL syntax.

3. Click [...] next to **Edit schema** to open the schema editor.

In this example, the *IsWon* and *FiscalYear* columns in the query are located in the **Opportunity** module specified. The *Name* column is in a linked module called *Account*. To return a column from a linked module the correct syntax is to enter the name of the linked module, followed by the period character, then the name of the column of interest. Hence, the query required in this example is:

```
"SELECT IsWon, FiscalYear, Account.Name FROM Opportunity"
```

4. Click the plus button to add a new column for the fields taken from the *Name* column in the *Account* module.
5. Name this column *Opportunity\_Account\_Name* and click **OK** to save the changes.

*To retrieve a column from a linked module, it is necessary to define the column in a particular manner in the **Edit schema** view. The correct syntax is: *NameofCurrentModule\_NameofLinkedModule\_NameofColumnofInterest*. Hence, in this example, the column must be named: *Opportunity\_Account\_Name*. If this syntax is not respected then the data from the linked table will not be returned.*

## Setting up the connection to the Salesforce server for the child object

1. Double-click **tSalesforceInput\_2** to set its **Basic settings** in the **Component** tab.

2. Enter the **Salesforce Webservice URL** of the database you want to connect to in the corresponding field.  
The query scripts you enter must follow the SOQL syntax.
3. Enter your authentication information in the corresponding **Username** and **Password** fields.
4. Enter the desired query **Timeout (milliseconds)** limit.

## Setting the query and the schema for the child object

1. Select the **Module** (salesforce object) you want to query.
2. Select the **Manual input of SOQL Query** check box and enter your query scripts in the enabled **Query** field.

In this example we want to extract the *Id* and *CaseNumber* fields from the *Case* module as well as the *Name* fields from the *Account* module. The query is therefore: .

```
"SELECT Id, CaseNumber, Account.Name FROM Case"
```

3. Click [...] next to **Edit schema** to open the schema editor.

| Column            | Key                                 | Type   | <input checked="" type="checkbox"/> | N. | Date Patt... | Len... | Pre... | D... | Co... |
|-------------------|-------------------------------------|--------|-------------------------------------|----|--------------|--------|--------|------|-------|
| Id                | <input checked="" type="checkbox"/> | String | <input checked="" type="checkbox"/> |    |              | 18     | 0      |      |       |
| CaseNumber        | <input type="checkbox"/>            | String | <input checked="" type="checkbox"/> |    |              | 30     | 0      |      |       |
| Case_Account_Name | <input type="checkbox"/>            | String | <input checked="" type="checkbox"/> |    |              |        |        |      |       |

4. Click the plus button to add a new column for the fields taken from the *Name* column in the *Account* module.
5. Name this column *Case\_Account\_Name* and click **OK** to save the changes.

## Job execution

1. Click each **tLogRow** component and set their component properties in the **Basic settings** view as desired.

In this example, there is no need to modify the **tLogRow** settings.

2. Press **Ctrl+S** to save your Job and press **F6** to execute it.

The results are displayed in the **Run** tab:

| <b>Limitation</b>        | n/a                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Scenario 1: Deleting data from the Account object

This scenario describes a two-component Job that removes an entry from the Account object.

### Dragging and dropping as well as connecting the components

1. Drop **tSalesforceInput** and **tSalesforceOutput** from the **Palette** onto the design workspace.
2. Connect the two components together using a **Row > Main** link.

### Configuring the components

#### Querying the content to be deleted

1. Double-click **tSalesforceInput** to display its **Basic settings** view and define the component properties.

| salesforce(tSalesforceInput_1) |                                                                              |
|--------------------------------|------------------------------------------------------------------------------|
| <b>Basic settings</b>          | Property Type: Built-In                                                      |
| Advanced settings              | Salesforce WebService URL: "https://www.salesforce.com/services/Soap/u/10.0" |
| Dynamic settings               | Username: "cantoine@talend.com"                                              |
| View                           | Password: " talendSalesforcePassword"                                        |
| Documentation                  | Module: Account                                                              |
|                                | Schema: Built-In                                                             |
|                                | Query Condition: "name='sForce'"                                             |
|                                | <input type="checkbox"/> Manual input of SOQL query                          |

2. In the **Salesforce WebService URL** field, use the default URL of the Salesforce Web service or enter the URL you want to access or select the **Use an existing connection** check box to use an established connection.
3. In the **Username** and **Password** fields, enter your login and password for the Web service.
4. Type in your intended query timeout in the **Timeout (milliseconds)** field. In this example, use the default number.
5. From the **Module** list, select the object you want to access, **Account** in this example.
6. Click the three-dot button next to the **Edit schema** field to open the dialog box where you can set the schema manually.
7. In the **Query Condition** field, enter the query you want to apply. In this example, we want to retrieve the clients whose names are *sForce*. To do this, we use the query: "name= 'sForce' ".

- For a more advanced query, select the Manual input of SOQL query and enter the query manually.

## Deleting the queried contents

- Double-click **tSalesforceOutput** to display its **Basic settings** view and define the component properties.

- In the **Salesforce Webservice URL** field, use the default URL of the Salesforce Web service or enter the URL you want to access.
- In the **Username** and **Password** fields, enter your login and password for the Web service.
- Type in your intended query timeout in the **Timeout (milliseconds)** field. In this example, use the default number.
- From the **Action** list, select the operation you want to carry out. In this example we select **Delete** to delete the *sForce* account selected in the previous component.
- From the **Module** list, select the object you want to access, **Account** in this example.
- Click **Sync columns** to retrieve the schema of the preceding component.
- Press **Ctrl+S** to save your Job.

## Executing the Job

- Press **F6** to execute the Job.

Check the content of the **Account** object and verify that the *sForce* account(s) is/are deleted from the server.

## Scenario 2: Gathering erroneous data while inserting data to a module at Salesforce.com

In this scenario, data in a local file is inserted to the **AdditionalNumber** module. Meanwhile, erroneous data in that file is collected via a **Row > Reject** link.

## Dragging and dropping components and linking them together

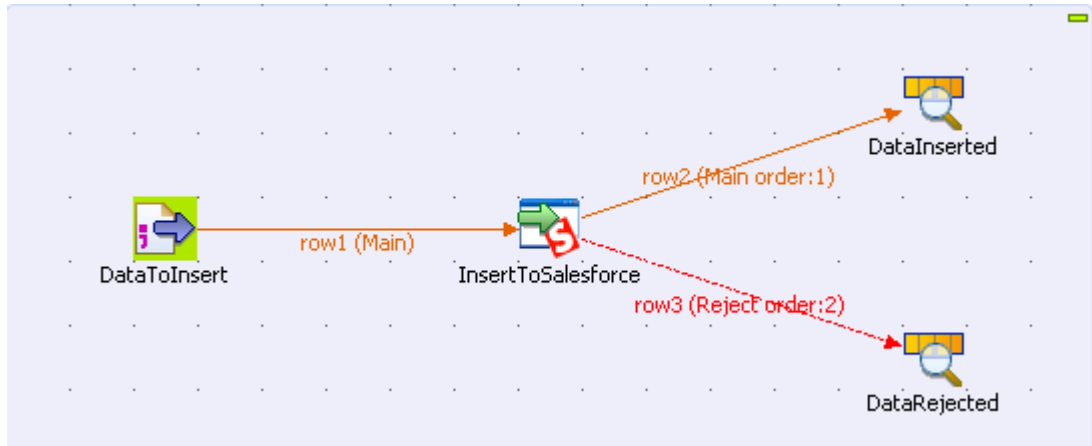

- Drag and drop the following components from the **Palette** onto the workspace: **tFileInputDelimited**, **tSalesforceOutput** and two **tLogRow** components.

- Rename **tFileInputDelimited** as **DataToInsert**, **tSalesforceOutput** as **InsertToSalesforce**, and the two **tLogRow** components as **DataInserted** as well as **DataRejected** respectively.
- Link **DataToInsert** to **InsertToSalesforce** using a **Row > Main** connection.
- Link **InsertToSalesforce** to **DataInserted** using a **Row > Main** connection.
- Link **InsertToSalesforce** to **DataRejected** using a **Row > Reject** connection.

Deselect the **Extended Output** and **Die on error** check boxes in the **Advanced settings** view of the **tSalesforceOutput** component so that the **Reject** link is available .

## Configuring the components

### Configuring the data source

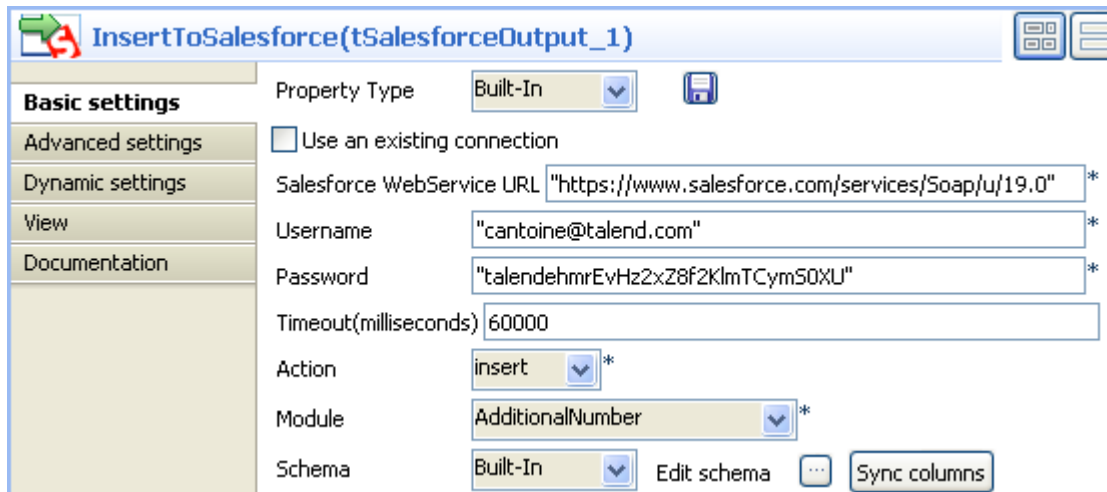

- Double-click **DataToInsert** to open its **Basic settings** view in the **Component** tab.

| DataToInsert (tFileInputDelimited_1) |                                                                                                                                           |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Basic settings</b>                | Property Type: Built-In                                                                                                                   |
| Advanced settings                    | "When the input source is a stream or a zip file, footer and random shouldn't be bigger than 0."                                          |
| Dynamic settings                     | File name/Stream: "E:/salesforceout.csv" *                                                                                                |
| View                                 | Row Separator: "\n"      Field Separator: ";" *                                                                                           |
| Documentation                        | <input type="checkbox"/> CSV options                                                                                                      |
|                                      | Header: 1      Footer: 0      Limit:                                                                                                      |
|                                      | Schema: Built-In      Edit schema: ...                                                                                                    |
|                                      | <input checked="" type="checkbox"/> Skip empty rows <input type="checkbox"/> Uncompress as zip file <input type="checkbox"/> Die on error |

- In the **File name/Stream** field, type in the path of the source file, for example, *E:/salesforceout.csv*.
- In the **Header** field, type in *1* to retrieve the column names. Keep the default settings for other fields.

### Configuring the module for data insertion

- Double-click **InsertToSalesforce** to open its **Basic settings** view in the **Component** tab.

2. In the **Username** field, enter your username, for example, *cantoine@talend.com*.
3. In the **Password** field, enter your password, for example, *talendehmrEvHz2xZ8f2KlmTCymS0XU*.
4. In the **Action** drop-down list, select **insert**.
5. In the **Module** drop-down list, select **AdditionalNumber**.

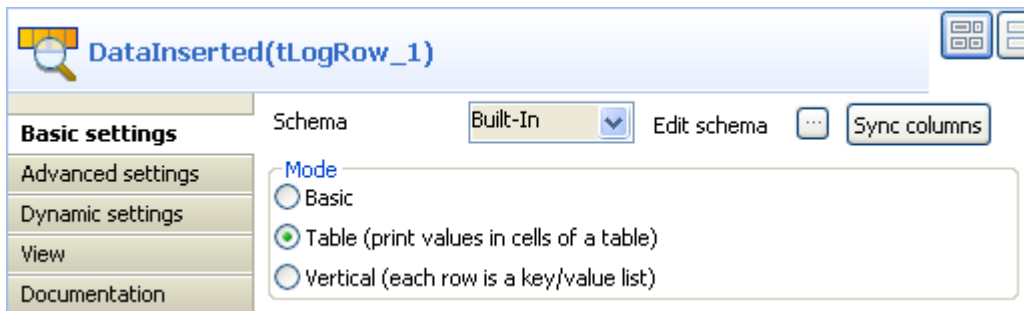

When linking the components earlier, the **Extended Output** and **Die on error** check boxes have been deselected in the **Advanced settings** view so that the **Reject** link can appear.

6. Keep the default settings for other fields.

### Configuring the console display

1. Double-click **DataInserted** to open its **Basic settings** view in the **Component** tab.

2. In the **Mode** area, select **Table (print values in cells of a table)** for a better view.
3. Perform the same operation for **DataRejected**.
4. Press **Ctrl+S** to save your Job.

### Executing the Job

- Press **F6** to run the Job and you can find the erroneous data (if any) is displayed in the **Run** view.

```

tLogRow_2
|-----+-----+-----+-----|
|-----+-----+-----+-----|
|CallCenterId |Name |Description |Phone
|errorCode |errorFields|errorMessage |
|-----+-----+-----+-----|
|-----+-----+-----+-----|
|03m70000000CaZBAA0|Talend Testing V19|Conduct testing on
TOS|0086-010-88888888|FIELD_INTEGRITY_EXCEPTION|CallCenterId|Call Center ID:
id value of incorrect type: 03m70000000CaZBAA0|
|04m70000000CaZBAA0|Talend Testing V19|Conduct testing on
TOS|0086-010-88888888|FIELD_INTEGRITY_EXCEPTION|CallCenterId|Call Center ID:
id value of incorrect type: 04m70000000CaZBAA0|
|-----+-----+-----+-----|
|-----+-----+-----+-----|

```

As shown above, there are two **Call Center ID** fields that have incorrect data.

# tSalesforceOutputBulk

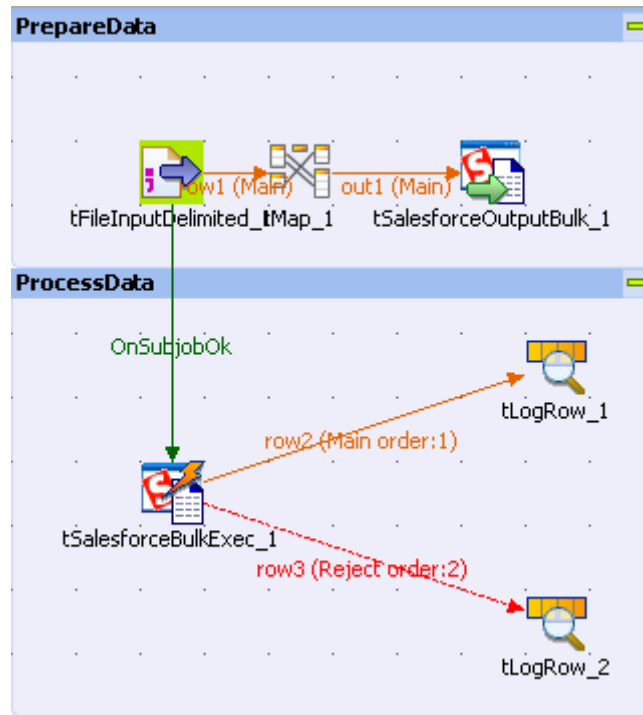

## tSalesforceOutputBulk Properties

**tSalesforceOutputBulk** and **tSalesforceBulkExec** components are used together to output the needed file and then execute intended actions on the file for your Salesforce.com. These two steps compose the **tSalesforceOutputBulkExec** component, detailed in a separate section. The interest in having two separate elements lies in the fact that it allows transformations to be carried out before the data loading.

|                          |                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Usage</b>             | This component is intended for the use along with <b>tSalesforceBulkExec</b> component. Used together they gain performance while feeding or modifying information in Salesforce.com.                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Limitation</b>        | Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> . |                                                                                                                                                                                                                                                                                                                                                                                              |

## Scenario: Inserting transformed bulk data into your Salesforce.com

This scenario describes a six-component Job that transforms .csv data suitable for bulk processing, load them in Salesforce.com and then displays the Job execution results in the console.

This Job is composed of two steps: preparing data by transformation and processing the transformed data.

Before starting this scenario, you need to prepare the input file which offers the data to be processed by the Job. In this use case, this file is *sforcebulk.txt*, containing some customer information.

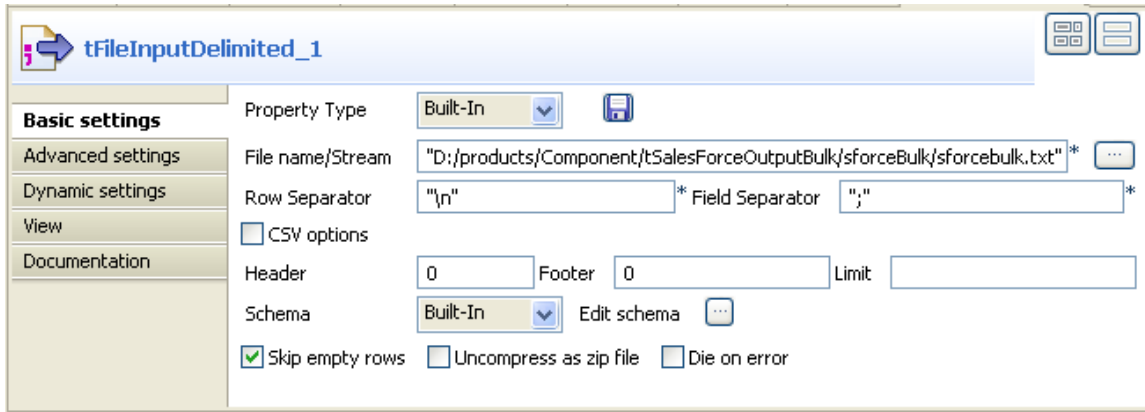

Then to create and execute this Job, operate as follows:

## Setting up the Job

1. Drop **tFileInputDelimited**, **tMap**, **tSalesforceOutputBulk**, **tSalesforceBulkExec** and **tLogRow** from the **Palette** onto the workspace of your studio.
2. Use a **Row > Main** connection to connect **tFileInputDelimited** to **tMap**, and **Row > out1** from **tMap** to **tSalesforceOutputBulk**.
3. Use a **Row > Main** connection and a **Row > Reject** connection to connect **tSalesforceBulkExec** respectively to the two **tLogRow** components.
4. Use a **Trigger > OnSubjobOk** connection to connect **tFileInputDelimited** and **tSalesforceBulkExec**.

## Configuring the input component

1. Double-click **tFileInputDelimited** to display its **Basic settings** view and define the component properties.

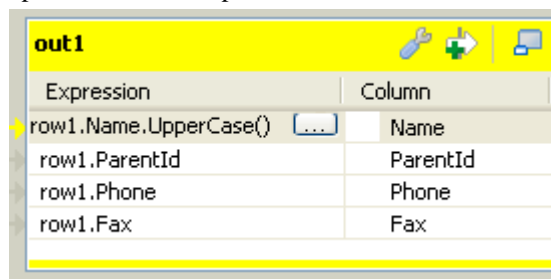

- Next to the **File name/Stream** field, click the [...] button to browse to the input file you prepared for the scenario, for example, *sforcebulk.txt*.
- Click the three-dot button next to the **Edit schema** field to open the dialog box to set the schema. In this scenario, the schema is made of four columns: *Name*, *ParentId*, *Phone* and *Fax*.

| Column   | Key                      | Type   | <input checked="" type="checkbox"/> | N... | Date Patt... | Length | Pre... | D... | Co... |
|----------|--------------------------|--------|-------------------------------------|------|--------------|--------|--------|------|-------|
| Name     | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |      |              |        |        |      |       |
| ParentId | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |      |              |        |        |      |       |
| Phone    | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |      |              |        |        |      |       |
| Fax      | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |      |              |        |        |      |       |

- According to your input file to be used by the Job, set the other fields like **Row Separator**, **Field Separator**...

## Setting up the mapping

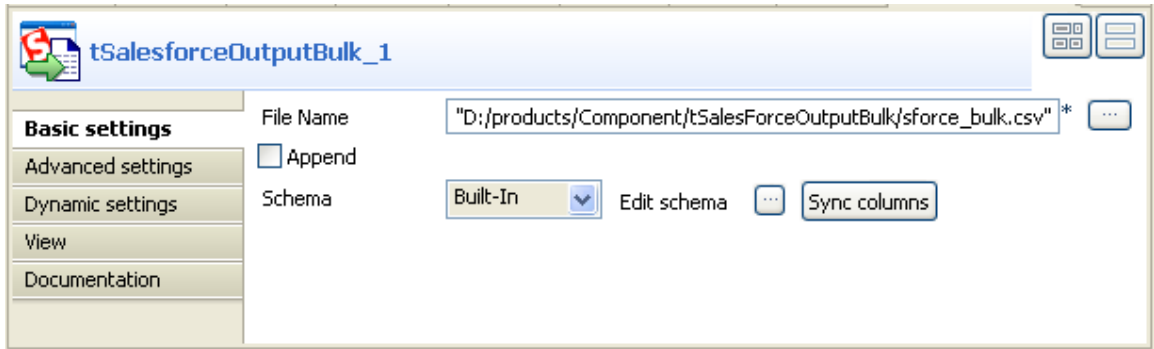

- Double-click the **tMap** component to open its editor and set the transformation.
- Drop all columns from the input table to the output table.

- Add `.toUpperCase()` behind the *Name* column.
- Click **OK** to validate the transformation.

## Defining the output path

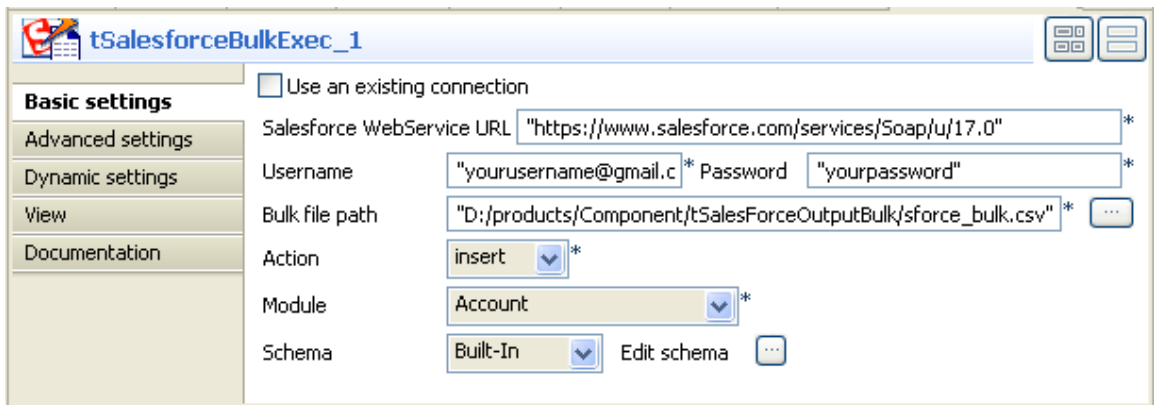

- Double-click **tSalesforceOutputBulk** to display its **Basic settings** view and define the component properties.

2. In the **File Name** field, type in or browse to the directory where you want to store the generated `.csv` data for bulk processing.
3. Click **Sync columns** to import the schema from its preceding component.

## Setting up the connection to the Salesforce server

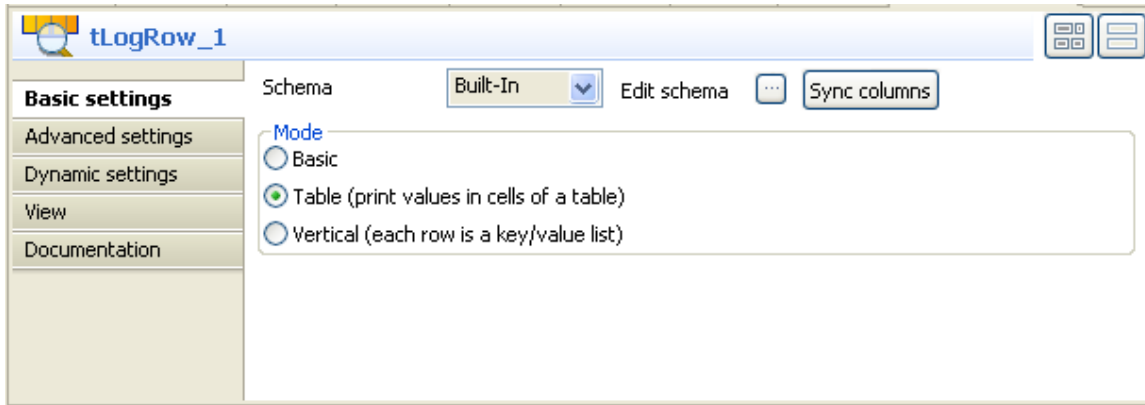

1. Double-click **tSalesforceBulkExec** to display its **Basic settings** view and define the component properties.

2. Use the by-default URL of the Salesforce Web service or enter the URL you want to access.
3. In the **Username** and **Password** fields, enter your username and password for the Web service.
4. In the **Bulk file path** field, browse to the directory where is stored the generated `.csv` file by **tSalesforceOutputBulk**.
5. From the **Action** list, select the action you want to carry out on the prepared bulk data. In this use case, **insert**.
6. From the **Module** list, select the object you want to access, **Account** in this example.
7. Click the three-dot button next to the **Edit schema** field to open the dialog box to set the schema. In this example, edit it conforming to the schema defined previously.

## Configuring the output component

1. Double-click **tLogRow\_1** to display its **Basic settings** view and define the component properties.

2. Click **Sync columns** to retrieve the schema from the preceding component.
3. Select **Table** mode to display the execution result.
4. Do the same with **tLogRow\_2**.

## Job execution

1. Press **CTRL+S** to save your Job.
2. Press **F6** to execute it.

You can check the execution result on the **Run** console.

```

In the **tLogRow\_1** table, you can read the data inserted into your Salesforce.com.

In the **tLogRow\_2** table, you can read the rejected data due to the incompatibility with the **Account** objects you have accessed.

All the customer names are written in upper case.

# tSalesforceOutputBulkExec

## tSalesforceOutputBulkExec Properties

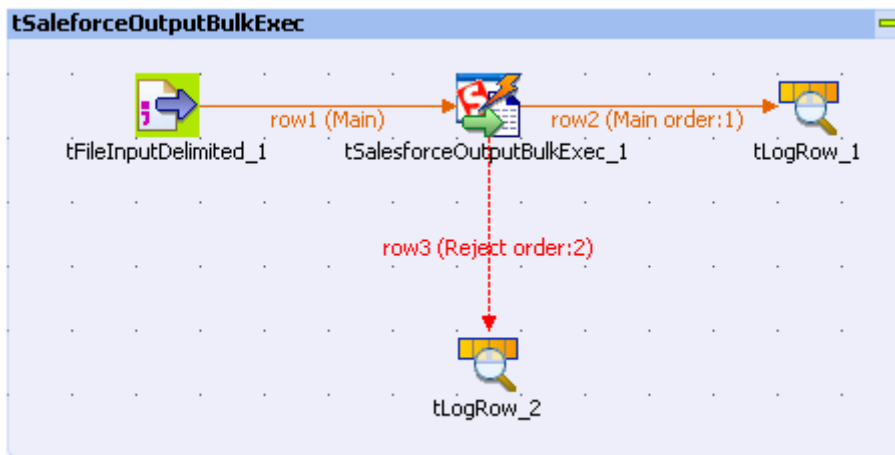

**tSalesforceOutputBulk** and **tSalesforceBulkExec** components are used together to output the needed file and then execute intended actions on the file for your Salesforce.com. These two steps compose the **tSalesforceOutputBulkExec** component, detailed in a separate section. The interest in having two separate elements lies in the fact that it allows transformations to be carried out before the data loading.

In this case, you should fill in the proxy parameters in the <b>Proxy host</b> , <b>Proxy port</b> , <b>Proxy username</b> and <b>Proxy password</b> fields which appear beneath.                                                                                                                                                        |
|                          | <i>Ignore NULL fields values</i>                                                                                          | Select this check box to ignore NULL values in <b>Update</b> or <b>Upsert</b> mode.                                                                                                                                                                                                                                                                                                               |
|                          | <i>tStatCatcher Statistics</i>                                                                                            | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.                                                                                                                                                                                                                                                                                    |
| <b>Usage</b>             | This component is mainly used when no particular transformation is required on the data to be loaded into Salesforce.com. |                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Limitation</b>        | The bulk data to be processed in Salesforce.com should be .csv format.                                                    |                                                                                                                                                                                                                                                                                                                                                                                                   |

## Scenario: Inserting bulk data into your Salesforce.com

This scenario describes a four-component Job that submits bulk data into Salesforce.com, executes your intended actions on the data, and ends up with displaying the Job execution results for your reference.

Before starting this scenario, you need to prepare the input file which offers the data to be processed by the Job. In this use case, this file is *sforcebulk.txt*, containing some customer information.

Then to create and execute this Job, operate as follows:

## Setting up the Job

1. Drop **tFileInputDelimited**, **tSalesforceOutputBulkExec**, and **tLogRow** from the **Palette** onto the workspace of your studio.
2. Use **Row > Main** connection to connect **tFileInputDelimited** to **tSalesforceOutputBulkExec**.
3. Use **Row > Main** and **Row > Reject** to connect **tSalesforceOutputBulkExec** respectively to the two **tLogRow** components.

## Setting the input data

1. Double-click **tFileInputDelimited** to display its **Basic settings** view and define the component properties.

The screenshot shows the 'Basic settings' view for the 'tFileInputDelimited\_1' component. The settings are as follows:

- Property Type: Built-In
- File name/Stream: "D:/products/Component/tSalesForceOutputBulk/sforceBulk/sforcebulk.txt"\*
- Row Separator: "\n" \* Field Separator: ";"\*
- CSV options:
- Header: 0 Footer: 0 Limit:
- Schema: Built-In Edit schema ...
- Skip empty rows  Uncompress as zip file  Die on error

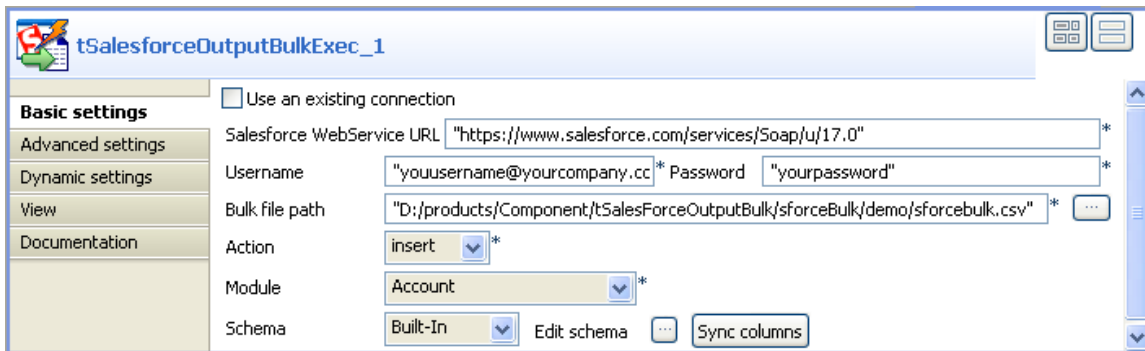

2. Next to the **File name/Stream** field, click the [...] button to browse to the input file you prepared for the scenario, for example, *sforcebulk.txt*.
3. Click the three-dot button next to the **Edit schema** field to open the dialog box where you can set the schema manually. In this scenario, the schema is made of four columns: *Name*, *ParentId*, *Phone* and *Fax*.

| Column   | Key                      | Type   | ✓                                   | N.. | Date Patt... | Length | Pre... | D... | Co... |
|----------|--------------------------|--------|-------------------------------------|-----|--------------|--------|--------|------|-------|
| Name     | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     |              |        |        |      |       |
| ParentId | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     |              |        |        |      |       |
| Phone    | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     |              |        |        |      |       |
| Fax      | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     |              |        |        |      |       |

4. According to your input file to be used by the Job, set the other fields like **Row Separator**, **Field Separator...**

## Setting up the connection to the Salesforce server

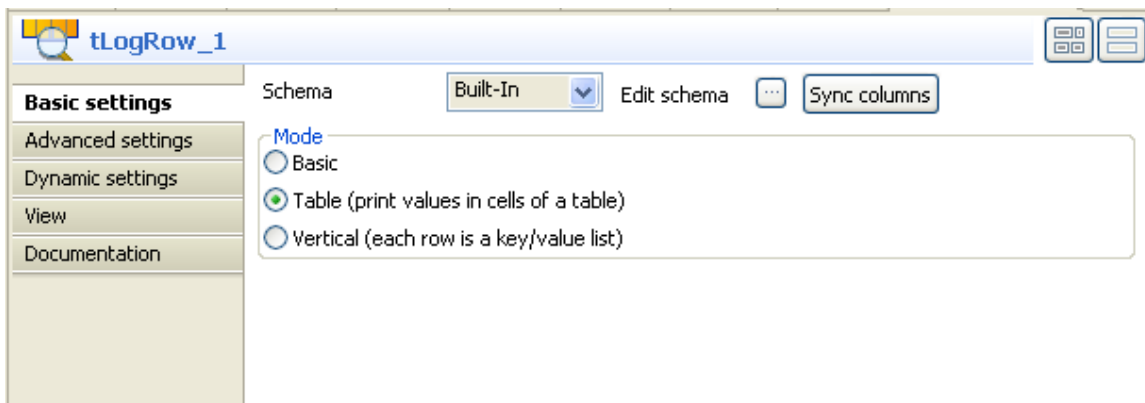

1. Double-click **tSalesforceOutputBulkExec** to display its **Basic settings** view and define the component properties.

2. In **Salesforce Webservice URL** field, use the by-default URL of the Salesforce Web service or enter the URL you want to access.
3. In the **Username** and **Password** fields, enter your username and password for the Web service.
4. In the **Bulk file path** field, browse to the directory where you store the bulk *.csv* data to be processed.
  -  The bulk file here to be processed must be in *.csv* format.
5. From the **Action** list, select the action you want to carry out on the prepared bulk data. In this use case, **insert**.
6. From the **Module** list, select the object you want to access, **Account** in this example.
7. Click the three-dot button next to the **Edit schema** field to open the dialog box where you can set the schema manually. In this example, edit it conforming to the schema defined previously.

## Job execution

1. Double-click **tLogRow\_1** to display its **Basic settings** view and define the component properties.

2. Click **Sync columns** to retrieve the schema from the preceding component.
3. Select **Table** mode to display the execution result.
4. Do the same with **tLogRow\_2**.
5. Press **CTRL+S** to save your Job and press **F6** to execute it.

On the console of the **Run** view, you can check the execution result.

```

[statistics] connected

 tLogRow_1

Name ParentId Phone Fax salesforce_id sales
Burlington Textiles Corp of America null (336) 222-7000 (336) 222-8000 0018000000gfDyDAAU true
Dickenson plc null (785) 241-6200 (785) 241-6201 0018000000gfDyEAAU true
GenePoint null (650) 867-3450 (650) 867-9895 0018000000gfDyFAAU true

 tLogRow_2

Name ParentId Phone Fax error
Edge Communications wrong id (512) 757-6000 (512) 757-9000 MALFORMED_ID:Parent Account ID: :
Grand Hotels & Resorts Ltd wrong id (312) 596-1000 (312) 596-1500 MALFORMED_ID:Parent Account ID: :

```

In the **tLogRow\_1** table, you can read the data inserted into your Salesforce.com.

In the **tLogRow\_2** table, you can read the rejected data due to the incompatibility with the **Account** objects you have accessed.

If you want to transform the input data before submitting them, you need to use **tSalesforceOutputBulk** and **tSalesforceBulkExec** in cooperation to achieve this purpose. For further information on the use of the two components, see [the section called “Scenario: Inserting transformed bulk data into your Salesforce.com”](#).

# tSAPBWInput

## tSAPBWInput Properties

|                          |                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                    |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Component family</b>  | Business                                                                                                                                                                                                          |                                                                                                                                                                                                                                                                                    |
| <b>Function</b>          | <b>tSAPBWInput</b> reads data from an SAP BW database using a JDBC API connection and extracts fields based on an SQL query.                                                                                      |                                                                                                                                                                                                                                                                                    |
| <b>Purpose</b>           | This component executes an SQL query with a strictly defined order which must correspond to your schema definition. Then it passes on the field list to the next component via a <b>Row &gt; Main</b> connection. |                                                                                                                                                                                                                                                                                    |
| <b>Basic settings</b>    | <i>Property type</i>                                                                                                                                                                                              | In <i>Talend Open Studio for Big Data</i> , the Property type is always <b>Built-in</b> :<br><b>Built-in</b> : No property data stored centrally.                                                                                                                                  |
|                          | <i>Schema and Edit Schema</i>                                                                                                                                                                                     | A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> .<br><br>Click <b>Edit Schema</b> to make changes to the schema. |
|                          | <i>JDBC URL</i>                                                                                                                                                                                                   | Enter the JDBC URL of the database you want to connect to. For example, enter: <i>jdbc:jdbc4olap://server_address/database_name</i> to connect to an SAP BW database.                                                                                                              |

## Scenario: Reading data from SAP BW database

This scenario describes a two-component Job that reads data from an SAP BW database. The data is fetched and displayed on the console.

Prior to setting up the Job, make sure the following prerequisites are met:

1. Copy the following .jar files which compose the jdbc4olap driver to your class path:

-activation.jar

-commons-codec.jar

-jdbc4olap.jar

-saaj-api.jar

-saaj-impl.jar

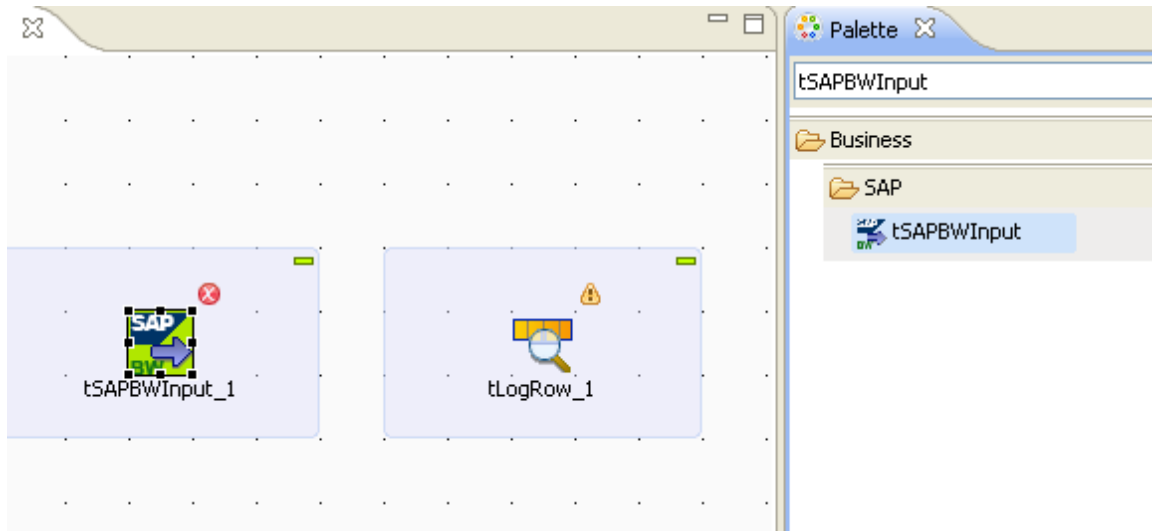

2. Make sure that you have the latest version of jdbc4olap driver. You can download the latest version of jdbc4olap driver from [jdbc4olap download section](#). For further information about the usage of jdbc4olap driver, see [jdbc4olap User Guide](#).

The procedure of this scenario requires 4 main steps detailed hereafter:

1. Set up the Job.
2. Set up the jdbc connection to the SAP BW server.
3. Set up a query.
4. Display the fetched data on the console.

### Set up the Job

1. Drop a **tSAPBWInput** component and a **tLogRow** component from the **Palette** onto the workspace.

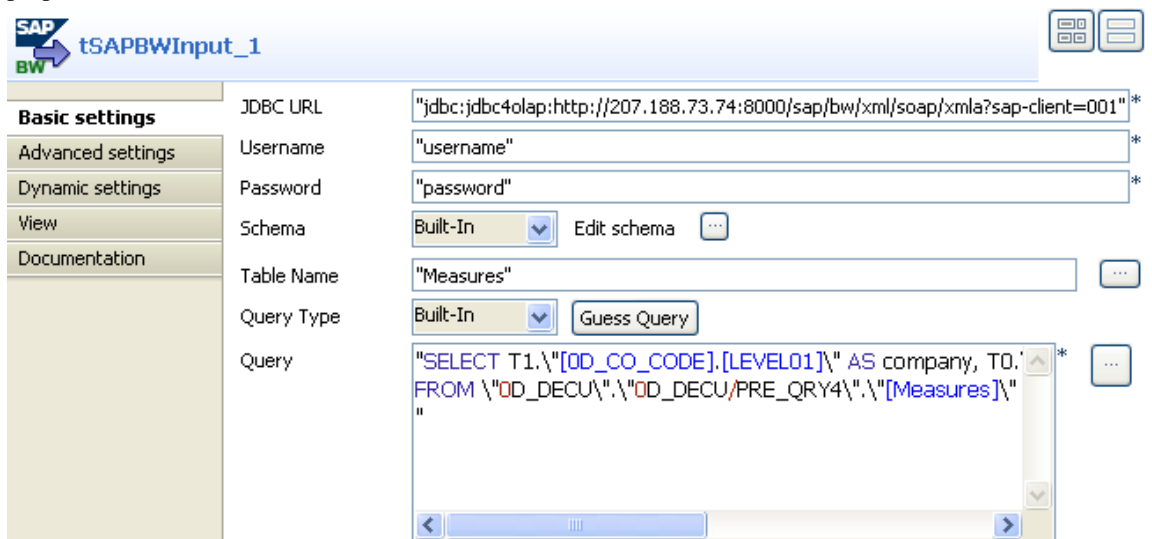

2. Connect the **tSAPBWInput** component and the **tLogRow** component using a **Row > Main** connection.

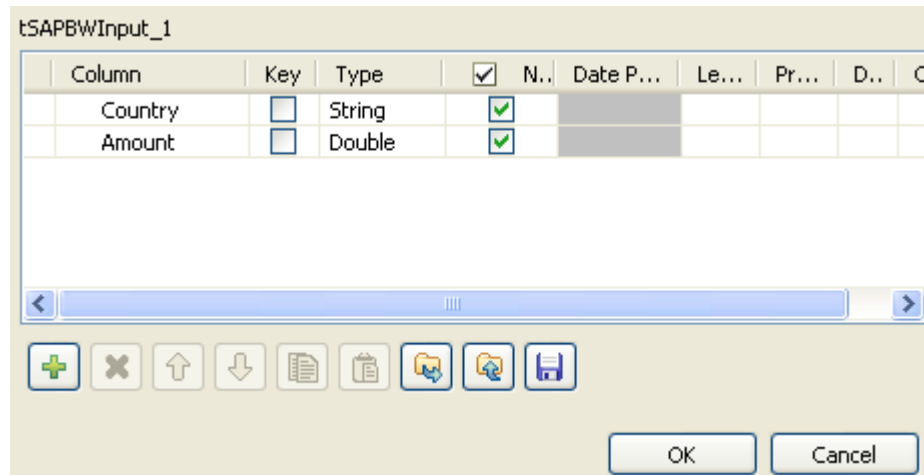

## Set up the jdbc connection to the SAP BW server

1. Double-click the **tSAPBWInput** component to open its **Basic settings** view and define the component properties.

2. Fill the **JDBC URL** field with the URL of your jdbc4olap server.  
Note that the URL displayed above is for demonstration only.
3. Fill the **Username** and **Password** fields with your username and password for the DB access authentication.
4. Click the three-dot button next to **Edit schema** to define the schema to be used.

5. Click the plus button to add new columns to the schema and set the data type for each column and click **OK** to save the schema settings.

## Set up a query

1. From the **Basic settings** view of **tSAPBWInput**, fill the **Table Name** field with the table name. In this scenario, table name "*Measures*" is for demonstration only.
2. Fill the **Query** area with the query script. In this example, we use:

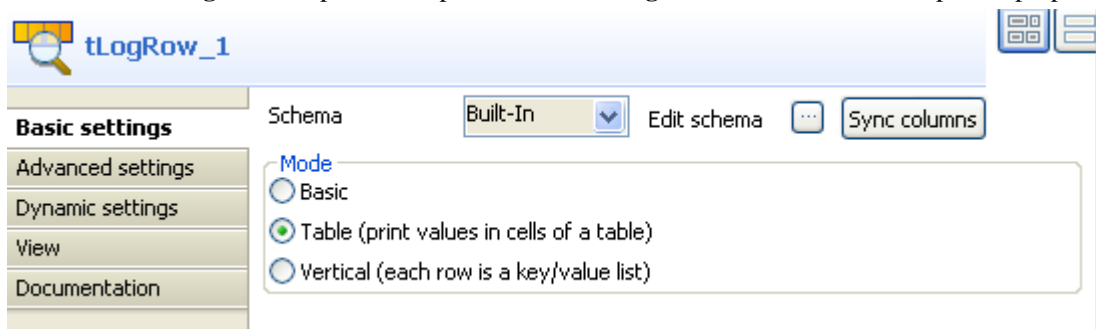

```
"SELECT
T1.\"[0D_CO_CODE].[LEVEL01]\" AS company,
T0.\"[Measures].[D68EEPPGGHUMSZ92PIJARDZ0KA]\" AS amount
FROM
\"0D_DECU\".\"0D_DECU/PRE_QRY4\".\"[Measures]\" T0,
\"0D_DECU\".\"0D_DECU/PRE_QRY4\".\"[0D_CO_CODE]\" T1 "
```

Due to the limitations of the supported SQL queries, the query scripts you use must be based on the grammar defined in the jdbc4olap driver. For further information about this grammar, see [jdbc4olap User Guide](#).

## Display the fetched data on the console

1. Double-click the **tLogRow** component to open its **Basic settings** view and define the component properties.

2. Click **Sync columns** to retrieve the schema defined in the preceding component.
3. Select **Table** in the **Mode** area.

4. Press **Ctrl+S** to save your Job and press **F6** to execute it.

```
[statistics] connecting to socket on port 3762
[statistics] connected
Jan 10, 2012 11:39:36 AM org.jdbc4olap.xmla.XmlaConn
execute
INFO: Query processed by OLAP server in 1199 ms, returning
4533 bytes.
```

| tLogRow_1          |           |
|--------------------|-----------|
| Country            | Amount    |
| IDES               | 976190.0  |
| Century Inc.       | 321678.0  |
| ACE Technology     | 1432954.0 |
| Haitec Enterprise  | 221580.0  |
| Cannon Electronics | 552852.0  |
| #                  | 0.0       |

```
[statistics] disconnected
Job Loop ended at 11:39 10/01/2012. [exit code=0]
```

The data in the table "Measure" is fetched and displayed on the console.

# tSAPCommit

## tSAPCommit Properties

This component is closely related to **tSAPConnection** and **tSAPRollback**. It usually does not make much sense to use these components separately in a transaction.

|                          |                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Related scenario

This component is closely related to **tSAPConnection** and **tSAPRollback**. It usually does not make much sense to use one of these without using a **tSAPConnection** component to open a connection for the current transaction.

For **tSAPCommit** related scenario, see [the section called “Scenario: Inserting data in mother/daughter tables”](#).

# tSAPConnection

## tSAPConnection properties

| <b>Limitation</b>        | n/a                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Scenario 1: Retrieving metadata from the SAP system

Talend SAP components (**tSAPInput** and **tSAPOutput**) as well as the SAP wizard are based on a library validated and provided by SAP (JCO) that allows the user to call functions and retrieve data from the SAP system at Table, RFC or BAPI, levels.

This scenario uses the SAP wizard that leads a user through dialog steps to create SAP connection and call RFC and BAPI functions. This SAP wizard is available only for **Talend Enterprise** users. If you are a user of **Talend Open Studio** or **Talend Integration Express**, you need to drop the **tSAPInput** component from the **Palette** and set its basic settings manually.

This scenario uses the SAP wizard to first create a connection to the SAP system, and then call a BAPI function to retrieve the details of a company from the SAP system. It finally displays in *Talend Open Studio for Big Data* the company details stored in the SAP system.

The following figure shows the company detail parameters stored in the SAP system and that we want to read in *Talend Open Studio for Big Data* using the **tSAPInput** component.

The screenshot shows the 'SAP Function wizard' dialog box, step 1/2, titled 'Retrieve SAP Function -step 1/2'. The search criteria are 'Name Filter: BAPI\_COMPANY\*' and 'Group Filter:'. The function 'BAPI\_COMPANY\_GETDETAIL' is selected, with an alias name of 'BAPI\_COMPANY\_GETDETAIL'. The purpose is 'Company details'. The dialog displays the input and output parameters for this function.

**Input Parameters:**

| Parameters: INPUT |           |
|-------------------|-----------|
| Index:            | 1         |
| Name:             | COMPANYID |
| Type:             | CHAR      |
| Size:             | 6         |
| Offset:           | 0         |
| Decimals:         | 0         |
| Value:            | " "       |

**Output Parameters:**

| Parameters: OUTPUT |                |           |
|--------------------|----------------|-----------|
| Index:             | 1              | 2         |
| Name:              | COMPANY_DETAIL | RETURN    |
| Type:              | STRUCTURE      | STRUCTURE |

## Setting and configuring the SAP connection using wizard

### Setting up the connection to the SAP system

1. Create a connection to the SAP system using the SAP connection wizard, in this scenario the SAP connection is called *sap* and is saved in the **Metadata** node.
2. Call the BAPI function *BAPI\_COMPANY\_GETDETAIL* using the SAP wizard to access the BAPI HTML document stored in the SAP system and see the company details.
3. In the **Name filter** field, type in *BAPI\** and click the **Search** button to display all available BAPI functions.
4. Select *BAPI\_COMPANY\_GETDETAIL* to display the schema that describes the company details.

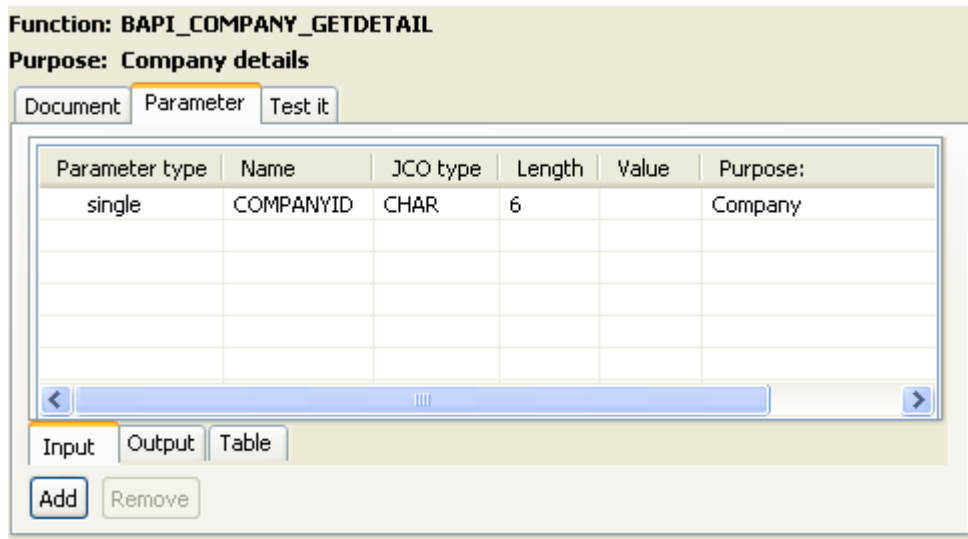

The three-tab view to the right of the wizard displays the metadata of the *BAPI\_COMPANY\_GETDETAIL* function and allows you to set the necessary parameters.

The **Document** view displays the SAP html document about the *BAPI\_COMPANY\_GETDETAIL* function.

The **Parameter** view provides information about the input and output parameters required by the *BAPI\_COMPANY\_GETDETAIL* function to return values.

### Setting the input and output parameters using the wizard

1. In the **Parameter** view, click the **Input** tab to list the input parameter(s). In this scenario, there is only one input parameter required by *BAPI\_COMPANY\_GETDETAIL* and it is called *COMPANYID*.

2. In the **Parameter** view, click the **Output** tab to list the output parameters returned by *BAPI\_COMPANY\_GETDETAIL*. In this scenario, there are two output parameters: *COMPANY\_DETAIL* and *RETURN*.

**Function: BAPI\_COMPANY\_GETDETAIL**  
**Purpose: Company details**

Document Parameter Test it

| Parameter type | Name           | JCO type | Length | Value | Purpose:                               |
|----------------|----------------|----------|--------|-------|----------------------------------------|
| [-] structure  | COMPANY_DETAIL |          | 0      |       |                                        |
| single         | COMPANY        | CHAR     | 6      |       | Company                                |

Input Output Table

Add Remove

Each of these two “structure” parameters consists of numerous “single” parameters.

The **Test it** view allows you to add or delete input parameters according to the called function. In this scenario, we want to retrieve the metadata of the *COMPANY\_DETAIL* “structure” parameter that consists of 14 “single” parameters.

**Function: BAPI\_COMPANY\_GETDETAIL**  
**Purpose: Company details**

Document Parameter **Test it**

| Name      | Parameter Type | JCO type | Structure Table | Length | Value  | Purpose: |

Add Remove

Output type:  Constructure|Table:

Launch

- In the **Value** column of the **COMPANYID** line in the first table, enter “000001” to send back company data corresponding to the value 000001.
- In the **Output type** list at the bottom of the wizard, select **output.table**.
- Click **Launch** at the bottom of the view to display the value of each “single” parameter returned by the *BAPI\_COMPANY\_GETDETAIL* function.
- Click **Finish** to close the wizard and create the connection.

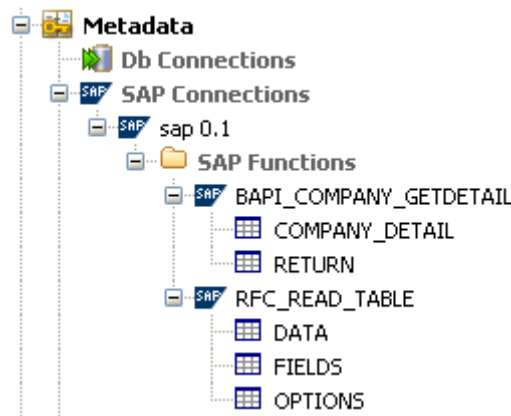

The *sap* connection and the new schema **BAI\_COMPANY\_GETDETAIL** display under the **SAP Connections** node in the **Repository** tree view.

## Retrieving different schemas of the SAP functions

To retrieve the different schemas of the **BAPI\_COMPANY\_GETDETAIL** function, do the following:

- Right-click **BAPI\_COMPANY\_GETDETAIL** in the **Repository** tree view and select **Retrieve schema** in the contextual menu.
- In the open dialog box, select the schemas you want to retrieve, **COMPANY\_DETAIL** and **RETURN** in this scenario.
- Click **Next** to display the two selected schemas and then **Finish** to close the dialog box.

The two schemas display under the **BAPI\_COMPANY\_GETDETAIL** function in the **Repository** tree view.

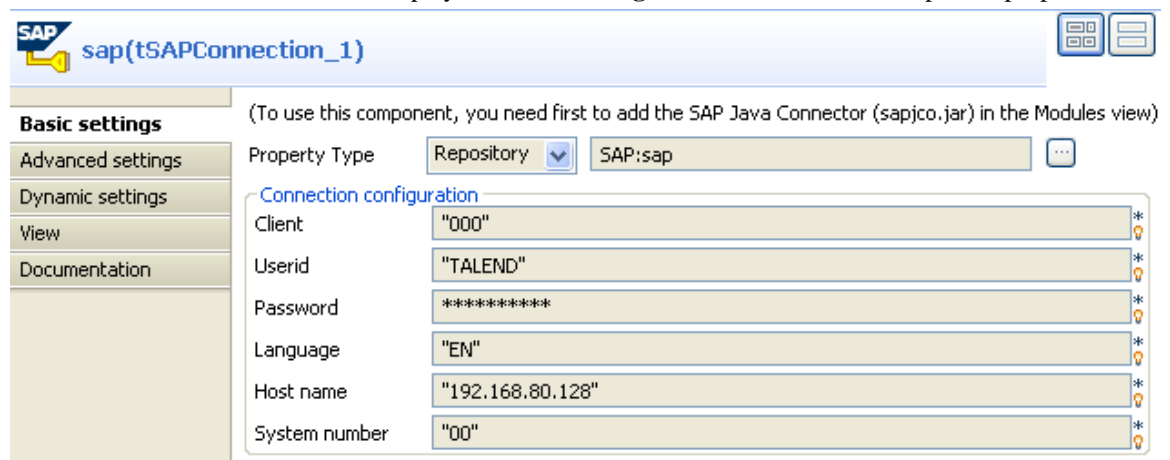

## Retrieving the company metadata

To retrieve the company metadata that corresponds to the 000001 value and display it in *Talend Open Studio for Big Data*, do the following:

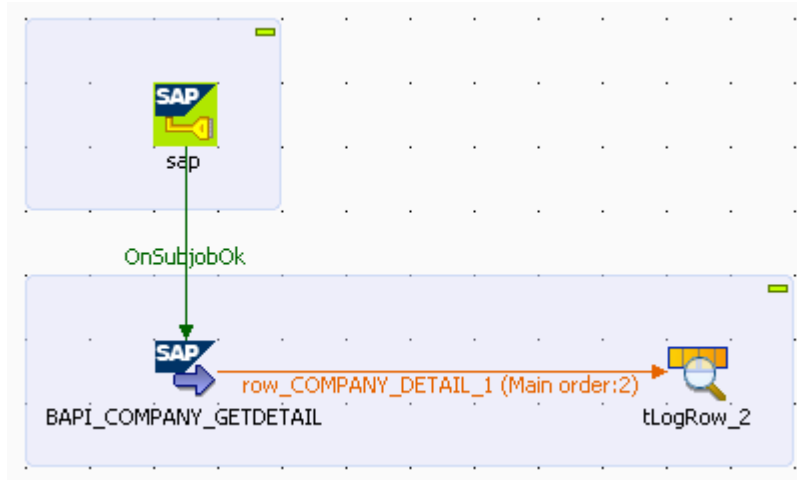

### Setting up the Job

1. In the **Repository** tree view, drop the SAP connection you already created to the design workspace to open a dialog box where you can select **tSAPConnection** from the component list and finally click **OK** to close the dialog box. The **tSAPConnection** component holding the SAP connection, *sap* in this example, displays on the design workspace.
2. Double-click **tSAPConnection** to display the **Basic settings** view and define the component properties.

If you store connection details in the **Metadata** node in the **Repository** tree view, the **Repository** mode is selected in the **Property Type** list and the fields that follow are pre-filled. If not, you need to select **Built-in** as “property type” and fill in the connection details manually.

3. In the **Repository** tree-view, expand **Metadata** and **sap** in succession and drop **RFC\_READ\_TABLE** to the design workspace to open a component list.
4. Select **tSAPInput** from the component list and click **OK**.
5. Drop **tFilterColumns** and **tLogRow** from the **Palette** to the design workspace.
6. Connect **tSAPConnection** and **tSAPInput** using a **Trigger > OnSubJobOk** link
7. To connect **tSAPInput** and **tLogRow**, right-click **tSAPInput** and select **Row > row\_COMPANY\_DETAIL\_1** and then click **tLogRow**.

- In the design workspace, double-click **tSAPInput** to display its **Basic settings** view and define the component properties.

The basic setting parameters for the **tSAPInput** component display automatically since the schema is stored in the **Metadata** node and the component is initialized by the SAP wizard.

(To use this component, you need first to add the SAP Java Connector (sapjco.jar) in the Modules view)

Use an existing connection    Component List: tSAPConnection\_1 - sap

FunName: "BAPI\_COMPANY\_GETDETAIL"\*

Initialize input

| ParameterValue | Type         | TableName(Str... | ParameterName |
|----------------|--------------|------------------|---------------|
| "000001"       | input_single | ""               | "COMPANYID"   |

Outputs

| Schema         | Type(for iterate) | TableName(Str... | Mapping          |
|----------------|-------------------|------------------|------------------|
| row_RETURN_1   | output_structure  | "RETURN"         | "TYPE","CODE",.. |
| row_COMPANY... | output_structure  | "COMPANY_DE...   | "COMPANY","N...  |

- Select the **Use an existing connection** check box and then in the **Component List**, select the relevant **tSAPConnection** component, **sap** in this scenario.

In the **Initialize input** area, we can see the input parameter needed by the **BAPI\_COMPANY\_GETDETAIL** function.

In the **Outputs** area, we can see all different schemas of the **BAPI\_COMPANY\_GETDETAIL** function, in particular, **COMPANY\_DETAIL** that we want to output.

### Job execution

- In the design workspace, double-click **tLogRow** to display the **Basic settings** view and define the component properties. For more information about this component, see [the section called "tLogRow"](#).
- Press **CTRL+S** to save your Job and press **F6** to execute it.

```

```

The **tSAPInput** component retrieved from the SAP system the metadata of the *COMPANY\_DETAIL* “structure” parameter and **tLogRow** displayed the information on the console.

## Scenario 2: Reading data in the different schemas of the RFC\_READ\_TABLE function

Talend SAP components (**tSAPInput** and **tSAPOutput**) as well as the SAP wizard are based on a library validated and provided by SAP (JCO) that allows the user to call functions and retrieve data from the SAP system at Table, RFC or BAPI, levels.

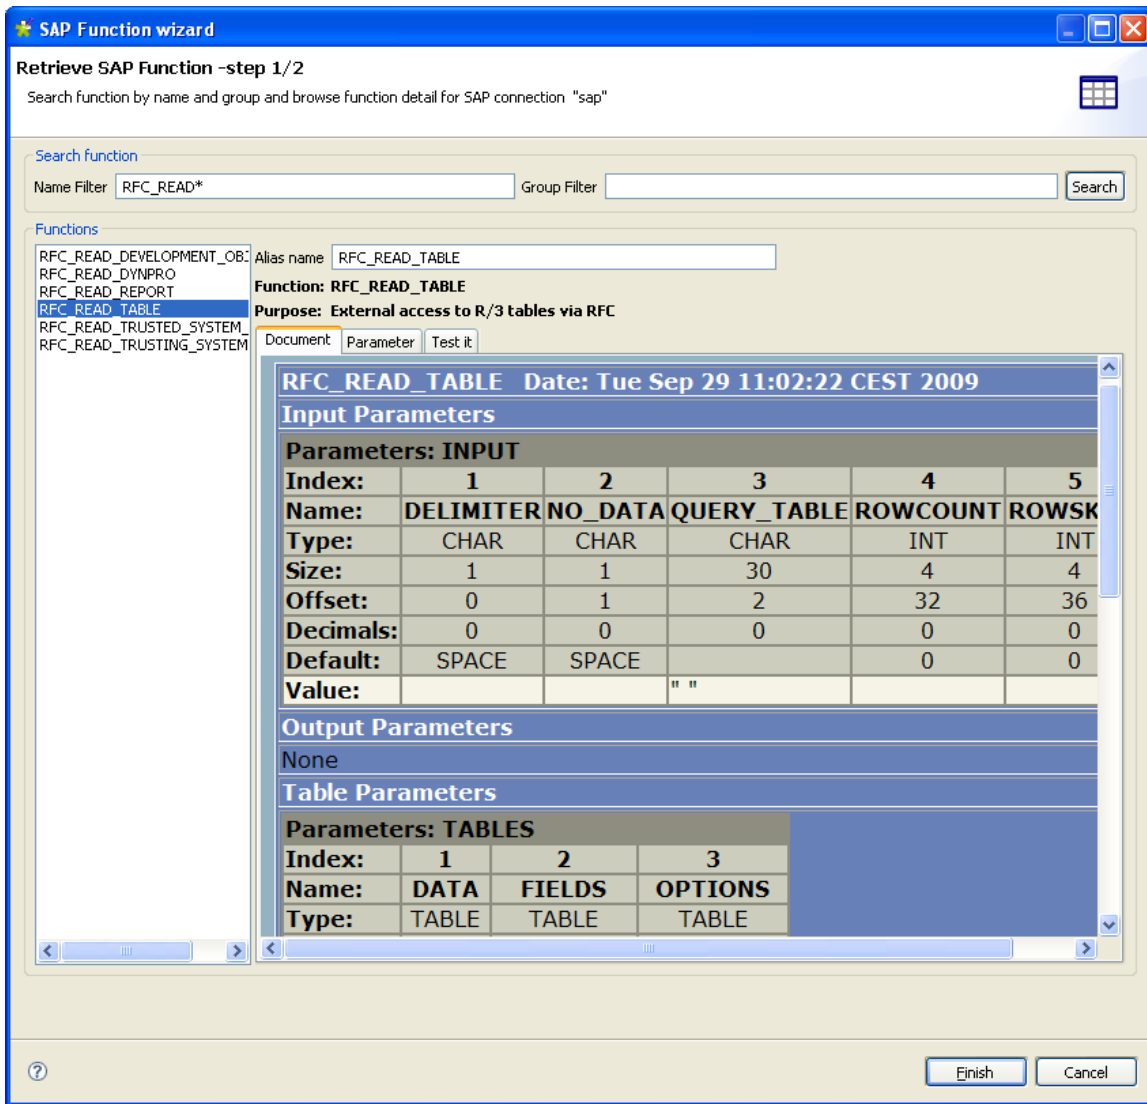

This scenario uses the SAP wizard that leads a user through dialog steps to create a SAP connection and call RFC and BAPI functions. This SAP wizard is available only for **Talend Enterprise** users. If you are a user of **Talend Open Studio** or **Talend Integration Express**, you need to drop the **tSAPInput** component from the **Palette** and set its basic settings manually.

This scenario uses the SAP wizard to first create a connection to the SAP system, and then call an RFC function to directly read from the SAP system a table called *SFLIGHT*. It finally displays in *Talend Open Studio for Big Data* the structure of the *SFLIGHT* table stored in the SAP system.

## Setting and configuring the SAP connection using wizard

### Setting up the connection to the SAP system

1. Create a connection to the SAP system using the SAP connection wizard, in this scenario the SAP connection is called *sap*.
2. Call the *RFC\_READ\_TABLE* RFC function using the SAP wizard to access the table in the SAP system and see its structure.
3. In the **Name filter** field, type in *RFC\** and click the **Search** button to display all available RFC functions.

4. Select *RFC\_READ\_TABLE* to display the schema that describe the table structure.

The three-tab view to the right of the wizard displays the metadata of the *RFC\_READ\_TABLE* function and allows you to set the necessary parameters.

The **Document** view displays the SAP html document about the *RFC\_READ\_TABLE* function.

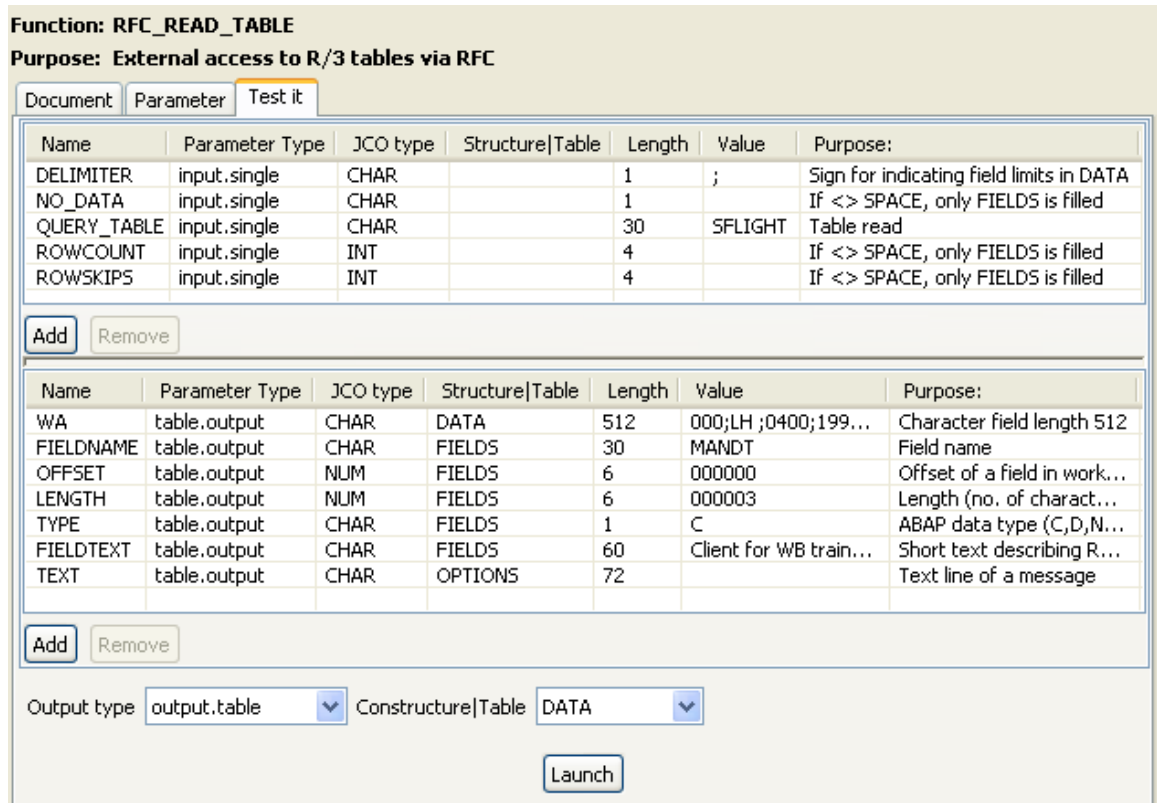

The **Parameter** view provides information about the parameters required by the *RFC\_READ\_TABLE* function to return parameter values.

### Setting the input and output parameters using the wizard

1. In the **Parameter** view, click the **Table** tab to show a description of the structure of the different tables of the *RFC\_READ\_TABLE* function.

The **Test it** view allows you to add or delete input parameters according to the called function. In this example, we want to retrieve the structure of the *SFLIGHT* table and not any data.

- In the **Value** column of the **DELIMITER** line, enter “;” as field separator.
- In the **Value** column of the **QUERY\_TABLE** line, enter *SFLIGHT* as the table to query.
- In the **Output type** list at the bottom of the view, select **output.table**.
- In the **Constructure|Table** list, select **DATA**.
- Click **Launch** at the bottom of the view to display the parameter values returned by the *RFC\_READ\_TABLE* function. In this example, the delimiter is “;” and the table to read is *SFLIGHT*.

7. Click **Finish** to close the wizard and create the connection.

## Retrieving the different schemas of the RFC\_READ\_TABLE function

The *sap* connection and the **RFC\_READ\_TABLE** function display under the **SAPConnections** node in the **Repository** tree view.

To retrieve the different schemas of the **RFC\_READ\_TABLE** function, do the following:

1. In the **Repository** tree view, right-click **RFC\_READ\_TABLE** and select **Retrieve schema** in the contextual menu. A dialog box displays.
2. Select in the list the schemas you want to retrieve, **DATA**, **FIELDS** and **OPTIONS** in this example.
3. Click **Next** to open a new view on the dialog box and display these different schemas.
4. Click **Finish** to validate your operation and close the dialog box.

The three schemas display under the **RFC\_READ\_TABLE** function in the **Repository** tree view.

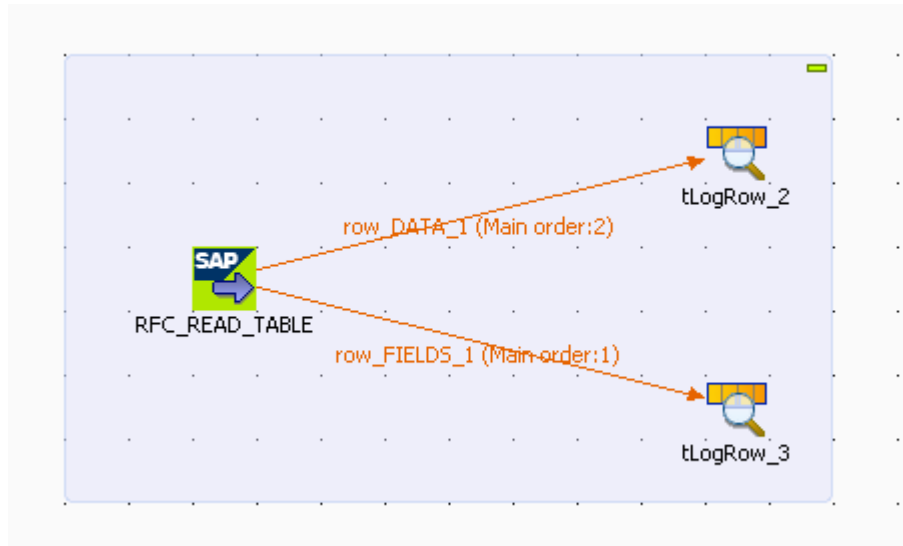

## Retrieving the data column names of the SFLIGHT table

In this example, we want to retrieve the data and column names of the **SFLIGHT** table and display them in *Talend Open Studio for Big Data*. To do that, proceed as the following:

### Setting up the Job

1. In the **Repository** tree view, drop the **RFC\_READ\_TABLE** function of the *sap* connection to the design workspace to open a dialog box where you can select **tSAPInput** from the component list and then click **OK** to close the dialog box. The **tSAPInput** component displays on the design workspace.
2. Drop two **tLogRow** components from the **Palette** to the design workspace.
3. Right-click **tSAPInput** and select **Row > row\_DATA\_1** and click the first **tLogRow** component.
4. Right-click **tSAPInput** and select **Row > row\_FIELDS\_1** and click the second **tLogRow** components.

In this example, we want to retrieve the **FIELDS** and **DATA** schemas and put them in two different output flows.

5. In the design workspace, double-click **tSAPInput** to open the **Basic settings** view and display the component properties.

(To use this component, you need first to add the SAP Java Connector (sapjco.jar) in the Modules view)

Property Type: Repository | SAP:sap

Use an existing connection

Connection configuration

Client: "000" \*

Userid: "TALEND" \*

Password: "\*\*\*\*\*" \*

Language: "EN" \*

Host name: "192.168.80.128" \*

System number: "00" \*

FunName: "RFC\_READ\_TABLE" \*

Initialize input

| ParameterValue | Type         | TableName(Str... | ParameterName |
|----------------|--------------|------------------|---------------|
| ","            | input_single | ""               | "DELIMITER"   |
| ""             | input_single | ""               | "NO_DATA"     |
| "SFLIGHT"      | input_single | ""               | "QUERY_TABLE" |
| 0              | input_single | ""               | "ROWCOUNT"    |
| 0              | input_single | ""               | "ROWSKIPS"    |

The basic setting parameters for the **tSAPInput** component display automatically since the schema is stored in the **Metadata** node and the component is initialized by the SAP wizard.

In the **Initialize input** area, we can see the input parameters necessary for the **RFC\_READ\_TABLE** function, the field delimiter “,” and the table name “**SFLIGHT**”.

In the **Outputs** area, we can see the different schemas of the **SFLIGHT** table.

Outputs

| Schema        | Type(for iterate) | TableName... | Mapping              |
|---------------|-------------------|--------------|----------------------|
| row_FIELDS_1  | table_output      | "FIELDS"     | "FIELDNAME","OFFSET" |
| row_OPTIONS_1 | table_output      | "OPTIONS"    | "TEXT"               |
| row_DATA_1    | table_output      | "DATA"       | "WA"                 |

### Job execution

1. In the design workspace, double click each of the two **tLogRow** components to display the **Basic settings** view and define the component properties. For more information on the properties of **tLogRow**, see [the section called "tLogRow"](#).
2. Press **CTRL+S** to save your Job and press **F6** to execute it.

# tSAPRollback

## tSAPRollback properties

This component is closely related to **tSAPCommit** and **tSAPConnection**. It usually does not make much sense to use these components separately in a transaction.

| <b>Purpose</b>           | Allows you to extract data from a SugarCRM DB based on a query.      |                                                                                                                                                                                                                                                                                                                                                         |
| <b>Basic settings</b>    | <i>SugarCRM Webservice URL</i>                                       | Type in the webservice URL to connect to the SugarCRM DB.                                                                                                                                                                                                                                                                                               |
|                          | <i>Username</i> and <i>Password</i>                                  | Type in the Webservice user authentication data.                                                                                                                                                                                                                                                                                                        |
|                          | <i>Module</i>                                                        | Select the relevant module from the list<br><br> To use customized tables, select <b>Use custom module</b> from the list. The <b>Custom module package name</b> and <b>Custom module name</b> fields which appear are automatically filled in with the relevant names. |
|                          | <i>Schema</i> and <i>Edit Schema</i>                                 | A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> make changes to the schema.<br><br>In this component the schema is related to the Module selected.                                    |
|                          | <i>Query condition</i>                                               | Type in the query to select the data to be extracted. Example: account_name= 'Talend'                                                                                                                                                                                                                                                                   |
| <b>Advanced settings</b> | <i>tStat Catcher Statistics</i>                                      | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                                       |
| <b>Usage</b>             | Usually used as a Start component. An output component is required.  |                                                                                                                                                                                                                                                                                                                                                         |
| <b>Limitation</b>        | n/a                                                                  |                                                                                                                                                                                                                                                                                                                                                         |

## Scenario: Extracting account data from SugarCRM

This scenario describes a two-component Job which extracts account information from a SugarCRM database and writes it to an Excel output file.

## Setting up the Job

1. Drop a **tSugarCRMInput** and a **tFileOutputExcel** component from the **Palette** onto the workspace.
2. Connect the input component to the output component using a **Row > Main** connection.

## Configuring the input component

1. Double-click **tSugarCRMInput** to define the component properties in its **Basic settings** view.

| Property                | Value                              |
|-------------------------|------------------------------------|
| SugarCRM WebService URL | "http://localhost/sugar/soap.php"  |
| Username                | "admin"                            |
| Password                | "root"                             |
| Module                  | Accounts                           |
| Schema                  | Built-In                           |
| Query Condition         | "billing_address_city='Sunnyvale'" |

2. Fill the **SugarCRM WebService URL** field with the connection information, and the **Username** and **Password** fields with the authentication you have.
3. Select the **Module** from the list of modules offered. In this example, *Accounts* is selected.

The **Schema** is then automatically set according to the module selected. But you can change it and remove the columns that you do not require in the output.

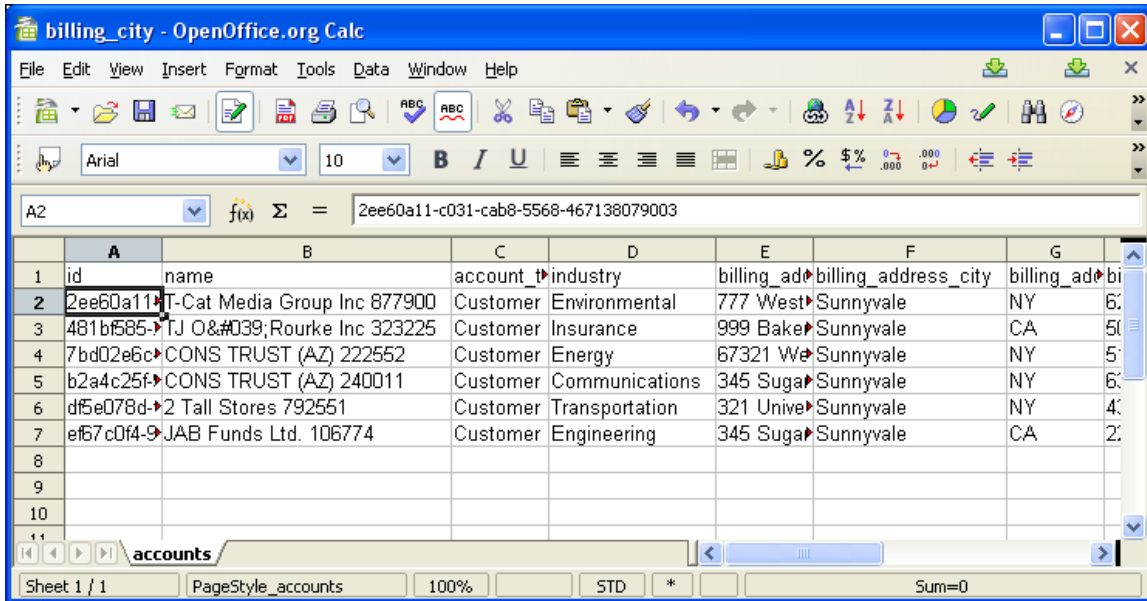

4. In the **Query Condition** field, type in the query you want to extract from the CRM. In this example: "billing\_address\_city='Sunnyvale'".

## Job execution

1. Double-click **tFileOutputExcel** to define the component properties in its **Basic settings** view.

|                |                                     |
|----------------|-------------------------------------|
| File Name      | "C:/Output/billing_city.xls"        |
| Sheet name     | "accounts"                          |
| Include header | <input checked="" type="checkbox"/> |
| Schema Type    | Built-In                            |
| Encoding Type  | ISO-8859-15                         |

2. Set the destination file name as well as the **Sheet** name and select the **Include header** check box.
3. Press **CTRL+S** to save your Job and press **F6** to execute it.

The filtered data is output in the defined spreadsheet of the specified Excel file.

# tSugarCRMOutput

## tSugarCRMOutput Properties

# Business Intelligence components

This chapter details the main components which belong to the **Business Intelligence** family in the *Talend Open Studio for Big Data Palette*.

The BI family groups connectors that cover needs such as reading or writing multidimensional or OLAP databases, outputting Jasper reports, tracking DB changes in slow changing dimension tables and so on.

For *Talend Open Studio for Big Data*, the **Property type**, **Schema** and **Query Type** of components are always **Built-in**. For how to edit a Built-in schema, see *Talend Open Studio for Big Data User Guide*.

|  | <i>Table</i>                  | Name of the table to be written. Note that only one table can be written at a time                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|  | <i>Action on table</i>        | <p>Select to perform one of the following operations on the table defined:</p> <p><b>None:</b> No action carried out on the table.</p> <p><b>Drop and create table:</b> The table is removed and created again</p> <p><b>Create table:</b> A new table gets created.</p> <p><b>Create table if not exists:</b> A table gets created if it does not exist.</p> <p><b>Clear table:</b> The table content is deleted. You have the possibility to rollback the operation.</p> <p><b>Truncate table:</b> The table content is deleted. You don not have the possibility to rollback the operation.</p>                                                                                                                                                                                                                                                     |
|  | <i>Schema and Edit schema</i> | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|  |                               | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|  | <i>Surrogate Key</i>          | Select the surrogate key column from the list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|  | <i>Creation</i>               | <p>Select the method to be used for the surrogate key generation.</p> <p>For more information regarding the creation methods, see <a href="#">the section called “SCD keys”</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|  | <i>Source Keys</i>            | Select one or more columns to be used as keys, to ensure the unicity of incoming data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|  | <i>Use SCD Type 1 fields</i>  | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|  | <i>Use SCD Type 2 fields</i>  | <p>Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.</p> <p><b>Start date:</b> Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.</p> <p><b>End Date:</b> Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select <b>Fixed Year value</b> and fill it in with a fictive year to avoid having a null value in the End Date field.</p> <p><b>Log Active Status:</b> Adds a column to your SCD schema to hold the <b>true</b> or <b>false</b> status value. This column helps to easily spot the active record.</p> |

|                          |                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                 |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
|                          |                                                                                                                                                                                                                                                                                                                                                                       | <b>Log versions:</b> Adds a column to your SCD schema to hold the version number of the record. |
| <b>Advanced settings</b> | <i>Debug mode</i>                                                                                                                                                                                                                                                                                                                                                     | Select this check box to display each step during processing entries in a database.             |
|                          | <i>tStat Catcher Statistics</i>                                                                                                                                                                                                                                                                                                                                       | Select this check box to collect log data at the component level.                               |
| <b>Usage</b>             | This component is used as an output component. It requires an input component and Row main link as input.                                                                                                                                                                                                                                                             |                                                                                                 |
| <b>Limitation</b>        | Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> . |                                                                                                 |

|                         | <i>Username</i> and <i>Password</i>                                                                                                                   | DB user authentication data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                          |                                 |                                                                                                                                                                                                              |
|--------------------------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>Table</i>                    | Name of the table to be written. Note that only one table can be written at a time.                                                                                                                          |
|                          | <i>Schema and Edit schema</i>   | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> . |
|                          |                                 | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                    |
|                          | <i>SCD Editor</i>               | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs.<br><br>For more information, see <a href="#">the section called “SCD management methodologies”</a> .        |
|                          | <i>Use memory saving Mode</i>   | Select this check box to maximize system performance.                                                                                                                                                        |
|                          | <i>Die on error</i>             | This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.                                                                                      |
| <b>Advanced settings</b> | <i>tStat Catcher Statistics</i> | Select this check box to collect log data at the component level.                                                                                                                                            |
|                          | <i>Debug mode</i>               | Select this check box to display each step during processing entries in a database.                                                                                                                          |
| <b>Usage</b>             |                                 | This component is used as Output component. It requires an Input component and Row main link as input.                                                                                                       |

|                          | <i>Debug mode</i>                 | Select this check box to display each step during processing entries in a database.                                                                                                                                                                                                     |
| <b>Usage</b>             |                                   | This component is used as Output component. It requires an Input component and Row main link as input.                                                                                                                                                                                  |

## SCD management methodologies

Slowly Changing Dimensions (SCDs) are dimensions that have data that slowly changes. The SCD editor offers the simplest method of building the data flow for the SCD outputs. In the SCD editor, you can map columns, select surrogate key columns, and set column change attributes through combining SCD types.

The following figure illustrates an example of the SCD editor.

SCD component editor

filter

**Unused**

age  
country

**Source keys**

id

**Surrogate keys**

name: SK  
creation: Auto increment  
complement:

**Type 0 fields**

firstname  
lastname

**Type 1 fields**

status

**Type 2 fields**

city

**Versioning**

| type                                | name      | creation       | complement |
|-------------------------------------|-----------|----------------|------------|
| start                               | scd_start | Job start time |            |
| end                                 | scd_end   | NULL           |            |
| <input checked="" type="checkbox"/> | version   | scd_version    |            |
| <input checked="" type="checkbox"/> | active    | scd_active     |            |

**Type 3 fields**

| current value | previous value   |
|---------------|------------------|
| company       | previous_company |

OK Cancel

## SCD keys

You must choose one or more source keys columns from the incoming data to ensure its unicity.

You must set one surrogate key column in the dimension table and map it to an input column in the source table. The value of the surrogate key links a record in the source to a record in the dimension table. The editor uses this mapping to locate the record in the dimension table and to determine whether a record is new or changing. The surrogate key is typically the primary key in the source, but it can be an alternate key as long as it uniquely identifies a record and its value does not change.

**Source keys:** Drag one or more columns from the **Unused** panel to the **Source keys** panel to be used as the key(s) that ensure the unicity of the incoming data.

**Surrogate keys:** Set the column where the generated surrogate key will be stored. A surrogate key can be generated based on a method selected on the **Creation** list.

**Creation:** Select any of the below methods to be used for the key generation:

**Auto increment:** auto-incremental key.

**Input field:** key is provided in an input field.

When selected, you can drag the appropriate field from the **Unused** panel to the **complement** field.

**Routine:** from the **complement** field, you can press **Ctrl+ Space** to display the autocompletion list and select the appropriate routine.

**Table max +1:** the maximum value from the SCD table is incremented to create a surrogate key.

**DB Sequence:** from the **complement** field, you can enter the name of the existing database sequence that will automatically increment the column indicated in the **name** field.

This option is only available through the **SCD Editor** of the **tOracleSCD** component.

## Combining SCD types

The Slowly Changing Dimensions support four types of changes: **Type 0** through **Type 3**. You can apply any of the SCD types to any column in a source table by a simple drag-and-drop operation.

**Type 0:** is not used frequently. Some dimension data may be overwritten and other may stay unchanged over time. This is most appropriate when no effort has been made to deal with the changing dimension issues.

**Type 1:** no history is kept in the database. New data overwrites old data. Use this type if tracking changes is not necessary. this is most appropriate when correcting certain typos, for example the spelling of a name.

**Type2:** the whole history is stored in the database. This type tracks historical data by inserting a new record in the dimensional table with a separate key each time a change is made. This is most appropriate to track updates, for example.

SCD **Type 2** principle lies in the fact that a new record is added to the SCD table when changes are detected on the columns defined. Note that although several changes may be made to the same record on various columns defined as SCD **Type 2**, only one additional line tracks these changes in the SCD table.

The SCD schema in this type should include SCD-specific extra columns that hold standard log information such as:

**-start:** adds a column to your SCD schema to hold the start date. You can select one of the input schema columns as a start date in the SCD table.

**-end:** adds a column to your SCD schema to hold the end date value for a record. When the record is currently active, the end date is **NULL** or you can select **Fixed Year Value** and fill in a fictive year to avoid having a null value in the end date field.

**-version:** adds a column to your SCD schema to hold the version number of the record.

**-active:** adds a column to your SCD schema to hold the **true** or **false** status value. this column helps to easily spot the active record.

**Type 3:** only the information about a previous value of a dimension is written into the database. This type tracks changes using separate columns. This is most appropriate to track only the previous value of a changing column.

## Scenario: Tracking changes using Slowly Changing Dimensions (type 0 through type 3)

This five-component Java scenario describes a Job that tracks changes in four of the columns in a source delimited file, writes changes and the history of changes in an SCD table, and displays error information on the **Run** console.

The source delimited file contains various personal details including *firstname*, *lastname*, *address*, *city*, *company*, *age*, and *status*. An *id* column helps ensuring the unicity of the data.

|   | A                                                                      | B | C | D | E | F |
|---|------------------------------------------------------------------------|---|---|---|---|---|
| 1 | id;firstname;lastname;address;city;company;age;status                  |   |   |   |   |   |
| 2 | 1;Janet;Anderson;511 Maple Ave. Apt. 1B;Agoura Hills;Adecco;30;married |   |   |   |   |   |
| 3 | 2;Harold;Smith;662 Lyons Circle;Alameda;Adidas;33;married              |   |   |   |   |   |
| 4 | 3;Adam;Brown;220 Vine Ave.;Albany;Bridgestone;28;single                |   |   |   |   |   |
| 5 | 4;Martin;Clinton;770 Exmoor Rd.;Alhambra;Cutco;25;single               |   |   |   |   |   |
| 6 | 5;Sue;White;1486 Oakwood;Covina;Black&White;35;married                 |   |   |   |   |   |

We want any change in the marital status to overwrite the existing old status record. This type of change is equivalent to an SCD **Type 1**.

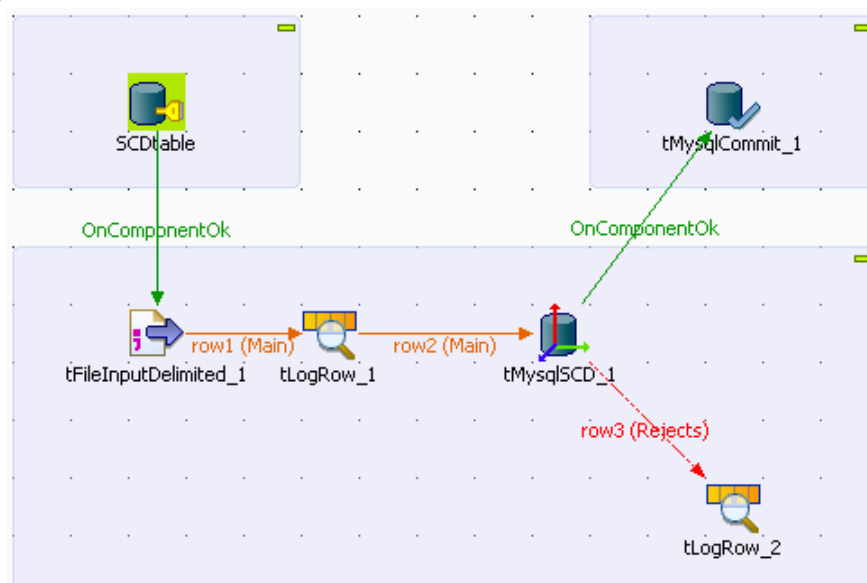

We want to insert a new record in the dimensional table with a separate key each time a person changes his/her company. This type of change is equivalent to an SCD **Type 2**.

We want to track only the previous city and previous address of a person. This type of change is equivalent to an SCD **Type 3**.

To realize this kind of scenario, it is better to divide it into three main steps: defining the main flow of the Job, setting up the SCD editor, and finally creating the relevant SCD table in the database.

## Defining the main flow of the Job

1. Drop the following components from the **Palette** onto the design workspace: a **tMySQLConnection**, a **tFileInputDelimited**, a **tMySQLSCD**, a **tMySQLCommit**, and two **tLogRow** components.
2. Connect the **tFileInputDelimited**, the first **tLogRow**, and the **tMySQLSCD** using the **Row Main** link. This is the main flow of your Job.
3. Connect the **tMySQLConnection** to the **tFileInputDelimited** and **tMySQLSCD** to **tMySQLCommit** using the **OnComponentOk** trigger.
4. Connect the **tMySQLSCD** to the second **tLogRow** using the **Row Rejects** link. Two columns, *errorCode* and *errorMessage*, are added to the schema. This connection collects error information.

## Configuring the DB connection and the input component

1. In the design workspace, double-click **tMySQLConnection** to display its **Basic settings** view and set the database connection details. The **tMySQLConnection** component should be used to avoid setting several times the same DB connection when multiple DB components are used.

In this scenario, we want to connect to the SCD table where changes in the source delimited file will be tracked down.

For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query type** of components are always **Built-in**. You have to complete the relevant settings manually in the specific Job.

2. In the design workspace, double-click **tFileInputDelimited** to display its **Basic settings** view.

3. Click the three-dot button next to the **File Name** field to select the path to the source delimited file, *dataset.csv* in this scenario, that contains the personal details.
4. Define the row and field separators used in the source file.

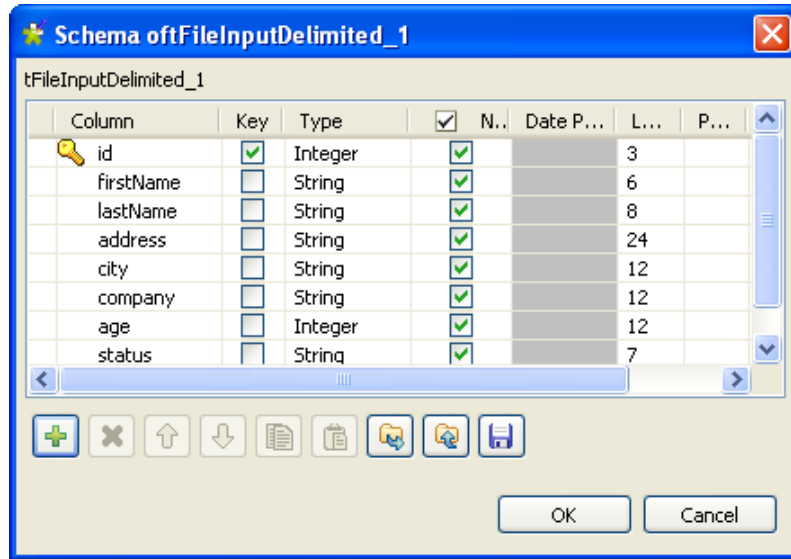

The **File Name**, **Row separator**, and **Field separators** are mandatory.

5. If needed, set **Header**, **Footer**, and **Limit**.

In this scenario, set **Header** to *1*. Footer and limit for the number of processed rows are not set.

6. Click **Edit schema** to describe the data structure of the source delimited file.

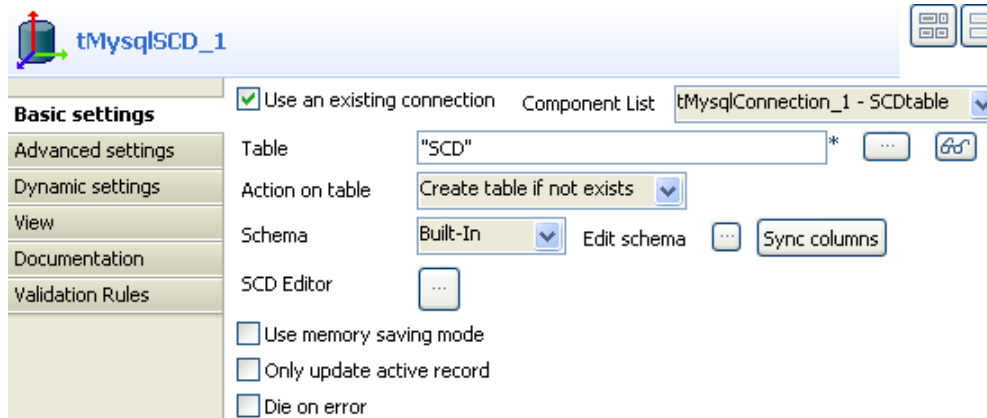

In this scenario, the source schema is made of eight columns: *id*, *firstName*, *lastName*, *address*, *city*, *company*, *age*, and *status*.

7. Define the basic settings for the first **tLogRow** in order to view the content of the source file with varying attributes in cells of a table on the console before being processed through the SCD component.

## Configuring tMysqlSCD and tMysqlCommit

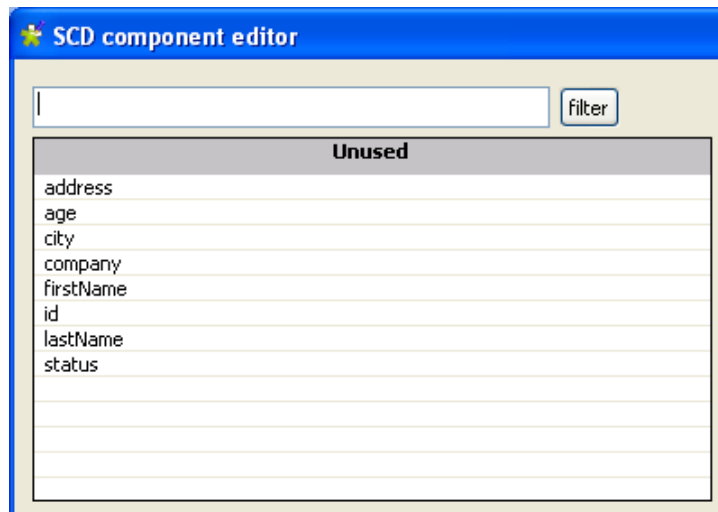

1. In the design workspace, click the **tMysqlSCD** and select the **Component** tab to define its basic settings.

2. In the **Basic settings** view, select the **Use an existing connection** check box to reuse the connection details defined on the **tMysqlConnection** properties.
3. In the **Table** field, enter the table name to be used to track changes.
4. If needed, click **Sync columns** to retrieve the output data structure from the **tFileInputDelimited**.
5. In the design workspace, double-click **tMysqlCommit** to define its basic settings.
6. Select the relevant connection on the **Component list** if more than one connection exists.
7. Define the basic settings of the second **tLogRow** in order to view reject information in cells of a table.

## Setting up the SCD editor

1. Double-click the **tMySQLSCD** component in the design workspace or click the three-dot button next to the **SCD Editor** in the component's **Basic settings** view to open the **SCD editor** and build the data flow for the SCD outputs.

All the columns from the preceding component are displayed in the **Unused** panel of the **SCD editor**. All the other panels in the **SCD editor** are empty.

2. From the **Unused** list, drop the *id* column to the **Source keys** panel to use it as the key to ensure the unicity of the incoming data.
3. In the **Surrogate keys** panel, enter a name for the surrogate key in the **Name** field, *SKI* in this scenario.
4. From the **Creation** list, select the method to be used for the surrogate key generation, **Auto-increment** in this scenario.
5. From the **Unused** list, drop the *firstname* and *lastname* columns to the **Type 0** panel, changes in these two columns do not interest us.
6. Drop the *status* column to the **Type 1** panel. The new value will overwrite the old value.
7. Drop the *company* column to the **Type 2** panel. Each time a person changes his/her company, a new record will be inserted in the dimensional table with a separate key.

In the **Versioning** area:

- Define the **start** and **end** columns of your SCD table that will hold the start and end date values. The end date is null for current records until a change is detected. Then the end date gets filled in and a new record is added with no end date.

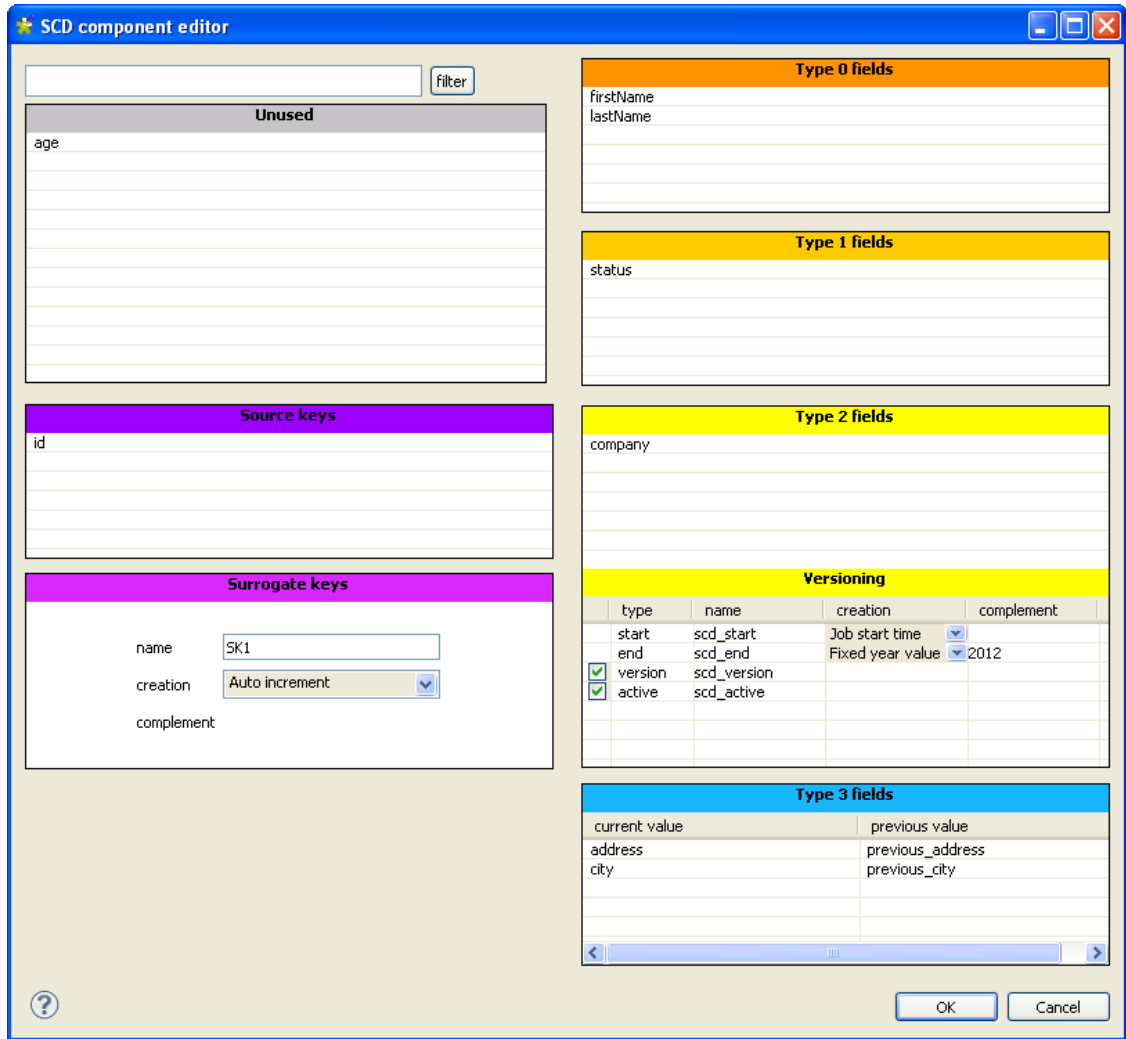

In this scenario, we select **Fixed Year Value** for the **end** column and fill in a fictive year to avoid having a null value in the end date field.

- Select the **version** check box to hold the version number of the record.

- Select the **active** check box to spot the column that will hold the **True** or **False** status. **True** for the current active record and **False** for the modified record.

8. Drop the *address* and *city* columns to the **Type 3** panel to track only the information about the previous value of the address and city.

For more information about SCD types, see [the section called “SCD management methodologies”](#).

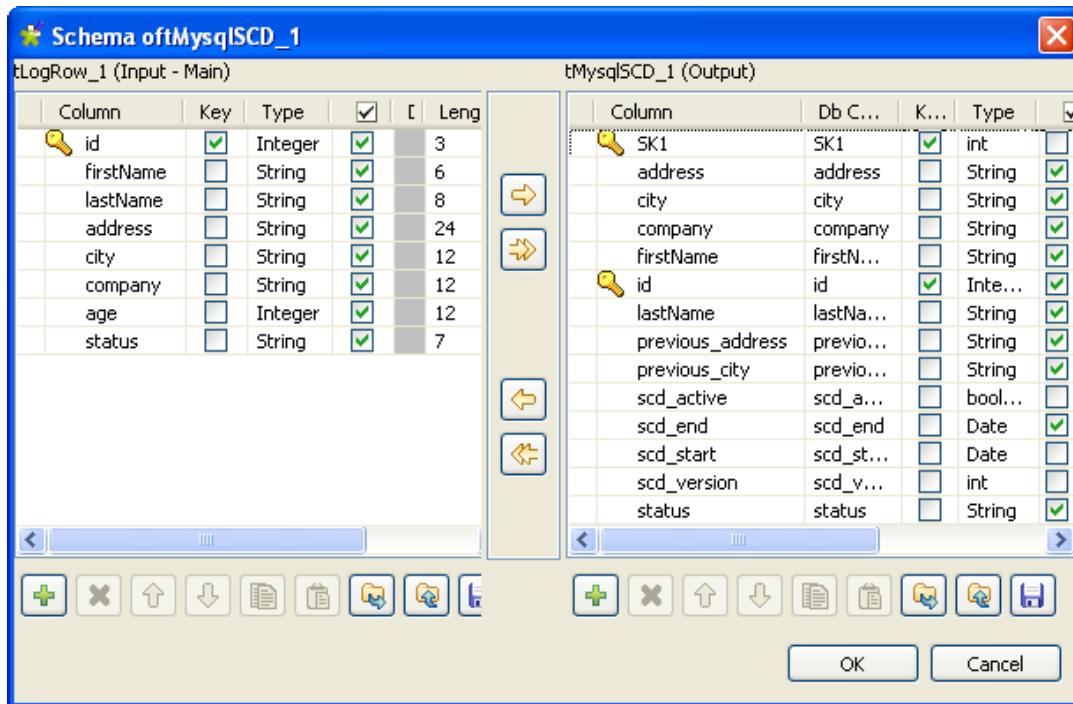

9. Click **OK** to validate your configuration and close the **SCD editor**.

## Creating the SCD table

1. Click **Edit schema** to view the input and output data structures.

The SCD output schema should include the SCD-specific columns defined in the **SCD editor** to hold standard log information.

 If you adjust any of the input schema definitions, you need to check, and reconfigure if necessary, the output flow definitions in the **SCD editor** to ensure that the output data structure is properly updated.

2. In the **Basic settings** view of the **tMysqlSCD** component, select **Create table if not exists** from the **Action on table** list to avoid creating and defining the SCD table manually.

## Job execution

Save your Job and press **F6** to execute it.

The console shows the content of the input delimited file, and your SCD table is created in your database, containing the initial dataset.

| SK1  | address                | city         | company     | firstName | id | lastName | previous_adr | previous_city | scd_ac                   | scd_end  | scd_st | scd_ve | status  |
|------|------------------------|--------------|-------------|-----------|----|----------|--------------|---------------|--------------------------|----------|--------|--------|---------|
| 1    | 511 Maple Ave. Apt. 1B | Agoura Hills | Adecco      | Janet     | 1  | Anderson | (NULL)       | (NULL)        | <input type="checkbox"/> | 2012-01- | 2011-0 | 1      | married |
| 2    | 662 Lyons Circle       | Alameda      | Adidas      | Harold    | 2  | Smith    | (NULL)       | (NULL)        | <input type="checkbox"/> | 2012-01- | 2011-0 | 1      | married |
| 3    | 220 Vine Ave.          | Albany       | Bridgestone | Adam      | 3  | Brown    | (NULL)       | (NULL)        | <input type="checkbox"/> | 2012-01- | 2011-0 | 1      | single  |
| 4    | 770 Exmoor Rd.         | Alhambra     | Cutco       | Martin    | 4  | Clinton  | (NULL)       | (NULL)        | <input type="checkbox"/> | 2012-01- | 2011-0 | 1      | single  |
| 5    | 1486 Oakwood           | Covina       | Black&White | Sue       | 5  | White    | (NULL)       | (NULL)        | <input type="checkbox"/> | 2012-01- | 2011-0 | 1      | married |
| JLL) | (NULL)                 | (NULL)       | (NULL)      | (NULL)    | 0  | (NULL)   | (NULL)       | (NULL)        | (NULL)                   | (NULL)   | (NULL) | (NULL) | (NULL)  |

*Janet gets divorced and moves to Adelanto at 355 Golf Rd. She works at Greenwood.*

*Adam gets married and moves to Belmont at 2505 Alisson ct. He works at Scoop.*

*Martin gets a new job at Phillips and Brothers.*

Update the delimited file with the above information and press **F6** to run your Job.

The console shows the updated personal information and the rejected data, and the SCD table shows the history of valid changes made to the input file along with the status and version number. Because the name of Martin's new company exceeds the length of the column *company* defined in the schema, this change is directed to the reject flow instead of being logged in the SCD table.

|  | <i>Surrogate Key</i>          | Select the surrogate key column from the list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|  | <i>Creation</i>               | <p>Select the method to be used for the surrogate key generation.</p> <p>For more information regarding the creation methods, see <a href="#">the section called "SCD keys"</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|  | <i>Source Keys</i>            | Select one or more columns to be used as keys, to ensure the unicity of incoming data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|  | <i>Use SCD Type 1 fields</i>  | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|  | <i>Use SCD Type 2 fields</i>  | <p>Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.</p> <p><b>Start date:</b> Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.</p> <p><b>End Date:</b> Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select <b>Fixed Year value</b> and fill it in with a fictive year to avoid having a null value in the End Date field.</p> |

|                          |                                                                                                           |                                                                                                                                                                                                                                                                                    |
|--------------------------|-----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                                                                           | <p><b>Log Active Status:</b> Adds a column to your SCD schema to hold the <b>true</b> or <b>false</b> status value. This column helps to easily spot the active record.</p> <p><b>Log versions:</b> Adds a column to your SCD schema to hold the version number of the record.</p> |
| <b>Advanced settings</b> | <i>Debug mode</i>                                                                                         | Select this check box to display each step during processing entries in a database.                                                                                                                                                                                                |
|                          | <i>tStat Catcher Statistics</i>                                                                           | Select this check box to collect log data at the component level.                                                                                                                                                                                                                  |
| <b>Usage</b>             | This component is used as an output component. It requires an input component and Row main link as input. |                                                                                                                                                                                                                                                                                    |

Note that only one table can be written at a time                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|  | <i>Action on table</i>             |                    | <p>Select to perform one of the following operations on the table defined:</p> <p><b>None:</b> No action carried out on the table.</p> <p><b>Drop and create table:</b> The table is removed and created again</p> <p><b>Create table:</b> A new table gets created.</p> <p><b>Create table if not exists:</b> A table gets created if it does not exist.</p> <p><b>Clear table:</b> The table content is deleted. You have the possibility to rollback the operation.</p> <p><b>Truncate table:</b> The table content is deleted. You don not have the possibility to rollback the operation.</p>                                                                         |
|  | <i>Schema</i><br><i>schema</i>     | and<br><i>Edit</i> | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|  |                                    |                    | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|  | <i>Surrogate Key</i>               |                    | Select the surrogate key column from the list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|  | <i>Creation</i>                    |                    | <p>Select the method to be used for the surrogate key generation.</p> <p>For more information regarding the creation methods, see <a href="#">the section called “SCD keys”</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|  | <i>Source Keys</i>                 |                    | Select one or more columns to be used as keys, to ensure the unicity of incoming data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|  | <i>Use SCD Type 1 fields</i>       |                    | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|  | <i>Use SCD Type 2 fields</i>       |                    | <p>Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.</p> <p><b>Start date:</b> Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.</p> <p><b>End Date:</b> Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select <b>Fixed Year value</b> and fill it in with a fictive year to avoid having a null value in the End Date field.</p> |

|                          |                                                                                                           |                                                                                                                                                                                                                                                                                    |
|--------------------------|-----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                                                                           | <p><b>Log Active Status:</b> Adds a column to your SCD schema to hold the <b>true</b> or <b>false</b> status value. This column helps to easily spot the active record.</p> <p><b>Log versions:</b> Adds a column to your SCD schema to hold the version number of the record.</p> |
| <b>Advanced settings</b> | <i>Additional parameters</i> <i>JDBC</i>                                                                  | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <b>Use an existing connection</b> check box in the <b>Basic settings</b> .                                                                  |
|                          | <i>Debug mode</i>                                                                                         | Select this check box to display each step during processing entries in a database.                                                                                                                                                                                                |
|                          | <i>tStatCatcher Statistics</i>                                                                            | Select this check box to collect log data at the component level.                                                                                                                                                                                                                  |
| <b>Usage</b>             | This component is used as an output component. It requires an input component and Row main link as input. |                                                                                                                                                                                                                                                                                    |

| <b>Function</b>                                                                                                                    | This component checks whether elements are present in an incoming data flow existing in a given cube.                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Purpose</b>                                                                                                                     | This component can be used along with <b>tPaloOutputMulti</b> . It checks if the elements from the input stream exist in the given cube, before writing them. It can also define a default value to be used for nonexistent elements. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Basic settings</b>                                                                                                              | <i>Use an existing connection</i>                                                                                                                                                                                                     | <p>Select this check box and choose the relevant DB connection component from the <b>Connection configuration</b> list to use predefined connection details.</p> <p> When a Job contains a parent Job and a child Job, <b>Connection configuration</b> only lists the connection components on the same Job level, so if you need to use an existing connection from another level, ensure that the connection components available are sharing the connection required.</p> <p>For further information about sharing DB connections across Job levels, refer to <b>Use or register a shared DB connection</b> in the properties table of the relevant connection component in <a href="#">Databases - traditional components</a>, <a href="#">Databases - appliance/datawarehouse components</a>, or <a href="#">Databases - other components</a>.</p> <p>Otherwise, you can deactivate the connection components and use the component's <b>Dynamic settings</b> to define the connection manually. In this case, ensure that the connection name is not used elsewhere in the job, on any level. For further information about <b>Dynamic settings</b>, see your studio user guide.</p> |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Limitation</b> | <p>The cube creation process does not create dimensions from scratch, so the dimensions to be used in the cube must be created beforehand.</p> <p>Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i>. For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i>.</p> |

## Scenario: Creating a cube in an existing database

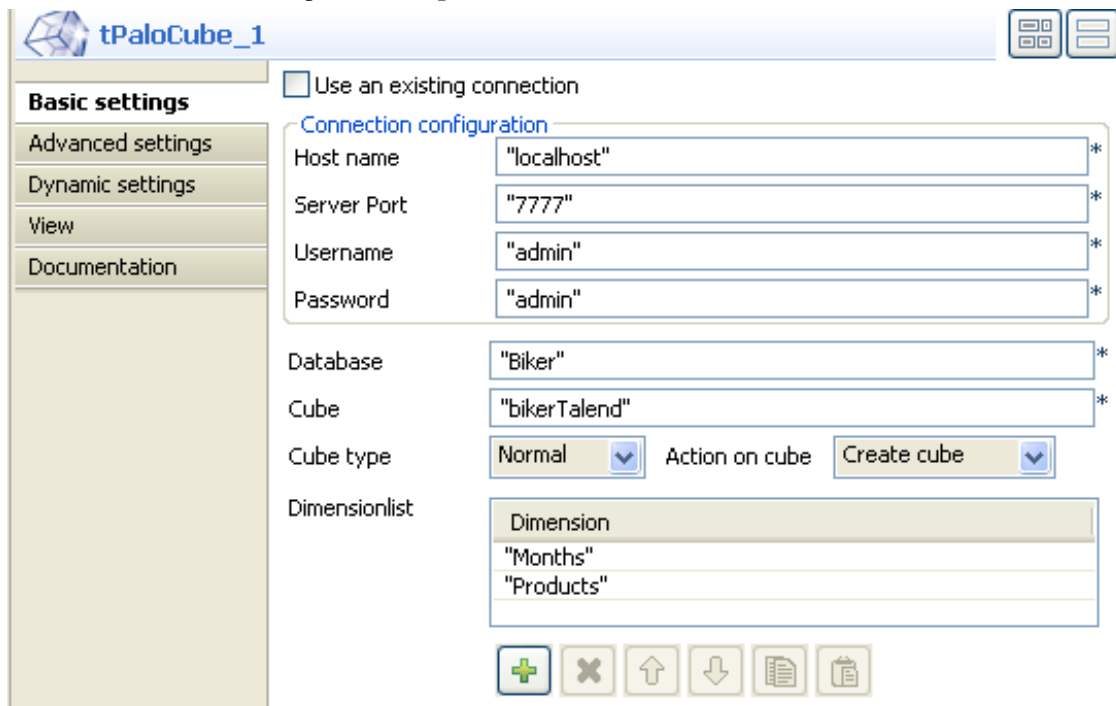

The Job in this scenario creates a new two dimensional cube in the Palo demo database *Biker*.

To replicate this scenario, proceed as follows:

## Configuring the tPaloCube component

1. Drop **tPaloCube** from the **Palette** onto the design workspace.
2. Double-click **tPaloCube** to open its **Component** view.

3. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
6. In the **Database** field, type in the database name in which you want to create the cube, *Biker* in this example.
7. In the **Cube** field, type in the name you want to use for the cube to be created, for example, *bikerTalend*.
8. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.
9. In the **Action on cube** field, select the action to be performed. In this scenario, select **Create cube**.
10. Under the **Dimension list** table, click the plus button twice to add two rows into the table.
11. In the **Dimension list** table, type in the name for each newly added row to replace the default row name. In this scenario, type in *Months* for the first row and *Products* for the second. These two dimensions exist already in the Biker database where the new cube will be created.

## Job execution

Press **F6** to run the Job.

A new cube has been created in the *Biker* database and the two dimensions are added into this cube.

# tPaloCubeList

## tPaloCubeList Properties

|                                                                                                                                    |                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i>. For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i>.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Discovering the read-only output schema of tPaloCubeList

The below table presents information related to the read-only schema of the **tPaloCubeList** component.

| Column  | Type | Description              |
|---------|------|--------------------------|
| Cube_id | int  | Internal id of the cube. |

| Column            | Type   | Description                                                                                                                                             |
|-------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cube_name         | string | Name of the cube.                                                                                                                                       |
| Cube_dimensions   | int    | Number of dimensions inside the cube.                                                                                                                   |
| Cube_cells        | long   | Number of calculated cells inside the cube.                                                                                                             |
| Cube_filled_cells | long   | Number of filled cells inside the cube.                                                                                                                 |
| Cube_status       | int    | Status of the cube. It may be:<br>- <b>0</b> : unloaded<br>- <b>1</b> : loaded<br>- <b>2</b> : changed                                                  |
| Cube_type         | int    | Type of the cube. It may be:<br>- <b>0</b> : normal<br>- <b>1</b> : system<br>- <b>2</b> : attribute<br>- <b>3</b> : user info<br>- <b>4</b> : gpu type |

## Scenario: Retrieving detailed cube information from a given database

The Job in this scenario retrieves detailed information of the cubes pertaining to the demo Palo database, *Biker*.

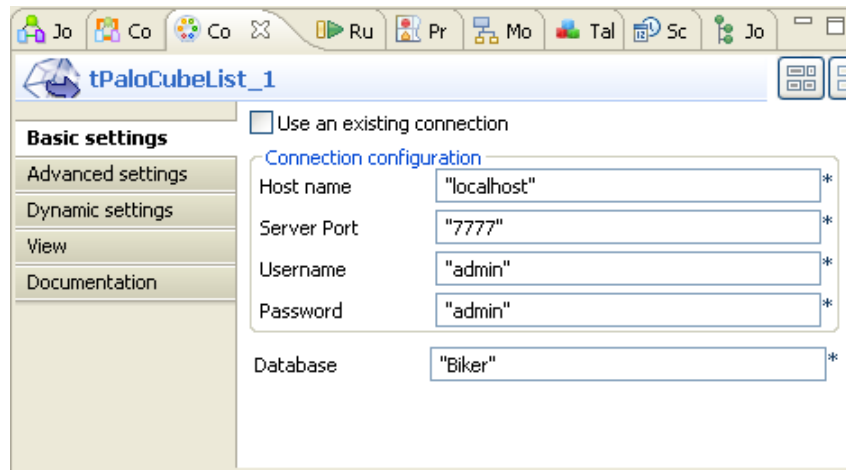

To replicate this scenario, proceed as follows:

### Setting up the Job

1. Drop **tPaloCubeList** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloCubeList** to open the contextual menu.
3. From this menu, select **Row > Main** to link the two components.

### Configuring the tPaloCube component

1. Double-click the **tPaloCube** component to open its **Component** view.

2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
5. In the **Database** field, type in the database name in which you want to create the cube, *Biker* in this example.

## Job execution

Press **F6** to run the Job.

The cube details are retrieved from the *Biker* database and are listed in the console of the **Run** view.

| <b>Limitation</b>        | Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> . |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

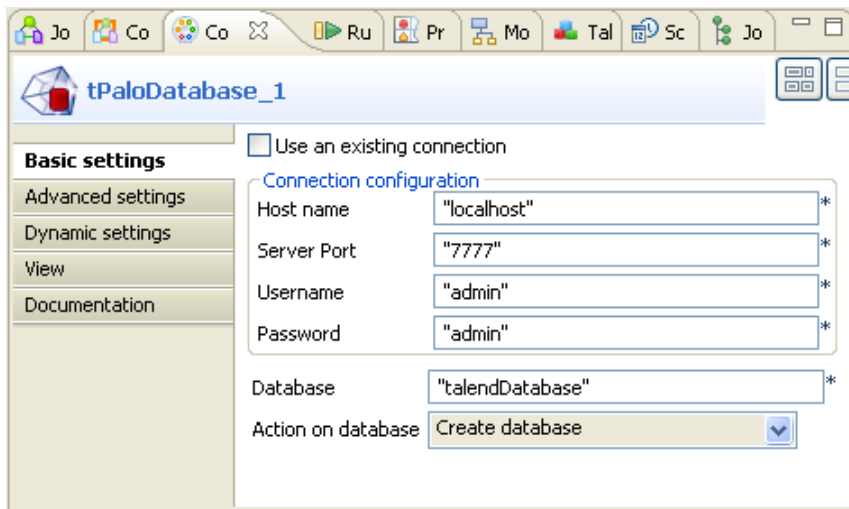

## Scenario: Creating a database

The Job in this scenario creates a new database on a given Palo server.

To replicate this scenario, proceed as follows:

1. Drop **tPaloDatabase** from the component **Palette** onto the design workspace.
2. Double-click the **tPaloDatabase** component to open its **Component** view.

3. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
6. In the **Database** field, type in the database name in which you want to create the cube, *talenddatabase* in this example.
7. In the **Action on database** field, select the action to be performed. In this scenario, select **Create database** as the database to be created does not exist.
8. Press **F6** to run the Job.

A new database is created on the given Palo server.

| <b>Limitation</b>       | <p>The output schema is fixed and read-only.</p> <p>Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i>. For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i>.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Discovering the read-only output schema of tPaloDatabaseList

The below table presents information related to the read-only output schema of the **tPaloDatabaseList** component.

| Database            | Type   | Description                               |
|---------------------|--------|-------------------------------------------|
| Database_id         | long   | Internal ID of the database.              |
| Database_name       | string | Name of the database.                     |
| Database_dimensions | int    | Number of dimensions inside the database. |
| Database_cubes      | int    | Number of cubes inside the database.      |
| Database_status     | int    | Status of the database.                   |

| Database       | Type | Description                                                           |
|----------------|------|-----------------------------------------------------------------------|
|                |      | - 0 = unloaded<br>- 1 = loaded<br>- 2 = changed                       |
| Database_types | int  | Type of the database.<br>- 0 =normal<br>- 1 =system<br>- 3 =user info |

## Scenario: Retrieving detailed database information from a given Palo server

The Job in this scenario retrieves details of all of the databases from a given Palo server.

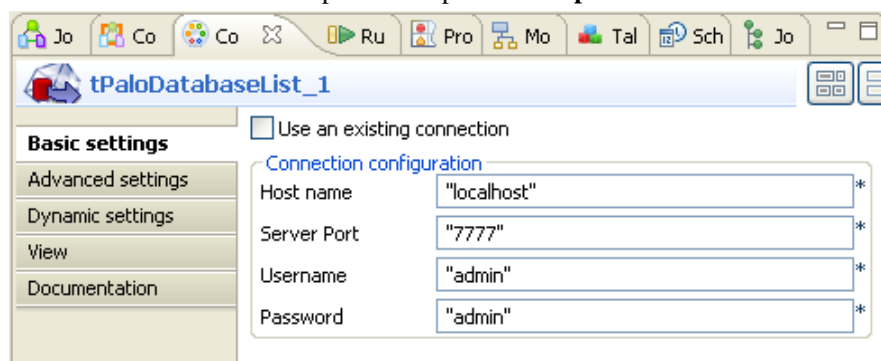

To replicate this scenario, proceed as follows:

### Setting up the Job

1. Drop **tPaloDatabaseList** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloDatabaseList** to open the contextual menu.
3. From this menu, select **Row > Main** to link the two components.

### Configuring the tPaloDatabaseList component

1. Double-click the **tPaloDatabaseList** component to open its **Component** view.

2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

## Job execution

Press **F6** to run the Job.

Details of all of the databases in the Palo server are retrieved and listed in the console of the **Run** view.

```
0|System|7|6|1|1
1|Demo|23|23|1|0
6|Biker|27|28|1|0
9|tx_g|17|17|1|0
25|DBHSE24|13|12|1|0
31|elmCreate|13|12|1|0
32|tPaloOutputMulit|15|15|1|0
```

For further information about the output schema, see [the section called “Discovering the read-only output schema of tPaloDatabaseList”](#).

# tPaloDimension

## tPaloDimension Properties

|                                                                                                                                    |                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                   | For further information regarding connections, see <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Limitation</b> | <p>Deletion of dimension elements is only possible with the consolidation type <b>None</b>. Only consolidation type <b>Self-Referenced</b> allows the placing of an factor on this consolidation.</p> <p>Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i>.</p> |

## Scenario: Creating a dimension with elements

The Job in this scenario creates a date dimension with simple element hierarchy composed of three levels: *Year, Month, Date*.

To replicate this scenario, proceed as follows:

### Setting up the Job

1. Drop **tPaloConnection**, **tRowGenerator**, **tMap**, **tPaloDimension** from the component **Palette** onto the design workspace.
2. Right-click **tPaloConnection** to open the contextual menu and select **Trigger > On Subjob Ok** to link it to **tRowGenerator**.
3. Right-click **tRowGenerator** to open the contextual menu and select **Row > Main** to link it to **tMap**.

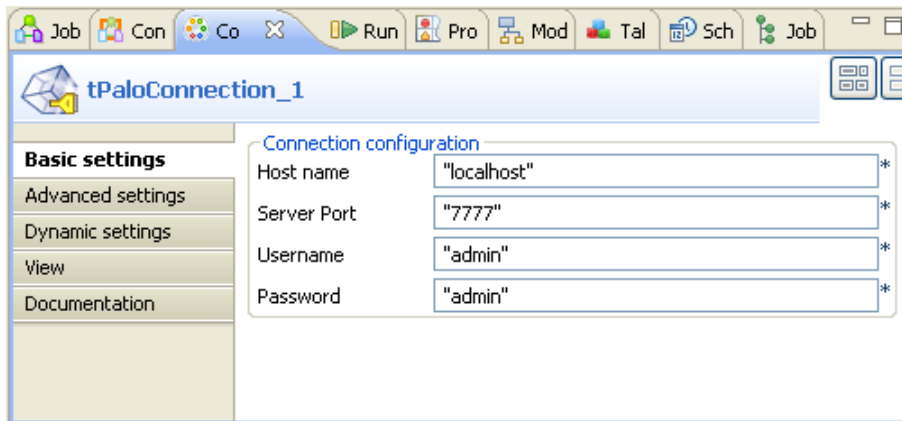

**tRowGenerator** is used to generate rows at random in order to simplify this process. In the real case, you can use one of the other input components to load your actual data.

4. Right-click **tMap** to open the contextual menu and select **Row > New output** to link to **tPaloDimension**, then name it as *out1* in the dialog box that pops up.

### Setting up the DB connection

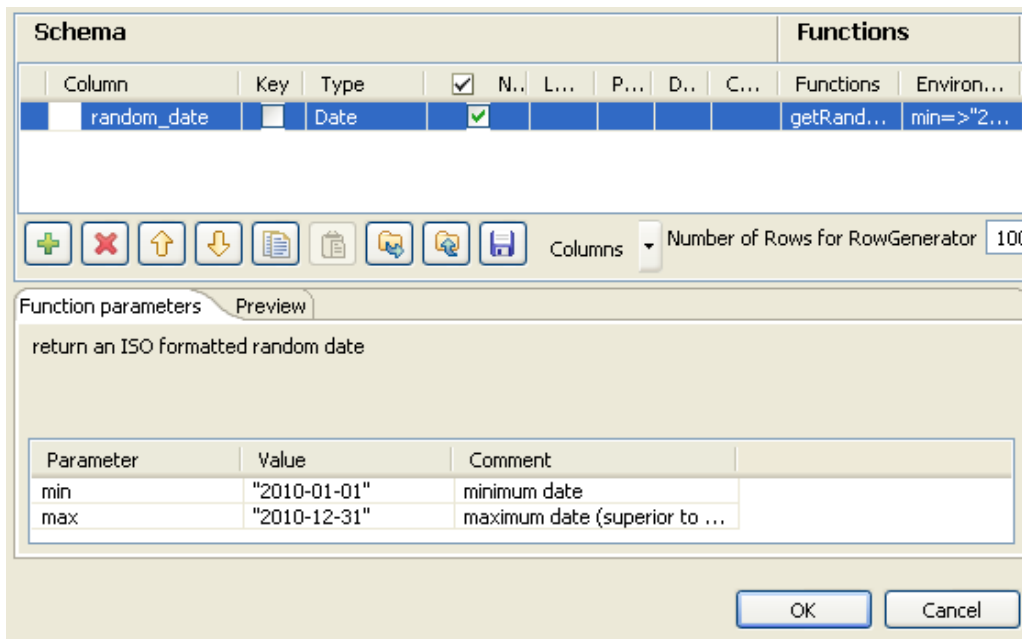

1. Double-click the **tPaloConnection** component to open its **Component** view.

2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

## Configuring the input component

1. Double-click **tRowGenerator** to open its editor.

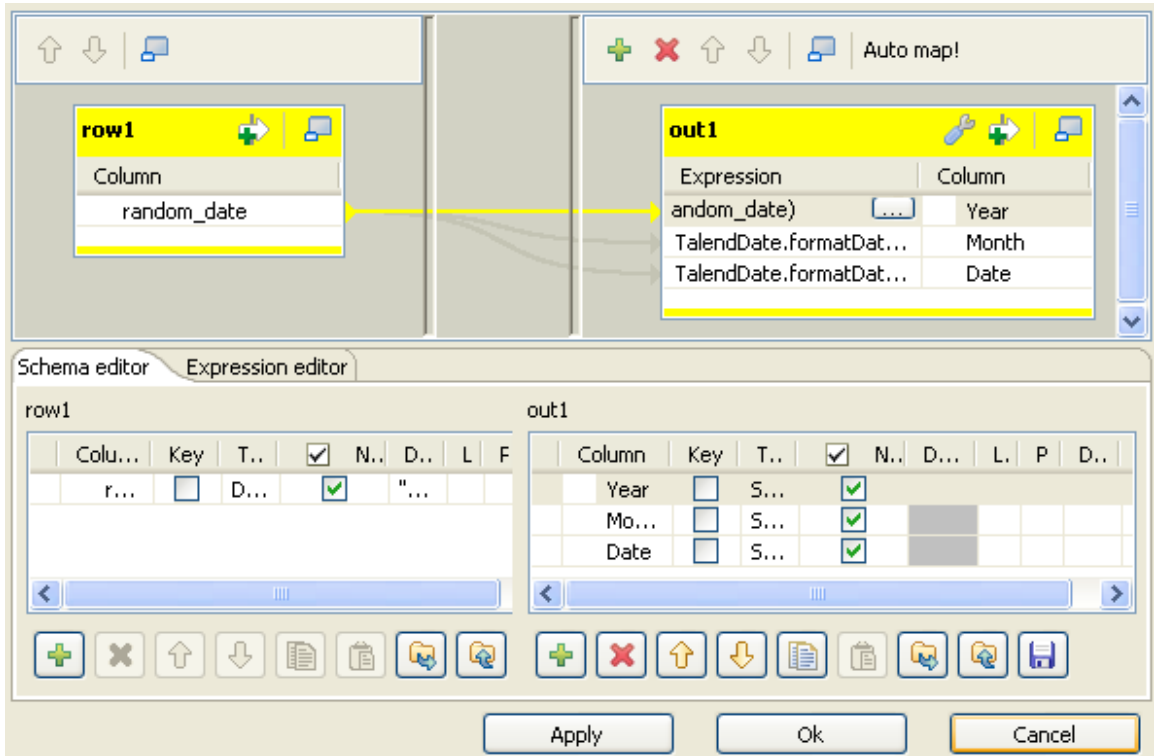

2. On the upper part of the editor, click the plus button to add one column and rename it as *random\_date* in the **Column** column.
3. In the newly added row, select *Date* in the **Type** column and **getRandomDate** in the **Functions** column.
4. In the **Function parameters** view on the lower part of this editor, type in the new minimum date and maximum date values in the **Value** column. In this example, the minimum is *2010-01-01*, the maximum is *2010-12-31*.
5. Click **OK** to validate your modifications and close the editor.
6. On the dialog box that pops up, click **OK** to propagate your changes.

## Configuration in the tMap editor

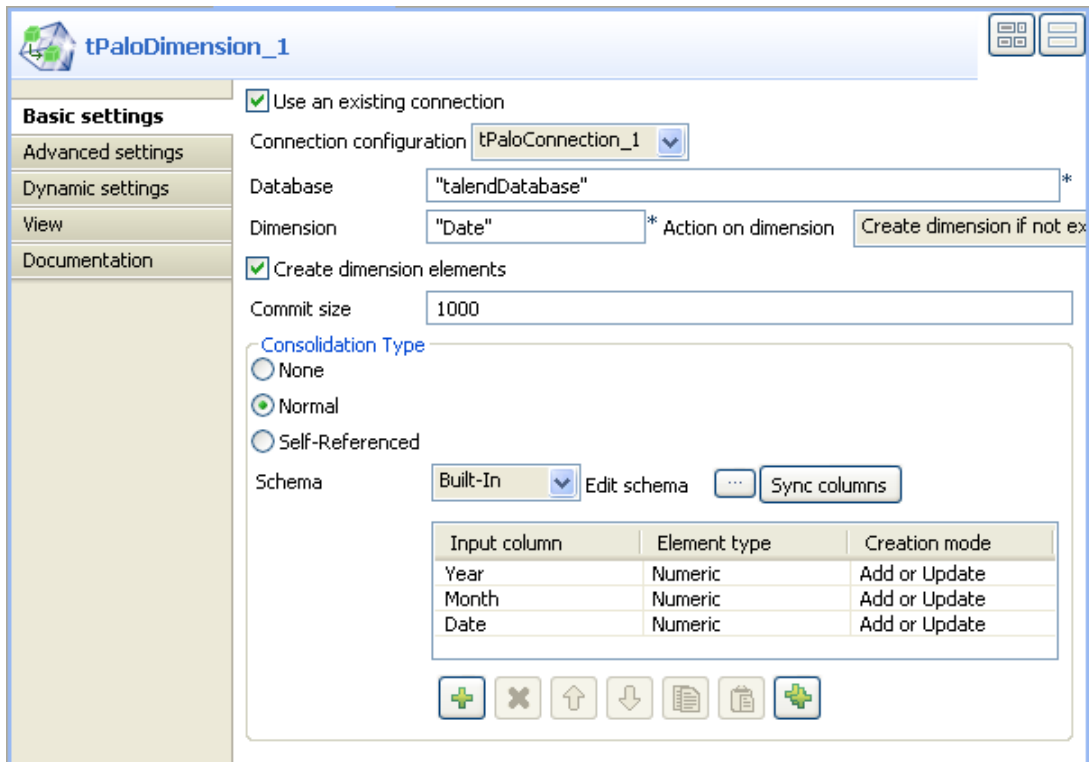

1. Double-click **tMap** to open its editor.

2. On the **Schema editor** view on the lower part of the **tMap** editor, under the **out1** table, click the plus button to add three rows.
3. In the **Column** column of the **out1** table, type in the new names for the three newly added rows. They are *Year*, *Month*, and *Date*. These rows are then added automatically into the **out1** table on the upper part of the **tMap** editor.
4. In the **out1** table on the upper part of the **tMap** editor, click the **Expression** column in the *Year* row to locate the cursor.
5. Press **Ctrl+space** to open the drop-down variable list.
6. Double-click **TalendDate.formatDate** to select it from the list. The expression to get the date displays in the *Year* row under the **Expression** column. The expression is `TalendDate.formatDate("yyyy-MM-dd HH:mm:ss", myDate)`.
7. Replace the default expression with `TalendDate.formatDate("yyyy", row1.random_date)`.
8. Do the same for the *Month* row and the *Date* row to add this default expression and to replace it with `TalendDate.formatDate("MM", row1.random_date)` for the *Month* row and with `TalendDate.formatDate("dd-MM-yyyy", row1.random_date)` for the *Date* row.
9. Click **OK** to validate this modification and accept the propagation by clicking **OK** in the dialog box that pops up.

## Configuring the tPaloDimension component

1. On the workspace, double-click **tPaloDimension** to open its **Component** view.

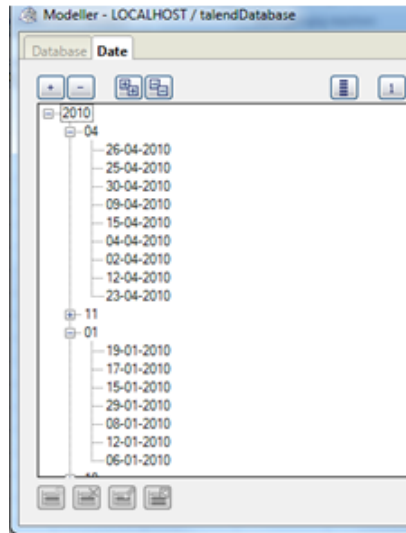

2. Select the **Use an existing connection** check box. Then **tPaloConnection\_1** displays automatically in the **Connection configuration** field.
3. In the **Database** field, type in the database in which the new dimension is created, *talendDatabase* for this scenario.
4. In the **Dimension** field, type in the name you want to use for the dimension to be created, for example, *Date*.
5. In the **Action on dimension** field, select the action to be performed. In this scenario, select **Create dimension if not exist**.
6. Select the **Create dimension elements** check box.
7. In the **Consolidation Type** area, select the **Normal** check box.
8. Under the element hierarchy table in the **Consolidation Type** area, click the plus button to add three rows into the table.
9. In the **Input column** column of the element hierarchy table, select *Year* from the drop-down list for the first row, *Month* for the second and *Date* for the third. This determines levels of elements from different columns of the input schema.

## Job execution

Press **F6** to run the Job.

A new dimension is then created in your Palo database *talendDatabase*.

# tPaloDimensionList

## tPaloDimensionList Properties

|                                                                                                                                    |                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i>. For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i>.</p> |                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Discovering the read-only output schema of tPaloDimensionList

The below table presents information related to the read-only output schema of the **tPaloDimensionList** component.

| Database                 | Type   | Description                                                                                                                          |
|--------------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------|
| Dimension_id             | long   | Internal ID of the dimension.                                                                                                        |
| Dimension_name           | string | Name of the dimension.                                                                                                               |
| Dimension_attribute_cube | string | Name of the cube of attributes.                                                                                                      |
| Dimension_rights_cube    | string | Name of the cube of rights.                                                                                                          |
| Dimension_elements       | int    | Number of the dimension elements                                                                                                     |
| Dimension_max_level      | int    | Maximum level of the dimension                                                                                                       |
| Dimension_max_indent     | int    | Maximum indent of the dimension                                                                                                      |
| Dimension_max_depth      | int    | Maximum depth of the dimension                                                                                                       |
| Dimension_type           | int    | Type of the dimension.<br><br>- <b>0</b> =normal<br><br>- <b>1</b> =system<br><br>- <b>2</b> =attribute<br><br>- <b>3</b> =user info |

## Scenario: Retrieving detailed dimension information from a given database

The Job in this scenario retrieves details of all of the dimensions from a given database.

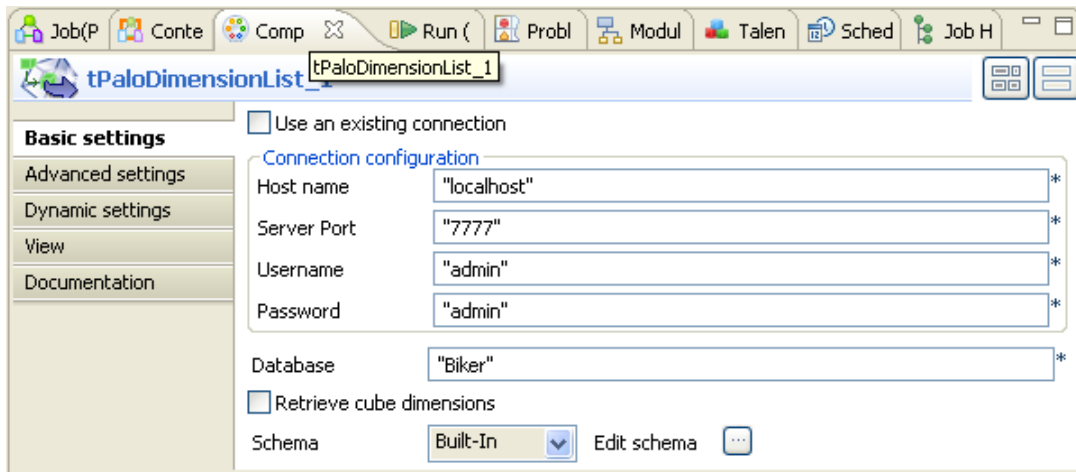

To replicate this scenario, proceed as follows:

### Setting up the Job

1. Drop **tPaloDimensionList** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloDimensionList** to open the contextual menu.
3. From this menu, select **Row > Main** to link the two components.

### Configuring the tPaloDimensionList component

1. Double-click the **tPaloDimensionList** component to open its **Component** view.

2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
5. In the **Database** field, type in the database name where the dimensions of interest reside, *Biker* in this example.

## Job execution

Press **F6** to run the Job.

Details of all the dimensions in the *Biker* database are retrieved and listed in the console of the **Run** view.

| <b>Limitation</b> | <p>According to the architecture of OLAP-Systems only one single value (text or numeric) could be retrieved from the cube. The <b>MEASURE</b> column and the <b>TEXT</b> column are fixed and read-only.</p> <p>Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i>. For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i>.</p> |

## Scenario: Retrieving dimension elements from a given cube

The Job in this scenario retrieves several dimension elements from a demo Palo cube *Sales*.

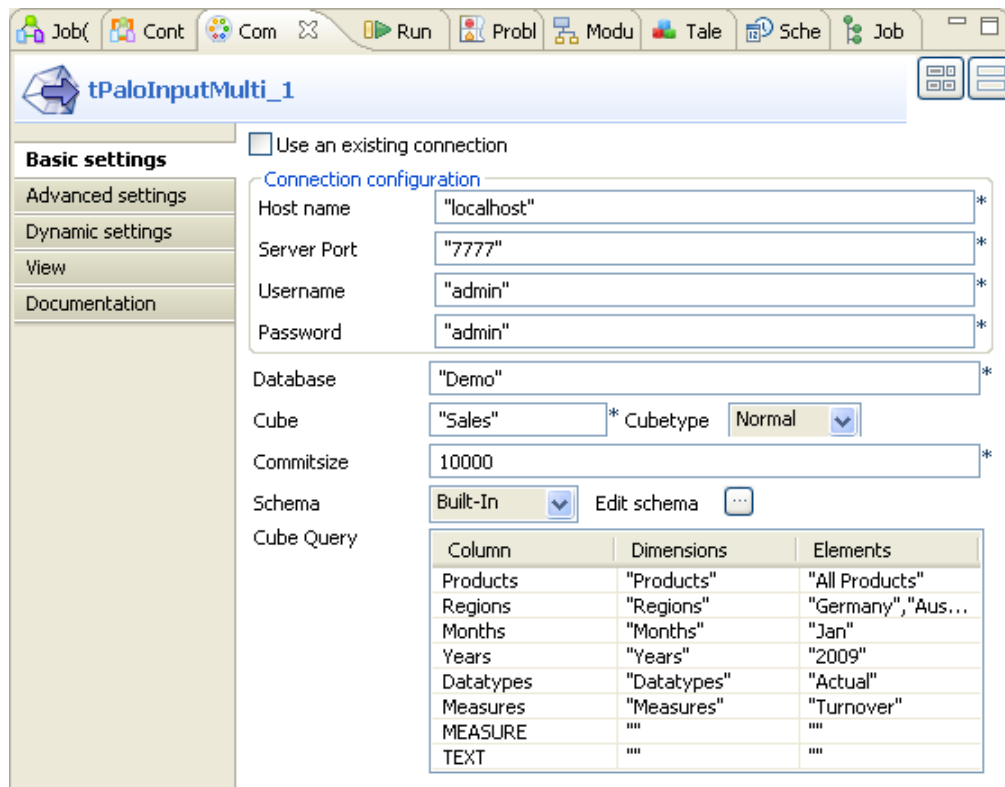

To replicate this scenario, proceed as follows:

### Setting up the Job

1. Drop **tPaloInputMulti** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloInputMulti** to open its contextual menu.
3. In the menu, select **Row > Main** to connect **tPaloInputMulti** to **tLogRow** with a **row** link.

### Setting up the DB connection

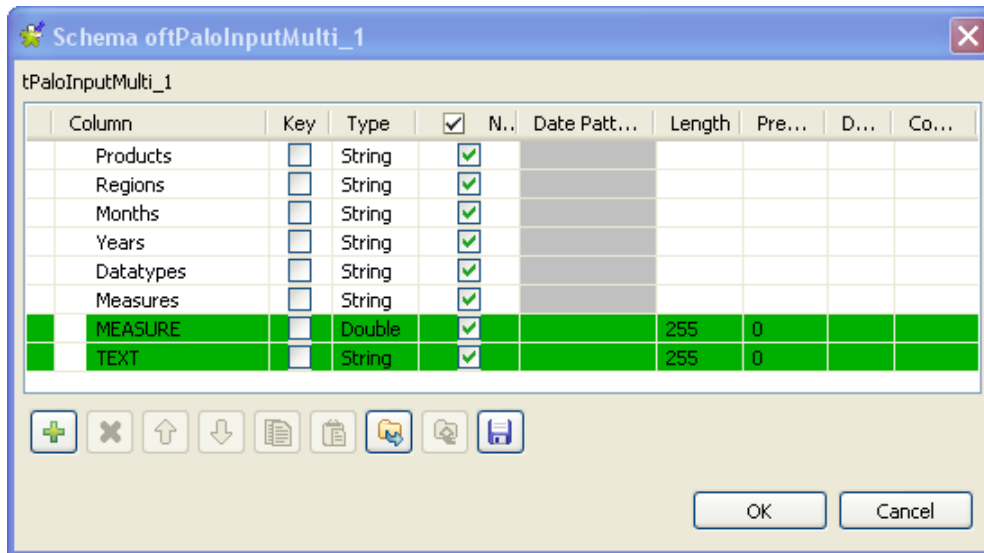

1. Double-click the **tPaloInputMulti** component to open its **Component** view.

2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

## Configuring the Cube Query

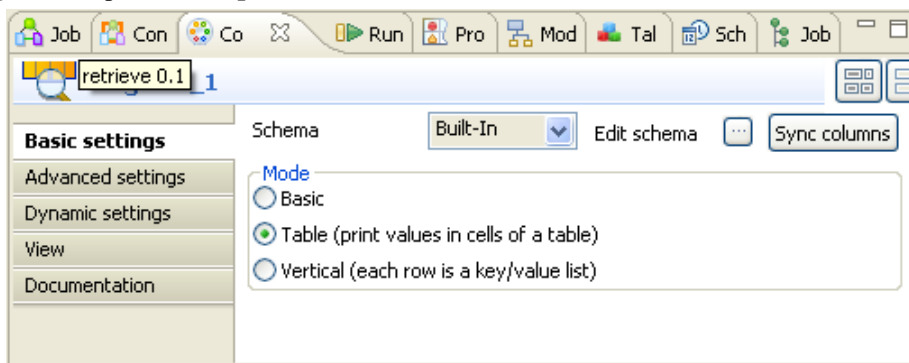

1. In the **Database** field, type in the database name in which the cube to be used is stored.
2. In the **Cube** field, type in the cube name in which the dimensions of interests are stored. In this scenario, it is one of the demo cubes *Sales*.
3. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.
4. Next to the **Edit schema** field, click the three-dot button to open the schema editor.

5. In the schema editor, click the plus button to add the rows of the schema to be edited. In this example, add rows corresponding to all of the dimensions stored in the *Sales* cube: *Products*, *Regions*, *Months*, *Years*, *Datatypes*, *Measures*. Type in them in the order given in this cube.
6. Click **OK** to validate this editing and accept the propagation of this change to the next component. Then these columns are added automatically into the **Column** column of the **Cube query** table in the **Component** view. If the order is not consistent with the one in the *Sales* cube, adapt it using the up and down arrows under the schema table.
7. In the **Dimensions** column of the **Cube query** table, type in each of the dimension names stored in the *Sales* cube regarding to each row in the **Column** column. In the *Sales* cube, the dimension names are: *Products*, *Regions*, *Months*, *Years*, *Datatypes*, *Measures*.
8. In the **Elements** columns of the **Cube query** table, type in the dimension elements you want to retrieve regarding to the dimensions they belong to. In this example, the elements to be retrieved are *All Products*, *Germany* and *Austria* (Belonging to the same dimension **Regions**, these two elements are entered in the same row and separated with a coma.), *Jan, 2009*, *Actual*, *Turnover*.

## Job execution

1. Click **tLogRow** to open its **Component** view.

2. In the **Mode** area, select the **Table (print values in cells of a table)** check box to display the execution result in a table.
3. Press **F6** to run the Job.

The dimension elements and the corresponding Measure values display in the **Run** console.

| <b>Limitation</b> | <p>Numeric measures are only be accepted as Double or String type. When the string type is used, write the value to be processed between quotation marks.</p> <p>Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i>. For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i>.</p> |

## Scenario 1: Writing data into a given cube

The Job in this scenario writes new values in the *Sales* cube given as demo in the *Demo* database installed with Palo.

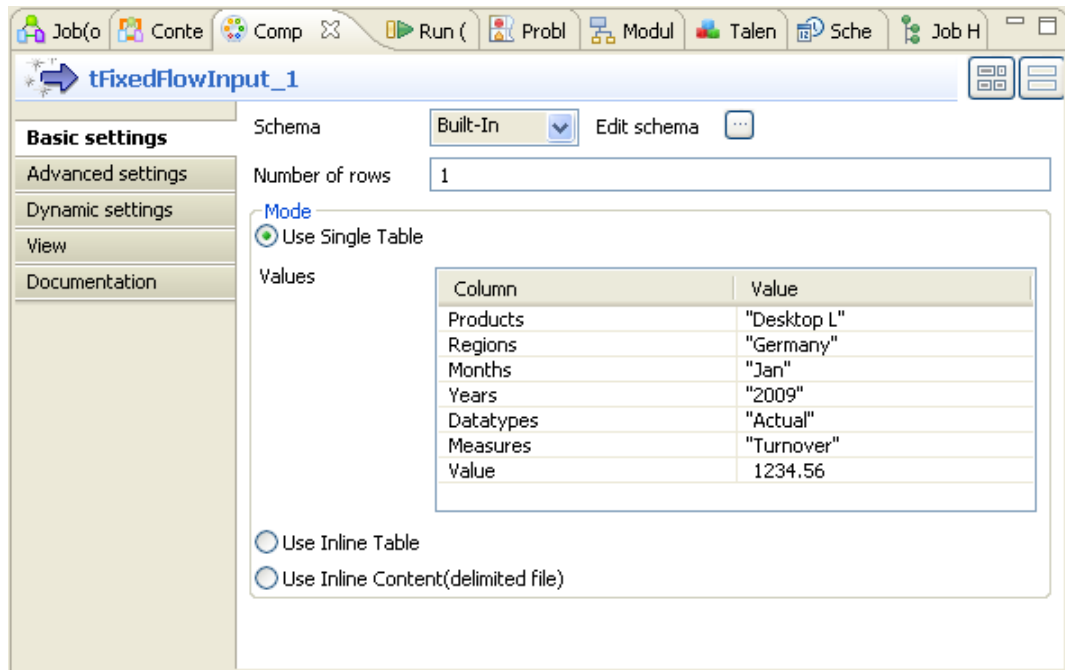

To replicate this scenario, proceed as follows:

### Setting up the Job

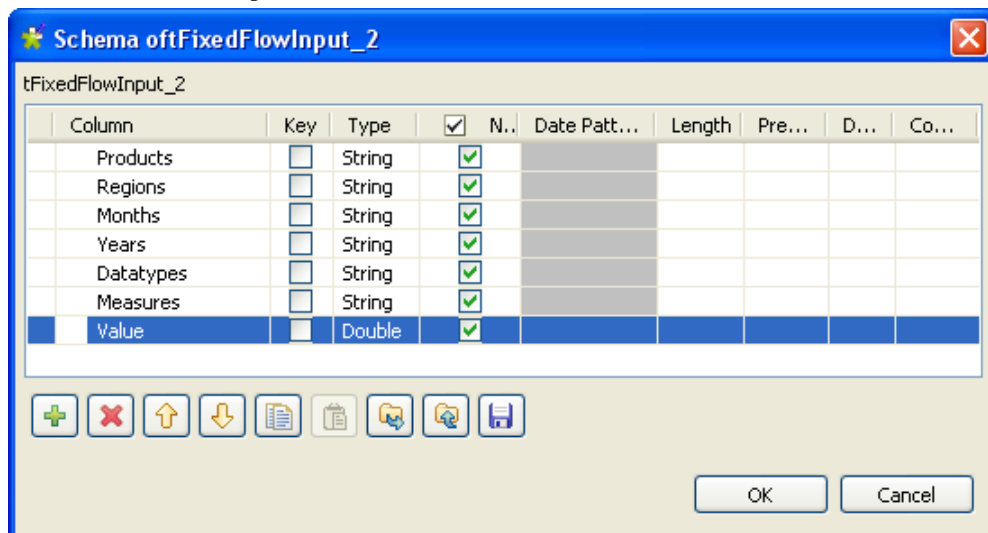

1. Drop **tFixedFlowInput** and **tPaloOutputMulti** from the component **Palette** onto the design workspace.
2. Right-click **tFixedFlowInput** to open its contextual menu.
3. In this menu, select **Row > Main** to connect this component to **tPaloOutputMulti**.

### Configuring the input component

1. Double-click the **tFixedFlowInput** component to open its **Component** view.

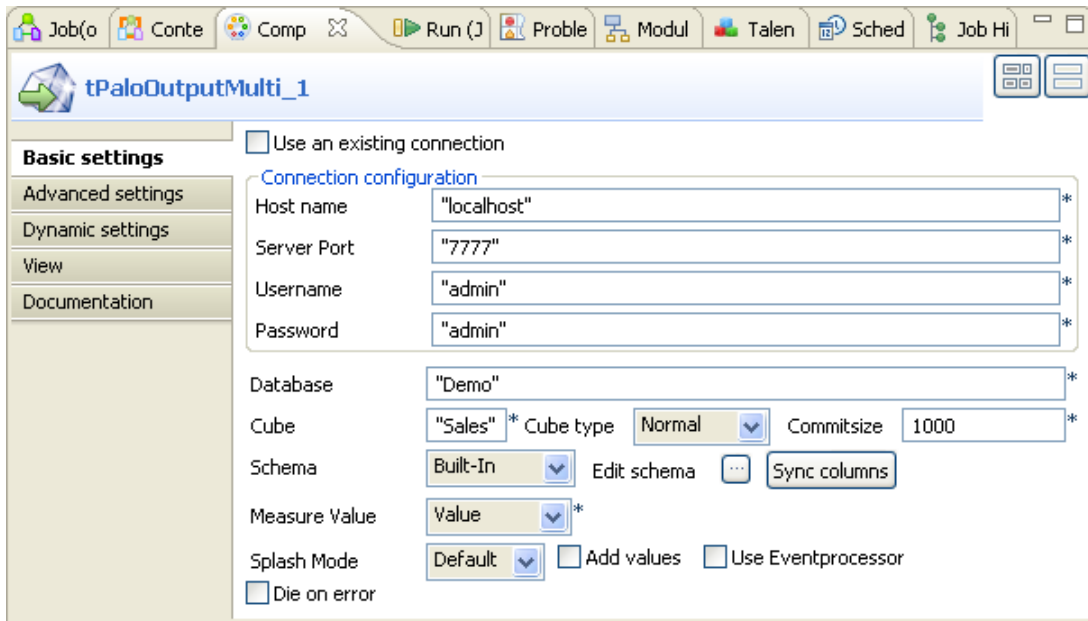

2. Click the three-dot button to open the schema editor.

3. In the schema editor, click the plus button to add 7 rows and rename them respectively as *Products*, *Regions*, *Months*, *Years*, *Datatypes*, *Measures* and *Values*. The order of these rows must be consistent with that of the corresponding dimensions in the *Sales* cube and the type of the *Value* column where the measure value resides is set to double/Double.
4. Click **OK** to validate the editing and accept the propagation prompted by the dialog box that pops up. Then the schema column labels display automatically in the **Value** table under the **Use single table** check box, in the **Mode** area.
5. In the **Value** table, type in values for each row in the **Value** column. In this example, these values are: *Desktop L*, *Germany*, *Jan*, *2009*, *Actual*, *Turnover*, *1234.56*.

## Configuring the output component

1. Double-click **tPaloOutputMulti** to open its **Component** view.

2. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.
3. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
4. In the **Database** field, type in the database name in which you want to create the cube, *Demo* in this example.
5. In the **Cube** field, type in the name of the cube you want to write data in, for example, *Sales*.
6. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.
7. In the **Measure Value** field, select the Measure element. In this scenario, select **Value**.

## Job execution

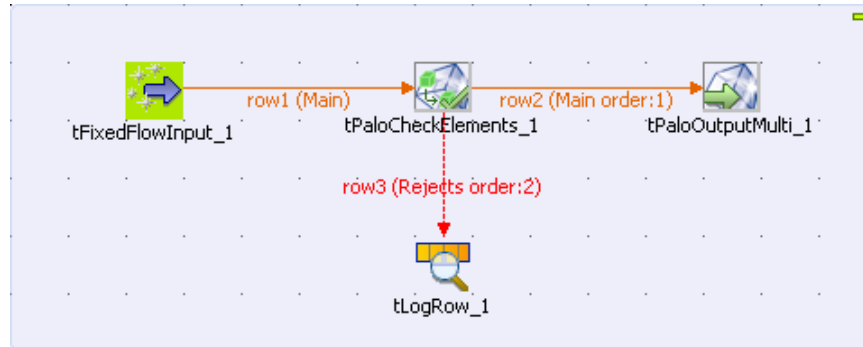

Press **F6** to run the Job.

The inflow data has been written into the *Sales* cube.

|    | A              |
|----|----------------|
| 1  | localhost/Demo |
| 2  | Sales          |
| 3  | Desktop L      |
| 4  | Germany        |
| 5  | Jan            |
| 6  | 2009           |
| 7  | Actual         |
| 8  | Turnover       |
| 9  |                |
| 10 | 1 234,56       |
| 11 |                |

## Scenario 2: Rejecting inflow data when the elements to be written do not exist in a given cube

The Job in this scenario tries to write data into the *Sales* cube but as the elements of interest do not exist in this cube, the inflow data is rejected.

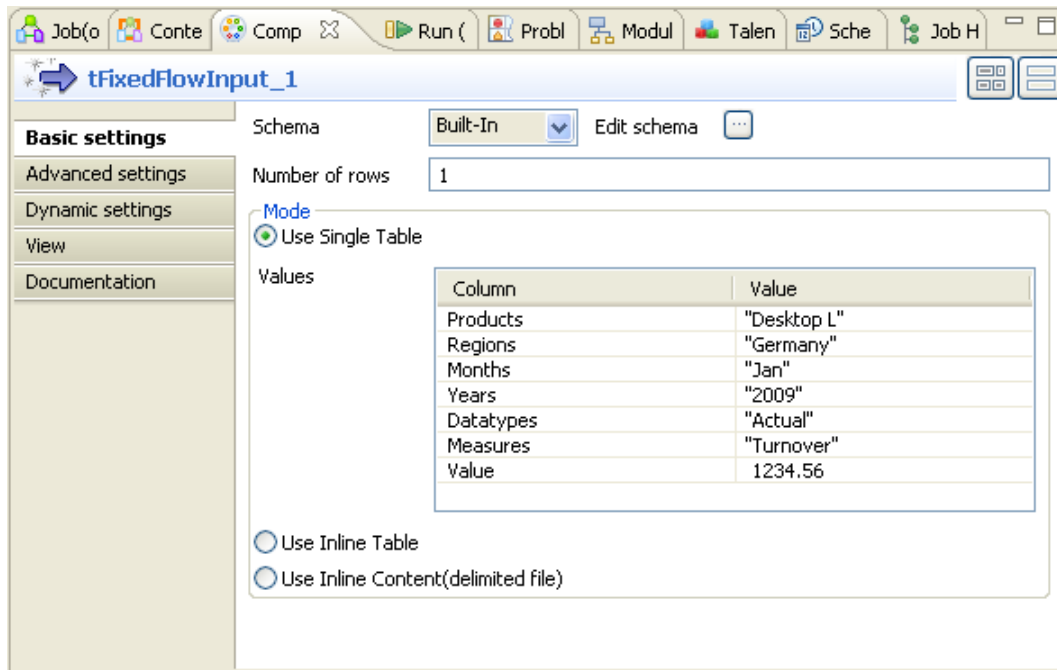

To replicate this scenario, proceed as follows:

### Setting up the Job

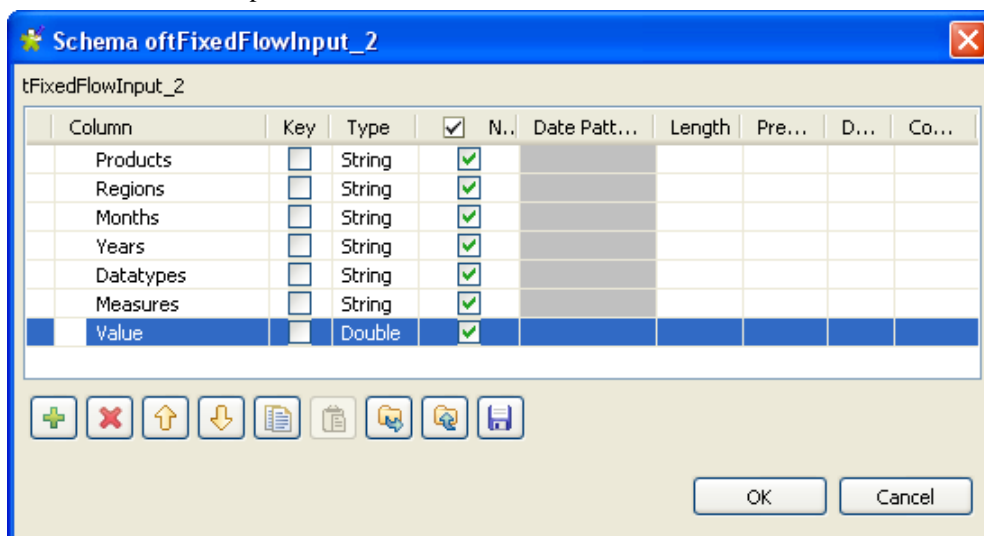

1. Drop **tFixedFlowInput**, **tPaloCheckElements**, **tPaloOutputMulti** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tFixedFlowInput** to open its contextual menu.
3. In this menu, select **Row > Main** to connect this component to **tPaloCheckElements**.
4. Do the same to connect **tPaloOutputMulti** using **row** link.
5. Right-click **tPaloCheckElements** to open its contextual menu.
6. In this menu, select **Row > Reject** to connect this component to **tLogRow**.

### Configuring the input component

1. Double-click the **tFixedFlowInput** component to open its **Component** view.

2. Click the three-dot button to open the schema editor.

3. In the schema editor, click the plus button to add 7 rows and rename them respectively as *Products*, *Regions*, *Months*, *Years*, *Datatypes*, *Measures* and *Values*. The order of these rows must be consistent with that of the corresponding dimensions in the *Sales* cube and the type of the *Value* column where the measure value resides is set to double/Double.
4. Click **OK** to validate the editing and accept the propagation prompted by the dialog box that pops up. Then the schema column labels display automatically in the **Value** table under the **Use single table** check box, in the **Mode** area.
5. In the **Value** table, type in values for each row in the **Value** column. In this example, these values are: *Smart Products*, *Germany*, *Jan*, *2009*, *Actual*, *Turnover*, *1234.56*. The *Smart Products* element does not exist in the *Sales* cube.

## Configuring the tPaloCheckElements component

1. Double-click **tPaloCheckElements** to open its **Component** view.

2. In the **Host name** field, type in *localhost*.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
5. In the **Database** field, type in the database name in which you want to create the cube, *Demo* in this example.
6. In the **Cube** field, type in the name of the cube you want to write data in, for example, *Sales*.
7. In the **On Element error** field, select **Reject row** from the drop-down list.
8. In the element table at the bottom of the **Basic settings** view, click the **Element type** column in the *Value* row and select **Measure** from the drop down list.

## Configuring the output component

1. Double-click **tPaloOutputMulti** to open its **Component** view.

2. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.
3. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
4. In the **Database** field, type in the database name in which you want to create the cube, *Demo* in this example.
5. In the **Cube** field, type in the name of the cube you want to write data in, for example, *Sales*.
6. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.
7. In the **Measure Value** field, select the Measure element. In this scenario, select **Value**.

## Job execution

Press **F6** to run the Job.

The data to be written is rejected and displayed in the console of the **Run** view. You can read that the error message is *Smart Products*.

*Starting job JobOutputExistingElements at 14:45 09/11/2010.*

| <b>Limitation</b>        | Update or deletion of a rule is available only when this rule has been created with external ID.<br><br>Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> . |                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Scenario: Creating a rule in a given cube

The Job in this scenario creates a rule applied on dimensions of a given cube.

To replicate this scenario, proceed as follows:

## Setting up the DB connection

1. Drop **tPaloRule** from the component **Palette** onto the design workspace.
2. Double-click the **tPaloRule** component to open its **Component** view.

 A screenshot of the 'tPaloRule\_1' component configuration dialog box. The dialog has a title bar with the component name and a 'fx' icon. On the left, there are tabs for 'Basic settings', 'Advanced settings', 'Dynamic settings', 'View', and 'Documentation'. The 'Basic settings' tab is active. At the top, there is a checkbox 'Use an existing connection' which is unchecked. Below it is the 'Connection configuration' section with several text input fields: 'Host name' (localhost), 'Server Port' (7777), 'Username' (admin), and 'Password' (admin). Below these are 'Database' (Biker) and 'Cube' (Orders). At the bottom, there is a 'Cube Rules' table.
 

| Definition     | External Id  | Comment           | <input checked="" type="checkbox"/> Activated | Action |
|----------------|--------------|-------------------|-----------------------------------------------|--------|
| "[2009] = 123" | "OrderRule1" | "Palo Demo Rules" | <input checked="" type="checkbox"/>           | Create |

 At the bottom of the dialog, there are several icons: a plus sign, a minus sign, an up arrow, a down arrow, a document icon, and a trash icon.

3. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
6. In the **Database** field, type in the database name in which the dimensions applying the created rules reside, *Biker* in this example.
7. In the **Cube** field, type in the name of the cube which the dimensions applying the created rules belong to, for example, *Orders*.

## Setting the Cube rules

1. Under the **Cube rules** table, click the plus button to add a new row.
2. In the **Cube rules** table, type in [ ' 2009 ' ] = 123 in the **Definition** column, OrderRule1 in the **External Id** column and Palo Demo Rules in the **Comment** column.
3. In the **Activated** column, select the check box.
4. In the **Action** column, select **Create** from the drop-down list.

## Job execution

Press **F6** to run the Job.

The new rule has been created and the value of every 2009 element is 123.

|    | A               |
|----|-----------------|
| 1  | localhost/Biker |
| 2  | Orders          |
| 3  | All Customers   |
| 4  | All Channels    |
| 5  | All Orders      |
| 6  | All Datatypes   |
| 7  | Units           |
| 8  | All Products    |
| 9  | All Months      |
| 10 | 2009            |
| 11 |                 |
| 12 | 123             |
| 13 |                 |

# tPaloRuleList

## tPaloRuleList Properties

| <b>Limitation</b>        | <p>The output schema is fixed and read-only.</p> <p>Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i>. For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i>.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Discovering the read-only output schema of tPaloRuleList

The following table presents information related to the read-only output schema of the **tPaloRuleList** component.

| Database        | Type    | Description                                                                                    |
|-----------------|---------|------------------------------------------------------------------------------------------------|
| rule_identifier | long    | The internal identifier/id for this rule..                                                     |
| rule_definition | string  | The formula of this rule. For further information about this formula, see the Palo user guide. |
| rule_extern_id  | string  | The user-defined external id.                                                                  |
| rule_comment    | string  | The user-edited comment on this rule.                                                          |
| rule_activated  | boolean | Indicates if this rule had been activated or not.                                              |

## Scenario: Retrieving detailed rule information from a given cube

The Job in this scenario retrieves rule details applied on the dimensions of a given cube.

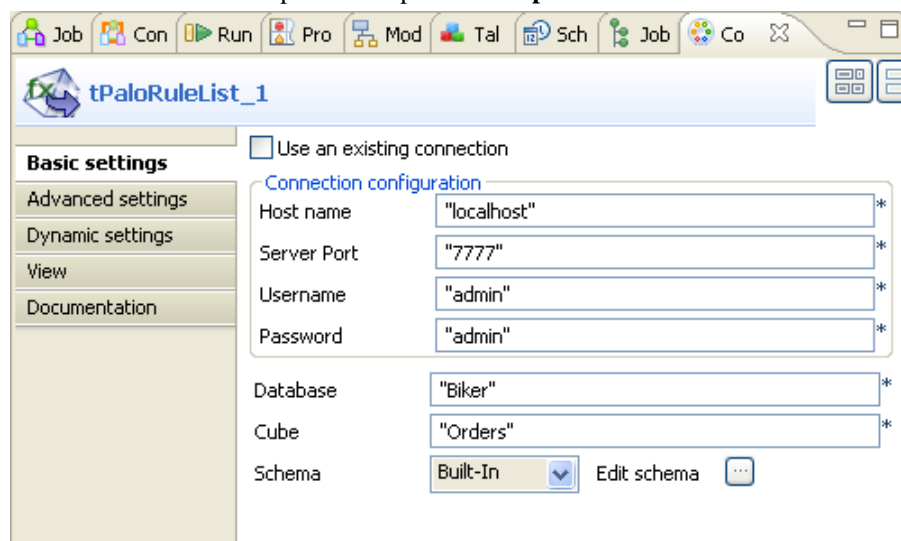

To replicate this scenario, proceed as follows:

### Setting up the Job

1. Drop **tPaloRuleList** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloRuleList** to open the contextual menu.
3. From this menu, select **Row > Main** to link the two components.

### Configuring the tPaloRuleList component

1. Double-click the **tPaloRuleList** component to open its **Component** view.

2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
4. In the **Username** and **Password** fields, type in the authentication information. In this example, both of them are *admin*.
5. In the **Database** field, type in the database name where the dimensions applying the rules of interest reside, *Biker* in this example.
6. In the **Cube** field, type in the name of the cube which the rules of interest belong to.

## Job execution

Press **F6** to run the Job.

Details of all of the rules in the *Orders* cube are retrieved and listed in the console of the **Run** view.

```
Starting job tpalo at 16:34 12/11/2010.
[statistics] connecting to socket on port 3743
[statistics] connected
+-----+-----+-----+-----+-----+
| |tLogRow_1| |
+-----+-----+-----+-----+-----+
|rule_identifier|rule_definition|rule_extern_id|rule_comment |rule_activated|
+-----+-----+-----+-----+-----+
|1 |['2009'] = 123 |OrderRule1 |Palo Demo Rules|true |
+-----+-----+-----+-----+-----+
[statistics] disconnected
Job tpalo ended at 16:35 12/11/2010. [exit code=0]
```

For further information about the output schema, see [the section called “Discovering the read-only output schema of tPaloRuleList”](#).

|  | <i>Schema</i><br><i>schema</i>     | and<br><i>Edit</i> | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|  |                                    |                    | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|  | <i>Surrogate Key</i>               |                    | Select the surrogate key column from the list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|  | <i>Creation</i>                    |                    | <p>Select the method to be used for the surrogate key generation.</p> <p>For more information regarding the creation methods, see <a href="#">the section called “SCD keys”</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|  | <i>Source Keys</i>                 |                    | Select one or more columns to be used as keys, to ensure the unicity of incoming data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|  | <i>Use SCD Type 1 fields</i>       |                    | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|  | <i>Use SCD Type 2 fields</i>       |                    | <p>Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.</p> <p><b>Start date:</b> Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.</p> <p><b>End Date:</b> Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select <b>Fixed Year value</b> and fill it in with a fictive year to avoid having a null value in the End Date field.</p> |

|                          |                                                                                                           |                                                                                                                                                                                                                                                                                    |
|--------------------------|-----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                                                                           | <p><b>Log Active Status:</b> Adds a column to your SCD schema to hold the <b>true</b> or <b>false</b> status value. This column helps to easily spot the active record.</p> <p><b>Log versions:</b> Adds a column to your SCD schema to hold the version number of the record.</p> |
| <b>Advanced settings</b> | <i>Debug mode</i>                                                                                         | Select this check box to display each step during processing entries in a database.                                                                                                                                                                                                |

You do not have the possibility to rollback the operation.</p>                                                                          |
|  | <i>Schema and Edit schema</i> | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|  |                               | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|  | <i>Surrogate Key</i>          | Select the surrogate key column from the list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|  | <i>Creation</i>               | <p>Select the method to be used for the surrogate key generation.</p> <p>For more information regarding the creation methods, see <a href="#">the section called “SCD keys”</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|  | <i>Source Keys</i>            | Select one or more columns to be used as keys, to ensure the unicity of incoming data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|  | <i>Use SCD Type 1 fields</i>  | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|  | <i>Use SCD Type 2 fields</i>  | <p>Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.</p> <p><b>Start date:</b> Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.</p> <p><b>End Date:</b> Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select <b>Fixed Year value</b> and fill it in with a fictive year to avoid having a null value in the End Date field.</p> |

|                          |                                                                                                           |                                                                                                                                                                                                                                                                                    |
|--------------------------|-----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                                                                           | <p><b>Log Active Status:</b> Adds a column to your SCD schema to hold the <b>true</b> or <b>false</b> status value. This column helps to easily spot the active record.</p> <p><b>Log versions:</b> Adds a column to your SCD schema to hold the version number of the record.</p> |
| <b>Advanced settings</b> | <i>Debug mode</i>                                                                                         | Select this check box to display each step during processing entries in a database.                                                                                                                                                                                                |

## Scenario: Displaying the content of an SPSS .sav file

The following scenario creates a two-component Job, which aims at reading each row of a .sav file and displaying the output on the log console.

### Setting up the Job

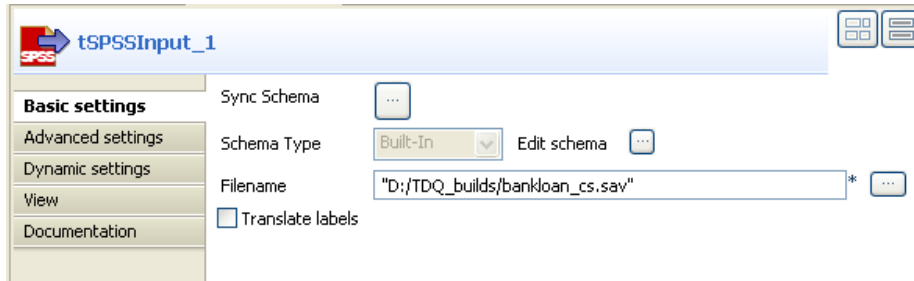

1. Drop a **tSPSSInput** component and a **tLogRow** component from the **Palette** onto the design workspace.

- Right-click on **tPSSInput** and connect it to **tLogRow** using a **Main Row** link.

## Configuring the input component

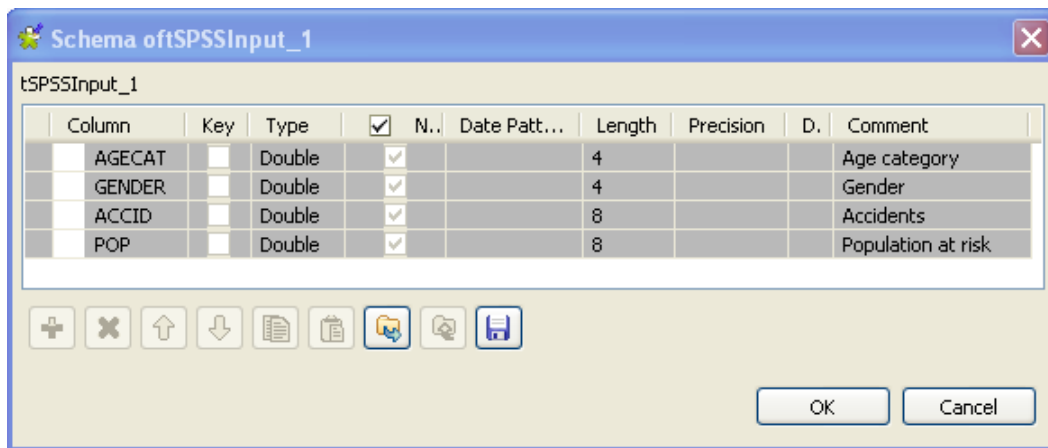

- Click **tPSSInput** to display its **Basic settings** view and define the component properties.

- Click the three-dot button next to the **Filename** field and browse to the SPSS .sav file you want to read.
- Click the three-dot button next to **Sync schema**. A message opens up prompting you to accept retrieving the schema from the defined SPSS file.

- Click **Yes** to close the message and proceed to the next step.
- If required, click the three-dot button next to **Edit schema** to view the pre-defined data structure of the source SPSS file.

- Click **OK** to close the dialog box.

## Job execution

Save the Job and press **F6** to execute it.

The SPSS file is read row by row and the extracted fields are displayed on the log console.

```

Starting job SPSS at 10:28 20/01/2010.
[statistics] connecting to socket on port 3802
[statistics] connected
1.0|1.0|57997.0|198522.0
2.0|1.0|57113.0|203200.0
3.0|1.0|54123.0|200744.0
1.0|0.0|63936.0|187791.0
2.0|0.0|64835.0|195714.0
3.0|0.0|66804.0|208239.0
[statistics] disconnected
Job SPSS ended at 10:28 20/01/2010. [exit code=0]

```

## Translating the stored values

To translate the stored values, complete the following:

1. In the **Basic settings** view, select the **Translate label** check box.
2. Click **Sync Schema** a second time to retrieve the schema after translation.

A message opens up prompting you to accept retrieving the schema from the defined SPSS file.

3. Click **Yes** to close the message and proceed to the next step.

A second message opens up prompting you to accept propagating the changes.

4. Click **Yes** to close the message and proceed to the next step.
5. Save the Job and press **F6** to execute it.

The SPSS file is read row by row and the extracted fields are displayed on the log console after translating the stored values.

```

Starting job SPSS at 10:32 20/01/2010.

| <b>Usage</b>             | This component can not be used as start component. It requires an input flow                                            |                                                                                                                                                                                                              |

## Scenario: Writing data in an .sav file

This Java scenario describes a very simple Job that writes data entries in an .sav file.

### Setting up the Job

1. Drop a **tRowGenerator** component and a **tSPSSOutput** component from the **Palette** onto the design workspace.
2. Right-click on **tRowGenerator** and connect it to **tSPSSOutput** using a **Main Row** link.

## Configuring the input component

1. In the design workspace, double click **tRowGenerator** to display its **Basic Settings** view and open its editor. Here you can define your schema.

| Schema  |                          |        |                                     |     |        |           |         |         |             | Functions  |              | Preview |
|---------|--------------------------|--------|-------------------------------------|-----|--------|-----------|---------|---------|-------------|------------|--------------|---------|
| Column  | Key                      | Type   | <input checked="" type="checkbox"/> | N.. | Length | Precision | Default | Comment | Functions   | Environ... | Preview      |         |
| id      | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     | 6      |           |         |         | getAscii... | length=... | R8Zx50       |         |
| country | <input type="checkbox"/> | String | <input checked="" type="checkbox"/> |     | 50     |           |         |         | getUsStr... |            | Burnett Road |         |

Columns: Number of Rows for RowGenerator: 100

Function parameters: Preview

10 Number of Rows for Preview Preview

|   | id     | country                   |
|---|--------|---------------------------|
| 1 | UTnwds | San Marcos                |
| 2 | ot9fzP | El Camino Real            |
| 3 | 08ydXS | East Calle Primera        |
| 4 | R8Zx50 | Burnett Road              |
| 5 | xMsv5d | French Camp Turnpike Road |

OK Cancel

2. Click the plus button to add the columns you want to write in the .sav file.
3. Define the schema and set the parameters to the columns.

*Make sure to define the length of your columns. Otherwise, an error message will display when building your Job.*

4. Click **OK** to validate your schema and close the editor.

## Configuring the output component

1. Click **tSPSSOutput** to display its **Basic settings** view and define the component properties.

tSPSSOutput\_1

**Basic settings** Sync Schema Schema Type Built-In Edit schema Sync columns

Advanced settings Filename "C:/Documents and Settings/hmassy/Bureau/out.sav" \*

Dynamic settings Write Type Write

View Documentation

2. Click the three-dot button next to the **Filename** field and browse to the SPSS .sav file in which you want to write data.
3. Click the three-dot button next to **Sync columns** to synchronize columns with the previous component. In this example, the schema to be inserted in the .sav file consists of the two columns: *id* and *country*.
4. If required, click **Edit schema** to view/edit the defined schema.
5. From the **Write Type** list, select **Write** or **Append** to simply write the input data in the .sav file or add it to the end of the .sav file.

## Job execution

Save the Job and press **F6** to execute it.

The data generated by the **tRowGenerator** component is written in the defined .sav file.

# tSPSSProperties

In order to benefit from all of the functional objectives of the SPSS components, do the following: -If you have already installed SPSS, add the path to the SPSS directory as the following: `SET PATH=%PATH%;<DR>:\program\SPSS`, or -If you have not installed SPSS, you must copy the SPSS IO "spssio32.dll" lib from the SPSS installation CD and paste it in the **Talend** root directory.

# tSPSSStructure

Before being able to benefit from all functional objectives of the SPSS components, make sure to do the following: -If you have already installed SPSS, add the path to the SPSS directory as the following: `SET PATH=%PATH%;<DR>:\program\SPSS`, or -If you have not installed SPSS, you must copy the SPSS IO "spssio32.dll" lib from the SPSS installation CD and paste it in **Talend** root directory.

## tSPSSStructure properties

|                          |                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                            |

|  | <i>Surrogate Key</i>          | Select the surrogate key column from the list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|  | <i>Creation</i>               | <p>Select the method to be used for the surrogate key generation.</p> <p>For more information regarding the creation methods, see <a href="#">the section called “SCD keys”</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|  | <i>Source Keys</i>            | Select one or more columns to be used as keys, to ensure the unicity of incoming data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|  | <i>Use SCD Type 1 fields</i>  | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|  | <i>Use SCD Type 2 fields</i>  | <p>Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.</p> <p><b>Start date:</b> Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.</p> <p><b>End Date:</b> Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select <b>Fixed Year value</b> and fill it in with a fictive year to avoid having a null value in the End Date field.</p> <p><b>Log Active Status:</b> Adds a column to your SCD schema to hold the <b>true</b> or <b>false</b> status value. This column helps to easily spot the active record.</p> |

|                          |                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                               |

|                          |                                                                                                                                                                                                                                                                                                                                                                       | <b>Log versions:</b> Adds a column to your SCD schema to hold the version number of the record.                                                                                                                               |
| <b>Advanced settings</b> | <i>Additional parameters</i>                                                                                                                                                                                                                                                                                                                                          | <i>JDBC</i> Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <b>Use an existing connection</b> check box in the <b>Basic settings</b> . |
|                          | <i>Debug mode</i>                                                                                                                                                                                                                                                                                                                                                     | Select this check box to display each step during processing entries in a database.                                                                                                                                           |
|                          | <i>tStatCatcher Statistics</i>                                                                                                                                                                                                                                                                                                                                        | Select this check box to collect log data at the component level.                                                                                                                                                             |
| <b>Usage</b>             | This component is used as an output component. It requires an input component and Row main link as input.                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                               |
| <b>Limitation</b>        | Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> . |                                                                                                                                                                                                                               |

## Related Scenario

For related topics, see [the section called “tMysqlSCD”](#) and [the section called “Scenario: Tracking changes using Slowly Changing Dimensions \(type 0 through type 3\)”](#).

# Cloud components

This chapter details the main components which you can find in the **Cloud** family of the *Talend Open Studio for Big Data Palette*.

Private and public cloud databases, data services and SaaS-based applications (CRM, HR, ERP, etc.) are springing up alongside on-premise applications and databases that have been the mainstay of corporate IT. The resulting hybrid IT environments have more sources, of more diverse types, which require more modes of integration, and more effort on data quality and consistency across sources.

The Cloud family comprises the most popular database connectors adapted to Cloud and SaaS applications and technologies.

For *Talend Open Studio for Big Data*, the **Property type**, **Schema** and **Query Type** of components are always **Built-in**. For how to edit a Built-in schema, see *Talend Open Studio for Big Data User Guide*.

# tAmazonMysqlClose

## tAmazonMysqlClose properties

|                          |                                                                                                                                               |                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Function</b>          | tAmazonMysqlClose closes the transaction committed in the connected DB.                                                                       |                                                                                                                             |
| <b>Purpose</b>           | Close a transaction.                                                                                                                          |                                                                                                                             |

## Related scenario

No scenario is available for this component yet.

# tAmazonMysqlCommit

## tAmazonMysqlCommit Properties

This component is closely related to **tAmazonMysqlConnection** and **tAmazonMysqlRollback**. It usually doesn't make much sense to use these components independently in a transaction.

|                          |                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Scenario: Inserting data in mother/daughter tables

The following Job is dedicated to advanced database users, who want to carry out multiple table insertions using a parent table id to feed a child table. As a prerequisite to this Job, follow the steps described below to create the relevant tables using an engine such as *innodb*.

### Setting up the Job

1. In a command line editor, connect to your Mysql server. Once connected to the relevant database, type in the following command to create the parent table: `create table f1090_mum(id int not null auto_increment, name varchar(10), primary key(id)) engine=innodb.`
2. Then create the second table: `create table baby (id_baby int not null, years int) engine=innodb.`

Back into *Talend Open Studio for Big Data*, the Job requires seven components including **tAmazonMysqlConnection** and **tAmazonMysqlCommit**.

3. Drag and drop the following components from the **Palette**: **tFileList**, **tFileInputDelimited**, **tMap**, **tAmazonMysqlOutput** (x2).
4. Connect the **tFileList** component to the input file component using an **Iterate** link as the name of the file to be processed will be dynamically filled in from the **tFileList** directory using a global variable.
5. Connect the **tFileInputDelimited** component to the **tMap** and dispatch the flow between the two output AmazonMysql DB components. Use a **Row** link for each for these connections representing the main data flow.
6. Set the **tFileList** component properties, such as the directory name where files will be fetched from.
7. Add a **tAmazonMysqlConnection** component and connect it to the starter component of this job, in this example, the **tFileList** component using an **OnComponentOk** link to define the execution order.

### Setting up the DB connection

In the **tAmazonMysqlConnection** Component view, set the connection details.

## Configuring the input component

1. On the **tFileInputDelimited** component's **Basic settings** panel, press **Ctrl+Space** bar to access the variable list. Set the **File Name** field to the global variable: *tFileList\_1.CURRENT\_FILEPATH*

2. Set the rest of the fields as usual, defining the row and field separators according to your file structure. Then set the schema manually through the **Edit schema** feature. Make sure the data type is correctly set, in accordance with the nature of the data processed.

## Configuring the tMap component

1. In the **tMap** Output area, add two output tables, one called **mum** for the parent table, the second called **baby**, for the child table.
2. Drag the *Name* column from the **Input** area, and drop it to the **mum** table. Drag the *Years* column from the **Input** area and drop it to the **baby** table.

Make sure the **mum** table is on the top of the **baby** table as the order is determining for the flow sequence hence the DB insert to perform correctly.

3. Then connect the output row link to distribute correctly the flow to the relevant DB output component.

## Configuring the output component

1. In each of the **tAmazonMysqlOutput** components' **Basic settings** panel, select the **Use an existing connection** check box to retrieve the **tAmazonMysqlConnection** details.

2. Set the **Table** name making sure it corresponds to the correct table, in this example either *f1090\_mum* or *f1090\_baby*.

There is no action on the table as they are already created.

3. Select **Insert** as **Action on data** for both output components. Click on **Sync columns** to retrieve the schema set in the **tMap**.
4. Go to the **Advanced settings** panel of each of the **tAmazonMysqlOutput** components. Notice that the **Commit every** field will get overridden by the **tAmazonMysqlCommit**.

5. In the **Additional columns** area of the DB output component corresponding to the child table (*f1090\_baby*), set the *id\_baby* column so that it reuses the *id* from the parent table. In the **SQL expression** field type in: `'(Select Last_Insert_id())'`.

The position is *Before* and the **Reference column** is *years*.

## Configuring the tAmazonMysqlCommit component

1. Add the **tAmazonMysqlCommit** component to the design workspace and connect it from the **tFileList** component using a **OnComponentOk** connection in order for the Job to terminate with the transaction commit.
2. On the **tAmazonMysqlCommit Component** view, select in the list the connection to be used.

## Job execution

Save your Job and press **F6** to execute it.

```
mysql> select * from f1090_mum
-> ;
+----+-----+
| id | names |
+----+-----+
6	john
7	bruce
8	beth
9	andrew
10	donald
11	betty
12	john
13	bruce
14	beth
15	andrew
16	donald
17	betty
+----+-----+
12 rows in set (0.00 sec)
```

```
mysql> select * from f1090_baby
-> ;
+----+-----+
| id_baby | years |
+----+-----+
6	10
7	23
8	34
9	10
10	23
11	34
12	10
13	23
14	34
15	10
16	23
17	34
+----+-----+
12 rows in set (0.00 sec)
```

The parent table *id* has been reused to feed the *id\_baby* column.

| <b>Usage</b>             | This component covers all possible SQL queries for Mysql databases. |                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Scenario1: Writing columns from a MySQL database to an output file

In this scenario we will read certain columns from a MySQL database, and then write them to a table in a local output file.

### Setting up the Job

1. Drop **tAmazonMysqlInput** and **tFileOutputDelimited** from the **Palette** onto the workspace.

2. Link **tAmazonMysqlInput** to **tFileOutputDelimited** using a **Row > Main** connection.

## Configuring the input component

1. Double-click **tAmazonMysqlInput** to open its **Basic Settings** view in the **Component** tab.

The screenshot shows the 'Basic settings' tab for the 'tAmazonMysqlInput' component. The configuration is as follows:

- Property Type:** Repository (dropdown), DB (MYSQL):mysql
- DB Version:** Mysql 5 (dropdown)
- Use an existing connection
- Host:** localhost (text), **Port:** 3306 (text)
- Database:** test (text)
- Username:** root (text), **Password:** \*\*\*\*\* (text)
- Schema:** Built-In (dropdown), Edit schema (button)
- Table Name:** employees (text)
- Query Type:** Built-In (dropdown), Guess Query (button), Guess schema (button)
- Query:** `"select id, first_name, city, salary from employees"` (text area)

For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query type** of components are always **Built-in**. You have to complete the relevant settings manually in the specific Job.

2. Define the database connection details.
3. Click **Edit schema** to define the desired schema.

The schema editor opens:

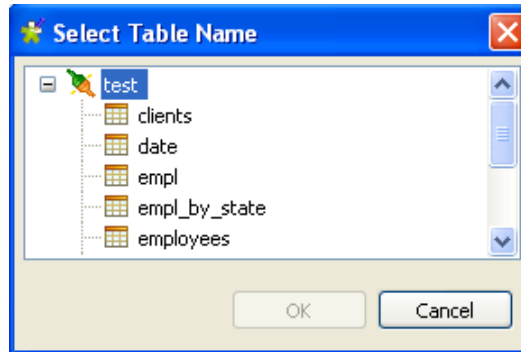

The screenshot shows the 'Schema of tAmazonMysqlInput\_1' dialog box. It contains a table with the following columns and rows:

| Column     | Key                                 | Type    | <input type="checkbox"/>            | N.. | Date P... | Le... | Pr... | D.. | C. |
|------------|-------------------------------------|---------|-------------------------------------|-----|-----------|-------|-------|-----|----|
| id         | <input checked="" type="checkbox"/> | int     | <input type="checkbox"/>            |     |           | 10    | 0     | "0" |    |
| first_name | <input type="checkbox"/>            | String  | <input checked="" type="checkbox"/> |     |           | 30    | 0     |     |    |
| city       | <input type="checkbox"/>            | String  | <input checked="" type="checkbox"/> |     |           | 30    | 0     |     |    |
| salary     | <input type="checkbox"/>            | Inte... | <input checked="" type="checkbox"/> |     |           | 10    | 0     |     |    |

Below the table are several icons for adding, deleting, and moving rows, and 'OK' and 'Cancel' buttons.

4. Click the [+] button to add the rows that you will use to define the schema, four columns in this example *id*, *first\_name*, *city* and *salary*.
5. Under **Column**, click in the fields to enter the corresponding column names.
6. Click the field under **Type** to define the type of data. Click **OK** to close the schema editor.
7. Next to the **Table Name** field, click the [...] button to select the database table of interest.

A dialog box displays a tree diagram of all the tables in the selected database:

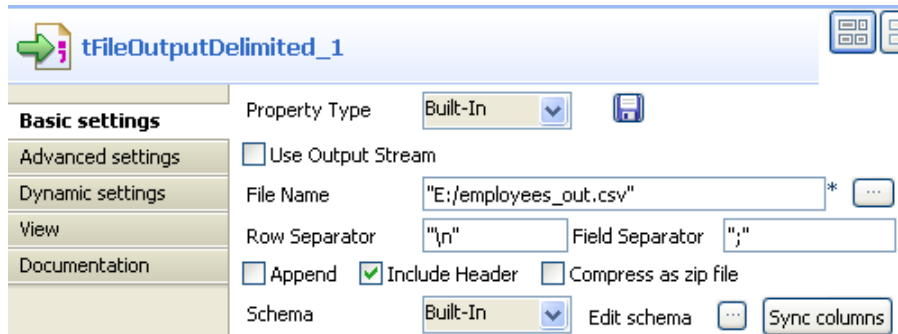

8. Click the table of interest and then click **OK** to close the dialog box.
9. In the **Query** box, enter the query required to retrieve the desired columns from the table.

## Configuring the output component

1. Double-click **tFileOutputDelimited** to set its **Basic Settings** in the **Component** tab.

2. Next to the **File Name** field, click the [...] button to browse your directory to where you want to save the output file, then enter a name for the file.
3. Select the **Include Header** check box to retrieve the column names as well as the data.

## Job execution

Save the Job and press **F6** to run it.

The output file is written with the desired column names and corresponding data, retrieved from the database:

```

1 id;first_name;city;salary
2 1;Martin;Sacramento;9011
3 2;Zachary;Atlanta;8118
4 3;James;Hartford;5087
5 4;Herbert;Charleston;9233
6 5;Herbert;Hartford;6289
7 6;Ulysses;Nashville;6269

```

The Job can also be run in the **Traces Debug** mode, which allows you to view the rows as they are being written to the output file, in the workspace.

# tAmazonMysqlOutput

## tAmazonMysqlOutput properties

|  | <i>Action on table</i> | <p>On the table defined, you can perform one of the following operations:</p> <p><b>None:</b> No operation is carried out.</p> <p><b>Drop and create table:</b> The table is removed and created again.</p> <p><b>Create table:</b> The table does not exist and gets created.</p> <p><b>Create table if not exists:</b> The table is created if it does not exist.</p> <p><b>Drop table if exists and create:</b> The table is removed if it already exists and created again.</p> <p><b>Clear table:</b> The table content is deleted.</p> <p><b>Truncate table:</b> The table content is quickly deleted. However, you will not be able to rollback the operation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|  | <i>Action on data</i>  | <p>On the data of the table defined, you can perform:</p> <p><b>Insert:</b> Add new entries to the table. If duplicates are found, the job stops.</p> <p><b>Update:</b> Make changes to existing entries.</p> <p><b>Insert or update:</b> Add entries or update existing ones.</p> <p><b>Update or insert:</b> Update existing entries or creates them if they do not exist.</p> <p><b>Delete:</b> Remove entries corresponding to the input flow.</p> <p><b>Replace:</b> Add new entries to the table. If an old row in the table has the same value as a new row for a PRIMARY KEY or a UNIQUE index, the old row is deleted before the new row is inserted.</p> <p><b>Insert or update on duplicate key or unique index:</b> Add entries if the inserted value does not exist or update entries if the inserted value already exists and there is a risk of violating a unique index or primary key.</p> <p><b>Insert Ignore:</b> Add only new rows to prevent duplicate key errors.</p> <p> <i>You must specify at least one column as a primary key on which the <b>Update</b> and <b>Delete</b> operations are based. You can do that by clicking <b>Edit Schema</b> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <b>Advanced settings</b> view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the <b>Use field options</b> check box and then in the <b>Key in update</b> column, select the check boxes next to the column name on which you want to base the update</i></p> |

|                          |                               |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Do the same in the <b>Key in delete</b> column for the deletion operation.</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                          | <i>Schema and Edit schema</i> |             | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                          |                               |             | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                          | <i>Die on error</i>           |             | This check box is selected by default. Clear the check box to skip the row in error and complete the process for error-free rows. If needed, you can retrieve the rows in error via a <b>Row &gt; Rejects</b> link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Advanced settings</b> | <i>Additional parameters</i>  | <i>JDBC</i> | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <b>Use an existing connection</b> check box in the <b>Basic settings</b> .<br><br> You can press <b>Ctrl+Space</b> to access a list of predefined global variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                          | <i>Extend Insert</i>          |             | Select this check box to carry out a bulk insert of a defined set of lines instead of inserting lines one by one. The gain in system performance is considerable.<br><br><b>Number of rows per insert:</b> enter the number of rows to be inserted per operation. Note that the higher the value specified, the lower performance levels shall be due to the increase in memory demands.<br><br> This option is not compatible with the <b>Reject</b> link. You should therefore clear the check box if you are using a <b>Row &gt; Rejects</b> link with this component.<br><br> <i>If you are using this component with <b>tMysqlLastInsertID</b>, ensure that the <b>Extend Insert</b> check box in <b>Advanced Settings</b> is not selected. <b>Extend Insert</b> allows for batch loading, however, if the check box is selected, only the ID of the last line of the last batch will be returned.</i> |
|                          | <i>Use batch size</i>         |             | Select this check box to activate the batch mode for data processing. In the <b>Batch Size</b> field that appears when this check box is selected, you can type in the number you need to define the batch size to be processed.<br><br> This check box is available only when you have selected, the <b>Update</b> or the <b>Delete</b> option in the <b>Action on data</b> field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                          | <i>Commit every</i>           |             | Number of rows to be included in the batch before it is committed to the DB. This option ensures transaction quality (but not rollback) and, above all, a higher performance level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                          | <i>Additional Columns</i>     |             | This option is not available if you have just created the DB table (even if you delete it beforehand). This option allows                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|              | <i>Enable debug mode</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Select this check box to display each step involved in the process of writing data in the database.                                                                                                                                                                                                                                                                                                                                                                                                             |
|              | <i>Use duplicate key update mode insert</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Updates the values of the columns specified, in the event of duplicate primary keys.:<br><br><b>Column:</b> Between double quotation marks, enter the name of the column to be updated.<br><br><b>Value:</b> Enter the action you want to carry out on the column.<br><br> To use this option you must first of all select the <b>Insert</b> mode in the <b>Action on data</b> list found in the <b>Basic Settings</b> view. |
|              | <i>tStatCatcher Statistics</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Usage</b> | This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.<br><br>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a MySQL database. It also allows you to create a reject flow using a <b>Row &gt; Rejects</b> link to filter data in error. For an example of <b>tAmazonMysqlOutput</b> in use, see <a href="#">the section called "Scenario 3: Retrieve data in error with a Reject link"</a> . |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Scenario 1: Adding a new column and altering data in a DB table

This Java scenario is a three-component Job that aims at creating random data using a **tRowGenerator**, duplicating a column to be altered using the **tMap** component, and eventually altering the data to be inserted based on an SQL expression using the **tAmazonMySQLOutput** component.

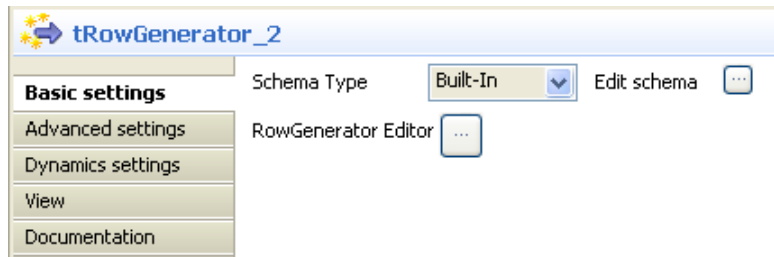

### Setting up the Job

1. Drop the following components from the **Palette** onto the design workspace: **tRowGenerator**, **tMap** and **tAmazonMySQLOutput**.
2. Connect **tRowGenerator**, **tMap**, and **tAmazonMySQLOutput** using the **Row Main** link.

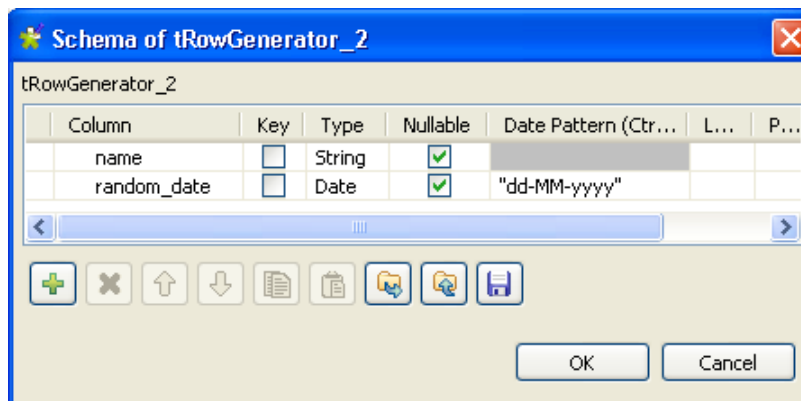

### Configuring the input component

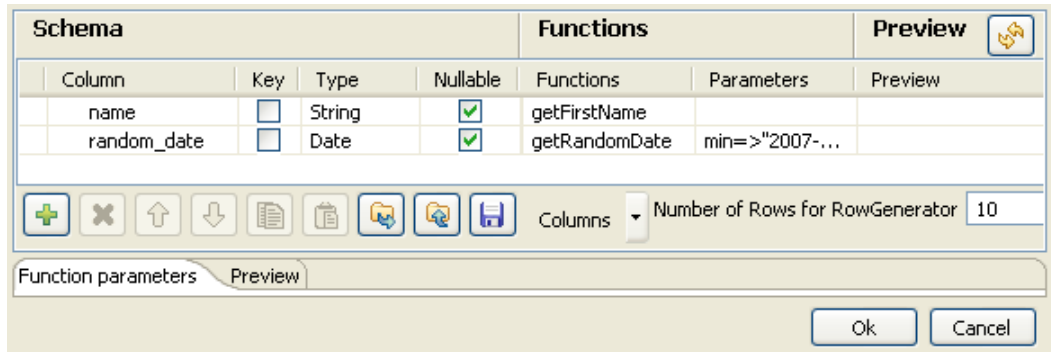

1. In the design workspace, select **tRowGenerator** to display its **Basic settings** view.

2. Click the **Edit schema** three-dot button to define the data to pass on to the **tMap** component, two columns in this scenario, *name* and *random\_date*.

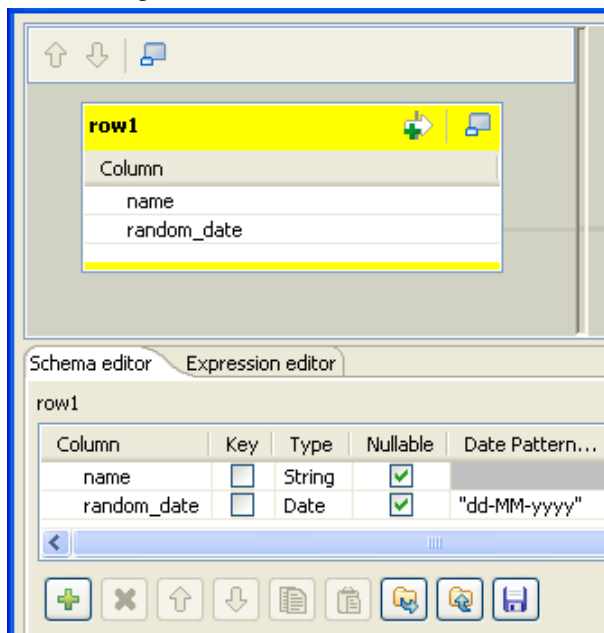

3. Click **OK** to close the dialog box.
4. Click the **RowGenerator Editor** three-dot button to open the editor and define the data to be generated.

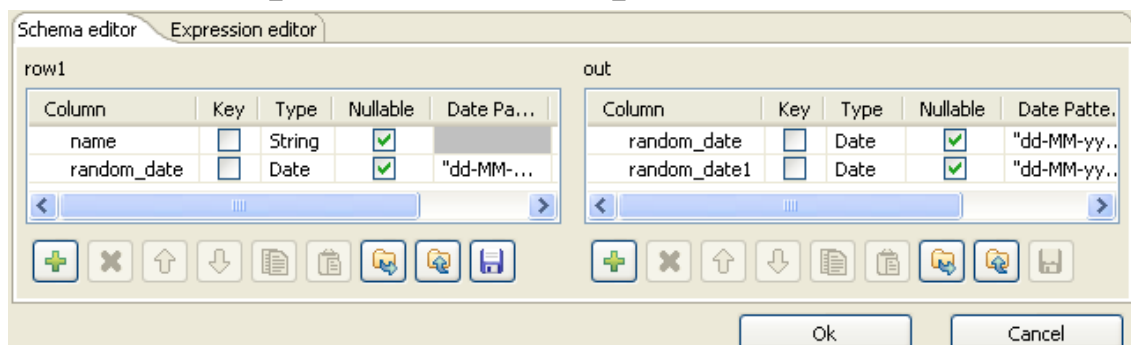

- Click in the corresponding **Functions** fields and select a function for each of the two columns, `getFirstName` for the first column and `getrandomDate` for the second column.
- In the **Number of Rows for Rowgenerator** field, enter 10 to generate ten first name rows and click **Ok** to close the editor.

## Configuring the tMap component

- Double-click the **tMap** component to open the Map editor. The Map editor opens displaying the input metadata of the **tRowGenerator** component.

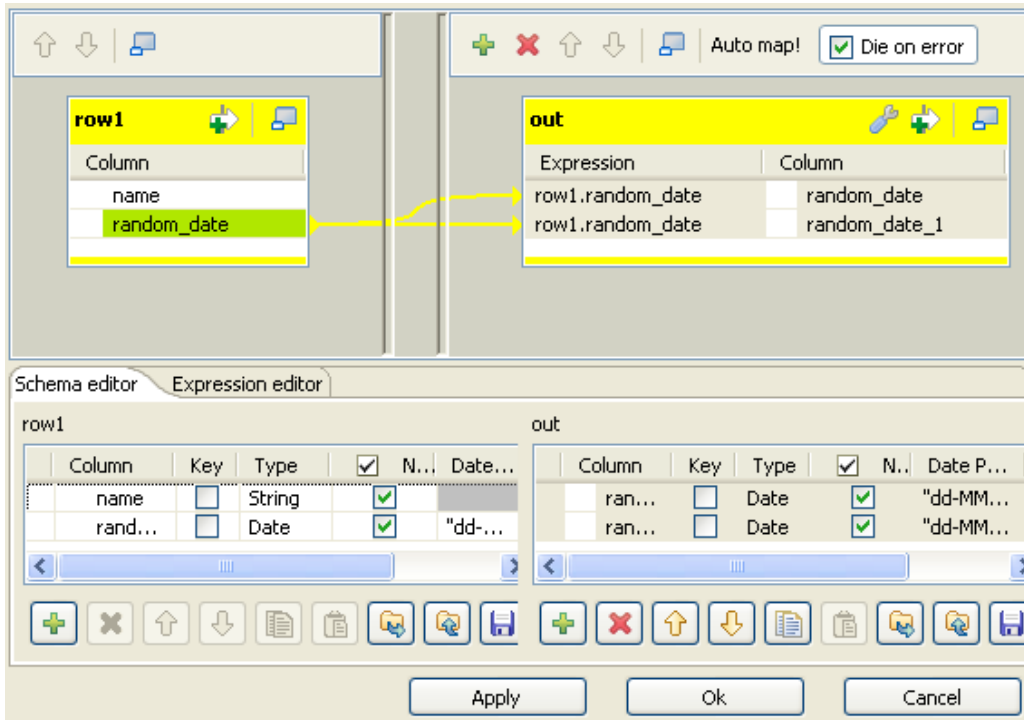

- In the **Schema editor** panel of the Map editor, click the **[+]** button of the output table to add two rows and define the first as `random_date` and the second as `random_date1`.

In this scenario, we want to duplicate the *random\_date* column and adapt the schema in order to alter the data in the output component.

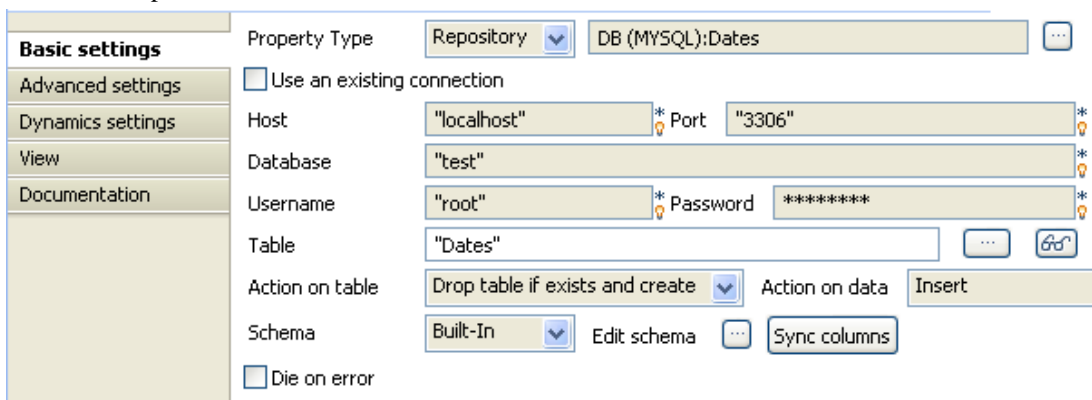

- In the Map editor, drag the *random\_date* row from the input table to the *random\_date* and *random\_date1* rows in the output table.

- Click **OK** to close the editor.

## Configuring the output component

- In the design workspace, double-click the **tAmazonMysqlOutput** component to display its **Basic settings** view and set its parameters.

*For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query type** of components are always **Built-in**. You have to complete the relevant settings manually in the specific Job.*

- Fill in the database connection details.
- Click the [...] button next to the **Table** field and select the table to be altered, *Dates* in this scenario.

4. On the **Action on table** list, select **Drop table if exists and create**, select *Insert* on the **Action on data** list.
5. If needed, click **Sync columns** to synchronize with the columns coming from the **tMap** component.
6. Click the **Advanced settings** tab to display the corresponding view and set the advanced parameters.

The screenshot shows the configuration interface for a database table. The 'Advanced settings' tab is active. The 'Additional columns' table is as follows:

| Name            | SQL expression | Position | Reference column |
|-----------------|----------------|----------|------------------|
| "One_Month_L... | VARCHAR(50)    | Replace  |                  |

Other visible settings include 'Additional JDBC Parameters' (empty), 'Extend Insert' (unchecked), and 'Commit every' (10000).

7. In the **Additional Columns** area, set the alteration to be performed on columns.

In this scenario, the *One\_month\_later* column replaces *random\_date\_1*. Also, the data itself gets altered using an SQL expression that adds one month to the randomly picked-up date of the *random\_date\_1* column. ex: 2007-08-12 becomes 2007-09-12.

-Enter *One\_Month\_Later* in the **Name** cell.

-In the **SQL expression** cell, enter the relevant addition script to be performed, "adddate(Random\_date, interval 1 month)" in this scenario.

-Select **Replace** on the **Position** list.

-Enter *Random\_date1* on the **Reference column** list.

For this job we duplicated the *random\_date\_1* column in the DB table before replacing one instance of it with the *One\_Month\_Later* column. The aim of this workaround was to be able to view upfront the modification performed.

## Job execution

Save your Job and press **F6** to execute it.

The new *One\_month\_later* column replaces the *random\_date1* column in the DB table and adds one month to each of the randomly generated dates.

| Random_date         | One_Month_Later     |

## Scenario 2: Updating data in a database table

This Java scenario describes a two-component Job that updates data in a MySQL table according to that in a delimited file.

### Setting up the Job

- Drop **tFileInputDelimited** and **tAmazonMysqlOutput** from the **Palette** onto the design workspace. Connect the two components together using a **Row Main** link.

### Configuring the input component

- Double-click **tFileInputDelimited** to display its **Basic settings** view and define the component properties.

For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query type** of components are always **Built-in**. You have to complete the relevant settings manually in the specific Job.

- Fill in the database connection details.
- In the **File Name** field, click the [...] button and browse to the source delimited file that contains the modifications to propagate in the MySQL table.

In this example, we use the *customer\_update* file that holds four columns: *id*, *CustomerName*, *CustomerAddress* and *idState*. Some of the data in these four columns is different from that in the MySQL table.

| id  | CustomerName                   | CustomerAddress        | idState |
|-----|--------------------------------|------------------------|---------|
| 858 | Froggy's Gourmet Catering      | 1831 Beverly Place #9D | 4       |
| 859 | Dependable Plumbing and Sewer  | 1550 Ridge Rd.         | 25      |
| 860 | Lickmen Restoration            | 1235 Easton Rd.        | 40      |
| 861 | Acturial Enterprises Ltd.      | 3148 cottonwood Ct.    | 18      |
| 862 | Rythmics Ltd.                  | 857 Woodbine Rd        | 30      |
| 863 | Acturial Enterprises Ltd.      | 1482 Concorde Circle   | 48      |
| 864 | Crosstracks Car Wash           | 218 Oakridge Ave.      | 39      |
| 865 | Meonits & Mogogni Inc.         | 616 Cobblestone Cir.   | 17      |
| 866 | Foy Aviation                   | 2220 Grant Blvd.       | 50      |
| 867 | Ebert Music Center             | 12 Broadview Lane      | 29      |
| 868 | janice Mann Accounting Service | 1660 Park Ave.         | 9       |
| 869 | Johnson, Erico & Co CPA's      | 2922 Twin Oaks Drive   | 40      |
| 870 | Corbins, Rodriguez, & Savocchi | 115 Pleasant Ave.      | 18      |
| 871 | Nina's Snow Plowing            | 3385 University Ave.   | 20      |
| 872 | Darcy Frame and Matting Servic | 1101 Deerfield Place   | 47      |
| 873 | Marks, Marks, and Kaplan Ltd.  | 1949 Cloverdale Rd.    | 9       |

- Define the row and field separators used in the source file in the corresponding fields. If needed, set **Header**, **Footer** and **Limit**.

In this example, **Header** is set to 1 since the first row holds the names of columns, therefore it should be ignored. Also, the number of processed lines is limited to 2000.

- Click the [...] button next to **Edit Schema** to open a dialog box where you can describe the data structure of the source delimited file that you want to pass to the component that follows.

| Column                                                                                 | Key                                 | Type    | <input checked="" type="checkbox"/> | Nullable                            |
|----------------------------------------------------------------------------------------|-------------------------------------|---------|-------------------------------------|-------------------------------------|
|  id | <input checked="" type="checkbox"/> | Integer | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CustomerName                                                                           | <input type="checkbox"/>            | String  | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CustomerAddress                                                                        | <input type="checkbox"/>            | String  | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| idState                                                                                | <input type="checkbox"/>            | Integer | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |

- Select the **Key** check box(es) next to the column name(s) you want to define as key column(s).

It is necessary to define at least one column as a key column for the Job to be executed correctly. Otherwise, the Job is automatically interrupted and an error message displays on the console.

## Configuring the output component

- In the design workspace, double-click **tAmazonMysqlOutput** to open its **Basic settings** view where you can define its properties.

Property Type Built-In 

Use an existing connection

Host "localhost" \* Port "3306" \*

Database "test" \*

Username "root" \* Password "toor" \*

Table "customers" ... 🔍

Action on table None ▼ Action on data Update ▼

Schema Built-In ▼ Edit schema ... Sync columns

Die on error

- Click **Sync columns** to retrieve the schema of the preceding component. If needed, click the [...] button next to **Edit schema** to open a dialog box where you can check the retrieved schema.

3. Fill in the database connection information in the corresponding fields.
4. In the **Table** field, enter the name of the table to update.
5. From the **Action on table** list, select the operation you want to perform, **None** in this example since the table already exists.
6. From the **Action on data** list, select the operation you want to perform on the data, **Update** in this example.

## Job execution

Save your Job and press **F6** to execute it.

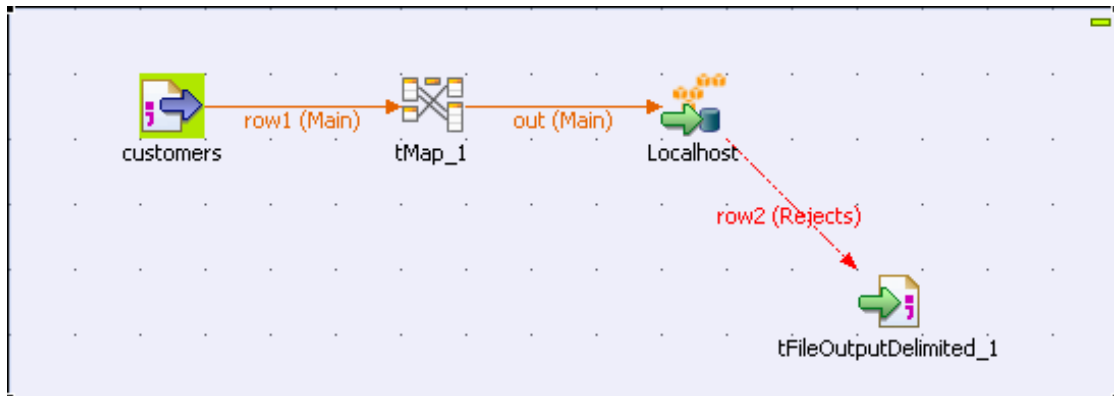

| id  | CustomerName                  | CustomerAddress        | idState |

Using your DB browser, you can verify if the MySQL table, *customers*, has been modified according to the delimited file.

In the above example, the database table has always the four columns *id*, *CustomerName*, *CustomerAddress* and *idState*, but certain fields have been modified according to the data in the delimited file used.

## Scenario 3: Retrieve data in error with a Reject link

This scenario describes a four-component Job that carries out migration from a customer file to a MySQL database table and redirects data in error towards a CSV file using a **Reject** link.

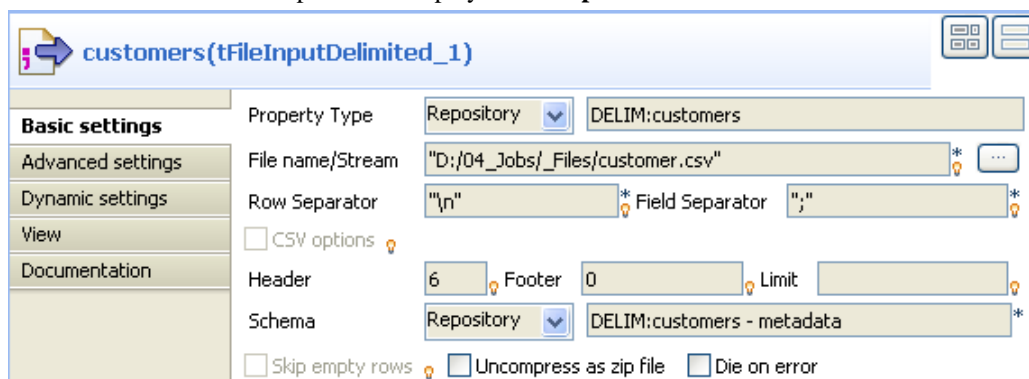

## Setting up the Job

1. Drop a **tFileInputDelimited** component from the family **File > Input**, in the **Palette**, and fill in its properties manually in the **Component** tab.
2. From the **Palette**, drop a **tMap** from the **Processing** family onto the workspace.
3. Drop a **tAmazonMysqlOutput** from the **Databases** family in the **Palette** and fill in its properties manually in the **Component** tab.
4. From the **Palette**, select a **tFileOutputDelimited** from the **File > Output** family, and drop it onto the workspace.
5. Link the **customers** component to the **tMap** component, and the **tMap** and **Localhost** with a **Row Main** link. Name this second link **out**.
6. Link the **Localhost** to the **tFileOutputDelimited** using a **Row > Reject** link.

## Configuring the input component

1. Double-click the **customers** component to display the **Component** view.

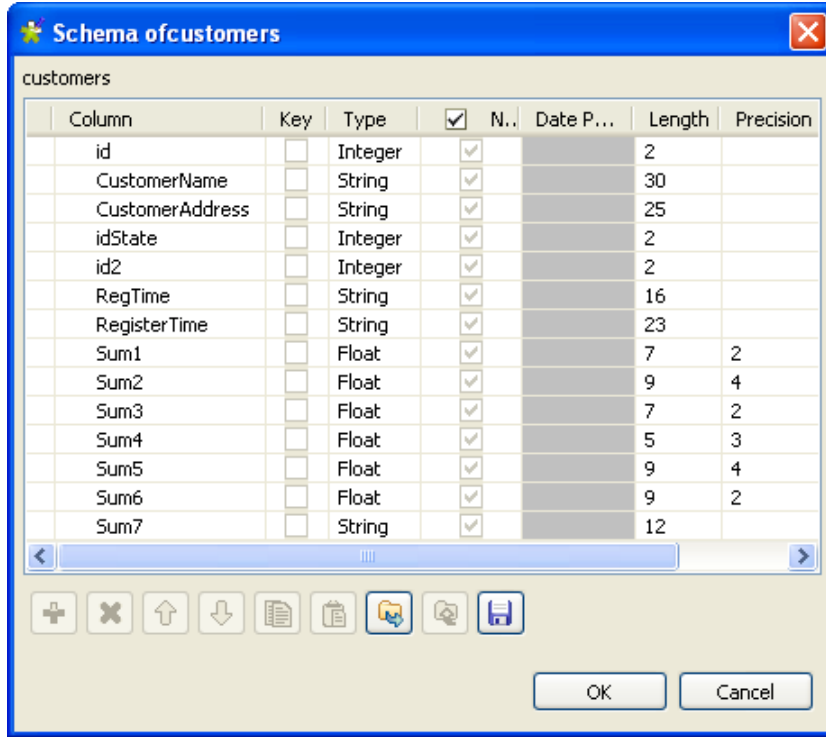

For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query type** of components are always **Built-in**. You have to complete the relevant settings manually in the specific Job.

2. Click the [...] button next to the **File Name** field, and fill in the path and the name of the file you want to use.
3. In the **Row** and **Field Separator** fields, type in between inverted commas the row and field separator used in the file.

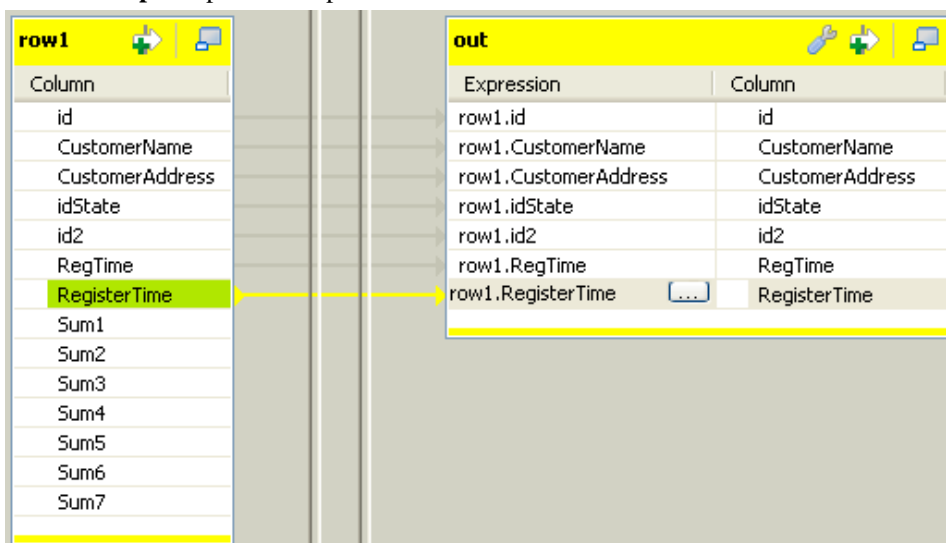

- In the **Header**, **Footer** and **Limit** fields, type in the number of headers and footers to ignore, and the number of rows to which processing should be limited.
- Click the [...] button next to the **Edit schema** field, and set the schema manually.

The schema is as follows:

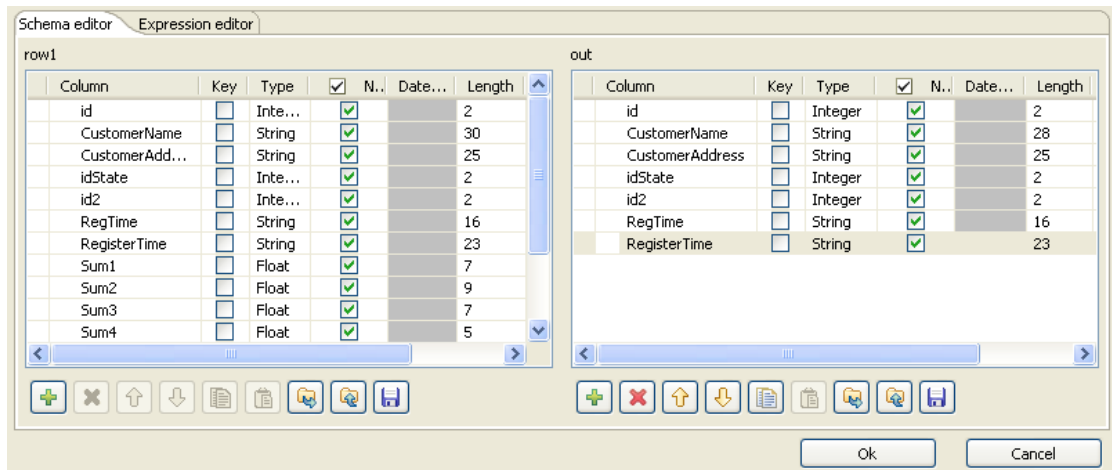

## Configuring the tMap component

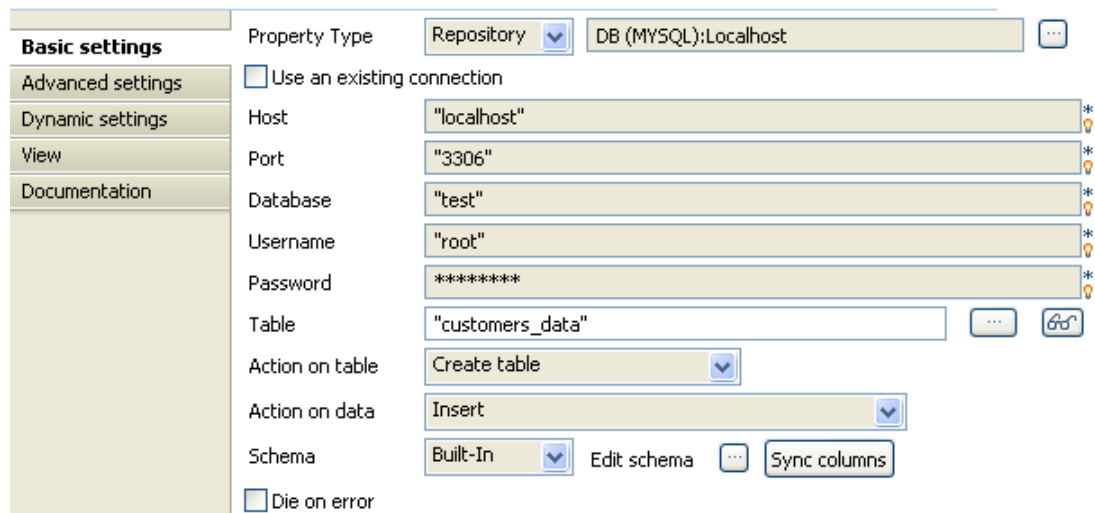

- Double-click the **tMap** component to open its editor.

- Select the *id*, *CustomerName*, *CustomerAddress*, *idState*, *id2*, *RegTime* and *RegisterTime* columns on the table on the left and drop them on the **out** table, on the right.

- In the **Schema editor** area, at the bottom of the **tMap** editor, in the right table, change the length of the **CustomerName** column to 28 to create an error. Thus, any data for which the length is greater than 28 will create errors, retrieved with the **Reject** link.
- Click **OK**. In the workspace, double-click the output **Localhost** component to display its **Component** view.

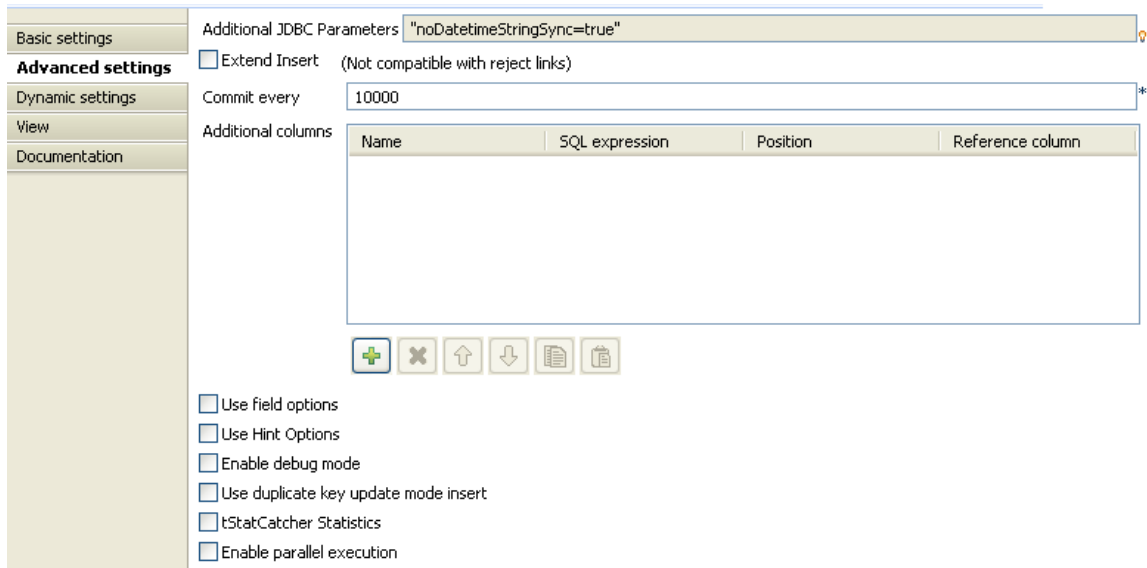

For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query type** of components are always **Built-in**. You have to complete the relevant settings manually in the specific Job.

- Fill in the database connection details in the corresponding fields.
- In the **Table** field, type in the name of the table to be created. In this scenario, we call it *customers\_data*. In the **Action on data** list, select the **Create table** option. Click the **Sync columns** button to retrieve the schema from the previous component.

Make sure the **Die on error** check box isn't selected, so that the Job can be executed despite the error you just created.

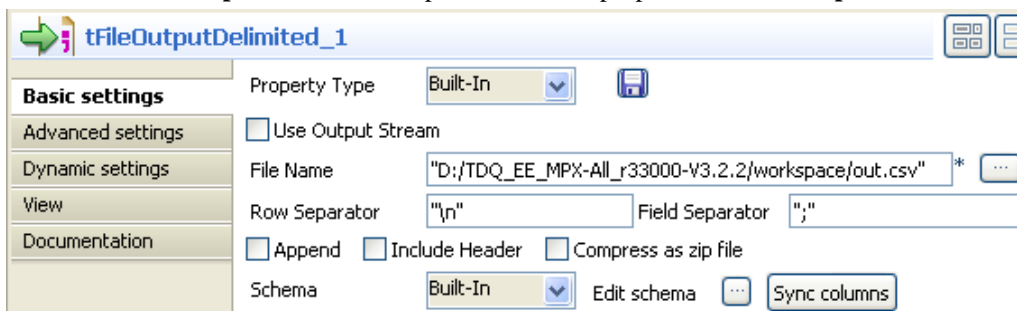

- Click the **Advanced settings** tab of the **Component** view to set the advanced parameters of the component.

8. Deselect the **Extend Insert** check box which enables you to insert rows in batch, because this option is not compatible with the **Reject** link.

## Configuring the output component

1. Double-click the **tFileOutputDelimited** component to set its properties in the **Component** view.

2. Click the [...] button next to the **File Name** field to fill in the path and name of the output file. Click the **Sync columns** button to retrieve the schema of the previous component.

## Job execution

Save your Job and press **F6** to execute it.

The data in error are sent to the delimited file, as well as the error type met. Here, we have: **Data truncation**.

# tAmazonMysqlRollback

## tAmazonMysqlRollback properties

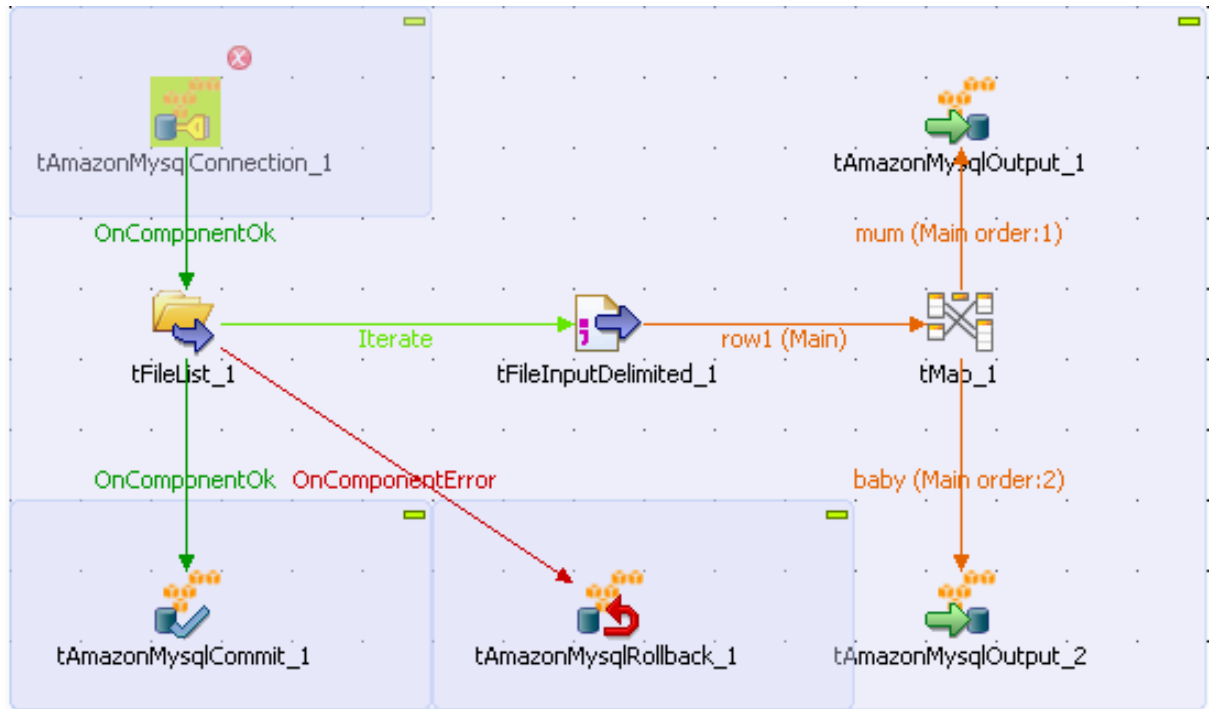

This component is closely related to **tAmazonMysqlCommit** and **tAmazonMysqlConnection**. It usually does not make much sense to use these components independently in a transaction.

|                          |                                                                                                                                                         |                                                                                                                             |

| <b>Limitation</b>        | n/a                                                                                                                                                     |                                                                                                                             |

## Scenario: Rollback from inserting data in mother/daughter tables

Based on [the section called “Scenario: Inserting data in mother/daughter tables”](#), insert a rollback function in order to prevent unwanted commit.

1. Drag and drop a **tAmazonMysqlRollback** to the design workspace and connect it to the Start component.
2. Set the Rollback unique field on the relevant DB connection.

This complementary element to the Job ensures that the transaction will not be partly committed.

# tAmazonMysqlRow

| <b>Function</b>         | tAmazonMysqlRow is the specific component for this database query. It executes the SQL query stated in the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Purpose</b>          | Depending on the nature of the query and the database, tAmazonMysqlRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                          | <i>Propagate QUERY's recordset</i> | Select this check box to insert the result of the query in a COLUMN of the current flow. Select this column from the <b>use column</b> list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                          | <i>Use PreparedStatement</i>       | Select this checkbox if you want to query the database using a PreparedStatement. In the <b>Set PreparedStatement Parameter</b> table, define the parameters represented by “?” in the SQL instruction of the <b>Query</b> field in the <b>Basic Settings</b> tab.<br><br><b>Parameter Index:</b> Enter the parameter position in the SQL instruction.<br><br><b>Parameter Type:</b> Enter the parameter type.<br><br><b>Parameter Value:</b> Enter the parameter value.<br><br> This option is very useful if you need to execute the same query several times. Performance levels are increased |
|                          | <i>Commit every</i>                | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                          | <i>tStatCatcher Statistics</i>     | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Usage</b>             |                                    | This component offers the flexibility of the DB query and covers all possible SQL queries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Scenario 1: Removing and regenerating a MySQL table index

This scenario describes a four-component job that removes a table index, applies a select insert action onto a table then regenerates the index.

### Setting up the Job

1. Select and drop the following components onto the design workspace: **tAmazonMysqlRow** (x2), **tRowGenerator**, and **tAmazonMysqlOutput**.
2. Connect **tRowGenerator** to **tAmazonMysqlOutput**.
3. Using a **OnComponentOk** connections, link the first **tAmazonMysqlRow** to **tRowGenerator** and **tRowGenerator** to the second **tAmazonMysqlRow**.

### Configuring the tAmazonMysqlRow component

1. Select the **tAmazonMysqlRow** to fill in the DB **Basic settings**.
2. Fill in the database connection details in the corresponding fields.
3. Propagate the properties and schema details onto the other components of the Job.
4. Type in the following SQL statement to alter the database entries: drop index <index\_name> on <table\_name>
5. Select the second **tAmazonMysqlRow** component, check the DB properties and schema.
6. Type in the SQL statement to recreate an index on the table using the following statement: create index <index\_name> on <table\_name> (<column\_name>)

The **tRowGenerator** component is used to generate automatically the columns to be added to the DB output table defined.

## Configuring the output component

1. Select the **tAmazonMySQLOutput** component and fill in the DB connection properties>. The table to be fed is named: *comprehensive*.
2. The schema should be automatically inherited from the data flow coming from the **tRowGenerator**. Edit the schema to check its structure and check that it corresponds to the schema expected on the DB table specified.
3. The **Action on table** is *None* and the **Action on data** is *Insert*.

## Job execution

Press **F6** to run the job.

If you manage to watch the action on DB data, you can notice that the index is dropped at the start of the job and recreated at the end of the insert action.

## Scenario 2: Using PreparedStatement objects to query data

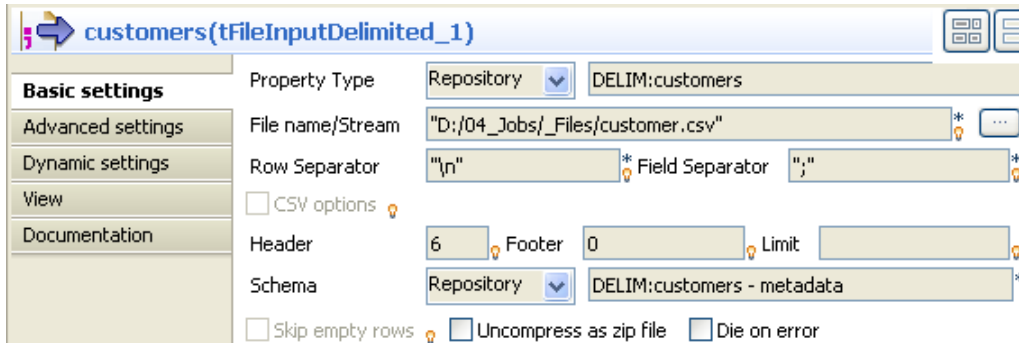

This scenario describes a four component job which allows you to link a table column with a client file. The MySQL table contains a list of all the American States along with the State ID, while the file contains the customer information including the ID of the State in which they live. We want to retrieve the name of the State for each client, using an SQL query. In order to process a large volume of data quickly, we use a PreparedStatement object which means that the query is executed only once rather than against each row in turn. Then each row is sent as a parameter.

For this scenario, we use a file and a database for which we have already stored the connection and properties in the Repository metadata. For further information concerning the creation of metadata in delimited files, the creation of database connection metadata and the usage of metadata, see *Talend Open Studio for Big Data User Guide*.

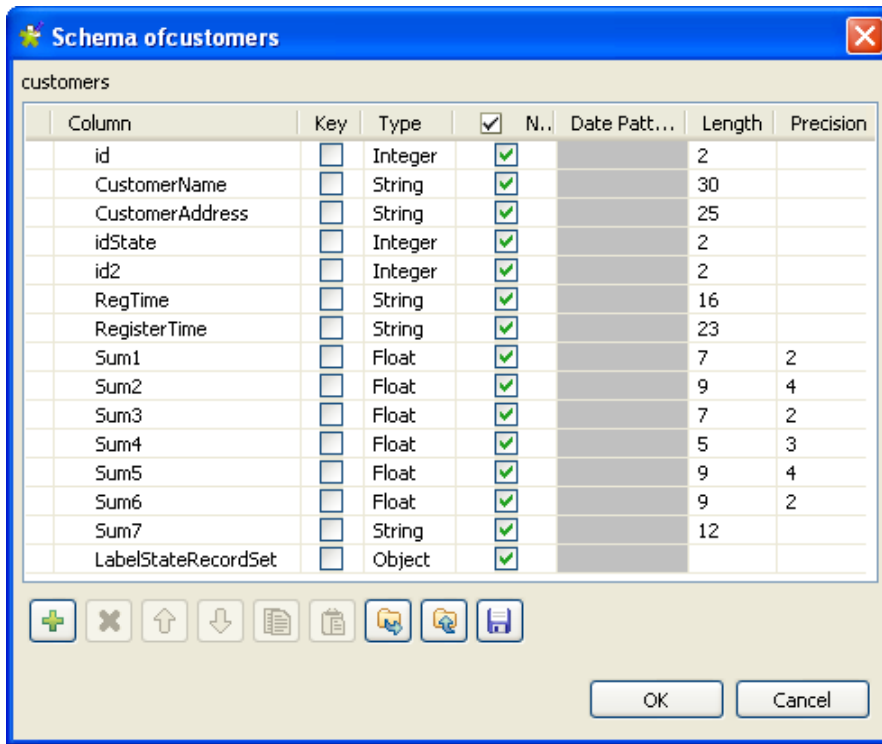

## Configuring the input component

1. Drop a **tFileInputDelimited** component from the **Palette** onto the design workspace, and double-click it to open its **Basic settings** view.

 For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query type** of components are always **Built-in**. You have to complete the relevant settings manually in the specific Job.

2. Define the path to the input file, the row separator, the field separator, the header, and the footer in the corresponding fields.
3. Click on [...] next to the **Edit schema** field to add a column into which the name of the State will be inserted.

4. Click on the [+] button to add a column to the schema. Rename this column *LabelStateRecordSet* and select **Object** from the **Type** list. Click **OK** to save your modifications.
5. From the **Palette**, select the **tAmazonMysqlRow**, **tParseRecordSet** and **tFileOutputDelimited** components and drop them onto the workspace. Connect the four components using **Row > Main** type links.

## Setting up the DB connection

1. Double-click **tAmazonMysqlRow** to set its properties in the **Basic settings** tab of the **Component** view.

 For Talend Open Studio for Big Data, the **Property type**, **Schema** and **Query type** of components are always **Built-in**. You have to complete the relevant settings manually in the specific Job.

2. Fill in the database connection details in the corresponding fields.
3. Click the **Sync columns** button to retrieve the schema from the preceding component.
4. In the **Query** field, enter the SQL query you want to use. Here, we want to retrieve the names of the American States from the *LabelState* column of the MySQL table, *us\_state*:

```
"SELECT LabelState
FROM us_state WHERE idState=?"
```

The question mark, “?”, represents the parameter to be set in the **Advanced settings** tab.

## Configuring the Advanced settings of tAmazonMysqlRow

1. Click **Advanced settings** to set the component's advanced properties.

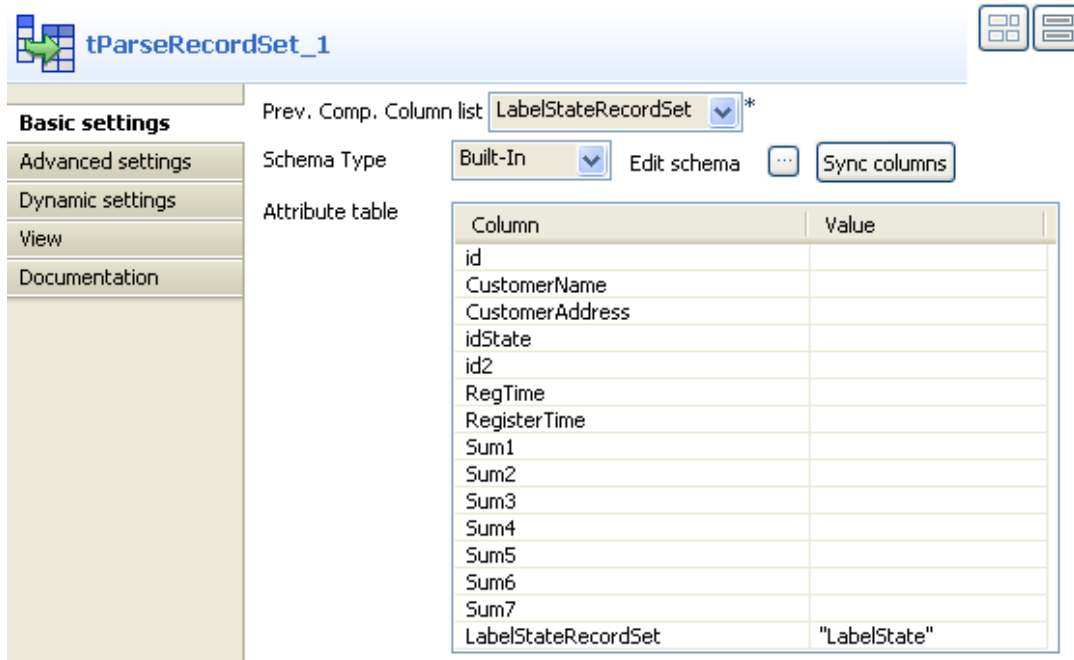

| Parameter Index | Parameter Type | Parameter Value |
|-----------------|----------------|-----------------|
| 1               | Int            | row1.idState    |

2. Select the **Propagate QUERY's recordset** check box and select the *LabelStateRecordSet* column from the **use column** list to insert the query results in that column.

3. Select the **Use PreparedStatement** check box and define the parameter used in the query in the **Set PreparedStatement Parameters** table. Click on the [+] button to add a parameter.
4. In the **Parameter Index** cell, enter the parameter position in the SQL instruction. Enter “1” as we are only using one parameter in this example.
5. In the **Parameter Type** cell, enter the type of parameter. Here, the parameter is a whole number, hence, select **Int** from the list.
6. In the **Parameter Value** cell, enter the parameter value. Here, we want to retrieve the name of the State based on the State ID for every client in the input file. Hence, enter “row1 . idState” .

## Configuring the tParseRecordSet component

1. Double-click **tParseRecordSet** to set its properties in the **Basic settings** tab of the **Component** view.

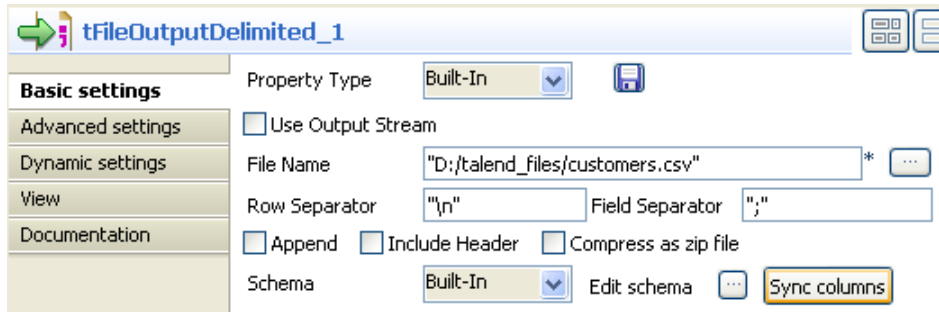

2. From the **Prev. Comp. Column list**, select the preceding components column for analysis. In this example, select *LabelStateRecordSet*.
3. Click on the **Sync columns** button to retrieve the schema from the preceding component. The **Attribute table** is automatically completed with the schema columns.
4. In the **Attribute table**, in the **Value** field which corresponds to the *LabelStateRecordSet*, enter the name of the column containing the State names to be retrieved and matched with each client, within double quotation marks. In this example, enter “*LabelState*”.

## Configuring the output component

1. Double-click **tFileOutputDelimited** to set its properties in the **Basic settings** tab of the **Component** view.

- In the **File Name** field, enter the access path and name of the output file. Click **Sync columns** to retrieve the schema from the preceding component.

## Job execution

Save your Job and press **F6** to run it.

## Related scenario

This component is closely related to **tAmazonOracleConnection** and **tAmazonOracleRollback**. It usually doesn't make much sense to use one of these without using a **tAmazonOracleConnection** component to open a connection for the current transaction.

For **tAmazonOracleCommit** related scenario, see [the section called "tMysqlConnection"](#)

# tAmazonOracleConnection

## tAmazonOracleConnection Properties

This component is closely related to **tAmazonOracleCommit** and **tAmazonOracleRollback**. It usually doesn't make much sense to use one of these without using a **tAmazonOracleConnection** component to open a connection for the current transaction.

|                   | connection components from different Job levels that can be either parent or child.<br><b>Shared DB Connection Name:</b> set or type in the shared connection name. |
| <b>Usage</b>      | This component is to be used along with AmazonOracle components, especially with <b>tAmazonOracleCommit</b> and <b>tAmazonOracleRollback</b> components.            |
| <b>Limitation</b> | n/a                                                                                                                                                                 |

## Related scenario

This component is closely related to **tAmazonOracleCommit** and **tAmazonOracleRollback**. It usually doesn't make much sense to use one of these without using a **tAmazonOracleConnection** component to open a connection for the current transaction.

For **tAmazonOracleConnection** related scenario, see [the section called "tMysqlConnection"](#)

| <b>Function</b>         | <b>tAmazonOracleInput</b> reads a database and extracts fields based on a query.                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Purpose</b>          | <b>tAmazonOracleInput</b> executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                         | <i>Use an existing connection</i>                                                                                                                                                  | <p>Select this check box when using a <b>tAmazonOracleConnection</b> component. When you deselect it, a check box appears (selected by default and followed by a field) in the <b>Advanced settings, Batch Size</b>, which enables you to define the number of lines in each processed batch.</p> <p> When a Job contains the parent Job and the child Job, <b>Component list</b> presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, make sure that the available connection components are sharing the intended connection.</p> <p>For more information on how to share a DB connection across Job levels, see <b>Use or register a shared DB connection</b> in any database connection component corresponding to the database you are using.</p> <p>Otherwise, you can as well deactivate the connection components and use <b>Dynamic settings</b> of the component to specify the intended connection manually. In this case, make sure the connection name is unique and distinctive all over through the two Job levels. For more information about <b>Dynamic settings</b>, see your studio user guide.</p> |

|  | <i>Oracle schema</i>                   | Name of the Oracle schema.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|  | <i>Table</i>                           | Name of the table to be written. Note that only one table can be written at a time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|  | <i>Action on table</i>                 | <p>On the table defined, you can perform one of the following operations:</p> <p><b>None:</b> No operation is carried out.</p> <p><b>Drop and create a table:</b> The table is removed and created again.</p> <p><b>Create a table:</b> The table does not exist and gets created.</p> <p><b>Create a table if not exists:</b> The table is created if it does not exist.</p> <p><b>Drop a table if exists and create:</b> The table is removed if it already exists and created again.</p> <p><b>Clear a table:</b> The table content is deleted.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|  | <i>Action on data</i>                  | <p>On the data of the table defined, you can perform:</p> <p><b>Insert:</b> Add new entries to the table. If duplicates are found, job stops.</p> <p><b>Update:</b> Make changes to existing entries</p> <p><b>Insert or update:</b> Add entries or update existing ones.</p> <p><b>Update or insert:</b> Update existing entries or create it if non existing</p> <p><b>Delete:</b> Remove entries corresponding to the input flow.</p> <p> <i>It is necessary to specify at least one column as a primary key on which the <b>Update</b> and <b>Delete</b> operations are based. You can do that by clicking <b>Edit Schema</b> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <b>Advanced settings</b> view where you can simultaneously define primary keys for the <b>Update</b> and <b>Delete</b> operations. To do that: Select the <b>Use field options</b> check box and then in the <b>Key in update column</b>, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the <b>Key in delete column</b> for the Delete operation.</i></p> |
|  | <i>Schema</i> and <i>Edit schema</i>   | A schema is a row description, i.e., it defines the number of fields to be processed and passed on to the next component. In <i>Talend Open Studio for Big Data</i> , the schema is always <b>Built-in</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                          |                                                            |                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                            | <b>Built-in:</b> The schema is created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                                                                                                                   |
|                          | <i>Die on error</i>                                        | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <b>Row &gt; Rejects</b> link.                                                                                                                                                                         |
| <b>Advanced settings</b> | <i>Additional parameters</i> <i>JDBC</i>                   | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <b>Use an existing connection</b> check box in the <b>Basic settings</b> .<br><br> You can press <b>Ctrl+Space</b> to access a list of predefined global variables. |
|                          | <i>Override any existing NLS_LANG environment variable</i> | Select this check box to override variables already set for a NLS language environment.                                                                                                                                                                                                                                                                                                     |
|                          | <i>Commit every</i>                                        | Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.                                                                                                                                                                                |
|                          | <i>tStatCatcher Statistics</i>                             | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                                                                           |
|                          | <i>Additional Columns</i>                                  | This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.                                                                                                                              |
|                          |                                                            | <b>Name:</b> Type in the name of the schema column to be altered or inserted as new column.                                                                                                                                                                                                                                                                                                 |
|                          |                                                            | <b>SQL expression:</b> Type in the SQL statement to be executed in order to alter or insert the relevant column data.                                                                                                                                                                                                                                                                       |
|                          |                                                            | <b>Position:</b> Select <b>Before</b> , <b>Replace</b> or <b>After</b> following the action to be performed on the reference column.                                                                                                                                                                                                                                                        |
|                          |                                                            | <b>Reference column:</b> Type in a column of reference that the <b>tDBOutput</b> can use to place or replace the new or altered column.                                                                                                                                                                                                                                                     |
|                          | <i>Use field options</i>                                   | Select this check box to customize a request, especially when there is double action on data.                                                                                                                                                                                                                                                                                               |
|                          | <i>Use Hint Options</i>                                    | Select this check box to activate the hint configuration area which helps you optimize a query's execution. In this area, parameters are:<br><br>- <b>HINT:</b> specify the hint you need, using the syntax<br><br><pre>/*+ */.</pre><br>- <b>POSITION:</b> specify where you put the hint in a SQL statement.<br><br>- <b>SQL STMT:</b> select the SQL statement you need to use.          |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                  |

|                   | <i>Support null in “SQL WHERE” statement</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Select this check box to validate null in “SQL WHERE” statement.                                                                                                                                                                                                                 |
| <b>Usage</b>      | <p>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.</p> <p>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Oracle database. It also allows you to create a reject flow using a <b>Row &gt; Rejects</b> link to filter data in error. For such an example, see <a href="#">the section called “Scenario 3: Retrieve data in error with a Reject link”</a>.</p> |                                                                                                                                                                                                                                                                                  |
| <b>Limitation</b> | Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> .                                                                                                                                   |                                                                                                                                                                                                                                                                                  |

## Related scenarios

For **tAmazonOracleOutput** related topics, see:

# tAmazonOracleRollback

## tAmazonOracleRollback properties

This component is closely related to **tAmazonOracleCommit** and **tAmazonOracleConnection**. It usually doesn't make much sense to use these components independently in a transaction.

| <b>Function</b>         | <b>tAmazonOracleRow</b> is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Purpose</b>          | Depending on the nature of the query and the database, <b>tAmazonOracleRow</b> acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                          | <i>Query type</i>                  | In <i>Talend Open Studio for Big Data</i> , the Query type is always <b>Built-in</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                          |                                    | <b>Built-in:</b> Fill in manually the query statement or build it graphically using SQLBuilder                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                          | <i>Query</i>                       | Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                          | <i>Die on error</i>                | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <b>Row &gt; Rejects</b> link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Advanced settings</b> | <i>Propagate QUERY's recordset</i> | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the <b>use column</b> list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                          | <i>Use PreparedStatement</i>       | Select this checkbox if you want to query the database using a PreparedStatement. In the <b>Set PreparedStatement Parameter</b> table, define the parameters represented by “?” in the SQL instruction of the <b>Query</b> field in the <b>Basic Settings</b> tab.<br><br><b>Parameter Index:</b> Enter the parameter position in the SQL instruction.<br><br><b>Parameter Type:</b> Enter the parameter type.<br><br><b>Parameter Value:</b> Enter the parameter value.<br><br> This option is very useful if you need to execute the same query several times. Performance levels are increased |
|                          | <i>Commit every</i>                | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                          | <i>tStatCatcher Statistics</i>     | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Usage</b>             |                                    | This component offers the flexibility of the DB query and covers all possible SQL queries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

# Custom Code components

This chapter details the major components which belong to the **Custom Code** family in the *Talend Open Studio for Big Data Palette*.

The **Custom Code** components enable you to create codes for specific needs, quickly and efficiently.

For *Talend Open Studio for Big Data*, the **Property type**, **Schema** and **Query Type** of components are always **Built-in**. For how to edit a Built-in schema, see *Talend Open Studio for Big Data User Guide*.

# tGroovy

## tGroovy properties

|                          |                                                                                                                                |                                                                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Component Family</b>  | Custom Code                                                                                                                    |                                                                                                                                            |
| <b>Function</b>          | <b>tGroovy</b> allows you to enter customized code which you can integrate in the Talend programme. The code is run only once. |                                                                                                                                            |
| <b>Purpose</b>           | <b>tGroovy</b> broadens the functionality if the Talend Job, using the Groovy language which is a simplified Java syntax.      |                                                                                                                                            |
| <b>Basic settings</b>    | <i>Groovy Script</i>                                                                                                           | Enter the Groovy code youou want to run.                                                                                                   |
|                          | <i>Variables</i>                                                                                                               | This table has two columns.<br><b>Name:</b> Name of the variable called in the code..<br><b>Value:</b> Value associated with the variable. |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                                                                                 | Select this check box to collect the log data at component level.                                                                          |
| <b>Usage</b>             | This component can be used alone or as a subjob along with one other component.                                                |                                                                                                                                            |
| <b>Limitation</b>        | Knowledge of the Groovy language is required.                                                                                  |                                                                                                                                            |

## Related Scenarios

## Scenario: Calling a file which contains Groovy code

This scenario uses **tGroovyFile**, on its own. The Job calls a file containing Groovy code in order to display the file information in the **Console**. Below, is an example of the information displayed:

## Setting up the Job

Open the **Custom\_Code** folder in the **Palette** and drop a **tGroovyFile** component onto the workspace.

## Configuring the tGroovyFile component

1. Double-click the component to display the **Component** view.
2. In the **Groovy File** field, enter the path to the file containing the Groovy code, or browse to the file in your directory.

3. In the **Variables** table, add a line by clicking the [+] button.
4. In the **Name** column, enter “age”, then in the Value column, enter 50, as in the screenshot.

## Job execution

Press **F6** to save and run the Job.

The **Console** displays the information contained in the input file, to which the variable result is added.

```
Starting job tGroovyFile at 09:49 17/02/2010.
[statistics] connecting to socket on port 4016
[statistics] connected
The captain is 50 years old
[statistics] disconnected
Job tGroovyFile ended at 09:49 17/02/2010. [exit code=0]
```

| <b>Usage</b>             | This component is generally used as a one-component subjob.                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Limitation</b>        | You should know Java language.                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Scenario: Printing out a variable content

The following scenario is a simple demo of the extended application of the **tJava** component. The Job aims at printing out the number of lines being processed using a Java command and the global variable provided in *Talend Open Studio for Big Data*.

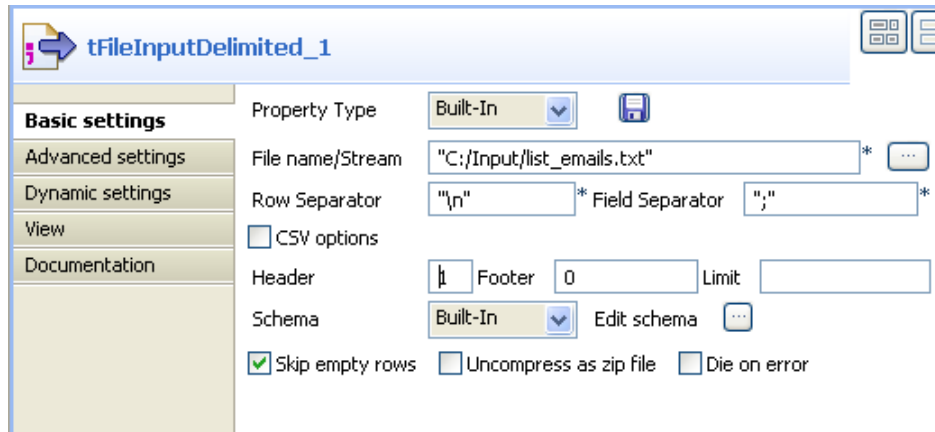

## Setting up the Job

1. Select and drop the following components from the **Palette** onto the design workspace: **tFileInputDelimited**, **tFileOutputExcel**, **tJava**.
2. Connect the **tFileInputDelimited** to the **tFileOutputExcel** using a **Row Main** connection. The content from a delimited txt file will be passed on through the connection to an xls-type of file without further transformation.
3. Then connect the **tFileInputDelimited** component to the **tJava** component using a **Then Run** link. This link sets a sequence ordering **tJava** to be executed at the end of the main process.

## Configuring the input component

1. Set the **Basic settings** of the **tFileInputDelimited** component.

2. Define the path to the input file in the **File name** field.

The input file used in this example is a simple text file made of two columns: *Names* and their respective *Emails*.

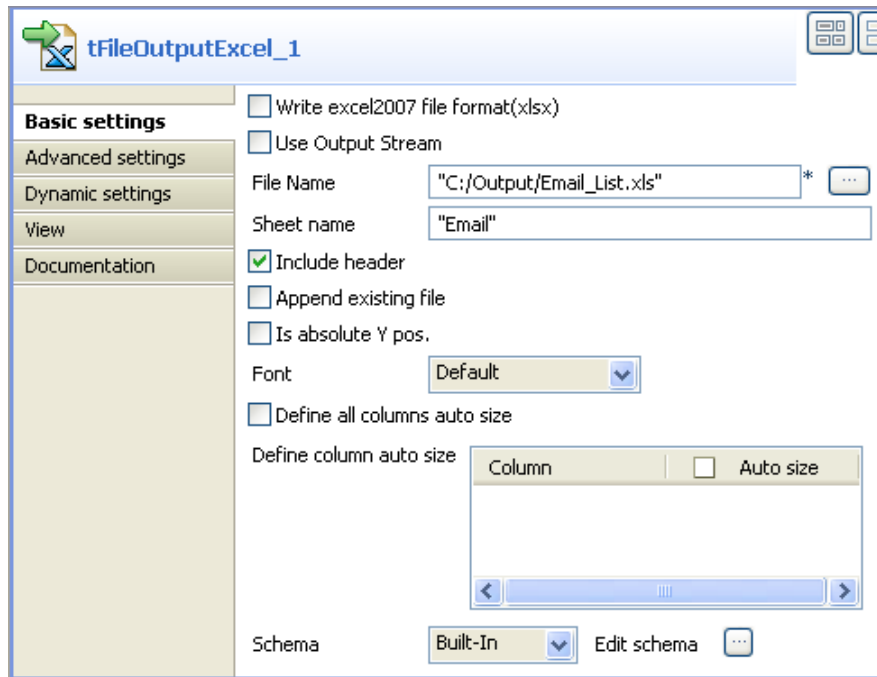

3. Click the **Edit Schema** button, and set the two-column schema. Then click **OK** to close the dialog box.

| Column | Key                                 | Type   | Nullable                            | Date P... | Le... | Pr... | D... | C... |
|--------|-------------------------------------|--------|-------------------------------------|-----------|-------|-------|------|------|
| Names  | <input checked="" type="checkbox"/> | String | <input checked="" type="checkbox"/> |           | 255   |       |      |      |
| Emails | <input type="checkbox"/>            | String | <input checked="" type="checkbox"/> |           | 255   |       |      |      |

4. When prompted, click **OK** to accept the propagation, so that the **tFileOutputExcel** component gets automatically set with the input schema.

## Configuring the output component

Set the output file to receive the input content without changes. If the file does not exist already, it will get created.

In this example, the **Sheet name** is *Email* and the **Include Header** box is selected.

## Configuring the tJava component

1. Then select the **tJava** component to set the Java command to execute.

2. In the **Code** area, type in the following command:

```
String var = "Nb of line processed: ";
var = var + globalMap.get("tFileInputDelimited_1_NB_LINE");
System.out.println(var);
```

In this use case, we use the *NB\_Line* variable. To access the global variable list, press **Ctrl + Space** bar on your keyboard and select the relevant global parameter.

## Job execution

Save your Job and press **F6** to execute it.

```
Starting job JavaDb at 13:53 20/08/2007.
Nb of line processed: 4
Job JavaDb ended at 13:53 20/08/2007. [exit code=0]
```

The content gets passed on to the Excel file defined and the Number of lines processed are displayed on the **Run** console.

| <b>Usage</b>             | You can use this component as a start, intermediate or output component. You can as well use it as a one-component subjob.                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Limitation</b>        | You should know the Java language.                                                                                                                                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                             |

## Scenario 1: Generating data flow

This scenario describes a two-components Job that generates a three-line data flow describing different personal titles (Miss, Mrs, and Mr) and displaying them on the console.

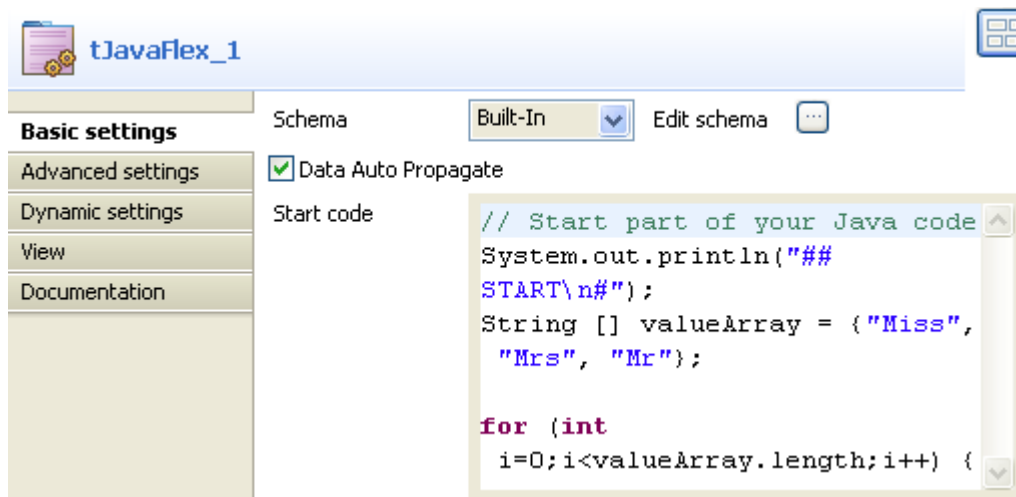

## Setting up the Job

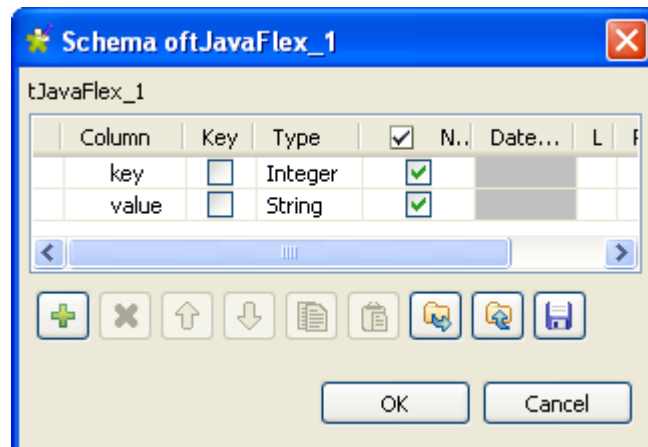

1. Drop **tJavaFlex** and **tLogRow** from the **Palette** onto the design workspace.
2. Connect the components together using a **Row > Main** link.

## Configuring the tJavaFlex component

1. Double-click **tJavaFlex** to display its **Basic settings** view and define its properties.

2. Click the three-dot button next to **Edit schema** to open the corresponding dialog box where you can define the data structure to pass to the component that follows.

3. Click the **[+]** button to add two columns: *key* and *value* and then set their types to **Integer** and **String** respectively.

- Click **OK** to validate your changes and close the dialog box.
- In the **Basic settings** view of **tJavaFlex**, select the **Data Auto Propagate** check box to automatically propagate data to the component that follows.

In this example, we do not want to do any transformation on the retrieved data.

- In the **Start code** field, enter the code to be executed in the initialization phase.

In this example, the code indicates the initialization of **tJavaFlex** by displaying the START message and sets up the loop and the variables to be used afterwards in the Java code:

```
System.out.println("## START\n#");
String [] valueArray = {"Miss", "Mrs", "Mr"};

for (int i=0;i<valueArray.length;i++) {
```

- In the **Main code** field, enter the code you want to apply on each of the data rows.

In this example, we want to display each key with its value:

```
row1.key = i;
row1.value = valueArray[i];
```

Main code

```
// Main part of your Java code
(loop)

row1.key = i;
row1.value = valueArray[i];
```

*In the **Main code** field, "row1" corresponds to the name of the link that comes out of **tJavaFlex**. If you rename this link, you have to modify the code of this field accordingly.*

- In the **End code** field, enter the code that will be executed in the closing phase.

In this example, the brace (curly bracket) closes the loop and the code indicates the end of the execution of **tJavaFlex** by displaying the END message:

```
}
System.out.println("#\n## END");
```

End code

```
// End part of your Java code

}
System.out.println("#\n##
END");
```

- If needed, double-click **tLogRow** and in its **Basic settings** view, click the [...] button next to **Edit schema** to make sure that the schema has been correctly propagated.

## Saving and executing the Job

1. Save your Job by pressing **Ctrl+S**.
2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

*Starting job tJavaFlex\_scenario1 at 14:49 02/09/2009.*

```
START
#
0 | Miss
1 | Mrs
2 | Mr
#
END
Job tJavaFlex_scenario1 ended at 14:49 02/09/2009. [exit code=0]
```

The three personal titles are displayed on the console along with their corresponding keys.

## Scenario 2: Processing rows of data with tJavaFlex

This scenario describes a two-component Job that generates random data and then collects that data and does some transformation on it line by line using Java code through the **tJavaFlex** component.

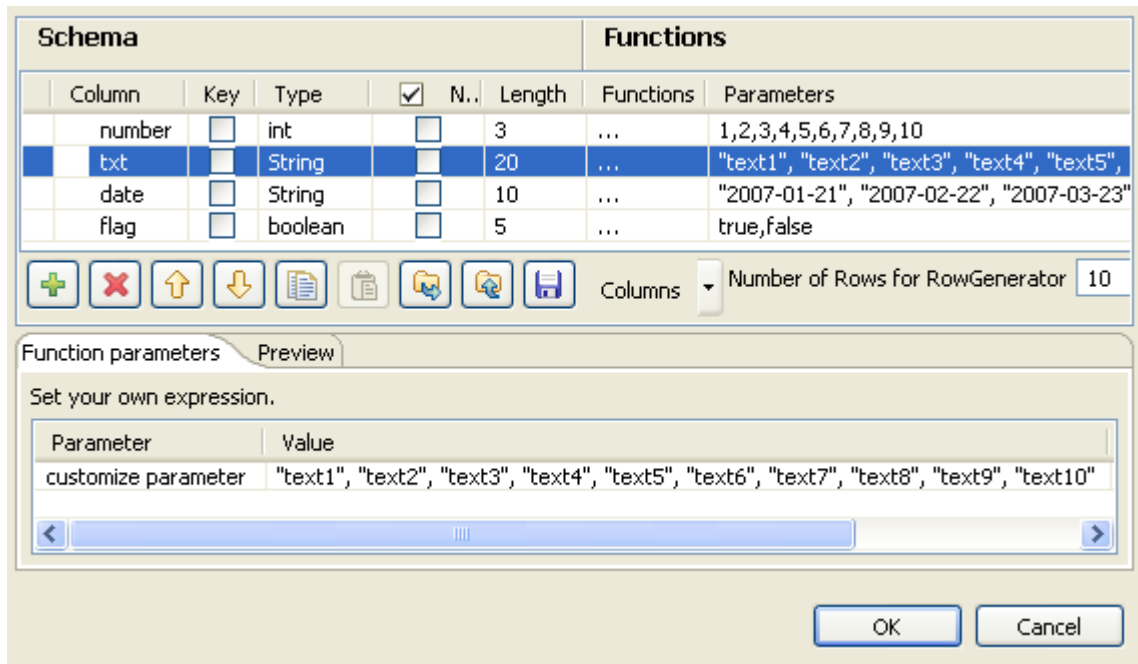

## Setting up the Job

1. Drop **tRowGenerator** and **tJavaFlex** from the **Palette** onto the design workspace.
2. Connect the components together using a **Row Main** link.

## Configuring the input component

1. Double-click **tRowGenerator** to display its **Basic settings** view and the **[RowGenerator Editor]** dialog box where you can define the component properties.

2. Click the plus button to add four columns: *number*, *txt*, *date* and *flag*.
3. Define the schema and set the parameters to the four columns according to the above capture.
4. In the **Functions** column, select the three-dot function [...] for each of the defined columns.
5. In the **Parameters** column, enter 10 different parameters for each of the defined columns. These 10 parameters corresponds to the data that will be randomly generated when executing **tRowGenerator**.
6. Click **OK** to validate your changes and close the editor.

## Configuring the tJavaFlex component

1. Double-click **tJavaFlex** to display its **Basic settings** view and define the components properties.

2. Click **Sync columns** to retrieve the schema from the preceding component.
3. In the **Start code** field, enter the code to be executed in the initialization phase.

In this example, the code indicates the initialization of the **tJavaFlex** component by displaying the START message and defining the variable to be used afterwards in the Java code:

```
System.out.println("## START\n#");
```

```
int i = 0;
```

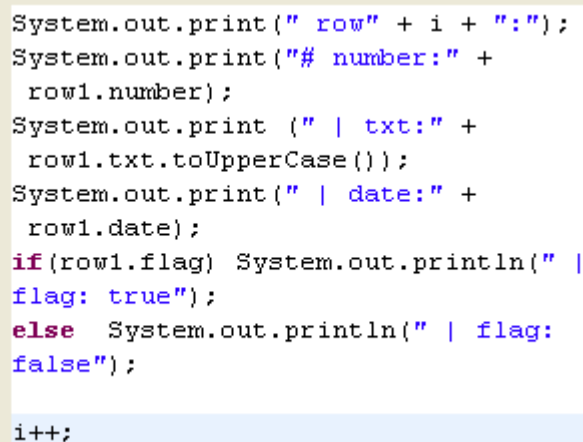

4. In the **Main code** field, enter the code to be applied on each line of data.

In this example, we want to show the number of each line starting from 0 and then the number and the random text transformed to upper case and finally the random date set in the editor of **tRowGenerator**. Then, we create a condition to show if the status is **true** or **false** and we increment the number of the line:

```
System.out.print(" row" + i + ":");
System.out.print("# number:" + row1.number);
System.out.print (" | txt:" + row1.txt.toUpperCase());
System.out.print(" | date:" + row1.date);
if(row1.flag) System.out.println(" | flag: true");
else System.out.println(" | flag: false");

i++;
```

Main code

```
System.out.print(" row" + i + ":");
System.out.print("# number:" +
 row1.number);
System.out.print (" | txt:" +
 row1.txt.toUpperCase());
System.out.print(" | date:" +
 row1.date);
if(row1.flag) System.out.println(" |
flag: true");
else System.out.println(" | flag:
false");

i++;
```

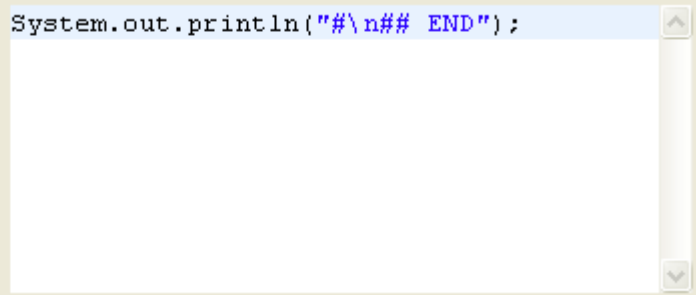

*In the **Main code** field, "row1" corresponds to the name of the link that connects to **tJavaFlex**. If you rename this link, you have to modify the code.*

5. In the **End code** field, enter the code that will be executed in the closing phase.

In this example, the code indicates the end of the execution of **tJavaFlex** by displaying the END message:

```
System.out.println("#\n## END");
```

End code

```
System.out.println("#\n## END");
```

## Saving and executing the Job

1. Save your Job by pressing **Ctrl+S**.

- Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

*Starting job tJavaFlex\_scenario2 at 18:35 02/09/2009.*

```
START
#
row0:# number:10 | txt:TEXT5 | date:2006-05-25 | flag: false
row1:# number:7 | txt:TEXT7 | date:2006-06-26 | flag: true
row2:# number:5 | txt:TEXT2 | date:2006-05-25 | flag: false
row3:# number:6 | txt:TEXT1 | date:2005-08-28 | flag: true
row4:# number:8 | txt:TEXT9 | date:2006-05-25 | flag: false
row5:# number:9 | txt:TEXT1 | date:2007-01-21 | flag: false
row6:# number:7 | txt:TEXT5 | date:2004-11-21 | flag: true
row7:# number:9 | txt:TEXT4 | date:2005-08-29 | flag: true
row8:# number:4 | txt:TEXT6 | date:2006-06-26 | flag: false
row9:# number:3 | txt:TEXT10 | date:2006-05-25 | flag: false
#
END
Job tJavaFlex_scenario2 ended at 18:35 02/09/2009. [exit
code=0]
```

The console displays the randomly generated data that was modified by the java command set through **tJavaFlex**.

# tJavaRow

|                          | <i>tStatCatcher Statistics</i>                                                                                                                                                               | Select this check box to collect the log data at a component level..                                                                                                                                                                                                                                                                                                        |
| <b>Usage</b>             | This component is used as an intermediary between two other components. It must be linked to both an input and an output component.                                                          |                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Limitation</b>        | Knowledge of Java language is necessary.                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                             |

## Scenario: Transforming data line by line using tJavaRow

In this scenario, the information of a few cities read from an input delimited file is transformed using Java code through the **tJavaRow** component and printed on the console.

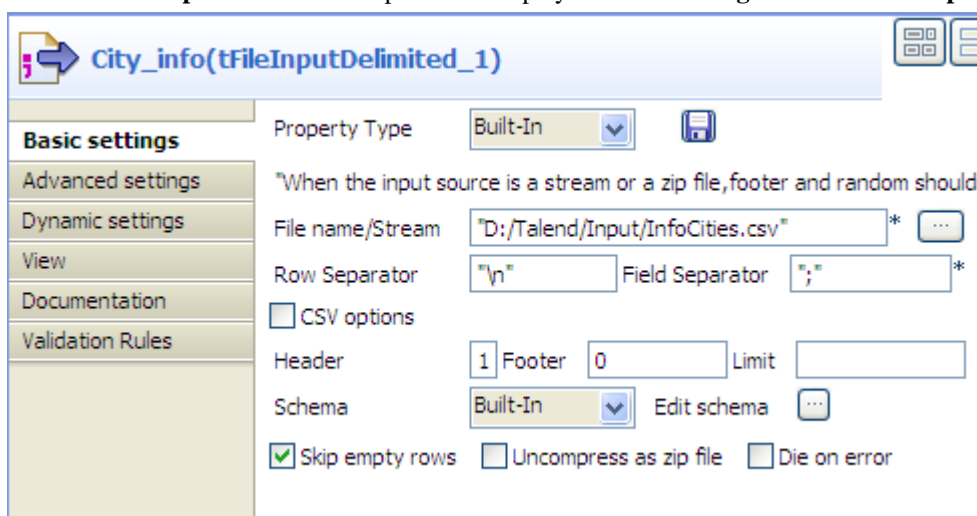

## Setting up the Job

1. Drop a **tFileInputDelimited** component and a **tJavaRow** component from the **Palette** onto the design workspace, and label them to better identify their roles in the Job.
2. Connect the two components using a **Row > Main** connection.

## Configuring the components

1. Double-click the **tFileInputDelimited** component to display its **Basic settings** view in the **Component** tab.

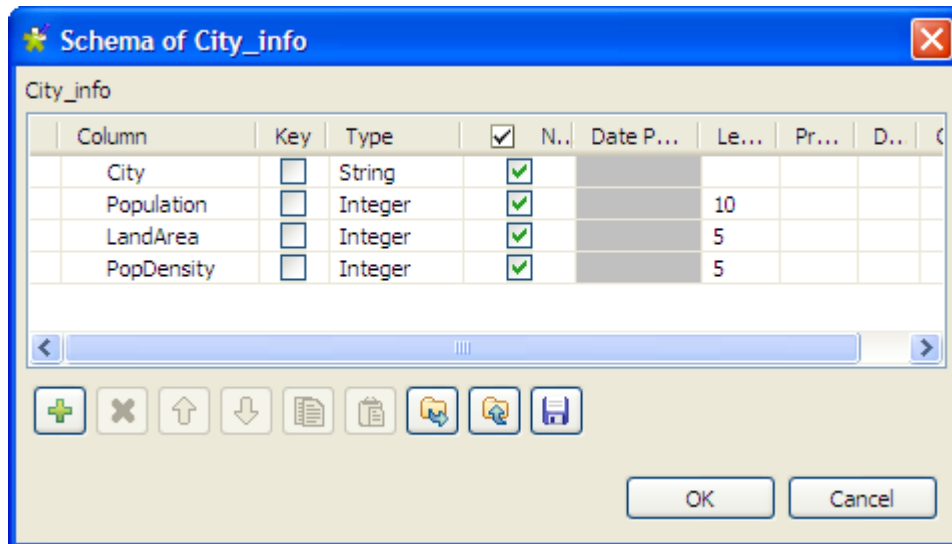

2. In the **File name/Stream** field, type in the path to the input file in double quotation marks, or browse to the path by clicking the [...] button, and define the first line of the file as the header.

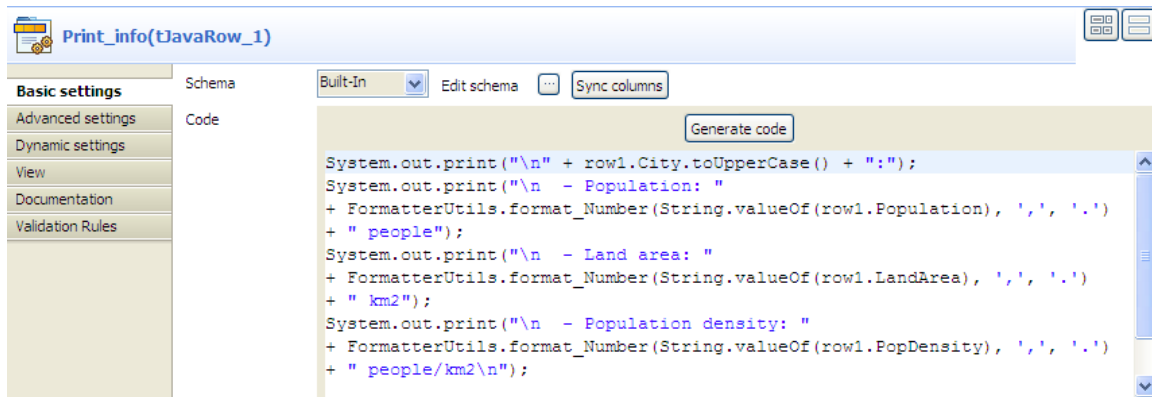

In this example, the input file has the following content:

```
City;Population;LandArea;PopDensity
Beijing;10233000;1418;7620
Moscow;10452000;1081;9644
Seoul;10422000;605;17215
Tokyo;8731000;617;14151
New York;8310000;789;10452
```

3. Click the [...] button next to Edit schema to open the [**Schema**] dialog box, and define the data structure of the input file. Then, click **OK** to validate the schema setting and close the dialog box.

- Double-click the **tJavaRow** component to display its **Basic settings** view in the **Component** tab.

- Click **Sync columns** to make sure that the schema is correctly retrieved from the preceding component.
- In the **Code** field, enter the code to be applied on each line of data based on the defined schema columns.

In this example, we want to transform the city names to upper case, group digits of numbers larger than 1000 using the thousands separator for ease of reading, and print the data on the console:

```
System.out.print("\n" + row1.City.toUpperCase() + ":");
System.out.print("\n - Population: "
+ FormatterUtils.format_Number(String.valueOf(row1.Population), ',', '.')
+ " people");
System.out.print("\n - Land area: "
+ FormatterUtils.format_Number(String.valueOf(row1.LandArea), ',', '.')
+ " km2");
System.out.print("\n - Population density: "
+ FormatterUtils.format_Number(String.valueOf(row1.PopDensity), ',', '.')
+ " people/km2\n");
```

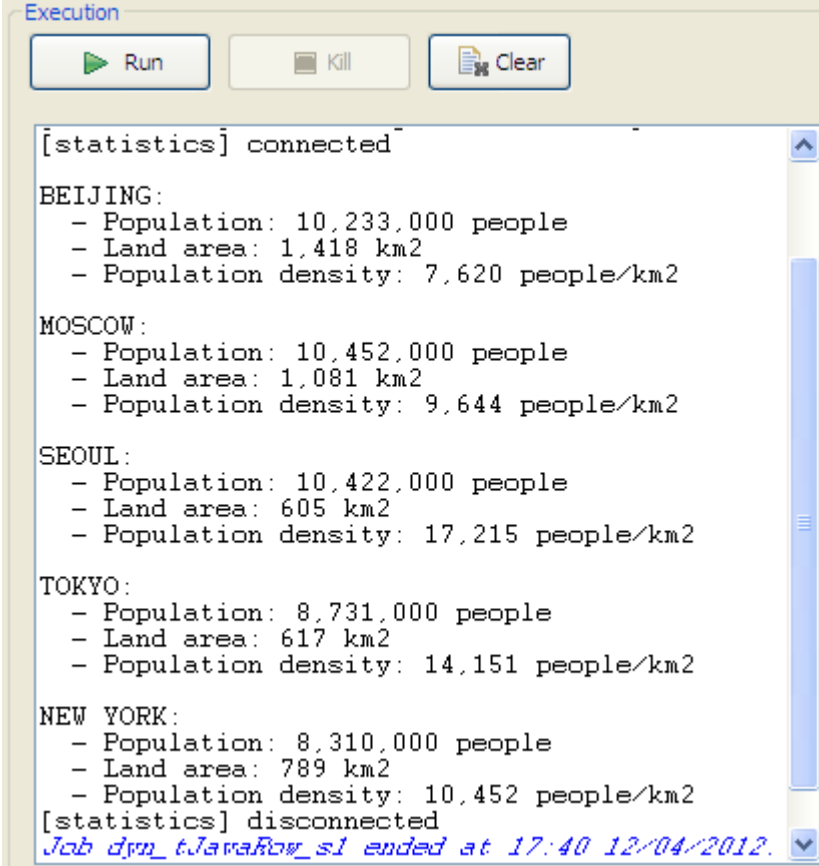

*In the **Code** field, "row1" refers to the name of the link that connects to **tJavaRow**. If you rename the link, you have to modify the code.*

## Saving and executing the Job

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the **Run** tab to execute the Job.

The city information is transformed by the Java code set through **tJavaRow** and displayed on the console.

```
Execution
Run Kill Clear

# tLibraryLoad

## tLibraryLoad properties

|                             |                                                                                           |                                                                                                                                                |
|-----------------------------|-------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Famille de composant</b> | Custom Code                                                                               |                                                                                                                                                |
| <b>Function</b>             | <b>tLibraryLoad</b> allows you to import a library.                                       |                                                                                                                                                |
| <b>Purpose</b>              | <b>tLibraryLoad</b> allows you to load useable Java libraries in a Job.                   |                                                                                                                                                |
| <b>Basic settings</b>       | <i>Library</i>                                                                            | Select the library you want to import from the list, or click on the [...] button to browse to the library in your directory.                  |
| <b>Advanced settings</b>    | <i>Dynamic Libs</i>                                                                       | <b>Lib Paths:</b> Enter the access path to your library, between double quotation marks.                                                       |
|                             | <i>Import</i>                                                                             | Enter the Java code required to import, if required, the external library used in the <b>Main code</b> field of the <b>Basic settings</b> tab. |
|                             | <i>tStatCatcher Statistics</i>                                                            | Select this check box to collect the log data at component level.                                                                              |
| <b>Usage</b>                | This component may be used alone, although it is more logical to use it as part of a Job. |                                                                                                                                                |
| <b>Limitation</b>           | n/a                                                                                       |                                                                                                                                                |

## Scenario: Checking the format of an e-mail address!

This scenario uses two components, a **tLibraryLoad** and a **tJava**. The goal of this scenario is to check the format of an e-mail address and verify whether the format is valid or not.

## Setting up the Job

1. In the **Palette**, open the **Custom\_Code** folder, and slide a **tLibraryLoad** and **tJava** component onto the workspace.

2. Connect **tLibraryLoad** to **tJava** using a **Trigger > OnSubjobOk** link.

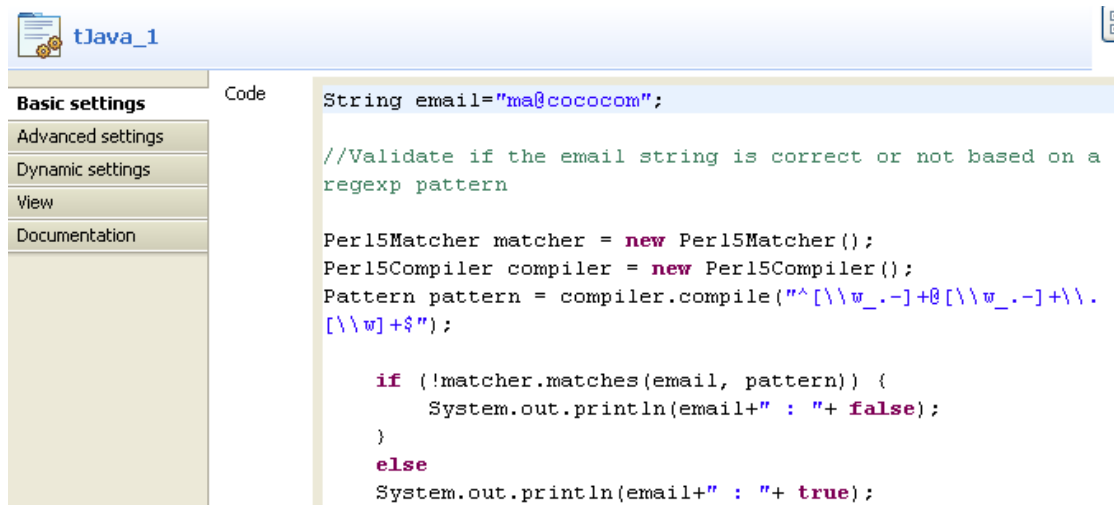

## Configuring the tLibraryLoad component

1. Double-click on **tLibraryLoad** to display its **Basic settings**. From the **Library** list, select *jakarta-oro-2.0.8.jar*.
2. In the **Import** field of the **Advanced settings** tab, type *import org.apache.oro.text.regex.\*;*

## Configuring the tJava component

1. Double-click on **tJava** to display its **Component** view.
2. In the **Basic settings** tab, enter your code, as in the screenshot below. The code allows you to check whether the character string pertains to an e-mail address, based on the regular expression: `"^[\\w_.-]+@[\\w_.-]+\\. [\\w]+$. "`.

## Job execution

Press **F6** to save and run the Job.

```
Starting job LibraryLoad at 16:51 18/02/2010.
[statistics] connecting to socket on port 3979
[statistics] connected
ma@cocom : false
[statistics] disconnected
Job LibraryLoad ended at 16:51 18/02/2010. [exit code=0]
```

The **Console** displays the boolean *false*. Hence, the e-mail address is not valid as the format is incorrect.

# tSetGlobalVar

## tSetGlobalVar properties

|                          |                                                                            |                                                                                                                                                          |

| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                             | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.                                           |
| <b>Usage</b>             | This component is generally used as a one-component subjob.                |                                                                                                                                                          |
| <b>Limitation</b>        | Knowledge of Java language is required.                                    |                                                                                                                                                          |

## Scenario: Printing out the content of a global variable

This scenario is a simple Job that prints out the value of a global variable defined in the **tSetGlobalVar** component.

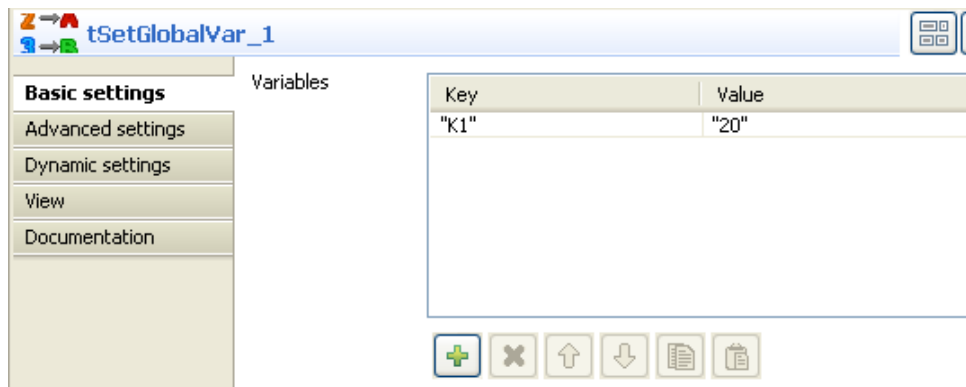

### Setting up the Job

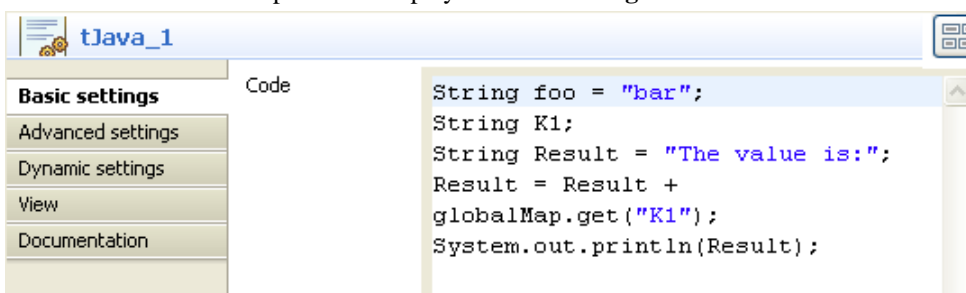

1. Drop the following components from the **Palette** onto the design workspace: **tSetGlobalVar** and **tJava**.
2. Connect the **tSetGlobalVar** component to the **tJava** component using a **Trigger** > **OnSubjobOk** connection.

### Configuring the tSetGlobalVar component

1. Double-click the **tSetGlobalVar** component to display its **Basic settings** view.

2. Click the plus button to add a line in the **Variables** table, and fill the **Key** and **Value** fields with *K1* and *20* respectively.
3. Then double-click the **tJava** component to display its **Basic settings** view.

4. In the **Code** area, type in the following lines:

```
String foo = "bar";
String K1;
String Result = "The value is:";

Result = Result + globalMap.get("K1");

System.out.println(Result);
```

In this use case, we use the *Result* variable. To access the global variable list, press **Ctrl + Space** bar on your keyboard and select the relevant global parameter.

## Job execution

Save your Job and press **F6** to execute it.

The content of global variable *K1* is displayed on the console.

```
Starting job SetGlobalVar at 16:22 25/02/2011.
[statistics] connecting to socket on port 3489
[statistics] connected
The value is:20
[statistics] disconnected
Job SetGlobalVar ended at 16:22 25/02/2011.
[exit code=0]
```

## Data Quality components

This chapter details the main components that you can find in the **Data Quality** family of the *Talend Open Studio for Big Data Palette*.

The Data Quality family comprises dedicated components that help you improve the quality of your data. These components covers various needs such as narrow down filtering the unique row, calculating CRC, finding data based on fuzzy matching, and so on.

For *Talend Open Studio for Big Data*, the **Property type**, **Schema** and **Query Type** of components are always **Built-in**. For how to edit a Built-in schema, see *Talend Open Studio for Big Data User Guide*.

# tAddCRCRow

| <b>Advanced Settings</b> | <i>CRC type</i>                                                                                                                                                                                                                                                                                                                                                       | Select a CRC type in the list. The longer the CRC, the least overlap you will have.                                                                                                                                                                                             |
|                          | <i>tStatCatcher Statistics</i>                                                                                                                                                                                                                                                                                                                                        | Select this check box to collect log data at the component level.                                                                                                                                                                                                               |
| <b>Usage</b>             | This component is an intermediary step. It requires an input flow as well as an output.                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                 |
| <b>Limitation</b>        | Due to license incompatibility, one or more JARs required to use this component are not provided. You can easily find out and add such JARs in <i>Talend Open Studio for Big Data</i> . For details, see the <i>Warnings and error icons on components</i> and <i>How to install external modules</i> sections of <i>Talend Open Studio for Big Data User Guide</i> . |                                                                                                                                                                                                                                                                                 |

## Scenario: Adding a surrogate key to a file

This scenario describes a Job adding a surrogate key to a delimited file schema.

## Setting up the Job

1. Drop the following components: **tFileInputDelimited**, **tAddCRCRow** and **tLogRow**.
2. Connect them using a **Main row** connection.

## Configuring the input component

For Talend Open Studio for Big Data, the **Property type** and **Schema** of components are always **Built-in**. For how to edit a built-in schema, see *Talend Open Studio for Big Data User Guide*.

1. In the **tFileInputDelimited Component** view, set the **File Name** path and all related properties in case these are not stored in the **Repository**.

2. Create the schema through the **Edit Schema** button. Remember to set the data type column and for more information on the Date pattern to be filled in, visit <http://docs.oracle.com/javase/6/docs/api/index.html>.

## Configuring the tAddCRCRow component

1. In the **tAddCRCRow Component** view, select the check boxes of the input flow columns to be used to calculate the CRC.

| Column | Use in CRC                          |
|--------|-------------------------------------|
| CRC    | <input checked="" type="checkbox"/> |

Notice that a CRC column (read-only) has been added at the end of the schema.

2. Select **CRC32** as **CRC Type** to get a longer surrogate key.

3. In the **Basic settings** view of **tLogRow**, select the **Print values in cells of a table** option to display the output data in a table on the Console.

## Job execution

Then save your Job and press **F6** to execute it.

*Starting job addcrc at 11:51 06/07/2007.*

| <b>Component family</b> | Data Quality                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Function</b>         | Compares a column from the main flow with a reference column from the lookup flow and outputs the main flow data displaying the distance |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Purpose</b>          | Helps ensuring the data quality of any source data against a reference data source.                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Basic settings</b>   | <i>Schema and Edit schema</i>                                                                                                            | <p>A schema is a row description, i.e., it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.</p> <p>Two read-only columns, Value and Match are added to the output schema automatically.</p> <p><b>Built-in:</b> The schema will be created and stored locally for this component only. Related topic: see <i>Talend Open Studio for Big Data User Guide</i>.</p> <p><b>Repository:</b> The schema already exists and is stored in the Repository, hence can be reused in various projects and job designs. Related topic: see <i>Talend Open Studio for Big Data User Guide</i>.</p>                                                                                                                                         |
|                         | <i>Matching type</i>                                                                                                                     | <p>Select the relevant matching algorithm among:</p> <p><b>Levenshtein:</b> Based on the edit distance theory. It calculates the number of insertion, deletion or substitution required for an entry to match the reference entry.</p> <p><b>Metaphone:</b> Based on a phonetic algorithm for indexing entries by their pronunciation. It first loads the phonetics of all entries of the lookup reference and checks all entries of the main flow against the entries of the reference flow.</p> <p><b>Double Metaphone:</b> a new version of the Metaphone phonetic algorithm, that produces more accurate results than the original algorithm. It can return both a primary and a secondary code for a string. This accounts for some ambiguous cases as well as for multiple variants of surnames with common ancestry.</p> |
|                         | <i>Min distance</i>                                                                                                                      | (Levenshtein only) Set the minimum number of changes allowed to match the reference. If set to 0, only perfect matches are returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                         | <i>Max distance</i>                                                                                                                      | (Levenshtein only) Set the maximum number of changes allowed to match the reference.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                         | <i>Matching column</i>                                                                                                                   | Select the column of the main flow that needs to be checked against the reference (lookup) key column                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|              |                                                                                                                  |                                                                                                                                                     |
|--------------|------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
|              | <i>Unique matching</i>                                                                                           | Select this check box if you want to get the best match possible, in case several matches are available.                                            |
|              | <i>Matching separator</i>                                                                                        | In case several matches are available, all of them are displayed unless the unique match box is selected. Define the delimiter between all matches. |
| <b>Usage</b> | This component is not startable (green background) and it requires two input components and an output component. |                                                                                                                                                     |

## Scenario 1: Levenshtein distance of 0 in first names

This scenario describes a four-component Job aiming at checking the edit distance between the *First Name* column of an input file with the data of the reference input file. The output of this Levenshtein type check is displayed along with the content of the main flow on a table

- Drag and drop the following components from the **Palette** to the design workspace: **tFileInputDelimited** (x2), **tFuzzyMatch**, **tFileOutputDelimited**.
- Define the first **tFileInputDelimited** Basic settings. Browse the system to the input file to be analyzed and most importantly set the schema to be used for the flow to be checked.
- In the schema, set the **Type** of data in the Java version, especially if you are in **Built-in** mode.
- Link the defined input to the **tFuzzyMatch** using a **Main** row link.
- Define the second **tFileInputDelimited** component the same way.

 *Make sure the reference column is set as key column in the schema of the lookup flow.*

- Then connect the second input component to the **tFuzzyMatch** using a main row (which displays as a **Lookup** row on the design workspace).
- Select the **tFuzzyMatch** Basic settings.
- The **Schema** should match the **Main** input flow schema in order for the main flow to be checked against the reference.

| Column       | Key | Type   | Nullable                            | Length | Precis... | Com... |
|--------------|-----|--------|-------------------------------------|--------|-----------|--------|
| O1_firstname |     | String | <input checked="" type="checkbox"/> | 13     |           |        |
| VALUE        |     | String | <input checked="" type="checkbox"/> | 255    |           |        |
| MATCHING     |     | String | <input checked="" type="checkbox"/> | 255    |           |        |

- Note that two columns, **Value** and **Matching**, are added to the output schema. These are standard matching information and are read-only.
- Select the method to be used to check the incoming data. In this scenario, *Levenshtein* is the **Matching type** to be used.
- Then set the distance. In this method, the distance is the number of char changes (insertion, deletion or substitution) that needs to be carried out in order for the entry to fully match the reference.

- In this use case, we want the distance be of 0 for the min. or for the max. This means only the exact matches will be output.
- Also, clear the **Case sensitive** check box.
- And select the column of the main flow schema that will be selected. In this example, the first name.
- No need to select the **Unique matching** check box nor hence the separator.
- Link the **tFuzzyMatch** to the standard output **tLogRow**. No other parameters than the display delimiter is to be set for this scenario.
- Save the Job and press **F6** to execute the Job.

augustus||
aukusti|

```

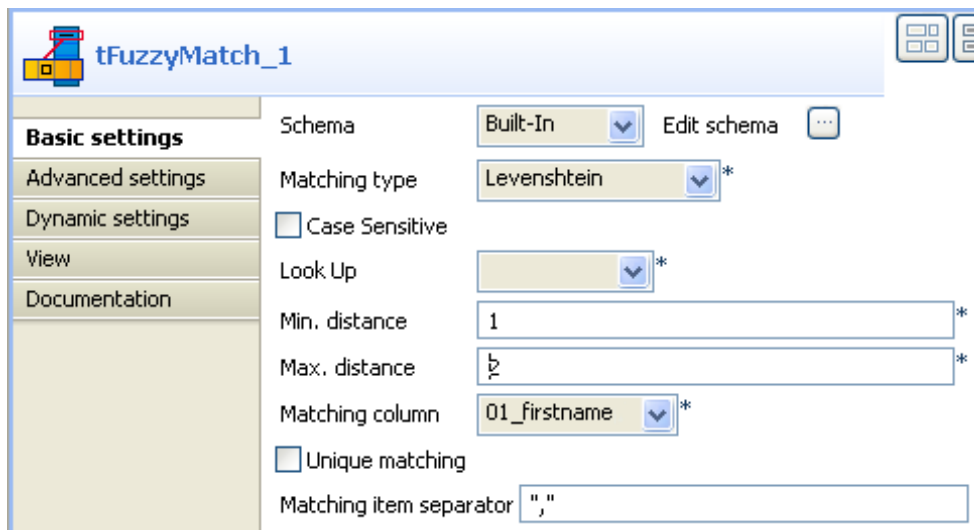

As the edit distance has been set to 0 (min and max), the output shows the result of a regular join between the main flow and the lookup (reference) flow, hence only full matches with Value of 0 are displayed.

A more obvious example is with a minimum distance of 1 and a max. distance of 2, see [the section called “Scenario 2: Levenshtein distance of 1 or 2 in first names”](#)

## Scenario 2: Levenshtein distance of 1 or 2 in first names

This scenario is based on the scenario 1 described above. Only the min and max distance settings in **tFuzzyMatch** component get modified, which will change the output displayed.

- In the **Component** view of the **tFuzzyMatch**, change the min distance from 0 to 1. This excludes straight away the exact matches (which would show a distance of 0).
- Change also the max distance to 2 as the max distance cannot be lower than the min distance. The output will provide all matching entries showing a discrepancy of 2 characters at most.

- No other change of the setting is required.
- Make sure the **Matching item separator** is defined, as several references might be matching the main flow entry.
- Save the new Job and press **F6** to run it.

aolay||
aulus|2|jules

```

As the edit distance has been set to 2, some entries of the main flow match several reference entries.

You can also use another method, the metaphone, to assess the distance between the main flow and the reference,

## Scenario 3: Metaphonic distance in first name

This scenario is based on the scenario 1 described above.

- Change the **Matching type** to **Metaphone**. There is no min nor max distance to set as the matching method is based on the discrepancies with the phonetics of the reference.
- Save the Job and press **F6**. The phonetics value is displayed along with the possible matches.

Select the check box if the boundary is strict.                                                                                                                                                                                                                             |
|                          | <i>Lookup Column max/bounds strictly (max)</i>                                                                                                                                              | Select the column containing the max value of the range. Select the check box if the boundary is strict.                                                                                                                                                                                                                             |
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                                                                                                                                              | Select this check box to collect log data at the component level.                                                                                                                                                                                                                                                                    |
| <b>Usage</b>             | This component handles flow of data therefore it requires input and output, hence is defined as an intermediary step.                                                                       |                                                                                                                                                                                                                                                                                                                                      |
| <b>Limitation</b>        | n/a                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                      |

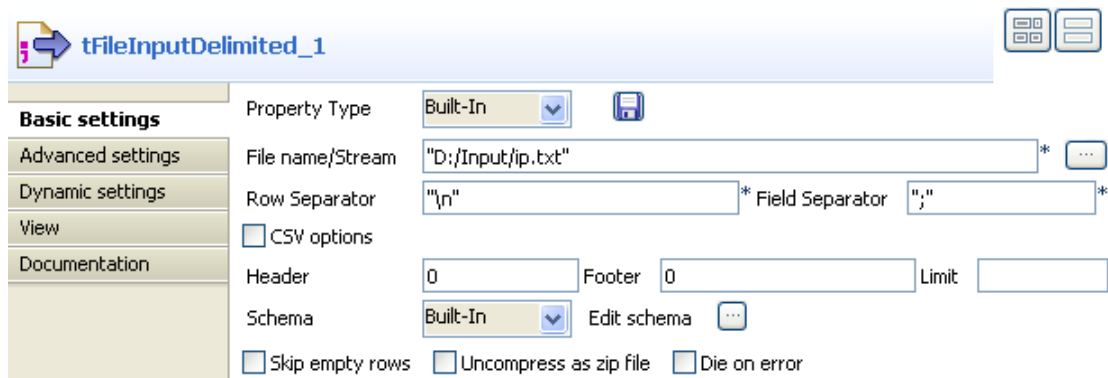

## Scenario: Identifying Ip country

In this Job, an incoming main flow provides 2 columns: *Documents* and *IP* dummy values. A second file used as lookup flow in Java contains a list of sorted IP ranges and their corresponding country. This Job aims at retrieving each document's country from their IP value, in other words, creating a Join between the main flow and the lookup flow.

The Job requires one extra **tFileInputDelimited**, a **tIntervalMatch** and a **tLogRow**.

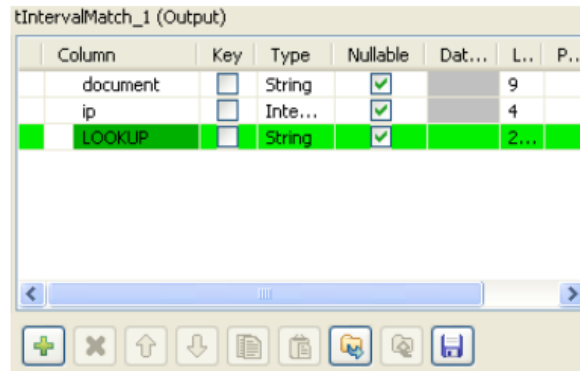

- Drop the components onto the design workspace.
- Set the basic settings of the **tFileInputDelimited** component.

- The schema is made of two columns, respectively *Document* and *IP*
- Set the **Type** column on **String** for the *Document* column and **Integer** for the *IP* column.
- Set now the second **tFileInputDelimited** properties.

| Column  | Key                      | Type    | Nullable                            | Date Patt... | Len... | Pre... | D... | Co... |
|---------|--------------------------|---------|-------------------------------------|--------------|--------|--------|------|-------|
| min     | <input type="checkbox"/> | Integer | <input checked="" type="checkbox"/> |              | 4      |        |      |       |
| max     | <input type="checkbox"/> | Integer | <input checked="" type="checkbox"/> |              | 4      |        |      |       |
| country | <input type="checkbox"/> | String  | <input checked="" type="checkbox"/> |              | 11     |        |      |       |

- Don't forget to define the **Type** of data.
- Propagate the schema from the incoming main flow to the **tIntervalMatch** component.

| Column   | Key                      | Type    | Nullable                            | Dat... | L..  | P.. |
|----------|--------------------------|---------|-------------------------------------|--------|------|-----|
| document | <input type="checkbox"/> | String  | <input checked="" type="checkbox"/> |        | 9    |     |
| ip       | <input type="checkbox"/> | Inte... | <input checked="" type="checkbox"/> |        | 4    |     |
| LOOKUP   | <input type="checkbox"/> | String  | <input checked="" type="checkbox"/> |        | 2... |     |

- Note that the output schema from the **tIntervalMatch** component is read-only and is made of the input schema plus an extra Lookup column which will output the requested lookup data.
- Set the other properties of the **tIntervalMatch** component.

Schema: Built-In

File Name: 'D:/Input/rangeip.txt'

Row Separator: "\n" Field Separator: ';'

Lookup column index: 0  Search column: ip

- Set the tIntervalMatch other properties such as the min and max column corresponding to the range bounds.

Schema: Built-In

Search Column: ip  Column (LOOKUP): row2.country

Lookup Column (min): row2.min   bounds strictly (min)

Lookup Column (max): row2.max   bounds strictly (max)

- In the **Column Lookup** field, select the column where are the values to be returned.
- In the **Search column** field, select the main flow column containing the values to be matched to the range values.
- The **tLogRow** component does not require any specific setting for this Job.

Following result is displayed:

```
Starting job intervalMatch at 17:05 01/02/2008.
document1 | 1200 | DEUTSCHLAND
document2 | 4500 |
document3 | 500 | FRANCE
document1 | 2201 | ITALIA
Job intervalMatch ended at 17:05 01/02/2008. [exit c
```

Only requested values (country) are included in the output.

# tReplaceList

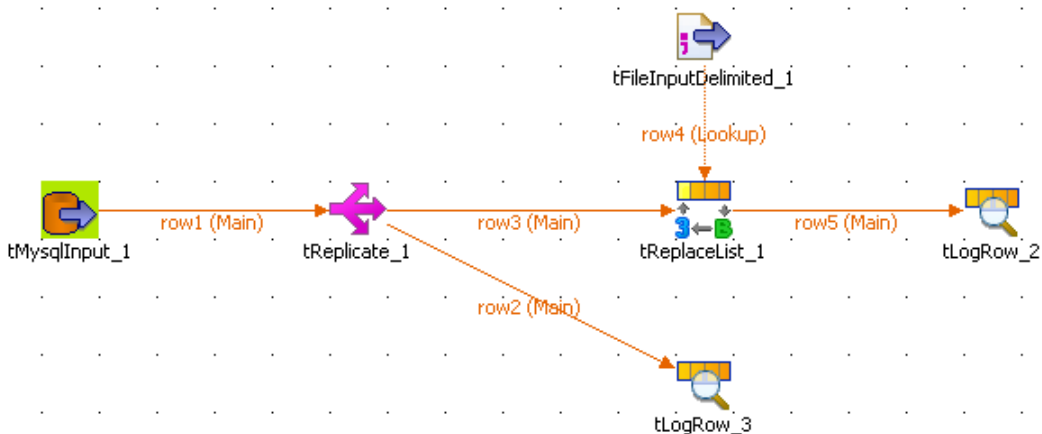

## tReplaceList Properties

|                         |                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|--------------------------|------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| <b>Advanced settings</b> | <i>tStatCatcher Statistics</i>                                                                       | Select this check box to collect log data at the component level. |
| <b>Usage</b>             | <b>tReplaceList</b> is an intermediary component. It requires an input flow and an output component. |                                                                   |

## Scenario: Replacement from a reference file

The following Job searches and replaces a list of countries with their corresponding codes. The relevant codes are taken from a reference file placed as lookup flow in the Job. The main flow is replicated and both outputs are displayed on the console, in order to show the main flow before and after replacement.

- Drop the following components from the **Palette** to the design workspace: **tMySQLInput**, **tFileInputDelimited**, **tReplicate**, **tReplaceList** and **tLogRow** (x2). Note that if your input schemas are stored in the Repository, you can simply drag and drop the relevant node from the Repository’s Metadata Manager onto the design workspace to retrieve automatically the input components’ setting. For more information, see *Talend Open Studio for Big Data User Guide*.
- Connect the components using **Main Row** connections via a right-click on each component. Notice that the main row coming from the reference flow (**tFileInputDelimited**) is called a lookup row.
- Select the **tMySQLInput** component and set the input flow parameters.

Property Type:  Repository: \*

Use an existing connection

Host:  Port:  Database: \*

Username: \* Password: \*

Schema:  \*  ...

Table Name:  ...

Query Type:

Query: \*

Encoding Type:

- The input schema is made of two columns: *Names*, *States*. The column *States* gathered the name of the United States of America which are to be replaced by their respective code.
- In the **Query** field, make sure the *State* column is included in the *Select* statement. In this use case, all columns are selected.

- Check the **tReplicate** component setting. The schema is simply duplicated into two identical flows, but no change to the schema can be made.
- Then double-click on the **tFileInputDelimited** component, to set the reference file.

- The file includes two columns: *Postal*, *State* where *Postal* provides the zipcode corresponding to the name given in the respective row of the *State* column.
- The fields are delimited by semicolons and rows are separated by carriage returns.
- Edit the lookup flow schema.

| Column           | Key                                 | Type   | Nullable                            | Length | Precision | Comment |
|------------------|-------------------------------------|--------|-------------------------------------|--------|-----------|---------|
| Postal           | <input type="checkbox"/>            | String | <input checked="" type="checkbox"/> | 10     |           |         |
| State            | <input checked="" type="checkbox"/> | String | <input checked="" type="checkbox"/> | 255    |           |         |
| Capital          | <input type="checkbox"/>            | String | <input checked="" type="checkbox"/> | 255    |           |         |
| MostPopulousCity | <input type="checkbox"/>            | String | <input checked="" type="checkbox"/> | 255    |           |         |

- Make sure the lookup search column (in this use case: *State*) is a key, in order to ensure the uniqueness of the values being searched.
- Select the **tReplaceList** and set the operation to carry out.
- The schema is retrieved from the previous component of the main flow.

| Column | Replace                             |
|--------|-------------------------------------|
| Name   | <input type="checkbox"/>            |
| States | <input checked="" type="checkbox"/> |

- In **Lookup search index** field, type in the position index of the column being searched. In this use case, *State* is the second column of the lookup input file, therefore type in **1** in this field.
- In **Lookup replacement index** field, fill in the position number of the column containing the replacement values, in this example: *Postal* for the *State* codes.

- In the **Column options** table, select the *States* column as in this use case, the State names are to be replaced with their corresponding code.
- In both **tLogRow** components, select the **Print values in table cells** check box for a better readability of the outputs.
- Save the Job and press **F6** to execute it.

*Starting job ReplaceList at 15:06 22/10/2007.*

*Job ReplaceList ended at 15:06 22/10/2007. [exit code=0]*

The first flow output shows the States column with full state names as it comes from the main input flow.

The second flow output shows the States column after the State column names have been replaced with their respective codes.

For more information about routines, see <i>Talend Open Studio for Big Data User Guide</i> . |
|                          | <i>Treat all empty string as NULL</i>                                                                                                                                                                                                                                                                                                                                                                                              | Select this check box to treat any empty fields in any columns as null values, instead of empty strings.<br><br>By default, this check box is selected. When it is cleared, the <b>Choose Column(s)</b> table shows to let you select individual columns.                         |
| <b>Usage</b>             | This component is an intermediary step in the flow allowing to exclude from the main flow the non-compliant data. This component cannot be a start component as it requires an input flow. It also requires at least one output component to gather the validated flow, and possibly a second output component for rejected data using Rejects link. For more information, see <i>Talend Open Studio for Big Data User Guide</i> . |                                                                                                                                                                                                                                                                                   |

## Scenario: Validating data against schema

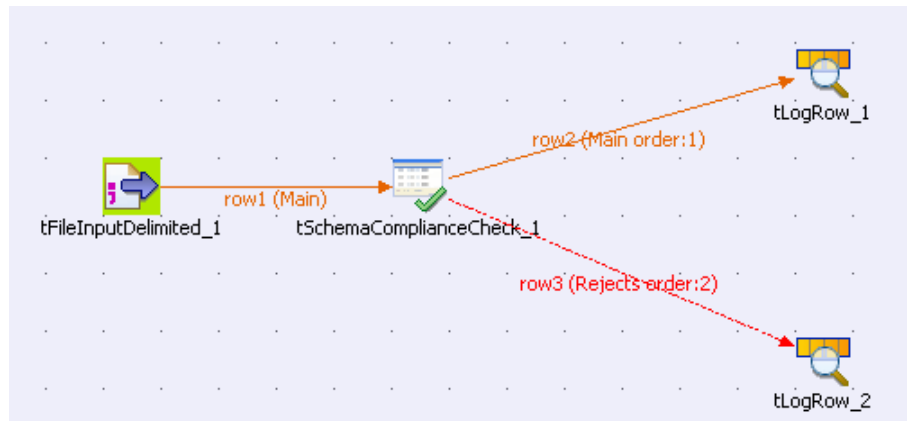

This very basic scenario shows how to check the type, nullability and length of an incoming flow against a defined reference schema. The incoming flow comes from a simple CSV file that contains heterogeneous data including wrong data type, data exceeding the maximum length, wrong ID and null values in non-nullable columns, as shown below:

```

1 ID;Name;BirthDate;State;City
2 1;Dwight;06-04-2008;Delaware;Concord
3 2;Warren;25-10-2008;Montana
4 3;Benjamin;17-08-2008;Washington;Austin
5 4;Harry;14-04-2008;Kansas;Annapolis
6 5;Ulysses;2007-04-12;Michigan;Raleigh
7 6;James;19-08-2007;Delaware;Charleston
8 .7;Bill;20-04-2007;Illinois;Bismarck
9 8;Ulysses;04-12-2008;;Saint Paul
10 9;Thomas;09-05-2008;Maryland;Albany
11 10;Ronald;11-02-2008;Florida;Hartford

```

Upon validation, the valid rows and the rejected rows are displayed respectively in two tables on the **Run** console.

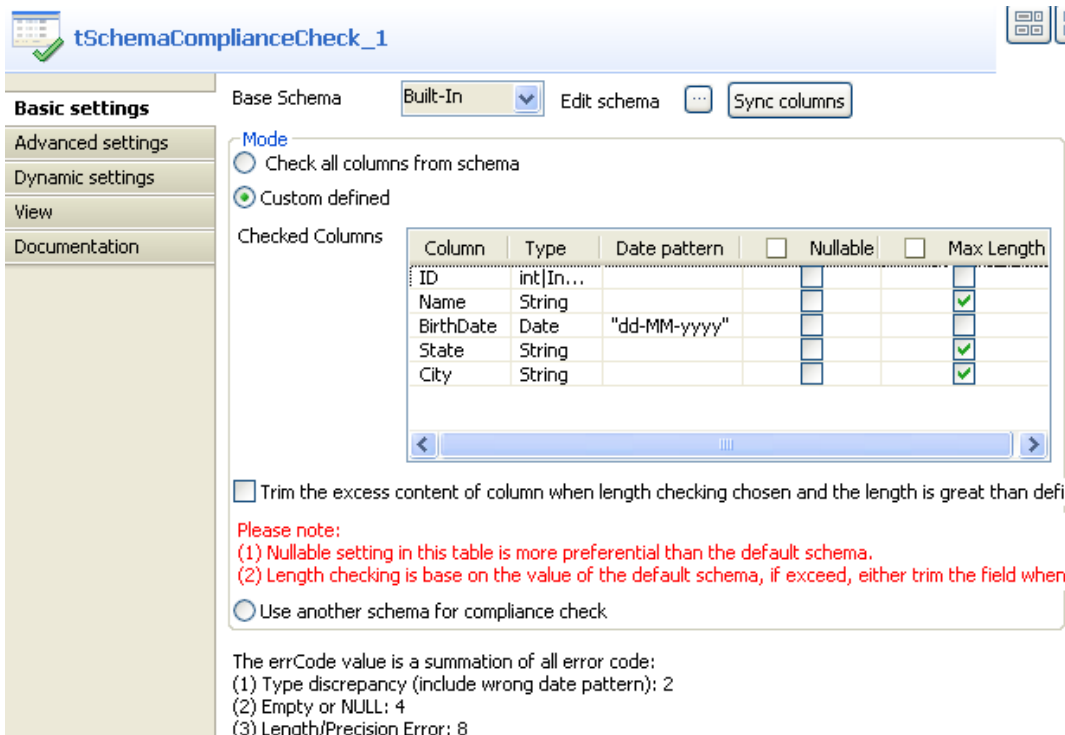

- Drop the following components: a **tFileInputDelimited**, a **tSchemaComplianceCheck**, and two **tLogRow** components from the **Palette** to the design workspace.
- Connect the **tFileInputDelimited** component to the **tSchemaComplianceCheck** component using a **Row > Main** connection.
- Connect the **tSchemaComplianceCheck** component to the first **tLogRow** component using a **Row > Main** connection. This output flow will gather the valid data.
- Connect the **tSchemaComplianceCheck** component to the second **tLogRow** component using a **Row > Rejects** connection. This second output flow will gather the non-compliant data.
- Select the **Rejects** connection, and notice that the schema passed to the second **tLogRow** contains two more columns: *ErrorCode* and *ErrorMessage*. These two read-only columns provide information about the rejected data to ease error handling and troubleshooting if needed.
- Double-click the **tFileInputDelimited** component to display its **Basic settings** view.

- Fill in the **File name** field by browsing to the input file.
- Specify the header row. In this use case, the first row of the input file is the header row.
- Leave the other parameters as they are.
- Click **Edit schema** to describe the data structure of the input file. In this use case, the schema is made of five columns: *ID*, *Name*, *BirthDate*, *State*, and *City*.

- Leave the **Type** field as permissive as possible. You will define the actual type of the data in the **tSchemaComplianceCheck** component.
- Fill the **Length** field for the *Name*, *State* and *City* columns with 7, 10 and 10 respectively.
- Click **OK** to propagate the schema and close the schema dialog box.
- Double-click the **tSchemaComplianceCheck** component to display its **Basic settings** view, wherein you will define most of the validation parameters.

- Select the **Custom defined** option in the **Mode** area to perform custom defined checks.
- In this example, we use the **Checked columns** table to set the validation parameters. However, you can also select the **Check all columns from schema** check box if you want to perform all the checks (type, nullability and length) on all the columns against the base schema, or select the **Use another schema for compliance check** option and define a new schema as the expected structure of the data.
- In the **Checked Columns** table, define the checks to be performed. In this use case:

- The type of the *ID* column should be **Int**.
- The length of the *Name*, *State* and *City* columns should be checked.
- The type of the *BirthDate* column should be **Date**, and the expected date pattern is *dd-MM-yyyy*.
- All the columns should be checked for null values, so clear the **Nullable** check box for all the columns.

To send rows containing fields exceeding the defined maximum length to the reject flow, make sure that the **Trim the excess content of column when length checking chosen and the length is greater than defined length** check box is cleared.

- In the **Advanced settings** view of the **tSchemaComplianceCheck** component, select the **Treat all empty string as NULL** option to sent any rows containing empty fields to the reject flow.
- To view the validation result in tables on the **Run** console, double-click each **tLogRow** component and select the **Table** option in the **Basic settings** view.
- Save your Job and press **F6** to launch it.

Two tables are displayed on the console, showing the valid data and rejected data respectively.

|                          | <i>Unique key</i>                                                     | <p>In this area, select one or more columns to carry out deduplication on the particular column(s)</p> <ul style="list-style-type: none"> <li>- Select the <b>Key attribute</b> check box to carry out deduplication on all the columns</li> <li>- Select the <b>Case sensitive</b> check box to differentiate upper case and lower case</li> </ul>                                                                                                                                                                                                                           |
| <b>Advanced settings</b> | <i>Only once each duplicated key</i>                                  | Select this check box if you want to have only the first duplicated entry in the column(s) defined as key(s) sent to the output flow for duplicates.                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                          | <i>Use of disk (suitable for processing large row set)</i>            | <p>Select this check box to enable generating temporary files on the hard disk when processing a large amount of data. This helps to prevent Job execution failure caused by memory overflow. With this check box selected, you need also to define:</p> <ul style="list-style-type: none"> <li>- <b>Buffer size in memory:</b> Select the number of rows that can be buffered in the memory before a temporary file is to be generated on the hard disk.</li> <li>- <b>Directory for temp files:</b> Set the location where the temporary files should be stored.</li> </ul> |

|                   |                                                                                                                       |                                                                                                                                                                                                        |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   |                                                                                                                       |  <i>Make sure that you specify an existing directory for temporary files; otherwise your Job execution will fail.</i> |
|                   | <i>tStatCatcher Statistics</i>                                                                                        | Select this check box to gather the job processing metadata at a job level as well as at each component level.                                                                                         |
| <b>Usage</b>      | This component handles flow of data therefore it requires input and output, hence is defined as an intermediary step. |                                                                                                                                                                                                        |
| <b>Limitation</b> | n/a                                                                                                                   |                                                                                                                                                                                                        |

## Scenario 1: Deduplicating entries

In this five-component Job, we will sort entries on an input name list, find out duplicated names, and display the unique names and the duplicated names on the **Run** console.

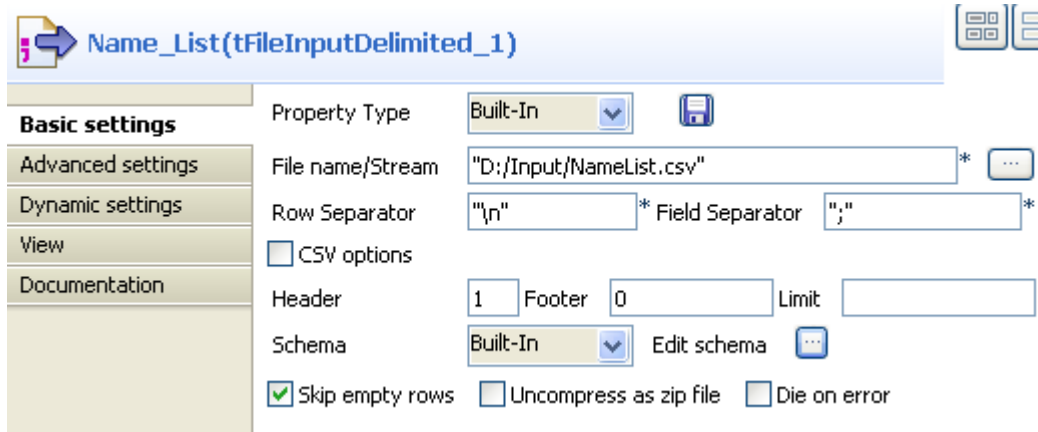

### Setting up the Job

1. Drop a **tFileInputDelimited**, a **tSortRow**, a **tUniqRow**, and two **tLogRow** components from the **Palette** to the design workspace, and name the components as shown above.
2. Connect the **tFileInputDelimited** component, the **tSortRow** component, and the **tUniqRow** component using **Row > Main** connections.
3. Connect the **tUniqRow** component and the first **tLogRow** component using a **Main > Uniques** connection.
4. Connect the **tUniqRow** component and the second **tLogRow** component using a **Main > Duplicates** connection.

### Configuring the components

1. Double-click the **tFileInputDelimited** component to display its **Basic settings** view.

2. Click the [...] button next to the **File Name** field to browse to your input file.
3. Define the header and footer rows. In this use case, the first row of the input file is the header row.
4. Click **Edit schema** to define the schema for this component. In this use case, the input file has five columns: *Id*, *FirstName*, *LastName*, *Age*, and *City*. Then click **OK** to propagate the schema and close the schema editor.
5. Double-click the **tSortRow** component to display its **Basic settings** view.

6. To rearrange the entries in the alphabetic order of the names, add two rows in the **Criteria** table by clicking the plus button, select the *FirstName* and *LastName* columns under **Schema column**, select *alpha* as the sorting type, and select the sorting order.
7. Double-click the **tUniqRow** component to display its **Basic settings** view.

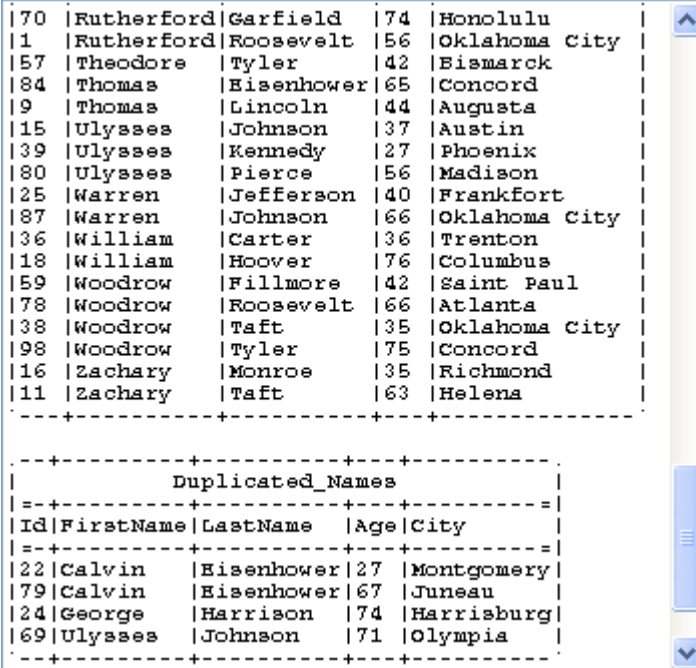

8. In the **Unique key** area, select the columns on which you want deduplication to be carried out. In this use case, you will sort out duplicated names.
9. In the **Basic settings** view of each of the **tLogRow** components, select the **Table** option to view the Job execution result in table mode.

## Saving and executing the Job

1. Press **Ctrl+S** to save your Job.
2. Run the Job by pressing **F6** or clicking the **Run** button on the **Run** tab.

The unique names and duplicated names are displayed in different tables on the **Run** console.
